About that time, in April, Pemberton announced that he had perfected his formula, but he needed a name for it. Since alliterative names were the norm for patent medicines at the time, Pemberton's partner Frank Robinson suggested naming it after its two chief ingredients, coca and kola (with the spelling changed to "cola" to highlight the alliteration; by this time, damiana was no longer an ingredient). The Coca-Cola Company's official historians, anxious to suppress the notion that cocaine was ever a part of their drink, deny that the name is anything but meaningless nonsense syllables. Pemberton's published comments, however, make clear that he considered coca leaf the most vital ingredient in the mixture. The first advertisement for the drink, in the May 29, 1886, *Atlanta Journal*, mentions both the coca leaf and the kola nut. Robinson's June 16, 1887, advertisement in the same paper was the first to use his Spenserian script logo.

Despite the temporary prohibition (it was repealed in November of 1887), Pemberton continued to sell his coca wines: A May 1, 1887, article in the *Atlanta Constitution* reported daily sales of five gross (720 bottles) of Pemberton's French Wine Coca, far more than his Coca-Cola sales (though the comparison is hard to make, since he sold Coca-Cola in syrup form, to be mixed in soda fountains at pharmacies). Realizing that he was near the end of his life, and hoping to leave behind a prosperous company for his son, now in his early thirties, Pemberton quickly prosecuted various schemes, some of them less than scrupulous, to ensure the perpetuation of his invention.

The way in which he secured legal title to his invention was typical of the patent medicine business of the time. "Patent" is a misnomer, for the purpose of a patent is to make every facet of an invention public, whereas makers of patent medicines found more security in keeping their formulas secret. The legal protection they sought was not a patent but a trademark, and Pemberton was granted one for the name Coca-Cola on June 28, 1887. At the same time, he sold the manufacturing equipment, the formula, and two-thirds of the right to the product to soda fountain owner Willis Venable and investor George Lowndes. That October, he placed a blind ad offering half interest in an unnamed business for $2,000. He sold a half interest to three buyers, a clear case of fraud. In March of 1888, Pemberton's dissolute son Charley asserted the right to the product that his father intended by incorporating with three partners the Coca-Cola Company. As the various "owners" of Coca-Cola tried in vain to work out the details, Pemberton died of stomach cancer in August of 1888.

IMPACT

Pemberton could not have dreamed that his invention would become the most recognized corporate name in the world, though he clearly understood that its sales would be nationwide. In fact, he claimed nationwide sales in his own advertising, though his claims may have been exaggerated, and thorough market penetration outside of Atlanta in the scant two years from the launch of Coke in April, 1886, to Pemberton's death in August, 1888, is unlikely. Nevertheless, it is impossible to overstate the cultural impact of Coca-Cola. It is the best-known brand name in the world, and the name itself is second only to "O.K." as the most-known word in the world. It is marketed in more than two hundred countries—more than the number of member states in the United Nations.

With only a few minor changes (and one major one, the "New Coke" fiasco of 1985), the formula for Coca-Cola has remained essentially the same as Pemberton's original. In 1904, the company substituted spent coca leaves—the remainder after the extraction of cocaine—for raw leaves. In 1935, it changed the source of two minor ingredients to allow Coke to be certified kosher. In 1985, the year of the New Coke controversy, much of the soft drink industry switched from cane sugar to high-fructose corn syrup. The New Coke outperformed the original formula in taste tests, but nostalgia for the old drink forced Coca-Cola to bring it back under the name of "Coca-Cola Classic" only months after launching New Coke. For better or for worse, Pemberton's soft drink has become an emblem of America—so much so that America's support of Israel led to an Arab League boycott of Coca-Cola in 1968.

John R. Pierce

American electrical engineer

Pierce invented the Echo and Telstar satellites, the first communication satellites. Other inventions of his include the Pierce electron gun and the klystron oscillator, electronic devices used in linear particle accelerators.

Born: March 27, 1910; Des Moines, Iowa
Died: April 2, 2002; Mountain View, California
Also known as: John Robinson Pierce (full name); J. J. Coupling (pseudonym)
Primary fields: Communications; electronics and electrical engineering
Primary invention: Echo and Telstar satellites

Early Life

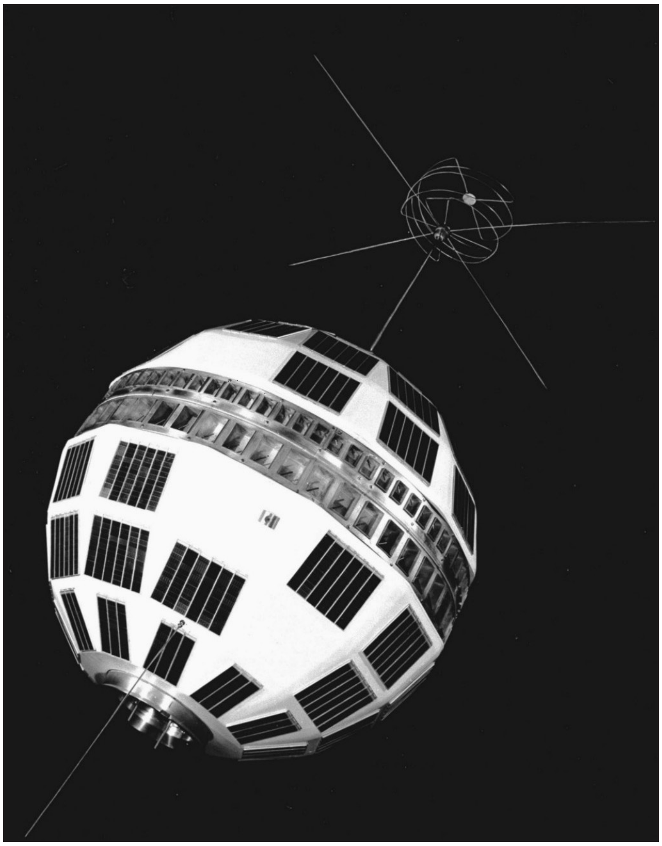
John Robinson Pierce was the son of an owner of a midwestern millinery chain. Pierce's father had no interest in science, but his mother was intensely involved in her son's scientific and inventing interests. Pierce was early interested in Meccano construction sets. He was fascinated by electric motors, which he regarded as "a sort of natural magic," and had his mother read to him about them. He became an avid reader of science and science fiction. Pierce attended high school for the first two years in Mason City, Iowa, then a year in St. Paul, Minnesota, and a final year in Long Beach, California. As a high school senior, he went through a phase of "glider mad-ness"; his mother even flew with him once. Before graduating in 1929, he and two friends won a silver cup at a glider meet in San Diego, California. That year, he published his first book, *How to Build and Fly Gliders*. In 1930, he published his first story in *Science Wonder Stories*.

Pierce attended the California Institute of Technology (Caltech) in Pasadena, where he pursued science, piano, and fiction writing. Initially, he pursued aeronautics but "got tired of rivets," and he turned to chemistry and amateur photography, planning to work for Eastman Kodak. Pierce found that he detested drafting and decided to pursue electrical engineering. After earning his Ph.D. in that discipline in 1936, he secured a job at Bell Telephone Laboratories in Murray Hill, New Jersey.

Life's Work

Pierce worked at Bell Labs from 1936 to 1971. There he would design most of his inventions, eighty-three in all. He was told to work on vacuum tubes despite initially knowing next to nothing about the technology. He soon made numerous inventions in that field and wrote several technical and popular books on it. In 1944, Pierce met Rudolf Kompfner at a British lab and brought him to Bell Labs in 1951. Pierce greatly improved and perfected Kompfner's traveling-wave tube, a specialized vacuum tube that amplifies microwave signals, giving it greater stability and more broadband capability. Pierce coinvented the low-voltage reflex klystron oscillator, used in X-band radar during World War II and later in satellites. Another notable invention of his was the Pierce electron gun, which produces high-density electron beams. He also introduced periodic focusing using permanent magnets, making the vacuum tubes much lighter for satellites and space travel.

In 1948, Claude Elwood Shannon (the creator of information theory), Bernard M. Oliver, and Pierce published a paper on pulse-code modulation (PCM), a technique for converting an analog signal to a digital one. "The Philosophy of PCM" became the manifesto for the eventual transformation of most analog devices into digital ones over the next half century.



Launched in 1962, Telstar was the first communication satellite, used to relay telephone and television signals. (AP/Wide World Photos)

In 1952, Pierce proposed the idea of communication satellites in his science-fiction story "Don't Write: Telegraph," written under the pseudonym J. J. Coupling. Pierce was unaware of Arthur C. Clarke's similar idea in a science-fiction story written a decade earlier. Pierce, however, went on to actually develop the technology. He learned of large weather balloons used by the Air Force and immediately thought of using one as a passive satellite communication device. He published a technical article on the topic in 1955 but got little response. The chief executive officer (CEO) of Bell Labs initially opposed the idea, citing fears of accusations of monopoly against Bell. The next CEO supported the project, leading to the launch of the Echo satellite in 1960. Pierce next developed an active satellite, Telstar, which transmitted signals rather than simply reflecting them. Launched in 1962, Telstar broadcast television signals across the Atlantic. A nearly identical satellite, Telstar 2, was launched in 1963.

In 1952, Pierce became director of electronics research at Bell Labs, a position he held until 1962. He served as executive director of the Research-Communications Principles Division from 1965 to 1971. Pierce excelled not only as a theorist and inventor but also as a manager and mentor for many other engineers at the company. He spent much time visiting labs, asking penetrating questions, and making ingenious suggestions. He was extraordinarily talented at translating technical descriptions of projects and inventions into clear, nontechnical prose that nonspecialists could understand. Sometimes he made the nature of the invention clearer to the inventors themselves. His dozen books of popular science reflect this talent.

Pierce did not tolerate vague statements dressed in technical jargon, nor did he put up with slowness and laziness. He was intellectually impatient and could be intimidating. He was highly critical of some lines of research. For instance, he called the discipline of artificial intelligence "real stupidity" and wrote a critical report on machine language translation that led to government defunding of the field, causing it to languish for decades.

While at Bell Labs, Pierce developed an interest in computer-generated music and psychoacoustics, and he wrote books on music theory and the nature of sound. He supported research in computer music at Bell against opposition by higher executives. After hearing a performance of music by Arnold Schoenberg, Pierce wrote pioneering computer music influenced by Shannon's information theory.

Pierce retired from Bell Labs in 1971 and took professorships at Caltech and the Jet Propulsion Laboratory (JPL), where he continued to invent. In 1983, Pierce retired from Caltech and moved to Stanford as a visiting professor of music. Finding that the computer music project at Stanford was poorly funded, he raised several million dollars to support it and never took a salary at the university. There he did major work on computer music and wrote *The Science of Musical Sound* (1983), on the physics of sound and the theory of computer music.

Pierce was as much a writer as an engineer and inventor. He published several science-fiction stories in *Astounding Science Fiction, Penthouse*, and other magazines during his career. Later in life, Pierce contracted Parkinson's disease and moved to an assisted-living home. He died in 2002 at the age of ninety-two, survived by his third wife and two children by his first wife.

Echo and Telstar Satellites

John R. Pierce first suggested a communication satellite in a science-fiction article in 1952. In 1955, he wrote an article in a technical journal outlining a plan for the device, leading to the development of the first communication satellite, Echo. Upon learning of the existence of large weather balloons, Pierce realized that a large balloon could reflect electromagnetic waves. He also realized that flat reflectors or mirrors would not be practical, but a hundred-foot-diameter sphere would work. General Mills had been making weather balloons but had never made one this large. The balloon would have to be folded into a compact mass in order to be launched in a rocket and then inflated in outer space. The pressure of the air in the inflated balloon against the vacuum of space would be huge. The first balloon, launched in October, 1959, exploded on inflation. It was made of more than eighty-two patches glued together. For the next attempt, a different adhesive was developed by G. T. Schjeldahl Company, whose founder developed an appropriately strong glue. This time, inflation in outer space was successful. A prerecorded speech by President Dwight D. Eisenhower was broadcast by reflecting it off Echo. Echo was a passive satellite, meaning that it could only reflect, not transmit, signals sent to it.

Pierce next oversaw the development of Telstar, an active satellite capable of transmitting signals. One commercial reason for using an active satellite was that it could handle television bandwidths. American Telephone and Telegraph (AT&T), Bell Labs, the National Aeronautics and Space Administration (NASA), and the British and French national post offices collaborated on the project. Traveling-wave tube transponders (used for signal transmission), developed by Rudolf Kompfner and perfected by Pierce, were used on the satellite. Telstar used solar cells for power. The satellite had a ring of feed horns that precisely directed the outgoing signals. Telstar was launched by NASA on July 10, 1962. Within two weeks, it transmitted its first live TV broadcast, a Major League Baseball game. The broadcast was supposed to have begun with remarks by President John F. Kennedy, but the signal was received before Kennedy spoke. Telstar subsequently had about four hundred transmission sessions of TV, telephone, and telegraph signals.

Unfortunately, the United States had tested a high-altitude nuclear bomb the day before Telstar was launched, exciting the Van Allen radiation belt where the satellite went into orbit. The radiation from this detonation, along with that of other Soviet and U.S. tests, eventually ruined the satellite's transistors, and Telstar 1 went dead five months after it was launched. It was restarted but failed for other reasons two months later. Many subsequent, more complex active satellites were named Telstars.

Impact

Pierce's work has influenced the fields of telecommunications, physics, digital technology, and music. His invention of the communication satellites made worldwide television broadcasting possible and eventually led to inexpensive long-distance telephone communication. The Telstar satellite made such an immediate social impact that various musicians wrote songs named for it. Pierce's klystrons are used in radar systems and in linear particle accelerators, such as the Stanford Linear Accelerator (SLAC). The PCM paper he coauthored inspired the decades-long development of digital systems, namely digital computers. In the field of music, Pierce codiscovered the Bohlen-Pierce musical scale, in which the octave triples rather than doubles the frequency of the original tone. The scale has been used by a handful of major computer musicians.

Roy J. Plunkett

American chemist

Plunkett is best known for his accidental discovery of Teflon while researching chlorofluorocarbon refrigerants. Teflon's nonstick and nonreactive properties made it an ideal material for many military, commercial, and medical applications and helped transform the plastics industry.

Born: June 26, 1910; New Carlisle, Ohio
Died: May 12, 1994; Corpus Christi, Texas
Primary field: Chemistry
Primary invention: Teflon

Early Life

Roy J. Plunkett was born in New Carlisle, Ohio, and spent his childhood on his parents' farm. He attended Manchester College in Indiana, where one of his roommates was Paul J. Flory, who later won the 1984 Nobel Prize in Chemistry for his contributions to polymer theory, the area in which Plunkett would make his greatest scientific contributions. Plunkett graduated with a B.A. in chemistry in 1932. He earned his master's degree and Ph.D. in chemistry from Ohio State University in 1933 and 1936, respectively. He would also receive honorary doctorate degrees from Manchester College, Washington College, and Ohio State University. After college, he married his wife, Lois, and had two sons, Michael and Patrick. Plunkett found his first job at E. I. du Pont de Nemours and Company (DuPont), the company with which he would spend his entire career. He was hired in 1936 as a research chemist at DuPont's Jackson Laboratory in Deepwater, New Jersey. His first assignment involved research into chlorofluorocarbon (CFC) refrigerants.

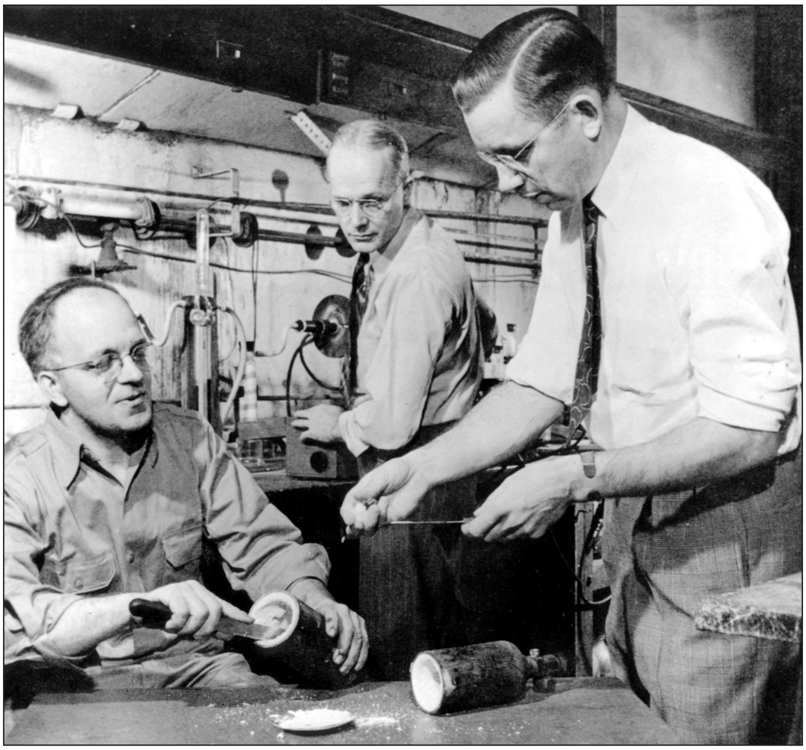
Life's Work

Plunkett was assigned to a joint research effort between DuPont and General Motors' Frigidaire Division to develop the chemistry of fluorocarbons. The project sought to replace the commonly used sulfur dioxide and ammonia for refrigerators and air conditioners with fluids that were nontoxic, nonflammable, odorless, and colorless. Plunkett was to research the coolant tetrafluoroethylene (TFE), a gas normally stored in small cylinders at room temperature. It was during an experiment on this project that Plunkett would accidentally discover what became his best-known invention, which would revolutionize the field of polymer research.

In 1938, the twenty-seven-year-old Plunkett opened the valve of one of his cylinders in order to retrieve the TFE stored inside, which had been chilled to a dry-ice temperature of –110° Fahrenheit (–76° Celsius). When no gas emerged, Plunkett at first believed that it had somehow leaked from the storage cylinder. After weighing the cylinder, however, Plunkett realized that the unchanged weight meant that the gas was somehow still inside. Also, further investigation revealed that the cylinder's valve was not clogged. Plunkett next cut the storage cylinder in half, revealing a white, waxy solid substance coating the inside. Plunkett had accidentally created polytetrafluoroethylene (PTFE), a fluorocarbon polymer formed when gas molecules join together in a chainlike reaction.

Plunkett received a patent for his invention in 1941. Although his discovery of PTFE was the accidental result of a failed experiment, he had the knowledge and intuition to realize that the substance had several physical properties that could make it useful and that it should be investigated. In particular, he noted its chemical inertness and slippery quality. DuPont's Central Research Division performed numerous experiments on PTFE over the next decade, testing its ability to withstand strong acids and bases, powerful chemicals and solvents, and extreme hot and cold temperatures. Despite its beneficial properties, PTFE at first proved too expensive to produce to make it commercially viable, but DuPont was able to introduce it to the commercial market under the brand name Teflon by the end of the decade.

While DuPont developed Teflon for commercial use, Plunkett continued to build his distinguished career with the company in other divisions. In 1939, Plunkett was promoted to chief chemist for the manufacture of tetraethyl lead at DuPont's largest plant, a role that he would fill until 1952. Tetraethyl lead was an important additive that raised octane levels when added to gasoline. After that, he served as DuPont's director of operations in the Freon Products Division in Wilmington, Delaware. Plunkett received numerous awards and other forms of recognition in his lifetime, including the Philadelphia Scott Medal in 1960, and induction into the Plastics Hall of Fame in 1973 and the Inventors Hall of Fame in 1985. He retired from DuPont in 1975 and died of cancer in Corpus Christi, Texas, on May 12, 1994, at the age of eighty-three.



Roy J. Plunkett, right, takes part in a reenactment of the discovery of Teflon. (Hagley Museum and Library)

TEFLON

Polytetrafluoroethylene (PTFE), commonly known by the DuPont trade name Teflon, is a synthetic fluoropolymer with a high molecular weight consisting of carbon and fluorine. At room temperature, it is a white, waxy, dull, plastic-like solid. Teflon is valued for its slipperiness and chemical inertness and can be used in different forms, such as a solid, a lubricant, or a powder. Even before it became commercially viable, Teflon made its first significant contribution in the field of military weapons production. One of its first uses involved the top-secret Manhattan Project, which developed the first atomic bomb during World War II. Teflon was used on gaskets within the bomb to seal pumps and piping because it would not corrode when it came in contact with the bomb's corrosive chemical elements.

Since this early use, Teflon has proven valuable in a number of other military and governmental applications. It continues to be used in the production of explosive devices and power reactors in places such as uranium-enrichment plants because of its nonreactive properties. Teflon-coated fibers have been used in the production of the pressurized space suits used by astronauts since the U.S. Apollo program designed to land a man on the Moon in the 1960's. Teflon prevented chafing and acted as a flame retardant. The space industry also uses Teflon to insulate spacecraft wires and cables and satellite components as well as to make nose cones and heat shields that protect spacecraft during launch and reentry into Earth's atmosphere.

Teflon has proven equally versatile in the private commercial and medical sectors. One of its earliest and best-known commercial uses was as a durable coating for frying pans and other cookware and utensils. Teflon's nontoxic and slippery qualities allow for easy cleaning. Teflon's flexibility and the fact that it does not produce harmful reactions in the human body make it an ideal material for myriad medical uses, including its use in implanted devices such as heart valves, pacemakers, bone and tendon substitutes, and artificial corneas as well as nonimplanted products such as dentures and body piercings. It is used in clothing manufacture and materials such as Gore-Tex because of its ability to protect garments from moisture damage, dirt, and other stains.

As a lubricant in machinery, Teflon reduces friction, preserving energy and preventing excessive wear and tear on machine parts. It has been used in electric wires, cables, and connector assemblies, microchip packaging, circuit boards, pyrotechnic compositions, infrared decoy flares, solid-fuel rocket propellant igniters, armor-piercing bullets, computer mice feet, plumbing, and thread seal tape. It is used to make containers for reactive and corrosive chemicals and has proved valuable to the field of optical radiometry. Teflon has even been shown to prevent insects from climbing up surfaces painted with it. One of its newer applications is its use in building materials. For example, Teflon was used in construction of the roof of the Hubert H. Humphrey Metrodome in Minneapolis, Minnesota, and the Millennium Dome in London.

IMPACT

Plunkett is remembered as a pioneer in the fields of polymer chemistry and materials science. His determination to study the result of a failed experiment became an often-cited example of the importance of recognizing the role of luck and an open mind in the process of scientific discovery. His work in fluoropolymers played a critical early role in the development of what became a multibillion-dollar plastics industry. Teflon's military applications, beginning with its use in production of the first atomic bombs, aided national defense. Teflon became so well known that it became a national catchphrase by the 1980's, when President Ronald Reagan became known as the "Teflon President" because the scandals that plagued his administration did not seem to "stick" to him personally and affect his popularity.

In addition to Plunkett's discovery of the polymer Teflon, his research and development contributions during his DuPont career have resulted in new products and processes utilized in the refrigeration, aerosol, electronics, plastics, and aerospace industries. Other useful polymers developed based on Plunkett's accidental discovery include neoprene and nylon. Plunkett's name also lives on through DuPont's Plunkett Awards, given each year in recognition of groundbreaking innovations using DuPont fluoropolymer products.

Joseph Priestley

English theologian and scientist

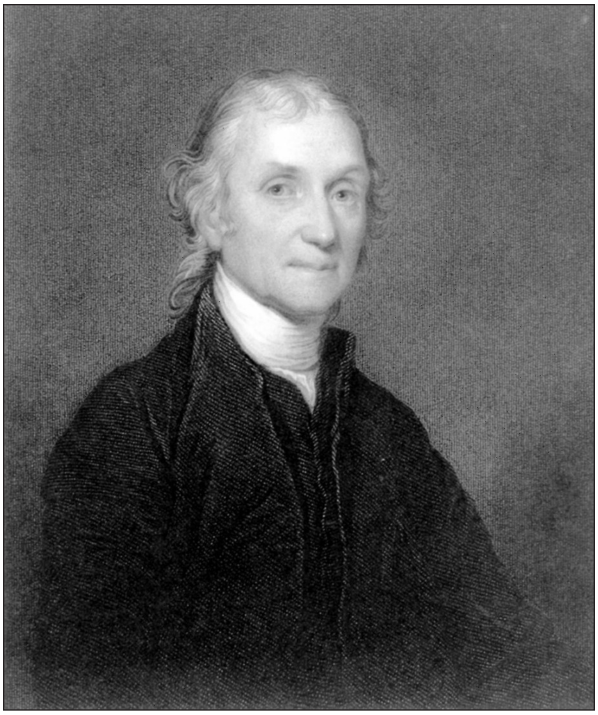
Although most famous for his discovery of oxygen, Priestley developed apparatuses for discovering other new gases. He also dissolved carbon dioxide in water, thereby creating soda water, and he found the first eraser, which he called a "rubber."

Born: March 13, 1733; Birstall Fieldhead, Yorkshire (now West Yorkshire), England
Died: February 6, 1804; Northumberland, Pennsylvania
Primary fields: Chemistry; physics
Primary inventions: Soda water; apparatuses for discovering gases; the eraser

Early Life

Joseph Priestley was born in Birstall Fieldhead in the north central English county of Yorkshire. His father, Jonas, was a weaver and finisher of woolen cloth, and his mother, Mary, was the daughter of a farmer. After his mother died in 1739, his father asked his sister Sarah and her husband, John Keighley, to raise Joseph, which they did, sending him to Batley Grammar School, where he mastered Latin and began learning Greek. Sarah Keighley's interest in Nonconformist religions influenced Joseph, particularly after a bout with consumption interrupted his education. Through self-study and the help of a tutor, he learned several modern languages, including French, Italian, and German, as well as the rudiments of mathematics. Although his illness left him with a stutter, he was determined to become a minister, and in 1752 he traveled south to Daventry, near Northampton, where he entered a Dissenting academy. After studying the Bible and reading such books as David Hartley's *Observations on Man, His Frame, His Duty, and His Expectations* (1749), Priestley changed his religious views from Calvinism through Arminianism to Arianism. He embarked on a lifelong quest to create a Christian philosophy in which religion and science were compatible.

When, in 1755, Priestley left Daventry to become an assistant minister to a small congregation at Needham Market in Suffolk, he had already acquired a deep knowledge of theology, history, and natural philosophy, and he



Joseph Priestley. (Library of Congress)

had begun to write his *Institutes of Natural and Revealed Religion* (1772-1774). However, his heterodox views and stammering speech made him a controversial and ineffective preacher. In 1758, he moved north to a ministry at Nantwich, near Manchester, in Cheshire. He opened a school where, in addition to languages and history, he taught natural philosophy, and he was even able to purchase scientific instruments and perform experiments. In 1761, he moved to Warrington, where he taught modern languages at the town's Dissenting academy, and where, in 1762, he married Mary Wilkinson, whom he had met at Nantwich and who proved to be an intelligent and supportive wife. He also found time to publish works on history, biography, and education, which led to his being awarded a doctor of laws degree from Edinburgh University in 1764, and thereafter he was known as "Dr. Priestley."

Life's Work

During his remaining years at Warrington, Priestley continued to write about the history of Christianity, but he also became interested in the history of science. He interpreted both histories as reflecting God's plan for the perfection of humanity. He met Benjamin Franklin in London during the winter of 1765-1766. Franklin, who had already invented the lightning rod, encouraged Priestley to complete his book on electricity. *The History and Present State of Electricity with Original Experiments*, first published in 1767, not only included Priestley's analysis of the experiments, discoveries, and inventions of others but also discussed some of his own experiments—for example, his discovery that charcoal conducted electricity.

The most important period for Priestley's contributions to science and invention began in 1767, when he moved from Warrington to Leeds. Here he became minister at Mill Hill Chapel and made two of his most important discoveries. The first was carbonated water, which was the result of his experiments at a brewery. The second occurred when, in 1770, he was working on a popularization of his history of electricity. He discovered that the hardened sap from certain trees in Brazil and India was able to rub out lead pencil marks. He published his observations on what he called a "rubber."

Priestley's experiments with "mephitic air" had begun while he was writing his history of electricity, and he had discovered that this gas (today's carbon dioxide) was a nonconductor. Joseph Black had done extensive work on this gas, which he called "fixed air," and Priestley, whose interest in chemistry had been piqued by a series of chemical lectures he had attended while at Warrington Academy, decided to turn his attention to chemistry. He studied Stephen Hales's *Vegetable Staticks* (1727) and adapted his techniques for the generation, collection, and manipulation of gases. The first new gas that Priestley discovered was "nitrous air" (today's nitric oxide). Although Hales had actually formed this gas, he did not investigate its properties, whereas Priestley subjected this gas to extensive physical and chemical analysis. He also invented a new technique for collecting those gases that dissolved in water. He used mercury instead of water and in this way discovered "acid air," later called "marine acid air" (today's hydrogen chloride).

His investigations of gases were facilitated when, in 1773, Lord Shelburne invited him to become librarian at his estate in Wiltshire. Here and at Lord Shelburne's town house in London, Priestley had sufficient leisure to conduct an important series of experiments in which he discovered several new gases. His most famous discovery was made when, using a powerful lens, he focused sunlight on a red compound of mercury, thereby generating a gas that had unusual properties. Compared to common air, a candle flame burned longer and brighter and a mouse lived longer in it. Because he was an ardent advocate of the phlogiston theory (which held that combustible substances contained a weightless fluid called phlogiston), he named his new gas “dephlogisticated air.” He had, in fact, discovered oxygen. Using his new techniques, he was able to discover other important gases, such as “dephlogisticated nitrous air” (today’s nitrous oxide, or laughing gas), “alkaline air” (today’s ammonia), “vitriolic acid air” (today’s sulfur dioxide), and “fluor acid air” (today’s silicon tetrafluoride). He was also able to deepen his understanding of plant respiration when, in modern terms, he found that plants absorb carbon dioxide from the atmosphere and release oxygen. He gradually published his *Experiments and Observations on Different Kinds of Air* in several volumes between 1774 and 1786.

Priestley and Lord Shelburne amicably parted in 1780, when Priestley became a minister at the New Meeting House in Birmingham. He settled his family, which now included three sons and a daughter, at Fairhill, and he became a member of an intellectual family through the Lunar Society, whose members included Erasmus Darwin, James Watt, and Matthew Boulton. They met on Mondays nearest the full moon to discuss scientific discoveries, inventions, and modern industry. Priestley, who had often expressed his sympathies for the American and French Revolutions, found that he was persona non grata for many commoners as well as magistrates, and his home was attacked on July 14, 1791, Bastille Day, with the tacit approval of officials. Although his books, papers, scientific apparatuses, and furniture were destroyed, he and his family managed to escape, eventually settling at Hackney, near London, where he taught for a while. The growing animus against him, however, extended even to members of the Royal Society, and he immigrated to the United States. He and his family created a home in Northumberland, Pennsylvania. He continued to defend his phlogistonist views and befriended such American radicals as John Adams and Thomas Jefferson. He refused to become an American citizen, preferring to live and die as an Englishman, which he did in 1804. He was buried in a Quaker cemetery.

Impact

Priestley approached the study of nature as an amateur. His vocation was to serve God and His people as a minister, but his avocation was to explore God’s world through his observations and experiments in physics and chemistry. For him, science and religion were not in conflict,

Soda Water

Like so much else in Joseph Priestley’s life, his discovery of soda water was serendipitous (he might say providential). When he first moved to Leeds in 1767, he happened to live next door to a brewery, and he became curious about the “mephitic air” that existed above fermenting fluids in the vats. He received permission to do experiments with this gas. For example, he found that this “air” snuffed out a candle flame, and it flowed down the side of the vat, because, as he discovered, it was heavier than common air. He then suspended containers of water above the vat, and he found that the water absorbed the gas, giving it a pleasant taste that reminded him of the mineral waters that had become so popular. He gave this carbonated water to some of his friends, who were as impressed as he was with its invigorating taste. However, in the summer of 1768 he moved away from the brewery to a house on Basinghall Street, and he made no more of what he began calling his “artificial Pyrmont water” (after a famous natural mineral water).

In the spring of 1772, an accidental occurrence while Priestley was dining with the duke of Northumberland stimulated him to return to his earlier discovery. The duke gave Priestley some distilled water that had been produced for the sailors of the Royal Navy. Priestley found it bland, and he told the duke that his carbonated water not only tasted better but also might combat the scurvy that was then decimating British crews on long voyages. Priestley returned to his laboratory and devised a new way of making soda water. By this time, he knew that his mephitic air was the same as the “fixed air” that Joseph Black had been the first to discover. He made a generator for fixed air by reacting “oil of vitriol” (today’s sulfuric acid) with powdered chalk (today’s calcium carbonate) in a container. He was able to transmit the gas created in the container via a tube into a bladder, on which he could exert pressure to force its fixed air into a container of water. In 1772, he published his discovery of soda water and the apparatus to make it in a pamphlet: “Directions for Impregnating Water with Fixed Air in order to communicate to it the peculiar Spirit and Virtues of Pyrmont Water and other Mineral Waters of a Similar Nature.” He made no attempt to patent his discovery or method, and he saw as his reward the happiness that his invention brought to people. Unfortunately, soda water did nothing to cure scurvy, but it did become a successful industry. For example, Jacob Schweppe made his fortune based on it. Others added sugar and flavorings to create a variety of soda drinks. In fact, many have called Priestley “the father of the modern soft-drink industry.”

since knowledge of the natural world would make people more content, loving, and prosperous. Although he insisted that his experiments were only his hobby, their results helped to create new sciences and industries, which would have pleased him, because, like his friend Benjamin Franklin, he felt that new knowledge should lead to practical consequences.

The new gases that Priestley discovered, more than any other scientist in history, helped to create the modern science of chemistry. Furthermore, several of his new gases turned out to have many uses in science, industry, and medicine. For example, oxygen has been used in the steel industry to make steel in oxygen furnaces, and the oxygen-acetylene torch is used in the welding of steel. Oxygen is widely used in many modern rockets. In medicine, oxygen has been found helpful in treating pneumonia, emphysema, and other diseases.

Like Franklin, Priestley refused to patent his discoveries and inventions. This gave entrepreneurs a free hand to develop such discoveries as soda water into profitable products. Priestley also had a lasting influence through his many books. For example, he helped shape the history of science through his books on electricity, optics, and pneumatic chemistry. His writings on history, biography, Christianity, human rights, and representative democracy influenced such pivotal thinkers as Jeremy Bentham and Thomas Jefferson, and his scientific writings influenced such significant figures as Antoine Lavoisier and Charles Darwin. Some scholars choose to separate Priestley's science from his theology and politics, but Priestley himself believed in their unity. This vision energized him to create one of the eighteenth century's most illuminating and influential bodies of work.

Ptolemy

Egyptian astronomer and mathematician

Ptolemy is most famous for the Ptolemaic astronomical system, which was the culmination of ancient Greek astronomy and the accepted explanation of the cosmos for fourteen hundred years. Ptolemy also published a major treatise on geography and a lesser-known one on optics.

Born: c. 100 c.e.; Possibly Ptolemais Hermii, Egypt
Died: c. 178 c.e.; Possibly Alexandria, Egypt
Also known as: Claudius Ptolemaeus (birth name)
Primary fields: Astronomy; geography
Primary invention: Ptolemaic astronomy

Early Life

Very little is known of the life of Ptolemy (TOL-uh-mee). The dates of his birth and death are unknown and must be estimated from the dates of his known works. The earliest astronomical observation Ptolemy made and recorded was in the year 127 c.e. The latest was in the year 150. He did enough work after his major astronomical writing to suggest that he might have lived a couple decades after that. Estimates of his birth year range from roughly 85 to 100. He lived to at least the year 150 and possibly to about 178.

Ptolemy apparently lived his entire life in Alexandria, site of the great ancient library, in Egypt. He recorded the location of his observations as Alexandria. However, he may have been born in Ptolemais Hermii, Egypt, rather than Alexandria. Though Ptolemy lived in Egypt, his name suggests that he was of Greek rather than Egyptian descent. The Claudius portion of his full name, Claudius Ptolemaeus, suggests Roman citizenship. One of the Roman emperors probably honored one of Ptolemy's ancestors with Roman citizenship.

Life's Work

Ptolemy's major contribution to the world's knowledge was in the field of astronomy. Building on the work of earlier Greek astronomers, notably Hipparchus, Ptolemy's book, the *Almagest* (c. 150), was the culmination of ancient Greek astronomy. In the *Almagest*'s thirteen books, Ptolemy works out his geocentric theory of the cosmos, which is now known as the Ptolemaic system. Ptolemy describes mathematically the motions of the then known heavenly bodies. Some of the *Almagest* uses Hipparchus's explanations of motions of heavenly bodies; however, Ptolemy added original ideas of his own.

Rather than jumping directly into Ptolemy's original contributions, the first two books of the *Almagest* provide an introduction to the basic observed motions of heavenly bodies and postulates of ancient Greek astronomy. Ptolemy postulated that Earth and the heavens were spherical and that all motions in the heavens were uniform circular motion. Book 3, on the Sun's motion and the length of the year, as well as book 6, on eclipses, add nothing to the earlier work of Hipparchus. Books 7 and 8 contain a catalog of 1,028 stars. Ptolemy's catalog was based on Hipparchus's observations corrected for precession (the 26,000-year wobble as Earth spins on its axis) to the epoch 137 c.e. Ptolemy apparently added no new observations. In book 5, Ptolemy discusses the astrolabe, used for measuring positions of heavenly bodies,

Ptolemy. (Library of Congress)

and uses observations of the Moon's parallax to deduce the ratio of the distances to the Sun and Moon. Ptolemy based these portions of the *Almagest* largely on Hipparchus's previous work, adding only minor new contributions.

Ptolemy's greatest original contributions are in his theories of the motions of the Moon, in book 4, and the five then known planets, in books 9 through 13. Hipparchus based his theory of the Moon's motion only on observations made during eclipses. By observing the Moon at other times, Ptolemy discovered new motions. Ptolemy's modified theory of the Moon's motions more accurately predicted the Moon's positions.

Ptolemy's greatest achievement, however, was his theory of planetary motions. Ptolemy made additional observations of planetary positions to add to Hipparchus's previous observations. Ptolemy also added two geometric devices to the two geometric devices invented by Hipparchus to predict planetary positions more accurately. Hipparchus used the deferent and epicycle to explain planetary motions. For greater accuracy, Ptolemy added the eccentric and equant point. Using these four geometric devices, he constructed a theory of planetary motion that predicted planetary positions to the accuracy of the observations available until Tycho Brahe made his observations in the sixteenth century. It is likely that Ptolemy considered his system of spheres to be a mathematical tool for calculating planetary positions rather than a physical reality.

Although most famous for his work in astronomy, Ptolemy did significant work in geography. Like his astronomy, Ptolemy's geography builds on previous work but adds his own original contribution. His geography builds on the foundation previously laid by Eratosthenes

Ptolemy's Geocentric System

Ptolemy's geocentric system of the cosmos used four geometric devices to explain observed motions of the planets. Two, the deferent and epicycle, were invented by Hipparchus and used by Ptolemy. The other two, the eccentric and equant, were invented by Ptolemy. One of the fundamental assumptions of ancient Greek astronomy was that heavenly bodies can only move in uniform circles. Hence, Ptolemy had to use combinations of circles to explain the observed planetary motions.

The Sun, Moon, and planets all appear to rise in the east, move across the sky, and set in the west. It is now known that Earth's daily rotation causes this motion. However, in the Greek geocentric system, Earth was stationary. Hipparchus and Ptolemy explained this basic daily motion with a circle called the deferent. The Sun, Moon, and each planet had its own individual deferent that circled the Earth to produce the observed daily cycles.

According to Ptolemy's system, the planets occasionally exhibit periods of retrograde motion, when they appear, for a few weeks, to reverse the direction of their motions as seen against the background of the fixed stars. It is now known that retrograde motion is an illusion caused by an inner planet overtaking an outer planet as they both orbit the Sun. However, Hipparchus, and later Ptolemy, used epicycles to explain retrograde motion. They both required uniform circular motion, so the epicycle was a small circle centered on the deferent. The planet moved on the epicycle while the center of the epicycle moved on the deferent. With the combination of the two uniform circular motions, the planet seemed to reverse direction, as seen from Earth, when it was on the inner portion of the epicycle.

The deferent and epicycle taken together explained retrograde motion; however, they did not accurately predict planetary positions. Ptolemy observed that the apparent speed of the planets varied. He invented the eccentric and equant to explain how planets seemed to change speed as seen from Earth.

Aristotle's physics required Earth to be at the center of the universe; however, it did not impose this requirement on the center of a planet's deferent. Ptolemy displaced the center of each planet's deferent a small amount from Earth and called this displaced point the eccentric. The planet's distance from Earth therefore varied. As the planet's epicycle was on the portion of the deferent closer to Earth, it appeared to move faster as seen from Earth.

Ptolemy also added the equant point, which was placed an equal distance from the Earth as the eccentric but in the opposite direction. Aristotle's physics required uniform circular motion; however, Ptolemy said that the uniform motion along the deferent was as seen from the equant point rather than as seen from the center of the deferent. He cheated on the uniform circular motion requirement to make his theory agree with observed positions of the planets.

Ptolemy used these four devices to accurately predict planetary positions. Nicolaus Copernicus, however, objected to the equant point, which eventually led to the downfall of his model.

and Hipparchus. Ptolemy was the first to use the terms "latitude" and "longitude." He did not invent the idea of a grid system for locations on Earth, but he improved the previous system. Modern maps usually have north at the top and east on the right, which is a convention started by Ptolemy. As both a geographer and astronomer, Ptolemy knew the Earth was spherical. He invented a projection for mapping the spherical Earth on a flat surface.

Ptolemy's geography also had some serious errors that resulted from the fact that Earth had not been sufficiently explored at the time. Ptolemy's most significant geographical error was the size of Earth. Eratosthenes had estimated Earth's size very accurately, but Ptolemy rejected this estimate and used the incorrect smaller value of 18,000 miles for Earth's circumference. Ptolemy also overestimated the size of Asia. The combination of these two errors led Christopher Columbus to think that he could travel from Spain to the East Indies by sailing west.

Ptolemy's work in astronomy and geography required the use of considerable mathematics, and he made important contributions to mathematics, most notably in trigonometry. He also applied his mathematical skill to the study of music theory. In addition, he published a four-volume work on astrology called *Tetrabiblos*. (In Ptolemy's time, astrology was considered an acceptable intellectual pursuit.) Ptolemy's lesser-known work on optics also contains original contributions. He experimentally verified the law of reflection and the fact that light is refracted when passing between media. This work is probably less known because it survives only in the form of imperfect translations. Ptolemy most likely completed it near the end of his life.

Impact

Ptolemy's geocentric theory of the cosmos, with its ability to accurately predict planetary positions, was the culmination of ancient Greek astronomy. The Ptolemaic system was so good that it was considered by most scholars to be the unchallenged authority on astronomy for fourteen centuries. From the time of Ptolemy to the time of Nicolaus Copernicus, Arab and European scholars preserved the Ptolemaic system. When required by observations, astronomers made minor adjustments to the system, such as adjusting the size or rate of a deferent or epicycle. However, the basic Ptolemaic system was not changed or seriously challenged until Copernicus published his heliocentric theory. The Ptolemaic system endured so long because, despite being incorrect, it was good science. Ptolemy based his astronomical system on the Greek ideas of aesthetics as well as the now defunct Aristotelian physics. Ptolemy's system of spheres also accurately predicted planetary positions.

Ptolemy's geography forms the basis of much modern geography. The terms "latitude" and "longitude" used to specify locations build on Ptolemy's work. Modern cartography uses various projections to map the spherical Earth on flat maps. Ptolemy pioneered this technique. Ptolemy's geographical work was lost to European civilization until the fourteenth century, but it had a profound effect on Western civilization. Ptolemy's knowledge that Earth was spherical, combined with his underestimate of Earth's size and overestimate of Asia's size influenced Columbus. Columbus thought that sailing west to reach the East Indies would be easy. This error, of course, led to the discovery of the New World.

—Paul A. Heckert

George Mortimer Pullman

American industrialist

Pullman revolutionized railroad car design in nineteenth century America. Founding the Pullman Palace Car Company in 1867, Pullman created luxury sleeping, dining, and parlor cars for railroad travelers. To house his employees, he created the planned industrial town of Pullman, Illinois.

Born: March 3, 1831; Brocton, New York
Died: October 19, 1897; Chicago, Illinois
Primary fields: Manufacturing; railway engineering
Primary invention: *Pioneer* sleeping car

Early Life

George Mortimer Pullman was born in Brocton, New York, on March 3, 1831, to James Lewis Pullman and Emily Caroline Minton. Pullman's formal education ended after the fourth grade. From 1845 to 1848, he worked in a general store in Westfield, New York, run by his maternal uncle. Pullman's father was a carpenter, and in 1848 the boy joined his father and two older brothers in Albion, New York, where they were working moving buildings along the Erie Canal. In 1853, Pullman's father died, and Pullman took over the business.

In Albion, Pullman became acquainted with Benjamin Field, who from 1854 to 1855 served in the New York State Senate. This acquaintance would lead to an important business partnership. Pullman previously had several very unpleasant experiences traveling by train, and he had come up with some ideas to make long-distance train travel more comfortable. For his part, Field had secured rights to run sleeping cars in the Western states. Soon, Pullman and Field would work together creating sleeping cars.

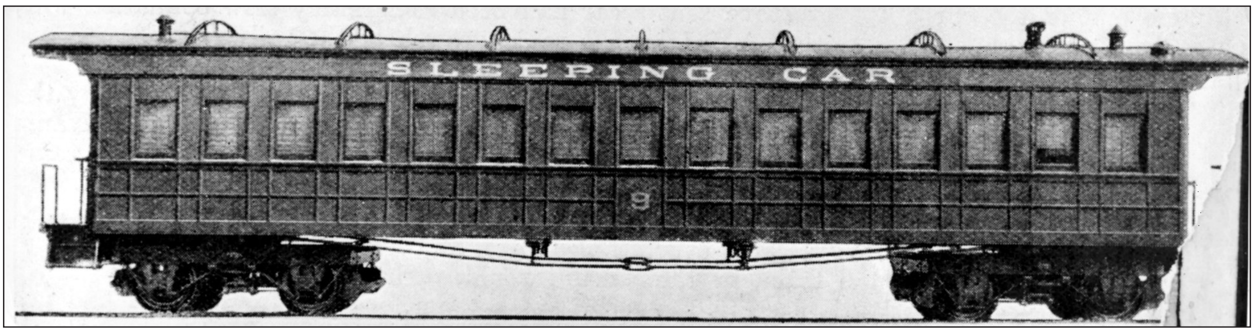
Because of the recession of 1858, Pullman traveled to Chicago, where the city was raising sunken streets, and he found work moving buildings. He was also hired to raise the famous Tremont Hotel. That year, Pullman began working with Field on remodeling two coaches into sleeping cars for the Chicago and Alton Railroad. In 1859, they produced a third sleeping car.

In order to gain capital, Pullman went to the Colorado Territory between 1860 and 1863, where he ran a number of lucrative businesses. While he was in Colorado, Pullman continued revising his designs for railroad sleeping cars. In 1863, he returned to Chicago, and in 1864 Pullman and Field began working on what would be their first Pullman sleeper. Called the *Pioneer*, it rolled into service in 1865. Among the design innovations in this first Pullman sleeper was their patented folding upper berth. At a cost of $20,000, this was the most luxurious sleeping car then in existence, and it set the tone for the creative manufacturing that would be the hallmark of the Pullman cars into the twentieth century.

Life's Work

Pullman's success was sealed when his *Pioneer* was used in the funeral train for President Abraham Lincoln. Mary Todd Lincoln had seen the *Pioneer* and is said to have personally requested its use for the journey of the funeral train between Chicago and Springfield, Illinois, where the president was buried. As the longest, widest, and highest passenger car on the American railroad, the *Pioneer* required that two feet of clearance be added to all railroad bridges and platforms along the route. The use of the *Pioneer* in Lincoln's funeral train led others to request it for different functions, and soon other railroad lines had to add additional clearance for Pullman's sleeping car.

In 1867, Pullman and Field launched the Pullman Pal-



The Pioneer *sleeping car, introduced in 1865 at a cost of $20,000, set the standard for luxury rail travel.* (Getty Images) ace Car Company. With a capital of $1 million, and 125,000 miles of track upon which they could operate, the company had access to the majority of American railway lines. Pullman advertised personalized service provided by porters, and fresh linen changed daily. Pullman hired African Americans, many of them recently freed slaves, to serve as porters. The Pullman Palace Car Company became the largest employer of African American men in the United States.

As quality food service upon trains was almost nonexistent in 1867, Pullman saw a market for such service. In 1867, Pullman built a "hotel car," the *President*, which was a sleeping car with an attached dining car. Styled a "hotel on wheels," the *President* boasted excellent food and service. In 1868, Pullman built the *Delmonico*, which provided first-class accommodation and food prepared by chefs from Delmonico's Restaurant in New York.

Pullman did not simply market railroad cars for the rich. Rather, they were advertised as "luxury for the middle class." By the mid-1870's, the company had seven hundred Pullman cars operating. Over time, the company created other cars, including parlor cars (1875) and vestibule cars (1887). In the 1890's, the company built "chapel cars," which were railroad cars built as portable churches. By the early 1890's, the Pullman Palace Car Company employed more than 12,000 employees and operated 2,135 cars. Approximately 100,000 persons a night slept on Pullman sleeping cars.

On June 13, 1867, Pullman married Harriett Amelia Sanger, daughter of James Y. Sanger (businessman and railroad builder) and Mary McKibben. They had four children. Pullman built a house in Chicago, and he added homes in Long Branch, New Jersey (where the Pullmans socialized with President Ulysses S. Grant and his family), and Castle Rest on Pullman Island in New York. Pullman also had a home in Albion.

In 1880, Pullman paid $800,000 to purchase four thousand acres west of Lake Calumet, Illinois. There, between 1880 and 1884, he built the planned industrial town of Pullman, Illinois, which cost $8 million to build. Pullman personally planned all aspects of life in the community. He hired architect Solon Beman and landscaper Nathan Barrett to design the town. In addition to railroad car shops for the workers, the town of Pullman had a number of amenities, including a hotel, a stable, a market hall, a bank (the Pullman Savings and Loan), a public park, a library, and a church. The rents for apartments, row houses, and single homes all went to Pullman himself.

The Panic of 1893 hit the railroad industry and the Pullman Palace Car Company in particular. A major cause of the financial panic was overbuilding by American railroads, who borrowed more money than they could repay. In the resulting depression, a number of railroads went bankrupt. Pullman reduced wages by 28 percent while maintaining the rent in the town of Pullman. Pullman

The *Pioneer*

George Mortimer Pullman's *Pioneer* was, upon its creation in 1865, the most elaborate railroad sleeping car in America. Costing $20,000, the *Pioneer* was built in Chicago at the Chicago and Alton Railroad works. Executives of the Chicago and Alton Railroad had expressed some doubts that the high cost of the *Pioneer* could be recouped. As it was under construction, some called the sleeping car "Pullman's Folly." However, when the car went into service, it quickly gained a reputation for comfort and luxury. Its use in President Abraham Lincoln's funeral train ensured its success. Mary Todd Lincoln herself was said to have observed the *Pioneer*, and she requested its use in her husband's funeral train. Afterward, drawn by the train's presidential connection and its growing reputation for opulence, many famous individuals rode the *Pioneer*, including General Ulysses S. Grant.

The *Pioneer* used Pullman and Benjamin Field's patented folding berth, which folded up into the ceiling of the railroad sleeping car. The car also had lower berths, which were formed from folding down the train seats. Pullman ensured that linen for these upper and lower berths was changed every day, something that was found on no other sleeping car then in existence.

The *Pioneer* had red carpeting, and fine wood paneling throughout added to the elegance of the car. The luxury car was recognized as having the most comfortable seats of any railroad car. The train was lit by coal lamps that were covered with worked silver. The *Pioneer* was higher than other trains in use, and the ventilator transoms near the ceiling added natural lighting while providing air circulation. The car had four state rooms that could be created by means of folding doors.

When it went into service, Pullman's *Pioneer* was the longest (fifty-four feet), widest (ten feet), and highest railroad car then in use. When the *Pioneer* was used on the route for the Lincoln funeral train, clearances at railroad platforms and trestles had to be expanded by two feet to accommodate it. As requests to use the car on other lines increased, clearances were altered accordingly. Thus, Pullman's *Pioneer* made railroad history by setting the standard for railroad design and luxury rail travel.

employees found this to be untenable. Negotiations between the company and representatives of Pullman employees ended with a companywide strike in May, 1894.

By the end of June, the American Railway Union joined the strikers, and 125,000 employees on twenty-nine different railroads refused to handle Pullman cars. Rail transportation was effectively brought to a halt. Pullman did not tolerate union activity, and he responded by requesting assistance from federal troops to break the strike. As the halt in rail transport hindered the delivery of the mail, President Grover Cleveland ordered out twelve thousand soldiers. This led to the destruction of more than $300,000 worth of property, the deaths of thirteen strikers, and the wounding of many more.

After the strike was broken, a federal commission found that Pullman was partly to blame for the strike, by charging excessive rents and thus ensuring that his employees suffered the most from the financial effects of the depression. In 1898, the Pullman Company was forced to cede ownership of the town of Pullman to the city of Chicago. Nonetheless, Pullman's company flourished, and it continued expanding and building newer and better railway cars. Pullman died of a heart attack on October 19, 1897. He was buried in Graceland Cemetery in a coffin covered by concrete and railroad T-rails.

Impact

Coming from a humble background and without a full formal education, Pullman rose to become one of America's best-known nineteenth century entrepreneurs. Pullman's resourcefulness helped create an entire industry. His Pullman Palace Car Company set the standard for railroads the world over. Pullman's attention to detail and his marketing genius made the Pullman name the epitome of luxury and comfort.

At his death, Pullman controlled 90 percent of the North American sleeping-car business. His company was worth $63.5 million, and it had a rolling stock of 2,490 railway cars. Pullman's personal estate was valued at $7.6 million. He left $1.2 million to endow an industrial school for the children of Pullman employees (opened 1915).

Upon Pullman's death, Robert Todd Lincoln, son of the late president, became president of the company. Under Lincoln's leadership, the Pullman Company continued to lead the industry in quality railroad cars. Many U.S. presidents and other world leaders traveled in style in Pullman coaches. In 1942, the Pullman Company refitted a car, the *Ferdinand Magellan*, for use by the president of the United States. Presidents Franklin D. Roosevelt, Harry S. Truman, and Dwight D. Eisenhower used the presidential car during their time in office. The *Ferdinand Magellan* was designated as a National Historic Landmark in 1985, the only railroad car to receive such a designation.

While George Mortimer Pullman was a creative entrepreneur who designed the most luxurious railroad cars in the world, his memory was tarnished by his handling of the 1894 Pullman Strike. Pullman's lack of understanding for the plight of his workers during the depression of 1894, and his calling in of federal troops to break the strike, have left a lasting negative imprint on American labor history.

—*J. Francis Watson*

Jacob Rabinow

American engineer

Rabinow was a prolific inventor with 230 U.S. patents to his credit for inventions ranging from automatic regulating clocks to letter-sorting machines to magnetic computer disk files to safety mechanisms for bombs.

Born: January 8, 1910; Kharkov, Ukraine, Russia (now Kharkiv, Ukraine)
Died: September 11, 1999; Bethesda, Maryland
Also known as: Yakov Aaronovich Rabinovich (birth name)
Primary fields: Computer science; electronics and electrical engineering; military technology and weaponry
Primary inventions: Optical character reader; magnetic disk memory storage; magnetic particle clutch; punch-card sorter; letter sorter

Early Life

Jacob Rabinow (RA-bih-now) was born in Kharkov, Ukraine, Russia, the son of Aaron and Helen Rabinovich. The Rabinovich family moved to Siberia in 1914, where Aaron ran a shoe factory. There Jacob constructed one of his first inventions, a device for throwing rocks based on a bucksaw that used a stick between two pieces of rope to tighten the blade. An adult saw it and commented on the Roman ballista he had built. It was the first time Jacob had heard of a ballista and also the first time he realized that sometimes people "invent" something they did not know had already been invented.

In 1919, his family moved to China, where his father died. In 1921, when he was eleven years old, his mother brought Jacob and his brother to the United States and settled in Brooklyn, New York. His mother went to work in a corset factory. Jacob attended Thomas Jefferson High School, where he was a member of the mathematics team and the drawing team. His coach, the head of the school's art department, told him that his drawings were very accurate but lacked spirit and that he should consider being an engineer. Jacob agreed, as that was exactly what he wanted to do, having been inspired by Jules Verne's stories and watching the workings of his father's automated shoe factory. He graduated high school in June, 1927, with high marks in his classes.

Lacking the funds to pay for college, Jacob worked at a radio store as a salesman, radio installer, and repairman until the winter of 1928, when he had saved enough money to enter the City College of New York. Told that the engineering field was closed to Jews, he took general studies instead. In 1929, when the Great Depression hit, he decided to study engineering anyway, rationalizing that if he could not get a job, he might as well not be able to get a job in a field that interested him. He also changed his last name from Rabinovich to Rabinow, a spelling that his mother had adopted a few years before.

Life's Work

Rabinow received a B.S. in electrical engineering in 1933 and an M.A. in electrical engineering in 1934. Willing to take almost any employment, he applied to be a high school science teacher but was rejected because of his Russian accent. In 1935, along with eight hundred other applicants, he took the civil service exams, receiving a 99 in electrical engineering and an 85 in mechanical engineering. While waiting for a job offer, he worked in radio factories.

In 1938, Rabinow applied for a job at the Brooklyn Navy Yard, and they sent him to Washington, D.C., to retrieve his papers from civil service. Civil service said his papers were at the National Bureau of Standards (NBS). When he went there, he was interviewed and hired on the spot to calibrate instruments that measure water flow. He found the instruments old and inaccurate and modified them. He soon earned a reputation as someone who could do original work, which garnered him a position in developing ordnance for war. With World War II on the horizon, the NBS assigned Rabinow the task of developing fuses for bombs. He designed proximity fuses and an acceleration integrator to calculate the velocity of the falling bombs, as well as gyroscopic steering mechanisms for missiles.

In 1946, the U.S. Census Bureau approached the NBS for help in buying a computer to do the upcoming 1950 census. Rabinow consulted on this task, and the Census Bureau purchased a UNIVAC. This project spurred Rabinow to design the first magnetic memory device, consisting of magnetic disks, to store the huge amounts of information generated by computers. He then went on to develop the magnetic particle clutch, which was used in tape recorders and disk drives. A larger version was used in cars. Another of his inventions related to computers was a punch-card sorter.

In 1954, Rabinow left the NBS to start his own company called Rabinow Engineering Co. He had enjoyed

Optical Character Recognition Machines

One of Jacob Rabinow's most significant inventions was the optical character recognition (OCR) machine, which could read both printed and handwritten words and numbers. He was inspired to work on this project in 1938 after discovering that a friend had become blind. Rabinow was curious to see if at least some aspects of human vision could be replicated by a machine.

In 1947, Rabinow was asked by a colleague to modify a U.S. Department of Agriculture machine that the colleague had developed but that did not work. This project led to Rabinow's development of an OCR machine. He made a proposal to his supervisor at the National Bureau of Standards, who agreed to give him the funds for the machine's development. Rabinow's first machine projected each letter of a word from a printed page one by one onto a large disk of photographic paper. There was a Nipkow disk scanner behind the paper and a photocell behind that. The letter on the printed page was compared to each letter on the disk scanner. The more the letter on the scanning disk matched the printed letter, the more light would be blocked to the photocell and the lower the voltage recorded by the cell. After the printed letter had been compared to each letter on the scanning disk, the different recorded voltages would be compared and the "best match" to the printed letter would be determined. This first machine worked, but it was very slow because of all the comparisons that had to be made for each letter. Nevertheless, the "best match" principle employed here would be key for developing more sophisticated machines that could read even handwriting.

Rabinow correctly realized that if standardized printed alphabets and numbers could be developed, they would greatly speed the ability of the OCR machines to read material. Starting in 1956, he spent years on several committees trying to convince them to develop such standardization, but it was slow in coming. Years later, others finally appreciated Rabinow's foresight, and alphabets and numbers were standardized. They are universally used on many media today, such as the bank routing numbers on checks. For the Post Office, where sometimes coding letters and numbers are written over by the person addressing the envelope, Rabinow designed standardized characters that his machines could read independently of overwriting. He streamlined recognition systems to simplify and speed up the reading process. He even incorporated dictionaries into his machines to help the machine decide a correct word by context if it was having difficulty deciphering the word. Today, Rabinow's OCR machines are used extensively throughout business and industry.

his work at the NBS but was concerned about the political climate at the time and various rumors, such as that the NBS would be taken over by the Army and run as a military laboratory or that it would be split up with various divisions being run by private companies. Sprague Electric offered to pay him $10,000 per year if he would spend half of his time on their projects, an arrangement that provided him with some financial security as he started his own endeavor.

Rabinow handled projects for many companies, including RCA, Remington-Rand, and Airborne Instruments, designing a device to automatically identify railroad freight cars, a machine to count small toy parts as they were packed, a metal statue-carving arm, and an automatic dimmer for car headlights. He even had time to design and receive patents in six countries for an improved continuous ribbon vertical Venetian blind system, because his wife hated the horizontal Venetian blinds in their home, as well as a device for his wife's beautician to use to mix nail polish. Some of his most successful inventions during this time were a self-regulating clock that was eventually used in automotive clocks, a machine that could sort mail that he designed for the U.S. Post Office, and machines that could read typed and handwritten materials through the development of optical character recognition.

By 1972, Rabinow tired of trying to operate his own business, so he sold it to Control Data. He returned to the National Bureau of Standards for a few years, retiring in 1975. His final work while at the NBS was the design of a pickproof lock.

Rabinow continued to act as a consultant to the NBS following his retirement. He began appearing as a guest speaker on college campuses and for professional organizations. He died on September 11, 1999. In 2005, Rabinow was inducted into the National Inventors Hall of Fame.

Impact

Rabinow was an ingenious inventor who held 230 patents for items as diverse as the fields that they influenced. Virtually every person in the United States and in many other countries has been affected by one or more of Rabinow's inventions. The safety mechanisms that he invented for bombs undoubtedly protected bombardiers, and his guidance mechanisms helped deliver bombs to their targets during World War II.

His automatic letter-sorting machine mechanized the U.S. Post Office and greatly increased the speed and efficiency of mail delivery. Prior to the adoption of his machine, postal workers had to sort all mail by hand, a tedious and time-consuming process. His magnetic disk memory storage device paved the way for the development of large-scale memory systems for computers. His magnetic particle clutch is still used today in some automobiles, airplanes, and other machinery. For many years, American automobiles came standard with a self-regulating clock that Rabinow had invented.

Rabinow's optical character recognition machines revolutionized business and industry by automating the reading of masses of printed and handwritten material, a process that previously had to be done by hand. The principle of "best match" that he developed for these machines has been a foundation for the development of "thinking" computer programs.

No project was too big to tackle or too small to overlook for Rabinow. Even his little inventions—such as vertical Venetian blinds, folding footstools for shorter people to use at the opera, and a device to mix nail polish—demonstrate his dedication to making the world function better, one invention at a time.

Jesse Ramsden

English designer of scientific tools

Ramsden developed a new way of calibrating measurement instruments, and he applied his method most spectacularly to the construction of large optical instruments, especially astronomical telescopes, of better quality than any that had been made in England before.

Born: October 6, 1735; Salterhebble, near Halifax, Yorkshire, England
Died: November 5, 1800; Brighton, Sussex, England
Primary fields: Astronomy; mechanical engineering
Primary inventions: Dividing engine; theodolite

Early Life

Jesse Ramsden was the son of Thomas Ramsden, an innkeeper, but little else is known about his family, and information relating to his upbringing is sparse. Between the ages of nine and twelve, he attended the free school in Halifax, and he then went to live with an uncle surnamed Craven somewhere in the North Riding of Yorkshire. While he was there, he studied mathematics with a clergyman surnamed Hall before being apprenticed to a cloth-worker in Halifax.

After completing his apprenticeship in 1755, Ramsden went to London, where he was initially employed as a clerk in a cloth warehouse, but in 1756 he bound himself as an apprentice, for a fee of £12, to Mark Burton, a mathematical instrument maker based on Denmark Street. He soon established a reputation in that occupation for the quality of his work and his assiduity, and he began trading in his own name in the Strand in 1763. He spent a great deal of time at the home of a near neighbor, John Dollond, whose family was famous as makers of optical instruments (its name was still preserved in the early years of the twenty-first century in that of the active firm of British opticians Dollond and Aitchison). On August 10, 1766, Ramsden married John Dollond's daughter Sarah (1743-1796) at St. Martin-in-the-Fields, at the western extremity of the Strand.

As part of his bride's dowry, Ramsden received a share in the patent rights to the achromatic lens, which John Dollond had developed and whose deployment improved astronomical telescopes markedly, although its similar impact on microscopy was delayed for nearly a century because of the difficulty of grinding the smaller lenses required by such instruments. Ramsden immediately opened his own premises as a dealer in optical instruments in the Haymarket. Sarah bore two sons and two daughters between 1767 and 1771, but only one child—John (1768-1841)—survived infancy.

LIFE'S WORK

Ramsden's own expertise as an inventor was mobilized by the desire to bring about improvements to the accuracy of astronomical instruments measuring angles, which were much in demand for mapping the heavens and attempting to determine stellar parallaxes—the key to measuring stellar distances. Although no stellar parallax would be measured until after his death, further pressure of demand was exerted by the Royal Navy's desire to find a means of accurately measuring longitude. Although this quest is often represented as one for better ships' chronometers, it also required minutely accurate sextants. It was a new method of "dividing" sextants—marking up their scales in degrees—that was Ramsden's first triumph as an engineer. He devised a machine—a "dividing engine"—that could lay out such scales mechanically with considerably greater speed and somewhat greater accuracy than a highly skilled craftsman working by hand.

The dividing engine worked on any instrument with a circular scale, including theodolites and octants as well as sextants. The first version became operational in 1767, a second and superior one in 1775. In the meantime, Ramsden moved to larger premises in Piccadilly, although Sarah and his son did not go with him, initially remaining in the Haymarket in a house owned by the Dollonds. The two dwellings were no more than a hundred yards apart, and Ramsden seemingly continued to use his contact with the Dollonds to cultivate useful acquaintances and clients. It is impossible to determine exactly what went wrong with the marriage, but the split was permanent; Sarah was living in Lambeth when she died. A profile of Ramsden published in *The Mirror of Literature, Amusement and Instruction* on July 28, 1827, represented him as living in contented domesticity surrounded by his apprentices, with whom he talked shop all day and all night, but reported that he frequently hummed or sang a popular ballad whose refrain included the couplet "If she is not so true to me/ What care I to whom she be?"

Ramsden's original dividing machine was sold to Jean Baptiste Gaspard Bochart de Saron and smuggled into France (England and France were at war at the time), where it was confiscated during the Revolution and ended up in one of the national collections. It is still on display. The second remained in England, working so successfully that the Commission of Longitude awarded Ramsden a bounty of £300 and bought the rights to the engine for a similar sum, on condition that he provided comprehensive details of its design and construction. He was subsequently able to charge six shillings for graduating sextants for clients. His *Description of an Engine for Dividing Mathematical Instruments* was published in 1777.

THE DIVIDING ENGINE

Jesse Ramsden's second dividing engine—a machine that marks graduations on measurement instruments—had a 45-inch wheel (half as big as that of his first model) incised with 2,160 teeth, which were engaged by a lead screw turned by a treadle, rotated through the desired angle. The body of the device to be divided—usually a sextant—was centered on the wheel. Operated by a semiskilled workman, the machine could divide up the 120° of a sextant's scale in thirty minutes, to a higher degree of accuracy than the most skilled handcraftsman, who would typically require several days to achieve the inferior result.

The importance of the dividing machine was not confined to its greater speed and superior accuracy; because it could graduate sextants of any practical size, to a lower limit of about eight inches in radius, it permitted smaller ones to be used without any loss of accuracy—a vital step forward in the miniaturization of marine instruments. By 1789, Ramsden and his employees had graduated more than a thousand sextants of various sizes, making a relatively inconspicuous but highly significant contribution to the success of British naval vessels in an era of heroic exploration and protracted warfare.

Ramsden then turned his hand to the development of dividing engines for straight line scales, attaining an accuracy of $\frac{1}{4,000}$ of an inch in 1779. In 1780, he expanded the Piccadilly premises considerably, giving him the space to work on large astronomical instruments, and that became his vocation thereafter, although a workforce of sixty men continued to work on smaller instruments in order to sustain his income. It was as well that they did, because he soon acquired a reputation for unpunctuality in executing major commissions, his perfectionism leaving him incapable of delivering a completed instrument until he was satisfied with its accuracy. An oft-quoted anecdote related that he once turned up at Kew Palace, mistakenly claiming to have an appointment with King George III to deliver a telescope; when the king graciously consented to see him, Ramsden allegedly pointed out that, although he had come on the right day, he had unfortunately "mistaken the year."

Ramsden was elected a fellow of the Royal Society on January 12, 1786. He was the first telescope maker to use a fully circular scale for measurement, which could not be divided mechanically and thus posed a severe challenge to his craftsmanship; he rarely completed one in less than 150 days and often took far longer if he hit a snag that required readjustment or—on occasion—a fresh start. His first full-scale astronomical apparatus was delivered to Giuseppe Piazzi in 1789 and was installed at Palermo Observatory, where it played a part in numerous significant observations of the solar system. It is arguable, however, that a more significant instrument of Ramsden's manufacture was a 36-inch theodolite that he designed for General William Roy's project to reevaluate the longitude between Greenwich and Paris, which was the seed of the Ordnance Survey.

Ramsden also experimented with clockwork-driven equatorial telescopes, based on a design he had published in 1774; he remodeled one in the Royal Observatory at Greenwich in 1775, but the best instrument of that kind he built was one constructed for Sir George Shuckburgh in 1793. Following in John Dollond's footsteps, Ramsden produced an achromatic "Ramsden eyepiece" for telescopes that was very widely used; he also produced two new micrometer designs and a wide variety of other instruments, including barometers, levels, precision balances, and pyrometers. In 1795, he received the Royal Society's Copley Medal for "various improvements to philosophical instruments." He corresponded with scientists throughout Europe, and he was granted membership of St. Petersburg Academy in 1794. Several of his apprentices went on to forge successful careers, including Thomas Jones (1775-1852), and his business was taken over after his death by his foreman, Matthew Berge, who continued trading in Piccadilly until his own death in 1819. Ramsden died in Brighton, but his body was brought back for burial in St. James's Piccadilly, in close proximity to his business premises.

Impact

Although it was his large instruments that made Ramsden famous—and delays in their delivery that earned him a wry notoriety—he certainly had a greater practical impact in his own day by virtue of his accurate calibration of small instruments, especially naval sextants. The marine chronometers that "solved" the problem of calculating longitudes at sea could not have done so had they not been operated in collaboration with accurate sextants, whose rapid production Ramsden made feasible. His discovery of the dividing machine was unspectacular by comparison with such contemporary innovations as the steam engine, but the sum of its tiny contributions to millions of measurements was nevertheless vast. His large telescopes did assist considerably, though, in making numerous astronomical discoveries, and his work on equatorial telescopes was a foundation on which many subsequent instrument makers built.

Ira Remsen

American chemist

Remsen was a distinguished chemistry teacher and a prolific writer of highly regarded textbooks. He is best known for his discovery, with Constantin Fahlberg, of the artificial sweetener saccharin.

Born: February 10, 1846; New York, New York
Died: March 4, 1927; Carmel, California
Primary field: Chemistry
Primary invention: Saccharin synthesis

Early Life

Ira Remsen (REHM-suhn), the only child of James Vanderbilt Remsen and Rosanna Remsen (neé Secor) to survive childhood, was born in New York City in 1846. When Ira was eight years old, his mother's health deteriorated and the family moved to a farm in Rockland County. In this rural setting, the boy acquired a lifelong love of the outdoors and a fascination with nature. His mother died just two years later, and he was sent to live with his maternal great-grandparents, James and Elizabeth Demarest. In this home of a scholarly Dutch Reformed pastor and his cultured wife, young Remsen gained a great love for learning, acquired a taste for scripture, and developed a strong sense of honesty. In later years, he recalled his two years with the Demarests as one of the happiest times of his life. While living with them, Remsen attended the local elementary school, but his father wished him to have a richer education, so they returned to New York City.

There Remsen attended public school until, at fourteen, he enrolled at the New York Free Academy, later the College of the City of New York (CCNY). His father wished his son to study medicine, so Remsen left his undergraduate program before completing his degree. He was placed as an assistant to a practicing physician who was also the professor of chemistry at a homeopathic medical school. It was not long before Remsen realized that he needed a much more rigorous program of study to become a skilled medical professional. He convinced his father that he should enroll in Columbia University's College of Physicians and Surgeons.

Though Remsen received his medical degree with honors in 1867, he was not certain about devoting his life and talents to medicine. As a student, he had acquired some chemistry experience, and after a year of what he later called "critical self-appraisal," he decided that chemistry was his passion. He set off to study with the renowned professors in Germany with their great teaching laboratories.

In Munich, Remsen received valuable training under Jacob Volhard, an analytical chemist of great stature, and he was also able to hear some of Justus Liebigs's outstanding lectures. Volhard advised Remsen to move to the University of Göttingen, where Remsen was introduced to Fredrich Wöhler. At Göttingen, Remsen worked under the direction of Rudolf Fittig and was awarded a Ph.D. in 1870. Upon graduation, he went with his mentor to the University of Tübingen as his assistant. There he had the opportunity to read extensively and to become completely immersed in the German system of graduate education. During these years, Remsen developed the major themes that would constitute his later work.

Life's Work

From his earliest days in Germany, Remsen had a keen interest in the subtle chemistry of the derivatives of benzene, which are referred to as "aromatic compounds" because some of the common members have a sweet odor. Benzene was discovered by English physicist Michael Faraday in 1825. Its molecular formula, C_6H_6, suggests great reactivity, yet the compound exhibits extraordinary stability. Remsen knew from his days at Göttingen that a carbon atom attached to benzene could be fully oxidized without changing the benzene. One of the great theoretical problems of early organic (or carbon) chemistry was to explain this marked stability.

In Germany, Remsen worked on the oxidation of xylenes, which possess a benzene ring, of which two carbon atoms are each bonded to a methyl group (CH_3). Later, at the University of Tübingen, he found that methyl groups attached adjacent to a sulfonic acid group (SO_3H) are protected from oxidation. He also found that chains of two or three carbon atoms are similarly protected. This observation has been referred to as Remsen's law. In addition, Remsen demonstrated that the more complex sulfamide group (SO_2NH_2) also prevents the oxidation of methyl groups. Later, at Johns Hopkins University, he discovered that the oxidizing agent potassium permanganate did allow the adjacent methyl group to be oxidized. In 1879, Remsen suggested to a postdoctoral student, Constantin Fahlberg, that he try this new oxidation method on 2-methylbenzenesulfonamide. This experiment resulted in the most practical invention of Remsen's career—what Fahlberg later named "saccharin," a substance three hundred to five hundred times sweeter than sugar.

These laboratory successes pale in comparison to Remsen's influence on his students. Remsen was one of those rare professors who possessed a genuine talent for impressing on young minds the beauty as well as the principles of science. When he began teaching at Williams College in Massachusetts in 1872, the year he returned from Germany, he was struck by the poor quality of chemistry textbooks in English. His translation of *Wöhler's Outlines of Organic Chemistry* was published in 1873. In 1876, while still at the college, he published the first of a series of exceedingly popular textbooks entitled *The Principles of Theoretical Chemistry*.

The upper-class liberal arts atmosphere at Williams was not consistent with Remsen's view of scientific education. He was delighted to receive the invitation of Daniel Coit Gilman, the founding president of Johns Hopkins University, to become the institution's first professor of chemistry. It was the intention of the university to offer graduate education based on the German model, and Remsen was just the man to implement that goal. He served the university from 1876 until his retirement in 1913. In 1901, Gilman resigned, and the board of trustees selected Remsen as the new president. He often alluded to the sense of loss he felt in giving up his teaching role, and his former students saw his administrative duties as a great loss to teaching and to the scientific community. Nevertheless, he worked diligently to promote the university's mandate and to serve the public interests of Baltimore as well.

One of Remsen's greatest contributions to the advancement of American chemistry was his founding of the *American Chemical Journal* in 1879. He was its only editor until the fiftieth volume in 1915. At that point, the journal merged with the *Journal of the American Chemical Society*, which remains one of the world's most prestigious scientific journals.

Remsen received many honors in his life. In 1903, he served as president of the American Association for the Advancement of Science. From 1907 to 1913, he was president of the National Academy of Sciences. In addition to a number of honorary degrees, Remsen won the gold medal of the Society of Chemical Industry and both the Willard Gibbs (1914) and the Priestley (1923) medals of the American Chemical Society, for which he had served as president in 1902.

Remsen had married Elizabeth Mallory in 1875, and they had two sons, Ira and Charles. After Remsen retired in 1913, he and his wife spent some tranquil years traveling. He died from a cerebral hemorrhage in 1927.

The Synthesis of Saccharin

The discovery of saccharin was a happy accident. In 1879 at Johns Hopkins University, Ira Remsen suggested to a postdoctoral student, Constantin Fahlberg, that he try Remsen's new oxidation method on 2-methylbenzenesulfonamide. One evening at dinner, Fahlberg noticed that his bread tasted unaccountably sweet and also noticed the taste on his unwashed hands. He traced the chemical residue to his laboratory and later named the synthetic compound "saccharin" (from *saccharum*, Latin for "sugar"), which was found to be more than three hundred times sweeter than sucrose. In 1880, the professor and student jointly published their findings in the *American Chemical Journal*, which Remsen had founded the previous year.

Remsen neither sought nor received money or acclaim for the discovery. However, Fahlberg recognized at once the tremendous economic possibilities of the sweet, calorie-free substance that contained no sugar. In 1884, he obtained a patent for the manufacture of saccharin and went on to become a very wealthy man. Known for his contempt for the commercialism of discovery, Remsen later called Fahlberg "a scoundrel." He never contested the patent.

Impact

During his career, Remsen and his graduate students studied a great many chemical reactions, and together they published more than 170 scientific articles. Remsen aimed to elucidate the principles of chemistry rather than to simply produce new compounds or even new reaction pathways. Nevertheless, he is best known for his discovery, with Fahlberg, of the first artificial sweetener, saccharin. Demand in the United States for the synthetic sweetener increased during the sugar shortages of World War I, and the calorie-free substance was a boon to the food and diet industries in later decades. Saccharin is found in low-calorie soft drinks as well as tabletop sweeteners such as Sweet'N Low.

JESSE W. RENO

American engineer

Reno invented moving stairs, the inclined elevator, better known as the escalator. Some escalators he designed were in use through the 1990's, more than fifty years after his death.

Born: August 4, 1861; Fort Leavenworth, Kansas
Died: June 2, 1947; Pelham Manor, New York
Also known as: Jesse Wilford Reno (full name)
Primary field: Mechanical engineering
Primary invention: Escalator

EARLY LIFE

Mary Bradley Beanes Cross and Jesse Lee Reno wed on November 1, 1853, in Washington D.C. Mary was a well-educated socialite from a prominent D.C. military family. By the time of their wedding, Jesse already had a successful military career, after graduating from the United States Military Academy in 1846. The family was living in Kansas, where Reno was in charge of the Fort Leavenworth arsenal, when their youngest son, Jesse Wilford Reno, was born on August 4, 1861. Jesse Lee was promoted to major general in 1862. He commanded the Ninth Corps during the Second Battle of Bull Run in Virginia on August 28-30, 1862. General Reno was killed in an attack on the evening of September 14 later that year during the Battle of South Mountain in Maryland.

Mary Reno and her children lived in several midwestern and Southern states in the years after the Civil War. During this time, she bought a family burial plot in a Washington, D.C., cemetery, and moved the bodies of her husband and three children who had died there. She was buried with them when she died a few years later.

Jesse W. Reno attended Lehigh University in Pennsylvania, where he majored in engineering. Reno was involved in several activities and organizations there, participating in choir, Chi Phi (Psi chapter), and the fra-

An Otis duplex cleat-type escalator, installed at the R. H. White Company store in Boston, Massachusetts, in 1903. (The Granger Collection, New York)

ternity's lawn tennis club, serving as class historian, and playing on the university's baseball team. He graduated in 1883. Reno worked as an engineer for a mining company in Colorado before moving to Georgia. While working for the Thomson-Houston Electric Company in Americus, Reno built the first electric railway in the southern United States.

LIFE'S WORK

In 1891, after moving to New York City, Reno applied for his first patent. The invention was an idea he had been considering since the age of sixteen: the "new and useful endless conveyor or elevator." The patent went into effect in 1892. Reno built one of the devices and installed it as a ride at Coney Island, New York, in 1896. This early model was more of an inclined bicycle. The ride was inclined 25°, reached a height of seven feet, and moved at a speed of seventy-five feet per minute. Passengers had to be careful when getting on and off the ride to avoid being kicked by fellow riders. Reno's inclined elevator was at Coney Island for two weeks, during which time seventy-five thousand people took rides.

In 1896, Reno submitted a design for a double-decker New York City subway system. Inclined elevators would move passengers from street level to the different underground train platforms. Reno estimated that it would take the city three years to build the system. New York City officials rejected Reno's plan. On January 15, 1901, Reno married the widowed baroness Marie G. Snowman in Kansas. The couple moved to London shortly after the wedding. Reno started the Reno Electric Stairways and Conveyors Company in 1902.

By this time, Reno escalators were being installed in stores throughout the United States and Europe. His early design had been modified into more of an inclined moving walkway. Rails guided a series of wooden pallets on a moving conveyor. Rubber cleats were installed on the wooden stairs to help passengers keep their footing. Early versions of comb plates were located at both ends of the escalator to clean the wooden treads. The machine had two handrails—one stationary, the other cloth-covered rubber that moved at the same speed as the escalator. One drawback of the moving handrail was that the lubrication oil often stained riders' clothing. Reno altered the design so that the inclined elevator was more steplike. The Manhattan Elevated Railroad Company purchased one hundred Reno escalators in 1900. Some of them remained in operation until 1955.

Reno then turned his attention to building a spiral escalator. In 1906, he was hired by the London Underground to install one in the Holloway Road train station. He partnered with William Henry Aston, who had developed a flexible pallet and chain system. They built a working model at their own expense for a London subway station. However, passengers never used the spiral walkway because it never passed safety inspections. Ninety years later, it was found in an abandoned tunnel of the station. Reno's spiral escalator is now on display in London's Transport Museum.

In 1903, Reno sold one-third of his business to the Otis Elevator Company. Otis had already begun producing its own version of the inclined elevator based on the patents of Charles Seeberger, who coined the term "escalator" by combining the Latin word *scala* (steps) and "elevator." Seeberger sold his patent rights to the Otis company in 1910, and Reno sold his company to Otis in 1911. Reno's design was sold as the "cleat-type escalator" until 1921, when Otis combined it with Seeberger's model to form the modern escalator.

In 1921, the American Society of Mechanical Engineers created a voluntary code committee as part of the American National Standards Institute (ANSI). Until then, safety and design issues were the responsibility of the manufacturers. Three changes were made at the suggestion of the committee that drastically improved passenger safety. Brakes and safety switches were created so the escalator could be stopped during power outages, mechanical failures, or when passenger's clothing became stuck in the machine. Handrails and balus-

ESCALATORS

Moving stairs, or escalators, are found throughout the world in stores, subway stations, shopping malls, airports, and numerous other places. They are a modern convenience often taken for granted by riders. The first patent for a moving staircase was issued in 1859. Nathan Ames's design was a revolving set of stairs that formed an equilateral triangle. On the left side, passengers would travel up to the point of the triangle, where they would have to exit quickly and avoid passengers attempting to travel down the right side stairs. The belt of stairs would be powered by steam. Ames's machine was never built.

In 1892, two patents were granted for escalator-type machines. The first patent was for Jesse W. Reno's inclined elevator, which he displayed as a ride at Coney Island, New York, in 1896. The second patent was issued to George H. Wheeler for his idea of a moving stairway. Wheeler never developed a prototype, and he sold the patent to Charles Seeberger in 1898. The Otis Elevator Company built and installed the first commercial escalators in 1901. The Seeberger-Otis wooden escalator was installed at the 1900 Paris Exposition, where the public could ride it for a penny. The escalator received the exposition's first prize.

The Otis Elevator Company bought out Seeberger in 1910. In 1911, Otis purchased Reno's company as well. For the next decade, Otis manufactured both Reno's "sloping tread" and Seeberger's "step" models. In the 1920's, David Lindquist and other engineers at Otis combined and improved the two models into the current escalator. Comb plates, placed at the end of escalators, were added around this time. Reno's model had comblike prongs twelve to sixteen inches long. The prongs produced quite a jolt to passengers, who often fell while trying to avoid them. The Seeberger-Otis model had a shunt, or transitional diagonal section, at the ends. Passengers had to sidestep onto the platform while the other foot was still on the moving stairs. The handrails were also redesigned. Reno's model had lubricated handrails to ease friction within the machine, but the lubricant would stain riders' clothing. Instead, Otis engineers switched to nonlubricated, tension-driven rubber handrails coated with canvas. The third change was the standardization of escalator speed, which had ranged from eighty to one hundred feet per minute. The speed was set to ninety feet per minute.

Architects and designers have tried to camouflage escalators for years, hoping to make sure that the machines did not detract from the surrounding environment. However, toward the end of the twentieth century, escalators became design tools. In 1988, the Mitsubishi Electric installed the first "spiral" escalator in the United States, although the San Francisco Center escalator is more of a semicircle than a true spiral like Reno's 1906 model.

trades (side panels) were extended past the comb plates; this modification allowed passengers to grasp the handrail before they stepped onto the escalator, giving them time to adjust to the speed and making it easier to get on and off. Also, this extension moved the point where the handrail entered the balustrade at the floor farther from the riders. Many injuries had occurred when hands, feet, or clothing became caught at the joint. The third change came in the 1930's, when metal treads replaced the original wooden ones. The metal steps hold up better over time and break less often than wood. Wooden treads also had wider-spaced grooves that objects such as high heels often got stuck in.

Reno died on June 2, 1947, in Pelham Manor, New York. He was buried alongside his parents and siblings in the family plot in Washington, D.C. Reno and his wife had no children.

Impact

Reno began developing the idea of a moving staircase, or inclined elevator, at the age of sixteen. Some Reno escalators remained in operation in the Boston subway system and Philadelphia department stores through the 1990's. Many of Reno's ideas are still part of the modern-day escalator. He invented the early comb plate to clean the stairs, and the moving covered rubber handrail. In the 1950's, the U.S. Patent Office decided that "escalator" had become part of the vernacular to mean any moving staircase, and the word was lowercased. Macy's downtown New York City store still has wooden escalators in use. Hong Kong, on the other hand, has the largest modern escalator system in the world, with over half a mile of tracks.

Charles Francis Richter

American seismologist and physicist

Richter is best remembered for developing a scale that measures the energy released by an earthquake. He was a pioneer in seismology and was instrumental in developing a database of all earthquakes that occur worldwide every year.

Born: April 26, 1900; near Hamilton, Ohio
Died: September 30, 1985; Pasadena, California
Also known as: Charles Francis Kinsinger (birth name)
Primary fields: Geology; physics
Primary invention: Richter scale

Early Life

Charles Francis Kinsinger was born on a farm near Hamilton, Ohio, north of Cincinnati. His father, Frederick William Kinsinger, a farmer, and his mother, Lillian Anna Richter, a schoolteacher, were married on July 15, 1891, in Butler County, Ohio. Charles's sister, Margaret, was born in 1892, but their parents divorced shortly after

Charles Francis Richter. (California Institute of Technology)

her birth. Their parents remarried before Charles's birth in 1900, but, unfortunately, the second attempt at matrimony was no more successful than the first. After separating from her husband, Lillian resumed using her maiden name and changed her children's names to Charles Francis and Margaret Richter. Returning to live in her father's household, she raised her children in Ohio until the death of her mother in 1907 prompted her father to move his family to Los Angeles, California, where he purchased a house in the Wilshire district.

Accounts of Charles Richter's early childhood family life indicate that he and his sister were educated at home while they were in Ohio but sent to Hobart Boulevard School when they arrived in Los Angeles. These accounts also depict a dysfunctional family in which his mother was extremely attached to her father. Charles, who had survived a bout of cholera when he was fifteen months old, was a small, thin boy, shy at school, lonely, and dominated by his extremely assertive sister at home. (Margaret's aggressive personality, in some ways, served her well; in an era in which women did not commonly pursue an advanced degree, she ultimately earned a Ph.D. at the prestigious Stanford University.)

Academically, Charles did well in public school and was soon transferred to a preparatory school where he developed a taste for astronomy, chemistry, mathematics, and physics. He performed very well in high school, and after graduating at the age of sixteen in 1916, he was accepted at Stanford University, where he obtained his bachelor's degree in physics in 1920 and his Ph.D. in 1928.

Although his intellectual assets served him well, Richter was so afflicted with depression, nervous breakdown, and mental confusion that he spent a year (1920-1921) in a private sanatorium under the care of a psychiatrist, Dr. Ross Moore. At Moore's suggestion, Richter put aside his academic work temporarily while he took a series of jobs (clerk in a hardware company, messenger for the Los Angeles County Museum) in order to gain a degree of financial (and social) independence from his mother. Moore also encouraged him to take up writing as a way to explore his emotions, sparking in Richter a love of poetry that lasted throughout his life. (The vast majority of the poems Richter wrote have been preserved in his personal papers, which he bequeathed to the California Institute of Technology library.)

Life's Work

In 1922, Richter returned to Stanford and tackled the research he needed to complete his doctorate in physics. After receiving his doctorate in 1928, Richter, who had been an isolated and lonely student, was invited to a friend's house where he met divorcée Lillian Brand. They were married on July 19, 1928. Ignoring the advice of his psychiatrist to separate himself from his mother's influence, Richter took his new family, which included Lillian's two-year-old son, Reginald "Butch" Floyer Saunders, Jr., to live with his mother and sister. Predictably, the arrangement was a social disaster; Richter's wife, mother, and sister argued continuously.

Fortunately for Richter, his professional life was more successful. At the end of 1927, he had been hired as a part-time research assistant at the Caltech Seismological Laboratory near Pasadena, under the direction of Robert Andrews Millikan. As soon as he received his Ph.D., Richter was hired full-time, acquiring at once a stable position and access to the emerging science of seismology that became his lifelong passion. Rarely do people spend their entire lives working at the same place. Richter was one of these rare people, remaining at Caltech until he retired in 1970.

The founding of the Caltech Seismological Laboratory in Pasadena made good sense in light of the fact that many earthquakes had occurred on the San Andreas

Fault in California. Under Millikan, a physicist, Harry Wood, an astronomer, Hugo Benioff, a former astronomer and newly appointed seismologist, and John Anderson, an engineer, the laboratory flourished. Creating and maintaining an almost perfect research atmosphere, the laboratory encouraged its members to achieve their best. All scientists would gather at 10:30 A.M. and 2:30 P.M. for coffee and at noon for a game of bridge. These daily meetings would keep everyone aware of the progress made in each scientist's research. Problems would be discussed and solutions offered.

Thanks to the new and precise seismometer that Wood and Anderson created, a network of seismic stations, each equipped with a seismometer, was put into place. These seismometers recorded the basic data necessary to create a catalog of earthquakes. The successes, technological advances, and energetic research projects of the Caltech Seismological Laboratory stimulated other research institutes, such as the Seismology Institute of the University of California, Berkeley, the Lick Observatory of San Jose, and St. Louis University, to a healthy competition in which the science of seismology flourished.

As the laboratory grew, new well-known geophysicists joined the staff. Among these new employees was Beno Gutenberg, a Jewish German seismologist who had received from Caltech a job offer he could not turn down; the salary and living conditions in California were excellent, while the situation in Germany was worsening for Jews. Upon his arrival in 1930, Gutenberg immediately teamed up with Richter in the difficult task of measuring earthquakes. They published their research in four scientific papers that studied the nature of the seismic waves, the way they reflect and refract, and how they move in the Earth's interior. Acknowledging the partnership that both scientists developed over the years, many researchers believe that the Richter scale, used for measuring the magnitude of (the amount of energy released by) an earthquake, should be called the Gutenberg or Gutenberg-Richter scale. In an interview in 1979, Richter himself said that the term "somewhat underrates Gutenberg's part in developing it for further use." Nevertheless, Richter is credited with having produced the scale, which was developed and used beginning in 1932.

The Richter Scale

Until the 1930's, seismologists measured earthquakes by examining the damage they caused to human-made and natural structures. This idea of categorizing earthquakes based on their visible impact on the surface of the earth was first systematized in 1783 by Pompeo Schiantarelli, who constructed his scale based on observations of the damage caused by earthquakes in Calabria, in the southern part of Italy. Over the following 150 years, the idea was refined and expanded by generations of scientists. Schiantarelli's scale was updated in 1874 by Italian seismologist Michele de Rossi, whose work, in turn, was revised by Swiss scientist François-Alphonse Forel in 1881, resulting in the Rossi-Forel scale, which identified ten levels of earthquake intensity. Revised again by Giuseppe Mercalli in 1883, the ten-degree intensity scale was improved by a careful consideration of a wider diversity of building types and materials. In 1902, Mercalli expanded the intensity scale so as to include twelve degrees. Variations of the twelve-degree Mercalli scale were soon developed by Sergei Medvedev, Wilhelm Sponheuer, and Vit Kárníck in Europe. Today, the Modified Mercalli Intensity Scale is still used in the United States.

Charles Francis Richter developed a scale by which the relative intensity of earthquakes could be expressed based on a more direct indication of the energy they released. With the development of seismographs, it became possible to measure the actual movement of the earth rather than simply identifying the damaging impact. In 1931, Richter read a paper written by Japanese seismologist Kiyoo Wadati in which Wadati graphed the maximum ground motion of shallow earthquakes that had occurred in Japan using a logarithmic scale. This paper gave Richter the idea of developing a classification of earthquakes based on the size of the largest wave recorded on a seismogram. The Richter scale is a base-10 logarithmic scale; thus, for example, an earthquake that measures 7.0 has ten times the wave amplitude as an earthquake registering 6.0, and one hundred times the wave amplitude of a 5.0 magnitude earthquake. Each whole-number step in magnitude corresponds to the release of roughly thirty times more energy than the amount associated with the preceding whole-number value.

Wadati's innovative way to examine earthquakes was borrowed by Richter and applied by him to a multitude of earthquakes recorded by the Wood-Anderson seismometer at the Caltech Seismological Laboratory in Pasadena, California. Between 1931 and 1935, Richter worked on developing the arguments for using this type of measurement to classify earthquakes. The result of Richter's work was published in the *Bulletin of the Seismological Society* in 1935. The paper explained how to transform these wave measurements into a scale, now called the Richter scale.

The paper that introduced it to the scientific community was published in the January, 1935, issue of the *Bulletin of the Seismological Society of America*.

The Richter scale is logarithmic and has no upper limit (although no earthquake greater than 9.5 has ever been recorded). Richter most certainly did his share in the development of the scale, and the contributions of Richter and Gutenberg to the science of seismology in their book *Seismicity of the Earth* (1941) are such that their book is still valued today.

Richter was an avid reader of science-fiction books and an excellent linguist. He also enjoyed hiking in the Sierra Nevada. Year after year, he would spend his vacation in Sequoia and Kings Canyon National Parks. This communion with nature was a perfect match for his shy personality. At the beginning of his marriage, his wife Lillian would accompany him, but within a few years, her health deteriorated when she developed acute colitis. Charles and Lillian lived very independent lives while married. She visited France and Africa without her husband, while Charles spent a year alone in Japan as a Fulbright scholar.

In 1969, Charles and Lillian moved to Altadena in a house with very large windows from which Charles could see the San Gabriel Mountains, a region where he loved to walk. Shortly after their move, Lillian developed intestinal cancer. She underwent surgery in July, 1970, but the cancer spread and she developed lymphoma. She had another surgery in October, 1972, but had complications leading to her death on November 6, 1972.

Richter's health declined after the death of his wife, but he continued to work in the field of seismology. Even after his retirement in 1970, Richter returned to the laboratory every time there was a major earthquake in the region. He progressively needed more and more nursing help but remained in his house in Altadena. In July, 1984, he suffered a heart attack that required him to move to a nursing home. He died on September 30, 1985, of congestive heart failure and was buried in the Mountain View cemetery in Altadena next to his wife and his stepson.

Richter was an unconventional man, plagued throughout his life with neurological disorders that researchers today identify as probably being Asperger's syndrome, a condition that makes social interaction very difficult. Perhaps this helps to explain his loneliness and his lifelong preference for solitary pursuits, and may even relate to his commitment to nudism. However, while people often remarked on his isolation, they also thought that he was a "walking encyclopedia" because of his incredible capacity to memorize terms in physics and seismology, and many were impressed with his commitment to teaching.

Impact

An accomplished teacher and prolific researcher, Richter published extensively and mentored generations of graduate students from 1927 to 1970 while working at Caltech Seismological Laboratory. Richter is remembered as a pioneer in the science of seismology; his achievements are even more enormous when one considers that plate tectonics had not been discovered when he coauthored his treatise *Seismicity of the Earth* with Beno Gutenberg in 1941. Richter's legacy encompasses not only his magnitude scale that revolutionized the measurement of earthquakes but also the earthquake-monitoring system. He produced his long-term catalogs of earthquakes that researchers still use today.

Norbert Rillieux

American engineer

Rillieux's invention of a vacuum evaporator revolutionized sugar refining. The process allowed sugar refineries to produce sugar more efficiently and with less intensive labor expenditure than ever before.

Born: March 17, 1806; New Orleans, Louisiana
Died: October 8, 1894; Paris, France
Primary field: Mechanical engineering
Primary invention: Multiple-effect vacuum evaporator

Early Life

Norbert Rillieux (RIHL-yuh) was born to Vincent Rillieux, a wealthy, French-born Louisiana engineer and sugarcane plantation owner, and Constant Vivant, a freed mulatto woman who had once been a slave on Rillieux's plantation. Norbert was a free Creole quadroon (a person of one-quarter black ancestry) and was baptized a Catholic. He was soon recognized as having a superior intellect and was sent to Catholic schools for his education. Eventually, his father sent him to France, where Norbert enrolled at the prestigious École Centrale in Paris to study engineering.

At age twenty-four, Rillieux became an instructor in applied mechanics at École Centrale, the youngest person ever to hold that position. By 1830, he had become an expert on steam power, publishing papers on the use of steam to operate machinery and on the economic benefits of this process.

Life's Work

In 1833, Rillieux returned to New Orleans and became involved in improving the labor-intensive sugar-refining process. The method in use at the time was called the "Jamaican Train," an expensive, inefficient process requiring a large labor force to perform dangerous, tedious steps to produce a product that was somewhat unpredictable in quantity and quality. The method involved pressing sugarcane juice out of the cane stalks, then heating the juice to induce evaporation and produce solid sugar. The process required workers, who were mostly slaves, to ladle the boiling hot juice from one kettle to another as the liquid thickened. Each kettle was heated by its own fire, so each pot had to be monitored to keep the sugar from burning, which occurred often. At the time, two other engineers named Howard and DeGrand had developed a device for evaporating the liquid portion of sugarcane juice. However, their process used steam inefficiently and produced a mediocre quality of sugar. Rillieux studied the process over the years and devised a method that could use condensation and evaporation more efficiently to convert the sugarcane juice into the coveted white sugar crystals.

Rillieux was aware of the British single-effect evaporator that was widely used in Europe to extract sugar from sugar beets. However, while it had some advantages over the more laborious refining method in use in the United States, it still made use of the several

Norbert Rillieux. (The Louisiana State Museum) open cauldrons and numerous fires to heat the juices. Rillieux realized that latent heat from one stage of the refining process could be harnessed for use in subsequent stages. Such harnessing could simplify the entire process, making it cheaper and safer to produce sugar crystals.

Rillieux invented a machine with a vacuum chamber with several pans stacked inside. The vacuum chamber enclosed coils for the condensation of the liquid in successive stages of the refining process, accomplishing the necessary multiple-effect evaporation. Because the boiling point of a liquid is lower in a vacuum than in the open air, the sugarcane juices could be boiled at a lower temperature. The steam rising from the pans at the lowest levels heated the pans at the top; thus, only one heat source was required for the process. This method reduced the amount of work involved because the liquid did not have to be shifted from one kettle to the next, and because the heat was under better control, the resulting sugar crystals would always be white instead of discolored.

Rillieux patented his multiple-effect evaporator system in 1843, and two years later his machine was successfully installed at a Louisiana plantation. In 1846, he persuaded several sugar manufacturers to use his machine, which had been perfected to the extent that it was capable of producing six thousand, twelve thousand, or eighteen thousand pounds of sugar per day. Manufacturers using the efficient machine were soon making such profits that the cost of the machine was quickly recovered.

Rillieux became quite wealthy and well known. The specter of the Civil War was looming, however, and by the 1850's he and all other free blacks living in New Orleans were facing increasingly negative attacks in the press, police harassment on the streets, and restrictions of various kinds that curtailed their lives in general. For a long time, Rillieux did not let these issues affect his interest in his work. When an outbreak of yellow fever threatened New Orleans, he devised a plan to halt the outbreak by eliminating the breeding grounds of the disease-carrying mosquitoes by draining the bayous surrounding the city and by improving the city's sewer system. When he presented his plan to the state legislature, there were those in office who disapproved of him, likely because of his ethnicity, and his plan was turned down. However, as the fever continued to spread for the next few years, some white engineers proposed an almost identical plan to the legislature, which was accepted.

The deteriorating conditions for free blacks in New Orleans finally pushed Rillieux beyond his limits. When an ordinance was passed requiring free blacks to carry a pass in order to travel, he returned to Paris in 1854. He lost some of his enthusiasm for engineering and instead got caught up in one of the fads of the time, Egyptology, studying Egyptian hieroglyphics with the family of Jean-François Champollion, the Frenchman who helped translate the Rosetta stone. Sometime during this period, Rillieux married Emily Cuckow.

At age seventy-five, Rillieux returned to sugar refining, attempting to solve the problems of extracting sugar from sugar beets. He patented a new system for this process; however, the French would not accept his invention, and he ultimately lost all the rights to his French patent. He died at the age of eighty-eight and was buried in the churchyard of Per La Chaise.

Multiple-Effect Vacuum Evaporator

Norbert Rillieux's invention of the multiple-effect vacuum evaporator for the improvement of sugar making helped establish the modern sugar industry. His machine used steam heat to evaporate water and consisted of apparatuses to heat and cool sugarcane juices in order to remove the moisture and leave crystallized sugar. The heater clarified the sugarcane juices to prepare them for the evaporation process. The evaporating pans, or boilers, were cylindrical, with the lower half of each extending to a chamber with a tube that connected each to the other chambers. This was to allow for the flow of water produced by vapor condensation. As the juices were heated and partly evaporated, the vapors from the juices in the lower pans rose to heat the juices in the upper pans. A fan blower created a current of air to cool the juices, producing the needed condensation.

While his invention was based on a sound chemical engineering principle, Rillieux was the first to put the principle to practical use. By using a single heat source to do the work that had previously been done by several heat sources, Rillieux opened the way for many other practical applications of his invention. Eventually, other industries used his invention in processes that required the evaporation of large amounts of water from a solution, such as producing salt from seawater, or even producing salt-free water.

Impact

Rillieux's vacuum evaporation system revolutionized sugar refining, cutting the costs of production and thus decreasing the retail price of sugar. The principles of the process also changed the way that such products as condensed milk, gelatin, soap, and glue were manufactured. Rillieux's basic invention has also been used by industries that recover waste liquids, such as paper-manufacturing plants and distilleries, and that process petrochemicals. Called a scientific genius who was ahead of his time, Rillieux invented a system that has had widespread applications.

John Augustus Roebling

German American civil engineer

Roebling perfected the manufacture of wire rope in the United States, was one of the pioneers in the development of suspension bridges using those cables, and was the designer of the Brooklyn Bridge, among other landmark structures.

Born: June 12, 1806; Mühlhausen, Prussia (now in Germany)
Died: July 22, 1869; Brooklyn Heights, New York
Primary fields: Architecture; civil engineering
Primary inventions: Wire cable; suspension bridge

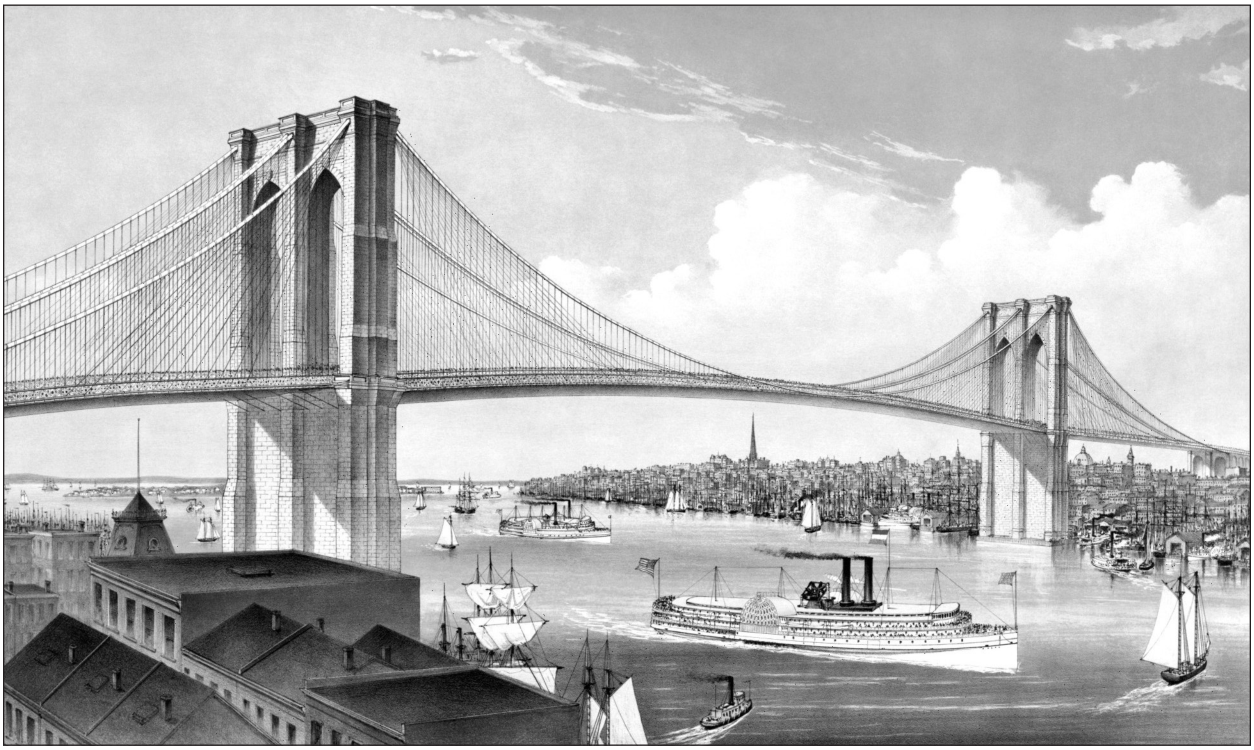
Early Life

John Augustus Roebling was the youngest son of Christoph Polycarpus Roebling, who owned a tobacco shop in Mühlhausen, Prussia (now in Germany) and Friederike Dorothea (Mueller). The young Roebling was educated in the public *Gymnasium* in Mühlhausen and pursued his studies in architecture and engineering at the Royal Polytechnic Institute in Berlin, where he also studied under the famous German philosopher Georg Wilhelm Friedrich Hegel. After graduation in 1826 with a degree in civil engineering, Roebling worked for three years building roads for the Prussian government in Westphalia. In 1831, with his brother Karl, Roebling led a group of fifty-three emigrants to America, and eventually into western Pennsylvania, where they founded a utopian community near Pittsburgh that they named Saxonburg. Growing bored with life as a farmer after a few years, however, Roebling went to work for the state of Pennsylvania as a surveyor and engineer on dams and bridges, at a moment when transportation projects were exploding across the country and the need for engineers was great. In 1841, he developed a method of spinning wires together to form cables (rope was previously employed on many bridges), and soon he began to manufacture these cables, at first in a workshop behind his house in Saxonburg and eventually in a plant he relocated in Trenton, New Jersey, the first wire rope factory in America.

Life's work

Roebling's career as a designer and builder of bridges actually began in 1845, when he won a competition for an aqueduct over the Allegheny River in Pittsburgh and built a suspension system using his own manufactured cable. In the remaining quarter century of his life, Roebling would plan and construct a dozen aqueducts and bridges, culminating in the Brooklyn Bridge, across the East River in New York City, completed by his son Washington fourteen years after its designer's death. (Washington Roebling had graduated from the Rensselaer Polytechnic Institute in 1857, and for the next dozen years—minus the time he served as an officer in the Union Army building bridges during the Civil War—worked side by side with his father.) Gifted with an inquisitive and philosophical mind, for more than twenty years John Roebling designed and built some of the longest and most beautiful suspension bridges in America. He worked on the Brooklyn Bridge for more than a decade. In three furious months in 1867, he produced all his drawings and his formal proposal for the bridge, but a ferry accident crushed his foot just after construction had begun in 1869, and he died of complications (tetanus, or lockjaw) several weeks later. At his death, he was worth more than a million dollars. Washington Roebling took over the construction of the bridge at the age of thirty-two and finished it in 1883, in the greatest celebration New York City had ever seen. The Roeblings perfected modern suspension bridge technology, and the cables they manufactured made these suspension bridges possible. John A. Roebling's Sons continues to operate to the present day.

Suspension bridges had been the subject of Roebling's thesis at the Royal Polytechnic Institute, and they continued to be a lifelong passion. Suspension bridges were appearing in Europe just as Roebling was growing up; the prototype for the Brooklyn Bridge was Thomas Telford's Menai Bridge in Wales, the first monumental metal suspension bridge (constructed from 1819 to 1826). Roebling saw the suspension bridge as the perfect balance of nature, and the cables he manufactured gave the bridges both their strength and structure and their beauty. Besides operating the first wire rope factory in America, Roebling devised a new method of stringing the cables across a river and invented a unique anchorage system for the cables on shore. In the same year he completed the Allegheny Aqueduct, Roebling built the Smithfield Street Bridge across the Monongahela River in Pittsburgh, and by 1850 he had constructed six suspended structures using his wire cables and had established the successful cable plant in Trenton.



John Augustus Roebling's Brooklyn Bridge. Upon completion in 1883, it was the longest suspension bridge in the world, spanning about 1,595 feet. (Library of Congress)

Each structure Roebling built seemed to be an improvement on the previous one. The Lackawaxen Aqueduct (completed in 1848) was a 535-foot-long suspension bridge over the Delaware River in northeastern Pennsylvania that would become a prototype for the Brooklyn Bridge. His Niagara Falls Bridge (1855), a railroad bridge connecting the New York Central Railroad and Great Western Railway of Canada over the Niagara River, spanned 825 feet. His Cincinnati-Covington Bridge (1866) had a main span of 1,057 feet over the Kentucky River, in a gorge deeper and wider than the Niagara. Renamed the John A. Roebling Suspension Bridge in 1984, the Cincinnati-Covington Bridge was the first to utilize both vertical suspenders and diagonal stays fanning out from either tower (Roebling would next employ those features on the Brooklyn Bridge), and it would be the longest suspension bridge until the completion of that more famous structure across New York's East River, the crowning achievement of Roebling's brief but intense engineering life.

The Brooklyn Bridge

The Brooklyn Bridge, which crosses New York's East River and connects the boroughs of Manhattan and Brooklyn, has been painted, photographed, and written about as often as any American icon. Writers and artists for more than a century have tried to capture the bridge's mystique: from the novelist John Dos Passos (*Manhattan Transfer*, 1925) and the poet Hart Crane (*The Bridge*, 1930), to painters such as Joseph Stella, Georgia O'Keefe, and John Marin, to photographers Edward Steichen, Berenice Abbott, and Walker Evans. The Brooklyn Bridge has become a symbol, comparable to those other monuments of New York City, the Statue of Liberty and the Empire State Building, and like them a structure that captures at once both America's power and its beauty.

John Augustus Roebling's major achievement in America was the use of wire rope in suspension bridges. The Brooklyn Bridge had four bundles of steel wires hanging from two stone towers anchored in the earth at both ends of the bridge with twenty-three-ton plates embedded in solid masonry foundations weighing 44,000 tons. Each of these four bundles carried 5,296 steel wires a distance of 3,578 feet. The unique design of the Brooklyn Bridge cable was that, instead of being woven like rope, the wires were arranged in a parallel fashion, thus reducing the stress. Roebling's improvements in the construction of the caissons and the design of the diagonal cable stays further added to the permanence and beauty of the bridge.

Roebling was the creator of this American icon. From the massive Gothic towers and their inviting archways, to the ways in which the bridge integrates its unique combination of steel and masonry, to the geometric beauty of its lines (such as the intersection of cables and suspenders), the Brooklyn Bridge is finally the product of the genius of John Roebling and combines his many gifts as designer, engineer, and architect. Few artists are able to leave such a symbol as their final legacy, and one that transcends its materials. The Brooklyn Bridge is somehow both mathematical and spiritual, an architectural structure that fuses technology with art to become what the late New York playwright Arthur Miller once called "steel poetry." Its Gothic stone towers draw viewers to some medieval past, but its use of steel points forward to the technology of the next century. Few structures in America are comparable to its power and grace, and it was only possible because of Roebling's designs and inventions, powerful vision, and multifaceted talents.

Impact

Roebling's career represents a near-perfect collision of genius and environment. It is clear from his multiple achievements—as inventor, designer, and manufacturer—that his talents were unlimited. If he can be compared to any designer before him, as both artist and inventor, it would have to be the Italian Renaissance painter Leonardo da Vinci. Obsessed with his vision, however, Roebling was also a distant and impersonal husband and father. Genius would have taken him far in any age, but his accomplishments came in part because he began to work at a time when transportation projects (the first roads and railways) were multiplying in the United States and there was a need for innovative thinkers. Money was abundant—President Andrew Jackson had authorized almost $100 million for public engineering projects the year before Roebling immigrated to America—and Roebling tapped the need for innovation in design and engineering.

The suspension bridges Roebling planned and built would last for a long time, and his achievements in design and structure would influence a century of civil engineers. It is important to remember that Roebling's bridges, like the tools and machinery he invented and manufactured, were all handmade, and that they were produced during what is called "the horse and buggy days," a period before the advent of the technology that would be taken for granted in the twentieth century. To give a perspective to Roebling's accomplishments, the

Brooklyn Bridge was halfway completed when the Battle of Little Bighorn was fought in Wyoming in 1876, and many of the revolutionary inventions of Alexander Graham Bell and Thomas Alva Edison came during the time the bridge was being constructed. Roebling was one of a handful of American designers and inventors who led the way from a frontier nineteenth century America into the modern twentieth century.

Heinrich Rohrer

Swiss physicist

The collaborative research work of Rohrer and Gerd Binnig led to advancements in microscopy that enabled scientists to see objects as tiny as individual atoms. Their scanning tunneling microscope (STM) generated three-dimensional images of material surfaces that helped researchers determine the size and form of atoms and molecules, defects and abnormalities on surfaces, and how chemicals interact with materials. The STM soon became standard equipment in laboratories worldwide.

Born: June 6, 1933; Buchs, St. Gallen, Switzerland
Primary field: Physics
Primary invention: Scanning tunneling microscope

Early Life

Heinrich Rohrer (HIN-rihk ROH-rur) was the third child born to Hans Heinrich and Katharina Ganpenbein Rohrer. His twin sister was born a half hour before him. His father worked as a distributer of manufactured products. Young Rohrer felt a special closeness to his mother, who always encouraged him to do his best and supported and assisted him when times were difficult.

Rohrer's childhood was carefree and delightful. He enjoyed playing a variety of games with his siblings and friends, doing farm work, and attending school. When he turned thirteen years old, his family moved from the rural country setting of Buchs, Switzerland, to the urban lifestyle of Zurich.

During his school years, Rohrer developed a strong interest in classical languages and natural sciences, particularly physics and chemistry. After enrolling at the Swiss Federal Institute of Technology in Zurich in 1951, he decided to pursue a degree in physics and earned a bachelor of science in that discipline in 1955. During that time, he was taught and influenced by Nobel laureate Wolfgang Pauli, who had discovered the Pauli exclusion principle for electrons in atoms.

In the fall of 1955, Rohrer began work on a doctoral degree in physics at the institute. Under the direction of Jörgen Lykke Olsen, he made intricate measurements on materials at the critical point where superconductivity was induced by a magnetic field. Since the measurements made with mechanical transducers were so sensitive to the slightest vibrations, Rohrer had to do his work during the early morning hours when Zurich was quiet. As a member of the Swiss army, his Ph.D. work was occasionally interrupted as he participated in basic training in the mountain infantry. He earned his Ph.D. in experimental physics in 1960.

During 1960-1961, Rohrer worked as a research assistant at the Swiss Federal Institute of Technology. In the summer of 1961, he married Rose-Marie Egger, who helped him to settle down. For their honeymoon, they traveled to the United States, where Rohrer carried out postdoctoral research at Rutgers University for two years on the thermal conductivity of type-II superconductors.

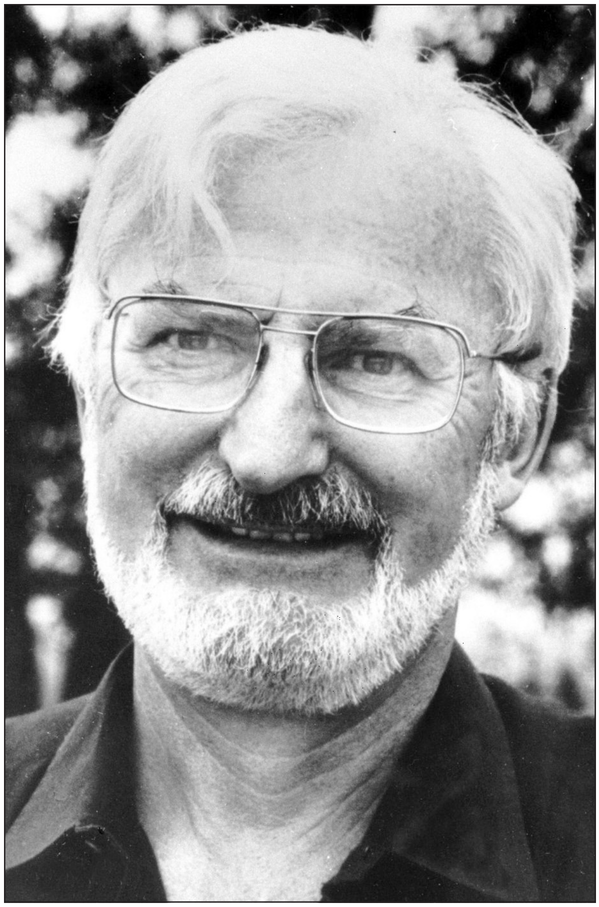
Life's Work

In 1963, Rohrer and his wife returned to Switzerland. Shortly thereafter, Rohrer was offered a research position with the recently founded International Business Machines (IBM) research laboratory in Rüschlikon, Switzerland, under the direction of Professor Ambros Speiser. His initial research work concentrated on changes in the thermal, electrical, and magnetic properties of nonmagnetic systems that contain small amounts of magnetic impurities. Such systems are referred to as Kondo systems. His focus was on Kondo systems exhibiting magnetoresistance in pulsed magnetic fields.

By 1969, Rohrer was working with Keith Blazey on optical experiments associated with antiferromagnets, which led him to the study of magnetic phase diagrams, phase transitions, and critical phenomena. During the 1974-1975 academic year, Rohrer took a sabbatical leave from IBM to do research on nuclear magnetic resonance with Alan King and Vince Jaccarino at the University of California, Santa Barbara. Prior to and following the sabbatical, Rohrer, his wife, and their two daughters, Doris and Ellen, took extended camping trips throughout the United States.

After returning to IBM, Rohrer became interested in the complex atomic structures of the surfaces of various materials. At the time, little was known about the nature of surface atoms. After German physicist Gerd Binnig joined IBM in 1978, he and Rohrer began exploring oxide layers on metal surfaces. Initially, they pursued the development of a spectroscopic probe to examine the surfaces. In the process, they invented a new type of microscope, the scanning tunneling microscope (STM), with the capability of examining the atomic structure of metal and semiconductor surfaces. Their idea was to scan the surface using the tip of a needle probe at a height of only a few atomic diameters above the surface.

In the development of their invention, Rohrer and Binnig encountered several problems. The most serious challenge was that the tip of the probe was very sensitive to any vibrations, a problem similar to that faced by Rohrer when he was collecting data during his Ph.D. research. Since the required magnification to see atoms was on the order of 100 million, any interference from vibration or noise would greatly distort the produced image. Using Rohrer's previous experience, he and Binnig decided to shield the probe from disturbances by conducting their experiments on a heavy stone table set on top of inflated rubber tires and by resting the STM on copper plates positioned between magnets. Any movement of the copper plates in the magnetic field would produce an induced current in the copper, and the interaction between the current and the field generated a feedback effect that damped any motion of the plates. Vibrations were reduced to the point where a vertical resolution on the order of one-tenth the diameter of an atom was achieved. Rohrer and Binnig built their first STM in 1981.



Heinrich Rohrer. (©The Nobel Foundation)

The Scanning Tunneling Microscope

A scanning tunneling microscope can produce a three-dimensional image of individual atoms that reside on the surface of a metal or a semiconductor. The tip of a needle, the STM probe, is scanned over the surface of the material of interest just a few atomic diameters above the surface. After a voltage is applied between the tip of the probe and the surface, a current flows between them as a result of the tunneling effect. Tunneling is a quantum mechanical effect. Electrons have a wavelike nature that causes them to create a spreading cloud, or aura, as they are emitted from the surface of a material. When the electron clouds from two closely spaced surfaces overlap, the electrons tunnel from one cloud to the other.

Heinrich Rohrer and Gerd Binnig suspended their STM probe on springs inside of a vacuum to scan the surface of the material of interest by using the tunneling effect. As the tip of the probe nears the sample, the electron clouds of the probe and material surfaces overlap and a tunneling current flows. Using a feedback mechanism, this current is used to keep the tip of the probe at a constant height above the sample surface. This enables the tip to follow the contours of the individual atoms of the scanned surface. The STM detects any minute variations in the distance electrons travel between the probe and the surface. This information is saved by a computer in a data file. Using these data, a computer algorithm processes the motion of the tip to produce a three-dimensional, high-resolution image of the electrical topography of the surface of the sample material.

By the mid-1980's, all but the vacuum chamber of the STM could fit into the palm of a human hand. The STM has opened up entirely new fields for studying the structure of matter. It has proven invaluable in studying the surfaces of semiconductors, metals, and biological samples, including viruses. The STM has even been reconfigured to manipulate molecules and atoms at the nanoscale level (billionths of a meter). Researchers and product developers can then observe what happens at the molecular and atomic levels, and by moving atoms from place to place, they can manufacture and modify useful products.

After Binnig and Rohrer were awarded the Nobel Prize in Physics in 1986, along with Ernst Ruska, who had invented the electron microscope, Rohrer was appointed as an IBM fellow, the most prestigious technical position at IBM. In this position, Rohrer had the freedom to pursue whatever research projects he felt were most important for IBM. During 1986-1988, he managed the Physical Sciences Department of the IBM Rüschlikon research laboratory. By 1987, Rohrer's research group had developed an STM the size of a human fingertip, with a resolution capability for seeing atomic-scale objects to within $^1/_{25}$ the diameter of a typical-sized atom.

Rohrer retired from IBM in July, 1997. Afterward, he participated in research appointments at the Consejo Superior de Investigaciones Cientifcas (CSIC) in Madrid, Spain, and at the Riken Institute and Tohoku University in Japan. His research focus became nanoscience, how matter behaves at submicroscopic levels on the order of a billionth of a meter in size, and nanotechnology, research and technology development at the atomic and molecular levels that allows the ability to manipulate particles on the atomic scale. Rohrer has been instrumental in encouraging the use of the STM as a major tool in nanotechnology to control atoms and molecules to help modify and manufacture products at the nanoscale level.

Impact

Since the invention of the first microscope, scientists searched for improvements for exploring the microscopic world. Optical microscopes were limited by the wavelength of light, which is approximately two thousand times larger than the diameter of a typical atom. Electron microscopes achieved much higher resolution due to the shorter wavelength of electrons in forming images, but they could not resolve images smaller than about five times the diameter of a typical atom. Being very familiar with the field of microscopy, Rohrer set a goal to image microscopic particles. During his many years of research, he had developed both the theoretical and experimental foundations and insights that were necessary to be successful.

In 1978, Rohrer and Binnig began their quest to invent an atomic microscope. Displaying foresight and fierce tenacity, the two solved a number of significant problems, particularly vibrational and noise sensitivity of their imaging probe, in the development of their scanning tunneling microscope. After numerous changes and additions to their experimental setup and equipment, their invention came to fruition in 1981. Only five years later, they were awarded the Nobel Prize in Physics.

Rohrer's practical abilities, inventive genius, and scientific contributions were rewarded with numerous prestigious awards in addition to the Nobel Prize. In 1984, Rohrer and Binnig received the King Faisal Prize and the Hewlett Packard Europhysics Prize for their invention of the STM. Rohrer was presented the Elliott Cresson Medal of the Franklin Institute in Philadelphia in 1987. In 1994, he was inducted into the United States National Inventors Hall of Fame. He has also been awarded numerous honorary doctorates by several universities throughout the world.

Wilhelm Conrad Röntgen

German physicist

Röntgen discovered X rays and pioneered their use in imaging structures inside the living human body. Medical X rays are considered to be one of the ten greatest discoveries in medical science.

Born: March 27, 1845; Lennep, Prussia (now Remscheid, Germany)
Died: February 10, 1923; Munich, Germany
Primary field: Physics
Primary invention: X-ray tube

Early Life

Wilhelm Conrad Röntgen (VIHL-hehlm KAHN-rad RUHNT-guhn) was the only son of Friedrich Conrad Röntgen, a textile manufacturer and merchant, and Charlotte Constanze Frowein of Holland. The family moved to Apeldoorn in Holland when young Röntgen was three years old. He attended a private boarding school there, and although he would rather be outdoors or working with his hands than studying, he did well enough to qualify to study at the *Gymnasium* (comparable to a U.S. college-preparatory high school).

His studies went well enough until crisis struck in 1862. A fellow student had drawn an unflattering caricature of a teacher. Röntgen knew who had done it, and the headmaster demanded that he reveal the culprit's name or face expulsion. Refusing to betray his classmate, Röntgen was not only expelled but also blacklisted, making it impossible for him to attend any other *Gymnasium* in Holland or Germany. Without a diploma from a *Gymnasium*, he could not enroll in a university in either country, so he studied for two and a half years at the Utrecht Technical School. Although this was not a college-preparatory school, he was able to pass the entrance examinations in 1865 and enroll at the Polytechnical School in Zurich, a route that would be followed thirty-one years later by Albert Einstein, who also ran afoul of the school system.

Röntgen studied mechanical engineering, receiving his diploma in 1868. One of his teachers, Professor August Kundt, became his mentor and sponsor and convinced him to change his studies to physics. Röntgen earned his Ph.D. only a year later. After receiving his degree, Röntgen became Kundt's assistant, largely because he was especially adept at constructing experimental equipment. While working in Zurich, Röntgen met his future wife, Anna Bertha Ludwig. In 1871, Kundt accepted a position at the University of Würzburg, and Röntgen went with him. Röntgen married Anna in 1872, and although they had no children, they adopted Anna's six-year-old niece in 1887.

LIFE'S WORK

Röntgen eventually separated from Kundt and struck out on his own. He did well, teaching at three universities and rising through the academic ranks. While at the University of Giessen, Röntgen demonstrated that moving a piece of insulating material, such as glass, in an electric field causes a magnetic field to appear in the insulator. This effect was predicted by James Clerk Maxwell, who had developed a set of equations known as Maxwell's equations, which contain all that is known about electricity and magnetism. Röntgen published this result in 1888 and later said that this was as important as his discovery of X rays, since it established that Maxwell's equations are correct. Also in the year 1888, he returned to Würzburg, but this time as department chair.

Röntgen was red-green color-blind. Some people with this problem become very keen observers in order to distinguish what others say are different colors. Röntgen became such an observer, and this helped him to become one of the best experimental physicists of his time. After examining Maxwell's equations, the famous scientist Hermann von Helmholtz predicted the existence of very penetrating short-wavelength radiation. Röntgen decided to look for these penetrating rays. In the fall of 1895, while studying cathode rays generated in Crookes tubes, he made a historic discovery.

Crookes tubes (named for the English chemist Sir William Crookes) are glass cylinders about the size of a one-liter bottle. An electrode is placed in each end, the tube is sealed, and the air is sucked out. When the air pressure is low enough and thousands of volts are placed across the electrodes, rays stream from the cathode (the negative electrode). Although the rays are invisible, their path can be traced by seeing where they hit on a fluorescent screen. Röntgen hypothesized that when cathode rays struck a target, they would create Helmholtz's penetrating radiation. For a detector, Röntgen had prepared a card painted with barium platinocyanide, which glowed when exposed to ultraviolet light. Röntgen darkened the room and completely covered the Crookes tube with black cardboard to block all light from the tube. When he turned on the high voltage to the tube, a flash of light from the chemically coated card caught his eye. He placed a sheet of paper in front of the card, and then a book, and then a wooden board;

One of the first X-ray photographs, taken by Wilhelm Conrad Röntgen and showing his wife's hand. (Getty Images)

The X-Ray Tube

When he discovered X rays in 1895, Wilhelm Conrad Röntgen was using a Crookes tube, named for the English chemist Sir William Crookes. A Crookes tube is a glass bulb from which almost all of the air has been evacuated. It is about as long as a large banana, but several times fatter, and it generally has electrodes sealed inside at the two ends. Producing X rays requires tens of thousands of volts. Using a circuit similar to that used by a modern automobile to generate high voltage for the spark plugs, the high voltage for the X-ray tube began with a storage battery equipped with a vibrating switch that turned the current on and off many times per second, since only changing current can be transformed. This current was fed into an induction coil and transformed into high voltage. When the high voltage was connected to the electrodes of a Crookes tube, invisible rays of some type streamed out from the cathode (negative terminal) and on through the Crookes tube. It was later discovered that these cathode rays are streams of high-energy electrons.

When some of these electrons struck the glass at the far end of the tube, the glass glowed green and produced X rays. More exactly, as electrons are brought to a stop in a target, such as an electrode or the glass wall of the tube, the decelerating electrons emit X rays. The positive electrode on the opposite end of the tube from the cathode is called the anode. Röntgen discovered that if the anode were made of a heavy metal such as platinum, more X rays were produced. X-ray photographs were produced by wrapping photographic film in lightproof paper, placing the object to be X-rayed on top of the film package, and then exposing the object and film package to X rays. Developing the film as normal camera film then revealed the shadowgraph called an X ray. Areas in the target that absorb most of the X rays, such as bone, appear whiter in the shadowgraph; areas in the target that transmit most of the X rays instead of absorbing them, such as muscle, appear darker.

Many laboratories had Crookes tubes along with the necessary electrical components and photographic facilities to make X-ray photographs. On February 8, 1896, just over one month from Röntgen's public announcement of X rays, Edwin Brant Frost in Dartmouth, Massachusetts, made an X ray of a fractured bone in Eddie McCarthy. Another early medical X ray was made by Professor John Cox of McGill University to locate a bullet that had festered for six weeks in a patient. It had previously escaped detection because it was lodged between the patient's tibia and fibula.

Within four months of Röntgen's public announcement about X rays, Thomas Alva Edison's company was selling X-ray kits. With such a kit, anyone could make X rays. Marie Curie and her daughter, Irene, voluntarily took an X-ray kit to the front lines in World War I. They used it to good effect on wounded soldiers. X rays have become so indispensable to modern medicine that every modern hospital is equipped with at least one X-ray machine.

the card continued to glow, demonstrating that the radiation was very penetrating. History was made when Röntgen held a lead disk in front of the screen. He saw not only the shadow of the lead disk but also the shadows of his finger bones.

In the culture of the times, seeing a skeleton was regarded as a premonition of death. Already meticulous by nature, Röntgen decided he needed to exercise extra care before announcing his discovery so that he would not be taken as a crackpot. Röntgen worked feverishly for six weeks to establish the properties of these newly discovered rays. He named them "X rays," with the *X* standing for unknown. He found that all substances were more or less transparent to X rays. Several substances such as calcium compounds and uranium glass fluoresced when exposed to the rays. X rays seemed to be a different phenomenon than light because Röntgen was not successful at reflecting or diffracting them. (Later, other scientists were successful at this.) X rays could not be a beam of charged particles like cathode rays because their path was not affected by a magnet. They could cause static electricity to leak away faster, so Röntgen concluded that X rays ionize air. Finally, photographic emulsions were sensitive to X rays. Röntgen used this property to make a shadowgraph of his wife's hand that showed a ring she was wearing.

On New Year's Day, 1896, Röntgen mailed copies of this X-ray picture titled, "Hand, mit Ringen" (hand with ring), along with an article describing his discovery of X rays to six prominent physicists. One of these pictures found its way into the newspaper, *Die Presse*, in Vienna on January 5, 1896. Röntgen became famous overnight. Some claimed the fame was undeserved and that his discovery was a lucky accident, but although it was happenstance that he saw the first glow, Röntgen's discovery was no accident. Had he not seen the glow, Röntgen would have next held the fluorescent screen close to the tube, according to his plan, and would have then seen the glow.

Impact

In addition to their use in medicine, X rays are used to authenticate art work, stamps, and coins. They are also used to reveal the crystal structure of minerals, to gauge the thickness of materials, to inspect welds, and to look for microscopic cracks in pipes. If X rays are used to strip inner electrons from atoms, and the electrons are then allowed to recombine with the ionized atoms, they will emit X rays that are characteristic of the chemical elements present. This technique, called X-ray fluorescence, can be used to detect trace amounts of various elements. Characteristic X rays have been used to identify elements on Mars and on the Moon.

Röntgen introduced a medical application of X rays with the publication of the X-ray photograph of his wife's hand, but, believing that medical X rays would be eminently useful, he never patented any aspect of the process, so others would be free to use it. Medical X rays have become so useful that their discovery is ranked as one of the most important discoveries in medical science. The first Nobel Prize in Physics ever awarded went to Röntgen in 1901. He donated the prize money to the University of Würzburg, but he got so flustered when speaking to an audience that he did not give a speech at the Nobel ceremony. Röntgen died of radiation effects at age seventy-eight. Although he received dozens of medals and over fifty honorary doctorates, he died nearly penniless.

In 1971, the English electrical engineer Godfrey Newbold Hounsfield led a group of scientists using a computer to guide the X-ray tube and to combine images. The result was a computed tomography (CT) scan. CT scans allow doctors to follow details inside a person through a series of computer-enhanced, stacked X-ray pictures. The scans are cheaper than magnetic resonance imaging (MRI), but MRIs do not expose the patient to radiation. Some tissues show up better with one technique, and some with the other, so it is most fortunate that both are now available.

Sylvester Roper

American mechanical engineer

Although a career inventor—completing groundbreaking designs of sewing machines, furnaces, machine tools, and firearms—Roper is best remembered for pioneering the application of steam engine technology to bicycle design, developing the steam velocipede, a self-propelled two-wheeled vehicle, the precursor of the gas-powered motorcycle.

Born: November 24, 1823; Francestown, New Hampshire
Died: June 1, 1896; Cambridge, Massachusetts
Also known as: Sylvester Howard Roper (full name)
Primary fields: Automotive technology; mechanical engineering
Primary invention: Steam velocipede

Early Life

Sylvester Howard Roper was born on November 24, 1823, in the tiny southern New Hampshire hamlet of Francestown. Largely because the impact of Roper's most daring designs were not appreciated until decades after his death and because Roper himself, despite nearly seven decades of engineering initiatives, never filed for a patent nor pursued commercial sales of his numerous inventions, little is known about his early life. There is no record of his education—historians have assumed that Roper's father, an expert cabinet-maker, most likely apprenticed his son. Roper wrote years later of the education he received watching his father, how he came to be fascinated by mechanical design, by efficient machinery, and specifically by the manipulation of steam power to direct machine operation. Before he was fifteen, he had worked out a design of a small steam engine; before he was seventeen, he had designed a more powerful engine in an effort to up the speeds of steam locomotives, whose heavy iron construction compromised their speed.

Records indicate that by 1854 Roper had moved several times before settling in Roxbury, outside Boston, where he worked as a machinist. He never stopped pursuing individual design projects. During the Civil War, Roper, nearly forty and too old to enlist, worked at the Springfield Armory. He would find considerable financial security after the war as a gunsmith. Among his more notable inventions was the shotgun choke.

The Steam Velocipede

Although Sylvester Roper redesigned the steam velocipede from 1867 until his death, addressing specifically its handling problems and its inability to sustain long distances, it is the 1869 Roper steam bicycle that is perhaps his landmark achievement. (The model is currently housed at the Smithsonian Institution.) It represented the foundational design elements of Roper's conception of steam-powered two-wheeled transportation. By attaching a twin-cylinder steam engine with a boiler and firebox (a basic Franklin stove) along with a manually operated water tank to the existing frame of a standard bicycle of the era (with the traditional two wheels with hickory spokes and forged iron band rims), Roper ushered in the era of machine transportation, anticipating the evolution fifty years later of gas-propelled internal combustion engines. The contraption was not designed for comfort (the solid heavy wheels made for a strong vibration) or aesthetics. Rather, it was compact and fast.

Roper attached one cylinder to each side of the bike's frame, each connected in turn to the driving cranks on the rear wheel axle. He suspended a lightweight vertical boiler on springs between the wheels, with a small angled chimney pointing back from the top of the boiler at the rear of the bike's saddle. The twin-cylinder design was Roper's own, drawing on his concept of manageability given the velocipede's precarious balance. The boiler would act as the vehicle's water storage tank as well. The lower half of the boiler was the firebox, in which the crushed coal was fed. For safety, a flue with an adjustable angle helped the driver contain and control the fire. The rider operated by hand a small water pump mounted at the left forward side of the boiler just under the saddle and fed water as the steam was used. Oscillating steam-driven cylinders in turn pivoted on each side of the bike's frame next to the chimney. Connecting rods running to the rear axle generated the bike's momentum from the compressed steam from the stored water after it had been heated at extremely high temperatures (which made the ride a bit precarious for the driver who straddled the boiler). A cable attached to the handlebars controlled the throttle, and turning the cable counterclockwise actually activated the braking system. Although later designs would increase the capacity of the water tank, the early designs accommodated relatively short distances, three to five miles at speeds approaching 30 miles per hour.

Life's Work

Nearly immediately after the war ended, Roper returned to his first love: the potential of steam. Steam was being used to propel ships and trains, and stationary steam engines managed entire industrial plants. However, what intrigued Roper was the idea of developing lighter machines that could use steam power to revolutionize the concept of speed itself. He was particularly intrigued by the new pedaled velocipede (or bicycle) that, unlike earlier designs that had relied on being pushed by the rider's feet or that were notoriously unstable because they had a huge front wheel and a smaller back wheel, featured wheels of equal size and thus promised better mobility.

Between 1867 and 1869 (Roper kept few accurate records of his prodigious number of ongoing projects), Roper attached a twin-cylinder steam engine to the velocipede frame. The bicycle was significantly modified by Roper: The saddle was moved far up to allow for placing the firebox and the boiler between the wooden wheels. Although the design had its problems—not the least of which was an iron boiler with a charcoal fire operating at nearly 300° Fahrenheit suspended between the wheels and thus percolating between the legs of the rider—Roper was encouraged by the design. The redesigned bicycle was of course bulky—estimates put the weight at more than 160 pounds—and was by all reports uncomfortable to ride. The boiler water supply, under the rider's seat, was manually pumped at the forward side of the boiler. The heated steam maintained the vehicle's momentum.

The steam velocipede was remarkably safe. Roper had designed a kind of twist-grip control mechanism for the handlebar to control the steam throttle and in turn to propel the velocipede. Although not a particularly attractive design, the steam-powered "motocycle" (as Roper called it) offered what Roper had long been fascinated with: speed. Despite generating enormous numbers of complaints from Roxbury residents over the machine's noise (it spooked horses), Roper delighted in motoring about the streets. He claimed that his machine could outrun a horse and climb any hill. Attempts were made to curb Roper's street demonstrations; he was actually arrested once, but of course, because city ordinances had yet to address specifically the problems posed by such innovative designs, Roper never served time or paid a fine.

Over the next thirty years, Roper devoted enormous resources of time to renovating the bicycle's design. He also worked on a design for a steam-driven automobile and had built steam engines for yachts. Given his financial security (he had made a fortune as a gunsmith and later, with his son, in developing a machine capable of making screws), Roper pursued his design, making each of the ten subsequent redesigns lighter and, of course, faster. He became something of a regional celebrity, taking his motocycles to tracks, circuses, and fairs and performing exhibition runs in which he himself, despite his advancing years, did the riding, although the machines were known for routinely achieving "dangerous" speeds of more than thirty miles per hour.

In 1895, Roper approached the Pope Manufacturing Company for joint sponsorship of a project designed to make his steam-powered bicycle more practical and ultimately available for a mass market. Since 1878, Pope had aggressively worked to corner the bicycle market and had pioneered several cutting-edge technological innovations in bicycle design; by the time Roper teamed up with the company, it had established itself as the dominant producer of bicycles in America. With that financial backing, Roper produced what would be his last prototype, a revolutionary design that was sleeker (a much smaller boiler over the coal firebox) and lighter (just under 150 pounds) and capable, with its one-gallon water reservoir, of more than twenty miles in one filling of coal.

Eager to test the vehicle and promote it in the process, Roper, although past the age of seventy, accepted an invitation to test-drive the vehicle before an interested crowd at a small (one-third-mile) wooden bike track along the Charles River. On the morning of June 1, 1896, Roper made three routine exhibition laps. As part of the carnivalesque atmosphere, he challenged and then bested bike riders, who, of course, could not keep pace with his machine. Journalists attending that day recorded that Roper covered a mile in two minutes and twelve seconds. Roper, who told reporters that he had gone closer to 40 miles per hour the week before, was determined to push the speed. He instructed his assistants to rebuild the steam pressure. On his first lap—in which, eyewitnesses estimated, the machine achieved nearly 60 miles per hour—the machine began to wobble. Roper lost control and was thrown off the track and into a sandy bank that surrounded the track. He was dead before volunteers could get to him. Although his death was widely used as a cautionary lesson against the dangers of the newfangled speed machines, autopsy reports later confirmed that Roper had actually died of a heart attack and was dead before the crash.

Impact

Although Roper is credited historically (and rightfully) with being the world's first motorcyclist, his is a far more fascinating legacy. He was an inventor—and just that. In an expanding industrial era when inventing itself was deemed a profession and inventors emerged among the savviest capitalist entrepreneurs, flooding the American market with new gadgets that would propel some inventors not only to celebrity status but also to significant fortune, Roper stands apart. He spent close to seven decades pursuing his simple love of design, his fascination with tinkering. With his wide-ranging intellect (he was entirely self-trained), he completed a staggering variety of inventions without pursuing the patent protection or even the marketing potential that gave much lesser engineers reputation and vast fortunes. Restless, curious, fascinated by the intricacies of design itself, he was drawn to the traditional problem-solution approach of old-school technology. In that, he is a singular presence amid the fierce competitive marketplace of late nineteenth century industrial technology.

That said, Roper has found a secure place within the mythos of the motorcycle culture, his steam velocipede a clear precursor of the gas-driven motorcycles of a generation later. Much of his work anticipated innovations that would shape motorcycle technology in its earliest years. His was a vision that saw two-wheeled vehicle transportation as an expression of both speed and convenience. His tireless promotion of its technology in the face of conservative resistance to its novelty and to its evident danger marks him as an early proponent of what would become the free spirit and aggressive individuality associated with motorcycle riding. Indeed, it is his death that most defines his impact within motorcycle culture: At seventy-three, his heart burst at the very moment when his machine achieved unprecedented speed, the essence of the daring temperament that would become the signature of motorcycle enthusiasts.

Ernst Ruska

German electrical engineer

Ruska's pioneer work leading to the invention of the electron microscope made it possible for researchers in various fields of science, ranging from biology through medicine and chemistry, to develop much more precise knowledge of the microscopic world of organic cells and until-then mysterious structures of inorganic material.

Born: December 25, 1906; Heidelberg, Germany
Died: May 30, 1988; West Berlin, West Germany (now Berlin, Germany)
Also known as: Ernst August Friedrich Ruska (full name)
Primary fields: Electronics and electrical engineering; physics
Primary invention: Electron microscope

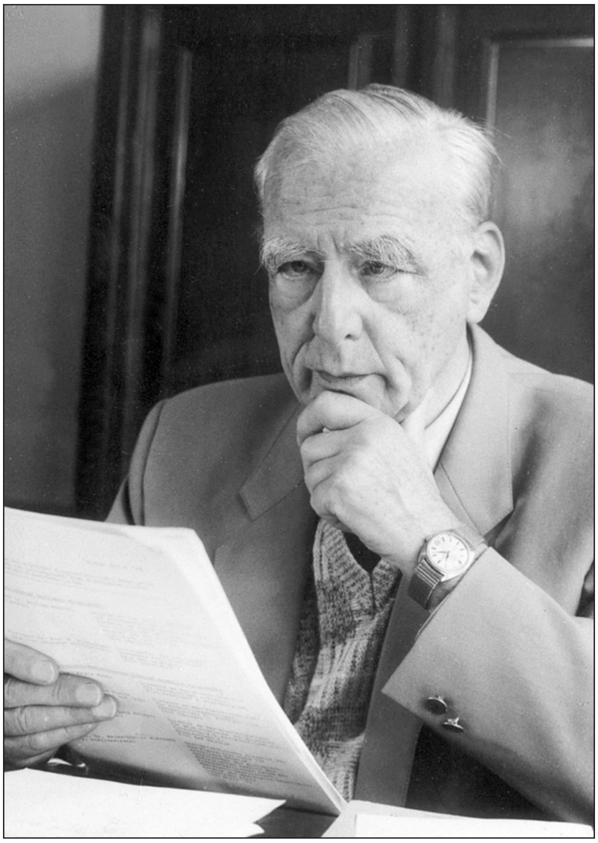
Early Life

Ernst August Friedrich Ruska (ehrnst OW-goost FREE-drihk ROOS-kah) was the fifth of seven children born to Julius Ruska and Elisabeth Ruska, née Merx. After finishing his early education in the famous university city of Heidelberg, Ruska went in 1925 to the Bavarian capital in Munich, where he studied electronics for two years at the Technical University of Munich. He completed these studies after 1927 at the Technical University in Berlin. His first practical working experience was gained as a research engineer, first at Brown-Boveri and Company in Mannheim, then at Fernseh AG in Berlin, and then with one of the future giants of the emerging electronics industry, Siemens and Halske, also in Berlin. By that time, Siemens and Halske, which had been involved in telegraphy and undersea telegraphic cable communications as well as electric tramway motors in the late nineteenth century, was becoming more and more engaged in the diverse applications of electrical engineering that would make it famous in the twentieth century.

Ruska's studies in Berlin had involved him in research under Adolf Matthias, director of the Institute of High Voltage. Matthias's doctoral students contributed to increasing knowledge of scientific instruments that would be quite relevant to Ruska's later development of the electron microscope, most notably in perfecting early models of the cathode-ray oscilloscope.

Life's Work

By the time he completed more advanced studies and received his doctoral degree in 1934, Ruska had developed scientific knowledge related to new approaches to microscopy. In a statement presented when he received the Nobel Prize in 1986, he mentioned his interest in 1929 in a contemporary physicist's (Hans Busch's) as yet unproven "theory of the effect of the magnetic field of a coil of wire through which an electric current is passed and which is then used as an electron lens." Within two years, Ruska, collaborating with his colleague Max Knoll, produced a preliminary model of a microscope incorporating the two principles that would become essential to his own ultimate success in breaking free of light-wave technology in microscopy and creating electron-lens technology with unparalleled short focal lengths: emission and radiation.



Ernst Ruska. (©The Nobel Foundation)

In 1933, the year in which he built the first operative electron microscope, Ruska began four years of employment with Fernseh, a German firm pioneering early television technology and photoelectric cells. He then moved to Siemens and Halske, where the Laboratory for Electron Optics was established and produced the first marketable electron microscope, named the Siemens Super Microscope. Siemens and Halske continued to support scientific collaboration on electronic microscopy throughout the period of World War II. Despite Germany's defeat, in 1945 more than thirty scientific institutions were using electron microscopes, a fact that suggests continued scientific exchanges between researchers even during the global conflict.

Four years of reconstruction made it possible for Ruska and his colleagues to begin developing a new generation of electron microscopes. Their work culminated in 1954 when Elmiskop 1 was introduced. Over the next few decades, this perfected electron microscope would become vital to the work of more than one thousand scientific institutions around the world.

After being named to posts at several prestigious institutions—most notably the institute that became the Fritz Haber Institute of the Max Planck Society in Berlin—Ruska was named (within the same institute) director of the Institute for Electron Microscopy. He held this post between 1957 and 1974, the year of his retirement.

In 1986, only two years before his death, Ernst Ruska was awarded one-half of the Nobel Prize in Physics in recognition of his pioneer contribution to electron microscopy. Two other German scientists, Gerg Binnig and Heinrich Rohrer, divided the honor of the other half of the 1986 Nobel Prize for their development of a later, somewhat distinct device of advanced microscopy—the scanning tunneling microscope.

Impact

The development of electron microscopy—which led to the technology that produced electron scanning microscopes and scanning tunneling microscopy—opened new horizons for scientific research in a number of

Electron Microscopy

Just as light waves (electromagnetic waves) are reflected to different degrees when they strike different areas of a specimen and can be magnified through an optical lens, electron waves can be reflected from a specimen and directed through a magnifying electrostatic and electromagnetic—as opposed to an optical—lens. The resulting image (essentially the pattern created by reflected electrons) captures and magnifies details thousands of times more minute than images under a light microscope. Typical light microscopy can magnify from five hundred to a thousand times. Improved light microscopy can achieve magnification of about two thousand times. Advanced electronic microscopy magnifies over a million times.

How does an electron microscope work? First, instead of directing a stream of light at a specimen, early electron microscopes used a cathode-ray oscilloscope to emit a barrage of electrons, which were brought into a very narrow focus by passing them through a narrow anode aperture. Electron microscopes are able to record highly detailed patterns created by such a stream of electrons coming into contact with the specimen (some electrons passing through parts of it, others variously deflected). These patterns are magnified by passing the altered electron stream through objective electromagnetic lenses. The image is recorded by exposing a chemically sensitive "photographic sheet" to the emerging electron stream.

It is essential that specimens be contained in a perfect vacuum; the presence of molecules of air anywhere near a specimen can produce inaccuracies in the imaging process. Many specimens require some form of preparatory treatment to enhance the image. This treatment can range from staining to a process called ion beam milling, in which ions of elements such as argon are beamed into the specimen at an angle, thinning the specimen until it becomes transparent to the electron beam.

The electron gun on evolving models of such microscopes (transmission electron microcscopes, or TEMs) used a tungsten filament cathode that marked an improvement over earlier cathode-ray oscilloscope sources for electron beams. Evolving TEM technology, especially once computer software programs could be employed, made it possible to increase levels of resolution. Succeeding generations of high-resolution electron microscopes (HRTEMs) would achieve magnification levels of fifty million times, enough to register the position of atoms within selected specimens in materials such as diamonds, in which individual carbon atoms are separated by only one hundred-millionth of a centimeter.

Beyond the family of TEMs and HRTEMs, a number of other devices emerged in the later twentieth century, including scanning electron microscopes. SEMs produce highly magnified—and nearly three-dimensional—images, not of one specific target but of a succession of areas in the specimen. SEMs obtain very detailed data by recording diverse forms of reaction between electrons in the specimen subareas they strike. Such reactions involve relative degrees of lost energy, manifested in the conversion of electron energy into heat, light (cathodoluminescence), or X rays.

Another category of advanced electron microscopes, called reflection electron microscopes (REMs), uses still another means of tracing electron trajectories by adding technology that can register not the "flying particle" itself but the reflected beam of scattered electrons.

fields. Electron microscopy made it possible to view a significant portion of the minuscule elements composing both organic and inorganic matter. Increased knowledge of the structure of cells and of the basic molecular composition of a large number of inorganic materials held out the promise of unparalleled advances in a variety of scientific and commercial fields. Advances in the field of space technology, for example, have ranged from the design of materials for use in the construction of space vehicles and equipment used to undertake space research to sophisticated analysis of samples of materials brought back to Earth from space missions.

Electron microscopy in several fields connected with medicine and genetic research continues to grow hand in hand with the development of specialized areas (DNA research, for example) that would have been inconceivable without the increased levels of microscopic examination and analysis that began with the work of Ruska and others.

It is important to add that, with the increasing sophistication of computer-driven research laboratories, it has become possible for researchers whose laboratories lack the expensive equipment needed for electron microscopy to benefit from high-resolution images from other laboratories transmitted over the Internet.

JAMES RUSSELL

American physicist

Russell's invention of optical digital recording (ODR) led directly to his development of the digital compact disc storage device, one of the most important technological advances of the twentieth century. The digital compact disc not only revolutionized the way digital media are stored but also transformed the music industry by leading the change from analog to digital recording and reproduction.

Born: February 23, 1931; Bremerton, Washington
Primary fields: Electronics and electrical engineering; music; physics
Primary inventions: Compact disc; optical digital recording

EARLY LIFE

James Russell was born in Bremerton, Washington, in 1931. When he was only six years old, he constructed a remote-controlled battleship, complete with a hidden compartment to store his lunch. Russell demonstrated an early interest in engineering and science and was an avid fan of classical music as a child. He later attended Reed College in Portland, Oregon, where he earned a B.A. in physics in 1953. After graduating, Russell was employed by the General Electric labs in Richland, Washington, where he worked as a physicist.

In his spare time, Russell was a lifelong avid music listener. For much of his life, the only music format available to consumers was the vinyl phonograph record, which was prone to scratches and other damage as a result of the direct contact between the stylus and the record surface necessary to generate sound. Russell was frustrated by the limited audio quality of vinyl records and began experimenting with various design improvements, including using a cactus needle as a stylus. As his part-time experiments continued, Russell began to conceive a music recording system that would be superior to vinyl records and that, in the course of time, would radically transform the music and recording industries.

Russell's ideal system was one that was capable of recording and replaying sounds without requiring physical contact between its parts, the Achilles heel of vinyl records. In order to create such a system, Russell knew that he would need to use light to encode and decode sound. Familiar with digital data recording in the form of punch cards and magnetic tape, Russell determined that, if he could record onto a photosensitive platter, he could represent binary 0's and 1's with dark and light binary pits, or dots, one micron in diameter. A laser could then be used to read the dot patterns of light and dark, which could then be converted by a computer into an electronic signal and made either audible or visible to consumers

The Digital Compact Disc

James Russell was the first person successfully to develop an optical digital recording device, which became the digital compact disc (CD). Russell's compact disc utilized light rather than physical contact to read the data stored on the surface of the device. As his ideas and experiments evolved, Russell eventually created a flat, round disc capable of storing significantly more data than its analog counterparts.

As major corporations purchased licenses to mass produce Russell's compact disc, alterations to the original design were made to accommodate household use. In general, compact discs today are made from nearly pure polycarbonate plastic and measure 1.2 millimeters thick. Data are stored on compact discs as a series of tiny indentations known as pits or dots, which are encoded in a spiral track molded into the top of the polycarbonate layer of the disc. The areas between pits are known as lands. Each pit is approximately 100 nanometers deep by 500 nanometers wide.

A CD player or CD-ROM drive reads by focusing a 780-nanometer-wavelength semiconductor laser through the bottom of the disc's polycarbonate layer. The change in height between the pits and lands results in a difference in intensity in the light reflected from the disc's surface. By measuring the intensity change with a photodiode, the encoded data can be read from the disc.

The pits and lands themselves do not directly represent the zeros and ones of binary data. Instead, non-return-to-zero, inverted (NRZI) encoding is used: A change from pit to land or land to pit indicates a one, while no change indicates a zero. These changes are then decoded by reversing the eight-to-fourteen modulation used in mastering the disc and then reversing the cross-interleaved Reed-Solomon coding, which reveals the raw data stored on the disc.

Russell's goal was to produce a data-storage device that was impervious to the normal wear and tear of repeated use that degraded vinyl records. CDs, however, remain susceptible to damage from both regular use and various environmental factors. Pits are much closer to the label side of a disc, resulting in defects and dirt on the clear side that can be out of focus during playback. Early music CDs were susceptible to "CD rot," or "laser rot," in which the internal reflective layer could degrade. When this occurs, the CD may become unplayable.

Russell's invention of the digital compact disc not only changed the way in which data were encoded for computing but also radically altered the landscape of the music industry, which transitioned from analog to digital recording in order to embrace the benefits of the compact disc. The CD, the CD-ROM, and the closely related DVD are present in tens of millions of homes in the United States and have rendered vinyl records and cassette tapes virtually obsolete.

repeatedly without ever wearing out. Russell immediately understood that if he was able to make the binary code compact enough, he could store a vast amount of information on a very small surface area.

Life's Work

Immediately following his graduation from Reed College, Russell was hired by General Electric, the private manager of the Atomic Energy Commission's Hanford Nuclear Plant, where his wife, Barbara, worked as a chemist. General Electric made Russell a "designated problem-solver" for its experimental unit, where he would meet with engineers experiencing technical difficulties. During this time, Russell patented several devices that assisted in running Hanford's nuclear reactors and also assisted in the development of complete computer controls for a test reactor. Russell was also among the first to use a keyboard and a color television monitor as the sole interface between computer and operator.

Some of Russell's additional responsibilities included designing and constructing the first electron-beam welder, which applies a beam of high-velocity electrons to fuse materials together. Later, in 1965, Russell joined the Columbus, Ohio-based Battelle Memorial Institute's Pacific Northwest Laboratory in Richland, Washington, to continue his work as a senior scientist.

Battelle let Russell pursue his digital data recording system project, and, after years of work, he finally succeeded in inventing the first digital-to-optical recording-and-playback system, the compact disc (CD), which was patented in 1970. The original design for the compact disc was quite different from the final product. Originally, Russell wanted to produce stereo discs measuring 3 × 5 inches that would fit in a shirt pocket, as well as a punch-card-sized video disc. The final design of the compact disc mimicked the familiar round, flat shape of the vinyl records that had originally inspired Russell. In 1974, Russell was honored with a Research and Development 100 award for his work on optical digital recording.

Under the sponsorship of Battelle, Russell worked on his digital data-recording system throughout the 1970's. He continued to refine the digital compact disc, adapting it to hold any form of data, and by 1980 he had made the first disc player. Like many revolutionary and potentially industry-changing devices, the CD initially found few interested investors. The idea of transforming the computer and music industries by adopting the compact disc as the primary storage medium was perceived to be risky, if not foolhardy, by many industry giants. For years, Russell continued to refine and market his invention, despite the lack of interest. After nearly two decades of unsuccessfully pitching the idea of digital data recording onto compact discs, Sony, Philips, and several other audio companies finally realized the far-reaching implications of Russell's work, purchased licenses for his product, and began mass producing compact discs for consumers.

By 1985, Russell had earned twenty-six patents for compact disc read-only memory (CD-ROM) technology. In 1991, Russell founded his own consulting firm, Ioptics, in Bellevue, Washington, with software entrepreneur Paul Nye. While at Ioptics, Russell continued to invent and patent improvements in optical storage systems, along with bar-code scanners, liquid crystal shutters, and other industrial optical instruments. Despite a multimillion-dollar investment from Microsoft, Ioptics did not remain active, and its patents were sold.

Russell received the Vollum Award for Distinguished Accomplishment in Science and Technology at Reed College's convocation in August, 2000. The Vollum Award is presented to those who exhibit perseverance, a fresh approach to problems and solutions, and creative imagination. Ever the inventor, Russell developed a new, high-speed optical data recorder and player with no moving parts, further reducing the chance of mechanical wear-and-tear or malfunction. Russell earned another eleven patents for this optical random-access memory (ORAM) device, which was initially targeted at handheld computers, cell phones, portable video games, and military devices. Russell hoped that the ORAM would eventually supplant the compact disc as the primary storage medium for a wide variety of information and entertainment devices.

Impact

Consumer electronics and developments in computers redefined life and work in the late twentieth century. The adoption of the CD-ROM revolutionized the way computers stored and retrieved data. The device's larger capacity and longevity led it eventually to replace the floppy disk. The music industry was similarly reinvented with the advent of the compact disc, as recording artists and consumers alike embraced the superior quality and durability of digital audio compared to analog.

The CD and the CD-ROM advanced the global transition toward digital technology, through which any information—from still pictures, to text, to music, to video content—can be expressed as a long string of binary code. Today, it is possible to reproduce information not only in rough miniature but also as a series of tiny binary pits. Russell saw how the billions of binary pits used by digital supercomputers could successfully make the transition from the laboratory into the living room.

After large corporations purchased licenses to mass produce compact discs, several modifications were made to Russell's original design in order to facilitate mass marketing and household use. The fact remains, however, that the basic mechanics of the compact discs adopted for use in millions of American homes, as well as the CD-ROMs used in the academic, commercial, medical, and scientific communities, faithfully represent Russell's original system. Russell's early work in optical recording technology formed the physical basis of the defunct videodisc, as well as CD and digital versatile disc (DVD) technologies, which have replaced analog audio and video cassettes in the mass market as a result of their durability and superior playback quality.

Burt Rutan

American aerospace engineer

Rutan was the primary designer of the suborbital rocket plane SpaceShipOne, *which was the first privately funded craft to exceed a height of sixty-two miles, the distance from Earth's surface to the edge of space, twice within two weeks. The feat opened the doors for a commercial space age.*

Born: June 17, 1943; Portland, Oregon
Also known as: Elbert Leander Rutan (full name)
Primary field: Aeronautics and aerospace technology
Primary invention: *SpaceShipOne*

Early Life

Elbert Leander Rutan, the second of three children, grew up in Dinuba, California. He has said that among the strongest of his childhood memories are the three popular space films that rocketry pioneer Wernher von Braun made in collaboration with the Walt Disney Company between 1955 and 1957 to convince the American public of the need for space exploration. The films, which fascinated Rutan, showed space travel to the Moon, Mars, and beyond as exciting and adventuresome yet somehow mundane.

As youngsters, Burt and his brother, Dick, were interested in building model airplanes. The boys would persuade their mother to drive them up and down the deserted valley roads late at night as they tested the aerodynamics of their model planes by holding the planes out of the car's windows. Burt kept this practice up, although without his mother's assistance, even as he went off to college. Rutan's interest in flight was so great that he had logged his first solo flight before he earned his license to drive an automobile.

Rutan's fascination with aeronautics led him to study aeronautical engineering at California State Polytechnic University. In 1964, he was chosen to represent his university at the Space Technology Summer Institute at the California Institute of Technology (Caltech). Rutan also took coursework in the Aerospace Research Pilot's School at Edwards Air Force Base. He received his degree in 1965 and met Wernher von Braun after accepting an award at a student design competition.

After graduation, Rutan went to work as a test engineer at Edwards Air Force Base in California's Mojave Desert. While working at the base, Rutan narrowly survived a test flight in an F-4 Phantom fighter. Rutan was on the flight to study ways to better control the F-4's notoriously dangerous handling, which was becoming renowned for killing American pilots in Vietnam.

Life's Work

In 1972, Rutan took a position as director of the Bede Test Center for Bede Aircraft in Kansas. Two years later, he left Bede and returned to the desert, founding his own company, the Rutan Aircraft Factory (RAF), with which he planned to design and sell plans for small, build-it-yourself planes for hobbyists. RAF was underfunded in its early days, so Rutan tested the aerodynamics of his designs by strapping parts to the roof of his station wagon and speeding down deserted roads.

RAF's first design, the Rutan VariViggen, was a two-seat pusher with a canard—a set of wings situated in front of the fuselage ahead of the larger set of wings. This arrangement not only is a staple of Rutan's designs but also makes his vehicles more stable and provides them more lift than a standard plane design. The other essential part of the Rutan design is that most of his vehicles are pushers—that is, the engines are mounted in front of the propellers. This arrangement reduces drag and increases efficiency.

The VariViggen was followed by such successes as the VariEze (and Long-EZ) models, in which RAF pioneered the use of moldless glass-reinforced plastic construction in hobbyists' plane kits. Other well-known RAF creations include the NASA AD-1, Quickie, Defiant, Solitaire, and Catbird. One of Rutan's most famous designs was the Voyager, which Dick Rutan and Jeana Yeager flew nonstop, without refueling, around the world in December of 1986, the first aircraft to accomplish this feat.

In 1982, Rutan formed Scaled Composites, also headquartered in the Mojave, a company that has gone on to be a world leader in aircraft and spaceship design. Scaled is perhaps best known for its work with unmanned aerial vehicles such as the Scarab Model 324 reconnaissance drone for Teledyne Ryan Aeronautical and multimission high-altitude aircraft such as the Proteus. Scaled also developed new ultralight and ultrastrong composite manufacturing processes for military, aerospace, and general aviation. In 1985, Scaled was purchased by Beech Aircraft, which was then sold to Wyman/Gordan in 1989, yet Rutan was retained at chief executive officer.

By the mid-1990's, both Scaled and Rutan had become successful and famous; however, Rutan was discontent. It was while working on the Proteus that Rutan started to draw design sketches of a large plane with a smaller rocket plane strapped to its belly. Then, in 1996, Peter Diamandis, a proponent of civilian space travel, announced a competition called the Ansari X Prize, a $10 million award to the first nongovernment organization to achieve spaceflight and then repeat the flight with the same vehicle within two weeks.

Rutan was contacted by Microsoft cofounder and billionaire Paul Allen, a space enthusiast, who agreed to fund a $20 million program (under the corporate name Mojave Aerospace Ventures, a partnership between Allen and Scaled Composites in their Tier 1 program) to make a serious run for the prize. Though he received the necessary funding, Rutan had some nagging doubts. Scaled had never built a supersonic craft, much less one that could attain Mach 3 (three times the speed of sound). Moreover, Scaled had never launched one aircraft from another, built the types of thrusters needed for spaceflight, or designed the kind of electronic navigational systems needed for spaceflight, not to men-

SpaceShipOne and *SpaceShipTwo*

Burt Rutan is known for designing unusual-looking, durable, and fuel-efficient aircraft and for his own private space program. His *SpaceShipOne*, which cost an estimated $20 million, allowed Rutan to send the first civilian astronaut into space in June 21, 2004. *SpaceShipOne* was designed by Rutan and developed by Scaled Composites. The craft is perhaps best technically described as a manned experimental air-launched suborbital spaceplane that used a hybrid rocket motor that burned a combination of nitrous oxide and rubber. *SpaceShipOne*, like most of Rutan's ideas, started as a drawing on a napkin. Those napkins are on display with *SpaceShipOne* at the Smithsonian National Air and Space Museum. Surprisingly, very little needed to be changed from Rutan's original napkin sketches to the final craft.

Scaled Composites and Sir Richard Branson's Virgin Group are developing *SpaceShipTwo*, which is a part of their Tier 1b program for space tourism. *SpaceShipTwo* will be a larger vehicle, roughly the size of a corporate Gulfstream jet. It will be capable of carrying six passengers and two pilots. Both *SpaceShipTwo* and its launch vehicle will be built from ultralight composite materials. As the launch vehicle for *SpaceShipTwo*, the new incarnation of the White Knight boasts a 140-foot wingspan and a three-fuselage, four-engine design that will allow the pilot to carry *SpaceShipTwo* high into the sky before releasing it. At the moment of release, *SpaceShipTwo* will fire its rocket engines, which will also burn a combination of nitrous oxide and a rubber-based solid fuel to push the craft past the sixty-two-mile mark and into the edge of space. Once there, as with the vehicle's predecessor, the pilot will engage its feathered wing, designed to slow the craft by increasing drag, as *SpaceShipTwo* glides back in for its reentry.

The planned apogee of *SpaceShipTwo* is 110 kilometers (68 miles), some 6 miles higher than the apogee of its predecessor. Despite a fatal accident during a fuel flow test that killed three Scaled employees, Rutan says that *SpaceShipTwo* will be at least as safe as airliners were in the 1920's. If *SpaceShipTwo* is successful, *SpaceShipThree* will likely be an orbital craft.

While some two hundred would-be astronauts have already put down $30 million in deposits with Branson's Virgin Galactic, as of this writing actual passenger flights are not expected to take place for another one to two years.

tion the fact that the company had no experience constructing rocket engines.

Luckily, the breakthroughs came fast. Most, like Rutan's feathered rotating wings on *SpaceShipOne*, which were designed to mitigate the heat of reentry, came from his typical "out-of-the-box" thinking. Although not every step along the path was smooth, enough progress was made so that Virgin Records and Virgin Atlantic Airlines mogul Sir Richard Branson, who was working with Rutan on a project called the GlobalFlyer (a Scaled Composites/Virgin Atlantic craft that would eventually allow pilot Steve Fossett to make the first nonstop, nonrefueled solo flight around the world), caught wind of *SpaceShipOne*. Branson signed on to fund a proposed space airline, flying Scaled Composites vehicles, called Virgin Galactic.

SpaceShipOne was registered with the Federal Aviation Administration as N328KF. The letter *N* is a prefix for a U.S.-registered aircraft; "328KF" was chosen by Scaled to stand for 328 kilo feet (approximately 100 kilometers, or 62 miles), the officially designated distance from Earth's surface to the edge of space. On April 1, 2004, Scaled received the U.S. Department of Transportation's first-ever license issued for suborbital flight. *SpaceShipOne* made history on June 21, 2004, by successfully completing the first privately funded manned civilian spaceflight, soaring to a height of 328,491 feet above the surface of Earth. Then, with successful flights on September 29 and October 4, 2004, Rutan claimed the Ansari X Prize.

Impact

Rutan's work has opened new vistas in both the commercial exploration of space and standard aeronautical engineering. *SpaceShipOne* and its launch vehicle, the White Knight (as well as the second-generation versions seen in *SpaceShipTwo*), demonstrated the most efficient and advanced designs in aerospace technology in years. Rutan's use of recycled and recyclable materials as well as the impressive fuel efficiency of his designs set his works decades ahead of those of his contemporaries. In addition, Rutan has shown venture capitalists that investing in commercial space exploration ventures can be profitable.

Jonas Salk

American physician and medical researcher

Salk developed the first safe killed-virus polio vaccine. Use of the Salk vaccine has led to the virtual eradication of polio in the United States and in many other countries around the world.

Born: October 28, 1914; New York, New York
Died: June 23, 1995; La Jolla, California
Also known as: Jonas Edward Salk (full name)
Primary field: Medicine and medical technology
Primary invention: Polio vaccine

Early Life

Jonas Salk was born in the Manhattan borough of New York City in 1914, the first of Dora and Daniel Salk's three sons. Dora and Daniel met while both worked in the garment industry. Although young Jonas loved reading and scholarship, he displayed little interest in science. Dora thought he might become a rabbi. Instead, he told his mother his goal was to go to law school and then become a politician. A gifted student, he attended Townsend Harris High School, which featured an accelerated degree program. Salk graduated at fifteen and immediately enrolled at the City College of New York (CCNY).

Like most colleges, CCNY required all students to take course work outside their proposed degree programs. Salk, who had declared a prelaw major, had to take chemistry. He quickly discovered that he loved science. Salk decided to become a doctor, although he planned to focus on research rather than clinical practice. In 1934, he enrolled at the New York University Medical School.

Salk's first-year courses included microbiology and chemistry. His analytical skills and attention to detail so impressed his professor, R. Keith Cannan, that Cannan persuaded Salk to take a one-year break from medical school to work with him as a research associate. Salk spent the year honing his laboratory skills and learning to breed large amounts of streptococcus bacteria for research. When the year ended, he resumed his medical studies and graduated in 1939. Shortly after graduating and before starting an internship at Mount Sinai Hospital, he married Donna Lindsay, whom he had met in Woods Hole, Massachusetts, the previous summer. It was while engaged to Donna that Salk added Edward as a middle name; from 1939 on, he would be known as Jonas E. Salk.

Jonas Salk. (Courtesy, March of Dimes)

Life's Work

In 1942, Salk's internship at Mount Sinai ended. The United States had entered World War II a few months earlier, and Salk considered enlisting. He knew the military needed doctors. Before he could sign up, Thomas Francis, the new head of the University of Michigan's Department of Epidemiology, offered Salk a job. Francis had taught at New York University and knew Salk from his days as a medical student. Francis had been impressed then with Salk's research skills. The position Francis offered Salk at the University of Michigan required teaching courses in epidemiology in addition to assisting Francis with influenza virus research. The U.S. military funded the research, which meant that Salk would be exempted from the draft, as the work was deemed necessary to the war effort, and would also know he was helping the troops.

Salk and Francis were determined to develop a killed-virus influenza vaccine. At the time, most researchers believed only a live-virus vaccine could

The Salk Polio Vaccine

Jonas Salk's polio vaccine, which was first used for widescale public immunization programs in 1955, is a killed-virus vaccine. Developed from the three strains of poliomyelitis virus responsible for illness in humans, the vaccine was grown using primates as a host and then killed and made harmless to people through the use of formaldehyde.

When Salk began his work with vaccines in the 1940's, most researchers believed that only a live-virus vaccine could produce an effective immune response in the vaccinated patient. Live-virus vaccines are created by passing viruses through hosts such as laboratory mice until the viral strain is sufficiently weakened that it will no longer trigger life-threatening illness. Instead, the weakened virus simply prompts the creation of antibodies resistant to the disease, with the result that exposures to stronger strains of the virus will not cause illness. In rare cases, live-virus vaccines will cause some patients to develop the life-threatening form of the illness. Salk decided that ideal vaccines would be ones that triggered an immune response and subsequent development of antibodies without placing patients at risk of actual illness. His research focused solely on the use of killed viruses.

Salk's initial research projects focused on verifying the major types of polio. By 1947, virologists knew three major types of polio definitely existed: type 1, the most common paralytic type; type 2, a milder form; and type 3, the most lethal. Type 1 apparently occurred in about 85 percent of cases, type 2 in perhaps 12 percent, and type 3 in perhaps 3 percent. After three years of research, Salk and other scientists were confident a vaccine addressing those three types would serve as an effective vaccine against all polio.

In the process of typing the polio virus, Salk and his associates improved on existing methods for growing large amounts of the virus. They built on the work of John Enders, who had first demonstrated a method for growing the virus in a laboratory culture in 1941. Large quantities of the virus would be needed when an effective vaccine was discovered. The live virus was then killed using the chemical formalin, the aqueous solution of formaldehyde.

After Salk tested the vaccine first on himself and then on small groups of volunteers, large-scale field trials were held in 1952. An objective review of the results indicated that the Salk vaccine was effective against all three types of polio. As a result, 1955 vaccination of the general public began. Salk was hailed as a hero by the American public. Polio had been conquered.

One of the drawbacks of the Salk vaccine is that immunity is not conferred with a single dose. The vaccine not only must be injected but also requires booster shots following the initial injection. In the early 1960's, U.S. vaccination programs discontinued use of the Salk vaccine and switched to the Sabin because it could administered as a single oral dose. The Salk vaccine remained in use in Europe.

Public health officials eventually realized that only a killed-virus vaccine such as Salk's could eliminate the disease completely. As the incidence of naturally occurring, or wild, polio declined, the live-virus vaccine increasingly presented an unacceptable risk. Every year, a small percentage of persons given the live-virus vaccine developed what is now known as vaccine-acquired paralytic polio. In the 1990's, the United States switched back to using the Salk vaccine.

produce an effective immune response in the vaccinated patient. Live-virus vaccines are created by passing viruses through hosts such as laboratory mice until the viral strain is sufficiently attenuated, or weakened, that it will no longer trigger acute, or life-threatening, illness. Instead, the attenuated virus simply prompts the creation of antibodies resistant to the disease, with the result that exposures to stronger strains of the virus will not cause illness. The drawback to live-virus vaccines is that in rare cases they will cause some patients to develop the acute form of the illness. Salk decided that ideal vaccines would be ones that triggered an immune response and subsequent development of antibodies without placing patients at risk of actual illness. His research, first with influenza and later with polio, focused solely on the use of killed viruses.

By 1943, Francis and Salk succeeded in developing an effective killed-virus influenza vaccine. This was a milestone in virology. Salk spent much of the next few years traveling, conducting epidemiological research on influenza outbreaks at military posts in the United States and in Europe. He learned that influenza presents complex challenges in immunization, as multiple subtypes of the virus exist. It would probably never be possible to develop a vaccine that would confer lifelong immunity to all strains of influenza. Instead, researchers would have to track the virus subtypes continually and alter the vaccines annually based on which types appeared most likely to be common in any given year. It was interesting work, but by 1947 Salk felt ready for a change. The University of Pittsburgh offered Salk the opportunity to head his own virology laboratory. Salk accepted. Going to Pittsburgh would give him the rare opportunity to build a laboratory and research staff essentially from scratch rather than taking over an existing research program. It was a daunting challenge, but the potential rewards were great. With a blank slate in front of him, Salk could pick any viral disease to serve as his lab's focus.

Salk decided to focus the lab's research efforts on poliomyelitis, a viral disease that remained poorly understood despite decades of research. Scientists now know that polio is an enteric disease in that the virus enters the body orally and reproduces in the intestinal tract. It is spread through contact with fecal matter. Unlike other enteric diseases such as typhoid and cholera that diminished in frequency as sanitation improved in the twentieth century, however, the incidence of polio paradoxically increased. Even worse, with each new outbreak the numbers of people struck by the most devastating form of the illness also seemed to climb. Thus, it is not surprising that when Salk began his polio research, scientists believed polio was an airborne infection and entered the body through the mucous membranes of the nose. This belief dated back to early research into the polio virus when a researcher tried infecting monkeys with polio and unfortunately chose a species that could not be infected by swallowing the virus, but did acquire the infection when the virus was applied using nasal swabs. Salk, like many other researchers, speculated that polio outbreaks were worse in the summer because the virus traveled with airborne allergens that aggravated its effects.

In 1947, Salk assembled a research team and began working on the polio virus. Using funds from the National Foundation for Infantile Paralysis (NFIP; the organization today known as the March of Dimes), Salk's initial research projects focused on verifying the major types of polio. Since its founding in 1937, the organization had raised millions of dollars to fund research. NFIP grants supported numerous projects, including Salk's later work on a killed-virus vaccine.

By 1947, virologists knew that three major types of polio definitely existed: type 1, the most common paralytic type; type 2, a milder form; and type 3, the most lethal. It is believed that three-fourths or more of persons infected with polio never exhibit symptoms, which meant that people could be active carriers without ever knowing they were spreading the virus. Any effective vaccine would have to be based on all three types. After three years of research, Salk and other scientists were confident that a vaccine addressing those three types would serve as an effective vaccine against all polio.

As Salk switched his focus from typing the virus to developing a vaccine, he found himself in an informal competition with other researchers such as Albert Sabin. Unlike Salk, Sabin thought that the only truly effective vaccine would be one that used an attenuated live virus. He did not believe it was possible to develop a killed-virus vaccine that was simultaneously safe and effective. When the time came for a widespread field trial of the Salk vaccine in 1954, Sabin attempted to block it. The field tests proceeded, and an objective review of the results declared the Salk vaccine safe and effective. The vaccine was approved for use by the general public in 1955.

Impact

Salk's work with a killed-virus vaccine for polio helped eliminate polio as a devastating disease in the United States. In addition, although U.S. immunization programs switched to the Sabin live-virus vaccine after it was introduced in 1959 because it was easier and cheaper to administer, it eventually became clear that only a killed-virus vaccine such as Salk's could eliminate the disease completely. The U.S. resumed using the Salk vaccine in the 1990's.

Henry Thomas Sampson

American nuclear engineer

Sampson designed innovative methods for preparing propellants for effective rocket and missile performance. He also developed an improved device for producing electricity from nuclear radiation. His inventions were appropriated for aerospace, military, and industrial applications.

Born: April 22, 1934; Jackson, Mississippi
Primary fields: Aeronautics and aerospace technology; electronics and electrical engineering
Primary inventions: Gamma-electric cell; propellant bonding process

Early Life

Henry Thomas Sampson was born on April 22, 1934, in Jackson, Mississippi, to Henry and Esther (Ellis) Sampson. His father, who earned a master's degree from the University of Chicago the year before Sampson's birth, was a mathematics professor and academic dean at Jackson College (later Jackson State University). In 1938, Sampson's family moved to Georgia when his father was appointed junior division dean at Savannah State College. In 1942, Sampson returned to Jackson, where Jackson College administrators named his father an executive dean. Sampson's mother, Jackson's first African American social worker, also served as that city's Head Start program executive director. His parents were community and church leaders and involved their children in related activities. Jackson State University later named its library and a mathematics award in honor of Sampson's father.

Sampson and his brother John attended segregated schools. Enthusiastic about learning, Sampson enjoyed trying to understand the principles and components necessary for mechanisms to function. On Saturdays, Sampson's godfather and neighbor, Mr. Patterson, took the brothers to matinees at African American theaters in Jackson. For six cents, Sampson delighted in watching a double feature with casts made up entirely of African American actors. Sampson realized that these independent films presented African Americans realistically and not as demeaning stereotypes often portrayed in mainstream Hollywood movies.

After Sampson graduated from Lanier High School in 1951, he enrolled in his father's alma mater, Morehouse College, in Atlanta, Georgia. There he focused on chemistry studies for two years. Interested in an engineering career, he transferred to Purdue University in West Lafayette, Indiana, and completed a bachelor's degree in chemical engineering in 1956. He sought employment with oil industries in Mississippi but was rejected by employers who discriminated against minorities. Sampson secured a civil service position at the U.S. Naval Weapons Center in China Lake, California, and traveled west by train from Jackson to begin his professional career.

Life's Work

At the Naval Weapons Center, Sampson utilized his chemical engineering skills and knowledge to conduct research for the Navy. He specialized in devising methods for developing solid propellants for rockets and case bonding materials for positioning those propellants in rocket motors. In addition to work, Sampson enrolled in graduate school at the University of California, Los Angeles (UCLA). He married Elizabeth A. Boland on February 26, 1961, in Clark County, Nevada, and their first child, Henry Thomas Sampson III, was born that year. They later had a second son, Martin Todd. During 1961, Sampson completed a master of science degree in engineering, writing a thesis titled "The Analysis of the Effects of Grain Defects on Solid Propellant Rocket Engines."

In October, 1961, Sampson received his first U.S. patent, number 3,212,256, for his invention "Case Bonding System for Cast Composite Propellants," assigning rights to the U.S. government to produce and use that invention. On February 2, 1962, Sampson filed for his second patent, for a "Process for Case Bonding Cast Composite Propellant Grains," which was issued eleven years later in May, 1973 (number 3,734,982), and also assigned to the U.S. government, for use directed by the secretary of the Navy. This invention described techniques for creating liners for securing propellant inside rocket motors or casings so that the propellant would withstand vibrations and extreme temperatures.

Sampson aspired to earn a doctorate in nuclear engineering, and he applied to the University of Illinois because it had a powerful nuclear reactor that suited his research interests. Leaving California in 1962, Sampson worked closely with Dr. George Hunter Miley, a nuclear engineering professor who advised him at Illinois. While attending graduate school, Sampson received a U.S. Navy Educational Fellowship (1962-1964) and an Atomic Energy Commission fellowship (1964-1967).

While attending the University of Illinois, Sampson was granted a patent for a "Binder System for Propellants and Explosives," in July, 1964. The patent outlined methods for making binder compositions from castor oil and several chemical compounds. It described a procedure for lining fuel tanks in rockets with plastics and adhesives and filling them with liquid fuel that solidified and attached to the liner when heated. This strategy prevented liner shrinkage, which might expose propellants to oxygen and increase pressure inside the tanks.

By 1965, Sampson had completed sufficient course work and original laboratory investigations at the University of Illinois to qualify for a master of science degree in nuclear engineering. He continued his studies, focusing on nuclear physics and energy research with Miley, and in 1967 he became one of the first African Americans to earn a Ph.D. in nuclear engineering. His dissertation was titled "A Theoretical and Experimental Analysis of the Gamma-Electric Cell." Sampson and Miley described their work in a November, 1966, *Transactions of the American Nuclear Society* report, "High Voltage Gamma-Electric Cell Theory and Experiment." They also published an article, "High Voltage Gamma-Electric Cell Operation," in *Nuclear Applications* in 1968. In July, 1968, the pair filed for a patent for their gamma-electric cell (GEC), which was issued three years later.

Gamma-Electric Cell

In the 1960's, Henry Thomas Sampson endeavored to improve existing electric cell technology created to produce electricity from radiation. Since the early twentieth century, scientists had noticed electrical charges associated with radium and pursued investigations to derive and store energy from radiation. To avoid structural flaws, Sampson studied electric cells designed by nuclear engineers and physicists, particularly Bernhard Gross. Sampson consulted Gross's 1964 U.S. patent, "Method and Apparatus for Measuring the Dosage of X-Rays and Gamma Rays" (number 3,122,640), which described an electric cell stimulated by gamma rays to create electrical energy. Sampson also read technical articles in periodicals such as *Nucleonics*.

Sampson and his mentor George Hunter Miley received a patent for their gamma-electric cell (GEC) invention in July, 1971 (number 3,591,860). Sampson constructed the GEC by building a central metal collector, usually made from tungsten or lead. He placed other collectors adjacent to the central collector. Unlike previous cell designers, Sampson encased the collectors with a substance—usually polystyrene, silicon, or epoxy—with dielectric properties, allowing electrical currents to pass through it. He waited for trapped gases to dissipate after he encapsulated the collector and then heated the materials at temperatures ranging from 40° to 60° Celsius (104°-140° Fahrenheit) for durations of several days or weeks. This curing process prevented surface charges (which diverted electricity) from forming.

When gamma-ray radiation contacted the dielectric material, that layer dispersed electrons in a process known as Compton scattering, and voltage accumulated in the collectors. Compared to other electric cells, which leaked voltage, Sampson's GEC produced abundant electricity. This voltage supplemented electrical power routinely provided by nuclear reactors to improve services to consumers and ensure more consistent power supplies. Sampson stated that nuclear reactor shields could use his invention to secure additional energy resources by gathering electricity from gamma-ray residue directed there. He also stressed that his GEC technology could be used to measure radiation in nuclear reactors and detect its presence elsewhere to protect communities vulnerable to exposure to that hazard.

Sampson's GEC influenced other inventors who referenced his patent in their applications in the 1980's and 1990's. Their inventions focused on energy generation or addressed safety issues associated with handling and discarding radiation to protect people, animals, and the environment.

Impressed with Sampson's accomplishments, administrators at the Aerospace Corporation in El Segundo, California, offered him a technical staff position. Returning to California in 1967, Sampson worked as a project engineer, contributing to the design and simulation of electrical power systems for spacecraft. Sampson shared his findings in presentations and publications. He belonged to the American Nuclear Society and the American Institute of Aeronautics and Astronautics. Starting in 1976, Sampson served on an advisory commission on nuclear engineering. In 1981, he was promoted to director of planning and operations for Aerospace Corporation's Space Test Program and continued this work until his retirement in the early twenty-first century.

After Sampson and his wife divorced in June, 1973, he began researching African American films by reading contemporary reviews in African American periodicals, interviewing African American filmmakers, and consulting archives and private collections. He wrote *Blacks in Black and White: A Source Book on Black Films* (1977), which inspired interest in

African American film scholarship. Sampson published four additional books about African American entertainment that combined his technical and cultural interests: *Blacks in Blackface: A Source Book on Early Black Musical Shows* (1980), *The Ghost Walks: A Chronological History of Blacks in Show Business, 1865-1910* (1988), *That's Enough, Folks: Black Images in Animated Cartoons, 1900-1960* (1998), and *Swingin' on the Ether Waves: A Chronological History of African Americans in Radio and Television Broadcasting, 1925-1955* (2005). Sampson's expertise on the subject resulted in his consulting and lecturing on African American films for documentaries and educational programs. In 2007, he married Laura Howzell Young, a music educator and author.

Impact

Sampson's inventions fulfilled energy, transportation, and communications needs for commercial, domestic, and military uses. His early inventions describing how to create solid rocket propellants and containers for those fuels helped minimize explosion risks and reduce costs associated with rocketry and propellant losses. His propellant bonding process improved safety for individuals using rockets and missiles. The Navy applied the process to submarine-based missiles in order to prevent those devices from prematurely detonating and killing crews and damaging crafts. His techniques were appropriated to aerospace engineering, particularly rockets launching spacecraft, including the space shuttle, to reduce propellant-related accidents. The full impact of Sampson's propellant-related inventions is unclear because of the secrecy associated with their use.

Sampson's gamma-electric cell proved useful as a radiation detector. Nuclear reactor employees used the GEC to monitor radiation levels. Government personnel appropriated Sampson's GEC to assess how much radiation resulted from nuclear weapons tests, then used it to transform dangerous radiation into benign forms of energy.

Other than patent references, public recognition for Sampson's accomplishments was limited to his peers and employer. The Aerospace Corporation presented Sampson its Black Image Award in 1982. The next year, the Los Angeles Council of Black Professional Engineers honored Sampson with the Blacks in Engineering, Applied Science, and Education Award.

Santorio Santorio

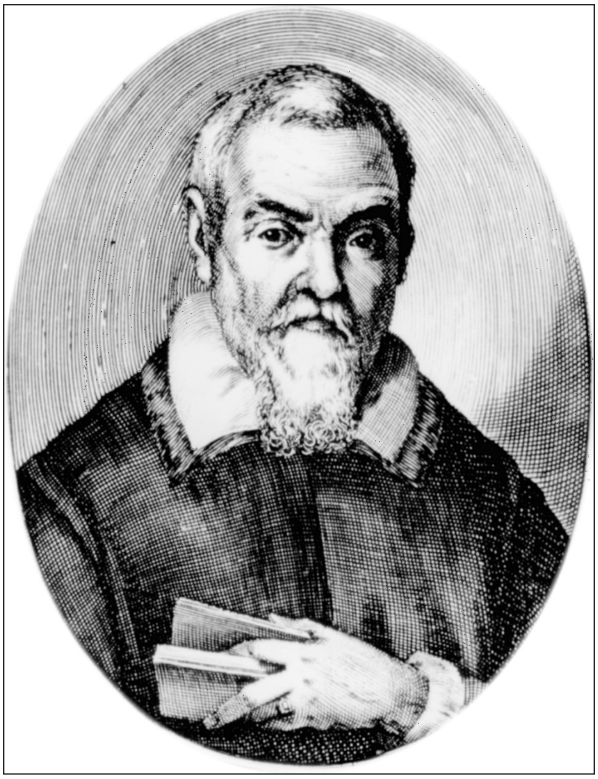
Italian physician

Santorio invented or improved several basic medical instruments, most notably the clinical thermometer. One of the earliest medical researchers to quantify data, he also studied the effects of respiration, environmental temperature, body temperature, and body weight on health and metabolism.

Born: March 26 or 29, 1561; Capodistria, Republic of Venice (now Koper, Slovenia)
Died: February 22 or March 6, 1636; Venice (now in Italy)
Also known as: Sanctorius Sanctorius
Primary field: Medicine and medical technology
Primary invention: Air and clinical thermometers

Early Life

Santorio Santorio was the son of a Venetian nobleman, Antonio Santorio, and his wife, Elisabetta, née Cordona, also from a noble family. His father served the Venetian Republic in military and diplomatic affairs. As the child of an aristocratic government official, Santorio received the best available education and established lifelong connections with wealthy citizens, such as the Morosini family, that would later provide patronage support for his work. After a classical education with tutors in Capodistria and Venice, he entered the University of Padua in 1575. There he studied philosophy, literature, and medicine, receiving his medical degree in 1582. Among his professors was the anatomist Girolamo Fabrizio d'Aquapendente, known as Hieronymus Fabricius.



Santorio Santorio. (Library of Congress)

What Santorio did between 1582 and 1587 is obscure, but from 1587 to 1599 he was the court physician to a Croatian nobleman, probably of the Zrinski family. In 1599, Santorio established a private medical practice in Venice along the Hippocratic and Galenic lines that were then standard. Through Andrea Morosini he became friends with the physicist Galileo and several other prominent scientists, including Galileo's student at the University of Padua, Giovanni Francesco Sagredo; the cryptographer Giambattista della Porta; the prominent churchman Fra Paolo Sarpi; and Fabrizio. This circle would prove fruitful not only for the scientific endeavors of each of its members but also for their political safety against the Inquisition. Sarpi represented relatively liberal Venice in its conflict with the papacy of Paul V. Fabrizio and Santorio performed the surgery that saved Sarpi's life after an assassination attempt by the pope's agents on October 5, 1607.

Life's Work

Santorio's prestige steadily increased in Venice. The Venetian senate appointed him in 1611 to a six-year term as professor of theoretical medicine at the University of Padua. In 1617, his appointment was renewed. After retiring from this professorship in 1624, retaining both his academic title and his full salary, he spent the rest of his life in Venice, continuing to see patients until his death, serving as president of the Venetian College of Physicians, and directing local efforts against the bubonic plague in 1630.

At Padua, Santorio participated equally in all three aspects of the medical profession: patient care, scientific research, and training new physicians. At the same time that he continued his clinical practice in Venice, he conducted the research on thermometry, metabolism, and measurement that would make him famous. His focus was on creating better instrumentation. Among his in-

Air and Clinical Thermometers

The need to measure heat in various contexts was gradually recognized during the Renaissance. Accordingly, the thermometer was not invented all at once, but several European inventors from 1593 to 1724 developed different thermometers for different purposes. The first of these inventors was Galileo, who between 1593 and 1596 invented an uncalibrated device to display visually the heat of air. This was not the well-known "Galileo thermometer," which uses rising and falling glass balls inside a sealed glass column of liquid to display ambient air temperature. That device was actually invented about half a century later, probably by the German Jesuit scientist Athanasius Kircher, whose work was based on Galileo's principles of liquid density and buoyancy.

Galileo's air thermometer was really a thermoscope, not a true thermometer, because, not being scaled, it only represented the temperature but did not measure it. Santorio Santorio saw that the greatest improvement to this instrument would be calibration. After making several design changes and adding a scale to create the first genuine air thermometer, Santorio used this knowledge to invent the clinical thermometer, which he introduced in 1612. His prototypes of a calibrated device to measure body heat were not entirely new instruments but rather variations of his air thermometer.

In Rome in 1611, Italian mathematician and engineer Bartolomeo Telioux wrote a Latin manuscript called *Mathematica maravigliosa*, which included the first known illustration of a calibrated air thermometer. Telioux attributed the instrument to Santorio and depicted it as two volumetric flasks, the thin neck of one inverted inside the thick neck of the other. A column of liquid rested normally around the midpoint of the two necks. A 48-degree scale was etched in eight divisions on the outer neck.

Santorio's 1612 book, *Commentaria in artem medicinalem Galeni* (commentary on Galen's art of medicine), contained the earliest printed mention of any thermometer, his own air thermometer. In 1625, his *Commentaria in primam fen primi libri canonis Avicennae* (commentary on the first section of the first book of the canon of Avicenna) contained both the first mention and the first four illustrations of clinical thermometers. The first of these woodcuts represents an uncalibrated Florence flask with its long, thin neck inverted in water. The instrument would detect body temperature when the patient grasped the body of the flask. Temperature was recorded by sliding circles of thread up and down the neck. The second woodcut shows an oral thermometer consisting of a calibrated flask with its tiny bulb to be placed inside the patient's mouth. Its amazingly long neck, which remained outside the body, increased the accuracy of its scale, and the thermometer's four switchback curves prevented it from being unwieldy. The third illustration shows a similar instrument with a larger bulb so that the patient would take it in the hand, not the mouth. The last woodcut depicts Santorio's third calibrated clinical thermometer, the least accurate, which provided for the patient to exhale into a funnel.

Developers of the calibrated air thermometer subsequent to Santorio included English physician Robert Fludd about 1615, Dutch glassblower Cornelis Drebbel before 1625, and German physicist Otto von Guericke about 1660. French Jesuit and mathematician Jean Leuréchon coined the term *thermomètre* (thermometer) from the Greek *thermos* (hot) and *metron* (measure) in 1624 to distinguish it from the thermoscope. French physician Jean Rey invented the liquid thermometer between 1630 and 1632. It lacked an airtight seal to avoid the influence of barometric pressure. Ferdinando II de' Medici, grand duke of Tuscany, developed the sealed liquid thermometer between 1641 and 1654. The modern thermometer was considered complete when the German physicist Daniel Gabriel Fahrenheit introduced the sealed alcohol thermometer in 1709, the sealed mercury thermometer in 1714, and the Fahrenheit scale in 1724.

ventions or improvements to existing inventions were gauges to measure the speed of wind and water; a hygrometer; a "pulsilogium," which used a pendulum to measure the human pulse rate; and several kinds of thermometers, syringes, and therapeutic beds and chairs. His aim was always precision, unusual for his time.

As a medical philosopher, Santorio was an iatromechanist. In the sixteenth and seventeenth centuries, two rival theories of medicine, iatrochemism and iatromechanism, sought to reduce medicine and physiology to other, presumably simpler, sciences. Iatrochemism was the idea that medical phenomena are essentially chemical or pharmacological, and that medicine accordingly could be reduced to chemistry, alchemy, and the study of drugs and mineral and herbal remedies. Iatromechanism, on the other hand, claimed that medical phenomena are essentially physical or mechanical, which would reduce medicine to physics, mechanics, and mathematics. It would be an oversimplification to say that iatrochemism advocated qualitative science while iatromechanism advocated quantitative. Nevertheless, many iatromechanists, including Santorio, made significant advances in quantitative study.

Santorio was particularly interested in the effects of changes in body heat on health and disease. He believed that reliably quantifying body heat and measuring its changes could help both diagnosis and subsequent therapy. The circulation of the blood was not yet understood; William Harvey, another University of Padua medical alumnus, would not publish his findings in this area until 1628. Still, Santorio suspected that a relation existed among respiration, body heat, and evaporation that would somehow involve the blood. He reasoned that accurately measuring small changes in body heat would facilitate the study of this relation. Because the instruments necessary to detect such small changes did not exist, Santorio invented them. In 1602, he published *Methodus vitandorum errorum omnium qui in arte medica contiguunt* (on the method to follow to avoid errors in the medical art), which presented his first quantitative innovations and developed specific protocols for bringing greater accuracy into medicine and physiology.

Impact

In an era when medical thought and research were typically speculative, qualitative, or even subjective, Santorio was a pioneer of meticulous observation and rigorous quantification. He was passionate about quantification. He believed in the close relationship between mathematics and science, which was controversial at the time, and that careful measuring was the key to scientific progress. For thirty years, he regularly weighed himself, everything he ate and drank, and everything he excreted. From these data, having noted that the weights of what he consumed and what he knowingly excreted did not match, even when considering changes in his body weight, he inferred the existence of an invisible excretion, "insensible perspiration," to account for the difference. He published the results of these experiments in 1614 as *De statica medicina* (on medical measurement). This book was widely read by physicians and stayed in print until 1784. Many of its physiological conclusions were verified in the eighteenth and nineteenth centuries and earned him distinction as a founder of basal metabolic research.

Santorio's introduction of the clinical thermometer into the medical arsenal aided not only direct patient care but also the physiological research that is the basis of patient care. His instruments and methods remained useful until the end of the eighteenth century and especially enabled progress in cardiovascular and respiratory physiology. They led in the 1660's to iatromechanists disproving Galen's belief that the function of the heart was to heat the body and the function of the lungs was to cool it, with their interaction striking a balance that, in health, would ensure the best possible body temperature. Giovanni Alfonso Borelli extended Santorio's research on respiration and evaporation to account for muscular movement and function according to iatromechanistic principles.

Thomas Savery

English engineer

Savery created and patented the first steam engine to power drainage pipes, especially in mines. Although his device was not successful in mines, his demonstration of the power of steam led to improved steam engines by such inventors as Thomas Newcomen and James Watt.

Born: c. 1650; Shilstone, Devonshire, England
Died: May, 1715; London, England
Primary field: Mechanical engineering
Primary invention: Savery pump

Early Life

Thomas Savery was born about 1650, a son of one Richard Savery and a grandson of Christopher Savery. Thomas's family were substantial landowners in the vicinity of Modbury in the county of Devonshire, England. Savery trained as a military engineer, rising in the military to the level of trench master. His early career, however, was spent devising machines or tools useful to the military, including a device to polish glass that he patented in 1696. He also produced a mechanism that could propel small boats in calm waters by using a capstan attached to two waterwheels. This latter device won him the admiration of the reigning monarch of England, William III, though it never was adopted by the British navy. Savery published in 1698 a description of his rowing mechanism in a pamphlet titled *Navigation Improved*.

Life's Work

Savery's work marked a change in the attitudes then prevailing about the world. There had long been a considerable interest in Earth and its position relative to the stars, and the work of Nicolaus Copernicus and others had made people aware that Earth was just one planet among a considerable body of stars and constellations, leading people to focus more particularly on the status of Earth itself and the observable features of its position in the cosmos. This in turn led to the realization that Earth was surrounded by an atmosphere, and that the atmosphere had weight. Without the atmosphere, a vacuum would exist, and that vacuum could be exploited as a force.

The first person to tap into the power of the vacuum was Otto von Guericke, an official of the German city of Magdeburg. In 1650, he constructed two hemispheres that he sealed together and then revealed that they could not be readily pulled apart if the air inside them had been removed. Robert Boyle, an Englishman and the seventh son of the earl of Cork, traveled widely on the Continent and learned of Guericke's work. When he returned home, he applied the principles used by Guericke and built a rudimentary pump that he demonstrated to the Royal Society, a learned society established by the restored English monarch, Charles II, in the early 1660's. In the 1690's, a collaborator of Boyle, a Frenchman named Denis Papin, constructed a cylinder and piston device that demonstrated the basic concept used by Savery, but he did not pursue this idea further.

Savery picked up on the concept (his military connections enabled him to make himself familiar with the ideas circulating in the Royal Society) and decided to apply it to the practical problem facing England at that time—a shortage of wood for fuel. This shortage had led to the exploitation of coal, and there were many mines in the England of that day that had been tapped into for several centuries. However, by the late seventeenth century, the easy deposits had already been mined, and many miners went down one hundred feet or more to tap into the coal. At that depth, many mines tended to fill with water, so what was needed was a way to pump out the water. Savery developed a water pump that heated water in a boiler that, when cooled, pulled out the steam in an adjacent, connected cylinder, leaving a vacuum. He demonstrated a prototype to the Royal Society and applied for a patent, which was granted in July of 1698. The original patent was for just fourteen years, but it was extended for another twenty-one years by an act of Parliament.

Savery's patent was for a "new Invention for Raiseing of Water and occasioning Motion to all Sorts of Mill Work by the Impellent Force of Fire," and this description was generally held to mean all steam engines, so that it precluded other inventions that used the force of steam to create a vacuum, the basic principle at stake. Savery, who seems in many ways to have been more a promoter than a scientific luminary, then wrote a pamphlet, titled *The Miner's Friend*, which he published in 1701. The pamphlet makes clear that his intended market was the mining industry, which in those days meant chiefly the coal-mining industry, although the mining of tin in southwest England suffered from the same problems.

In 1702, Savery set up a workshop in London where he displayed a working example of his pump with the intent of demonstrating it to potential purchasers. In fact, the pump in action revealed a number of defects. The

The Savery Pump

Thomas Savery's pump consisted of a containing cylinder with a piston inside it. Water was heated in an adjoining boiler, and the steam produced was fed into the cylinder, causing the piston to rise. The cylinder was then cooled, condensing the steam back to water, which fell back into the boiler, leaving a vacuum in the cylinder. The vacuum pulled water up into a pipe connected to the cylinder. It was intended that this vacuum be used to bring up water from the bottom of coal mines.

However, the application had limited value, as it soon became clear that the force of the atmosphere would pull up water only thirty-two feet in a contained pipe. Dual pipes could double that figure, but they were not enough to pump water out of mines that were often one hundred feet deep. Moreover, it was soon discovered that the Savery pump would function better if placed at the bottom of the mine, which proved to be impractical.

The practical difficulties encountered ensured that Savery's pump would not find much use in the coal-mining industry, for which it was intended. It did, however, find a number of applications on the estates of large landowners, and Savery's own social status helped to find it a market there. It was only the significantly modified version designed by Thomas Newcomen that found numerous industrial applications.

Nevertheless, the Savery pump represents the first known attempt to apply steam power to endeavors that had previously relied on human power or animal power (except in the rare cases in which wind or waterpower could be so used). It led directly to the inventions of Newcomen and, much later, James Watt. The concept of steam power was seized upon by other innovators and modified so as to be effective where Savery's machine was not. In particular, advances in metallurgical techniques were essential so that engines could be built that could withstand the great power of steam without disintegrating into their component parts. As others worked on this problem, the limitations of the atmospheric pump became clearer and inspired work that used elevated steam force to accomplish what the atmospheric pump could not.

The Savery pump was also significant in that Savery's patent made it impossible for anyone to produce a steam engine until the patent expired in 1733. That circumstance compelled Newcomen to work closely with Savery during the latter's lifetime and constrained him even after Savery's death while the patent was controlled by a trust.

skills of the metalworkers of the time made its construction difficult, for it relied on an airtight seal that was hard to produce. Common practice used copper in the construction of devices whose various components were attached to one another with solder, and these devices tended to blow apart under the pressures needed to produce a vacuum. The parts were constructed separately, and creating seals that would ensure a vacuum when the parts were joined together proved difficult.

Savery folded the London office after a few years, having made few sales (and apparently none to proprietors of coal mines), but continued on with his military career. By this time, he had been promoted to captain, and he was commonly referred to at that time as Captain Savery. In 1705, he received a patronage appointment from the government to a body dedicated to caring for naval veterans. In 1706, he was elected a fellow of the Royal Society, and he continued to produce a variety of inventions, including a kind of hand bellows that could elevate the temperature of a fire used to make metals pliable, for which he received another patent. His connection with the royal family led once again to a special appointment in 1713, when he became surveyor to the waterworks at Hampton Court, a royal palace. There his professional expertise could be put to good use. He died in London shortly thereafter.

Impact

Although Savery's original patent was for only fourteen years, an act of Parliament passed on April 25, 1699, extended the patent for a further twenty-one years. This patent history explains in part why Savery's invention was so important historically. Further work based on Savery's concept was done during his lifetime and in the years immediately after by Thomas Newcomen (1663-1729), who worked under Savery's patent, which expired in 1733. Newcomen's steam engine would become widely used throughout the eighteenth century.

Savery demonstrated that steam could be used to create power other than that generated by water, wind, or animals. In so doing, Savery inaugurated more than two centuries of the use of steam power to activate machines, most notably the steam engines that would run railroads, steamships, and an enormous list of industrial enterprises. Without the string of inventions, each built upon its predecessor, that turned steam into such a potent force, the Industrial Revolution would not have happened. The modern world owes much to Thomas Savery.

Arthur L. Schawlow

American physicist

Schawlow's numerous inventions and improvements to laser spectroscopy were rewarded with a Nobel Prize in Physics and revolutionized laser technology. They greatly increased both the types and the applications of lasers across a wide array of disciplines and arenas.

Born: May 5, 1921; Mount Vernon, New York
Died: April 28, 1999; Stanford, California
Also known as: Arthur Leonard Schawlow (full name)
Primary field: Physics
Primary invention: Laser spectroscopy

Early Life

Arthur Leonard Schawlow (SHAW-loh) was born in New York to a Canadian mother and a Latvian father. His father was an insurance salesman with a keen interest in mathematics. He moved with his family to Canada at age three and spent his entire youth there, although he remained an American citizen. Precocious as a child, Schawlow devoured *The Children's Encyclopedia* (1908; also known as *The Book of Knowledge*, 1911-1912) and books from the local library on aviation, electronics, and radios. He played with radios, learned to play clarinet, and devoted some energy to the Boy Scouts.

Schawlow completed high school in 1937, having just turned sixteen. He took the required Ontario provincial examinations and scored well enough to be offered a scholarship to attend the University of Toronto to study mathematics and physics, which he thought close enough to his primary interest, radio engineering. He graduated in 1941 with a B.A. in physics. By then, Canada had been engaged in World War II for two years. The final months of his bachelor's program consisted exclusively of working on government projects related to the war effort, rather than taking courses, which had been canceled.

Schawlow's master's program followed a similar pattern. He earned an M.A. in physics in 1942 based on some work he did on a centrifugal battery related to proximity fuses in artillery shells, despite the fact that superior work on this approach was already being conducted in the United States. Schawlow spent the next two years at the university teaching basic physics courses to military recruits. He then joined Research Enterprises, working to improve microwave antennae for radar for the remainder of the war.

Schawlow returned to the University of Toronto in 1945 in response to an offer of continuing scholarship support, as his family was of limited means. He earned a Ph.D. in physics in 1949, specializing in spectroscopy. His dissertation, written under Professor Malcolm F. Crawford, was titled "Nuclear Properties from Hyperfine Structures." He made it a practice throughout his doctoral work to scan weekly the entire set of new physics and engineering journals received by the university's library. In that way, Schawlow both developed and maintained an interest across the scope of physics that would prove useful throughout his career. He also played clarinet in the Delta Jazz Band and started collecting jazz records, a passion throughout his life: Any visitor to his scientific laboratories over the years could attest to the jazz music frequently played there.

Life's Work

While still a doctoral student, Schawlow heard a presentation by Nobel laureate Isidor Isaac Rabi of Columbia University at the Canadian Association of Physicists meeting in Ottawa. As a result of that presentation, he wrote to Rabi, as well as scholars at a few other American universities, seeking employment. Rabi suggested he apply for a Carbide and Carbon Chemicals Corporation postdoctoral fellowship to work under Charles Hard Townes at Columbia. Schawlow applied and was accepted, despite knowing nothing about the work Townes was doing.

Arthur L. Schawlow. (©The Nobel Foundation)

Thus began a long and creative relationship with the older Townes, who became Schawlow's brother-in-law in 1951 after his wife introduced Schawlow to Townes's younger sister Aurelia. The physics department at Columbia was at the center of physics work globally at this point, with eight current or future Nobel laureates emerging from the program. The illustrious faculty, engaging graduate students, ample facilities, and visits from world-renowned physicists produced a stimulating atmosphere in which Schawlow became familiar with many additional areas of physics and developed his ability to focus on conceptual problems.

When Schawlow's fellowship ended, it was impossible for him to take a job at Columbia, because his brother-in-law was the department chair. His wife wished to stay in New York as a musician and conductor, however, so Schawlow accepted a position as a physicist at Bell Telephone Laboratories, where Townes had previously worked. He worked at Bell Labs from 1951 to 1961, focusing on superconductivity and issues related to nuclear quadrupole resonance, but without significant results. The corporate laboratory environment, with its relative isolation, did not appeal much to Schawlow, although he ultimately found effective ways to reach out to others for assistance with his ideas. Every weekend found him continuing his collaboration with Townes on a substantial book, *Microwave Spectroscopy*, which they published in 1955 to critical acclaim.

Meanwhile, Townes, James P. Gordon, and Herbert Zeiger built a maser (an acronym for "microwave amplification by stimulated emission of radiation") in 1954, following up on an idea that Townes had had as early as 1951. Townes and Schawlow began to think about how the principals of a maser might be applied to visible light. They published a famous paper, "Infrared and Optical Masers" (1958), in *Physical Review*, summarizing their theoretical progress. This paper became the basis for a revolution in optics for visible energy (light).

A maser is a device that works at the molecular level to cause atoms to vibrate back and forth (oscillate), creating an energy difference between their excited and ground states. Focusing the energy (radiation) from this difference results in amplification of the beam. The Townes and Schawlow continued their "normal" work while tinkering further with their ideas concerning visible light. Townes selected metal potassium as a suitable material that yielded a light-emitting vapor when excited. Schawlow suggested using a pair of mirrors at the end of the tube to focus the resultant light into a weak beam.

The pair filed a patent application during this period, while Townes's questions to Columbia graduate student Gordon Gould resulted in Gould pursuing his own ideas independently and also filing several patent applications. Townes and Schawlow obtained the first patent for a laser ("light amplification by stimulated emission of radiation," a term coined by Gould at a 1959 conference that Schawlow chaired). Legal battles over many years, however, resulted in a 1977 ruling that awarded Gould millions of dollars in laser royalties on the basis of four patents, while Townes and Schawlow collected none. However, Townes rather than Gould won a Nobel Prize in Physics in 1964 for his work on the laser. Schawlow would wait many more years for his own Nobel Prize.

Schawlow had an intuitive hunch that the best way to create an excitation, amplification, and concentration of the energy of visible light might be to exploit the optical properties and spectra of solids. He was especially drawn to rubies because of their basic properties and the abundance of samples at Bell Labs. A false lead from a chemist at Bell Labs, however, led Schawlow down a wrong path. Meanwhile, Theodore Harold Maiman at the Hughes Research Laboratories succeeded in generating a ruby-laser pulsed light on May 16, 1960. Schawlow, upon learning of Maiman's feat, quickly replicated it and published the first detailed report on laser experiments.

Schawlow desired to return to the university environment and was eager to work with graduate students. He received offers from a number of institutions and chose Stanford University in 1961, both for its research opportunities and because of a special program available to the Schawlows' autistic son, Arthur. Schawlow remained at Stanford until his appointment to emeritus status in 1991 following the death of his beloved Aurelia in an automobile accident. Over the course of his tenure there, he helped launch many graduate and postdoctoral students into eminent careers within physics, as well as pioneering new methods and applications for lasers and laser spectroscopy. He also served as a director of several companies related to the production and uses of lasers and laser spectroscopy, although he frequently joked that had he been paid for every failure in this arena, he would have been a very rich man indeed.

Laser Spectroscopy

Laser spectroscopy resulted, in the memorable title of Arthur L. Schawlow's Nobel Prize acceptance speech, in putting "Spectroscopy in a New Light." In an interesting side-twist, scientific spectroscopy originated in Sweden in 1853, when Anders Ångström sent an electric spark through a gas. He produced a spectrum that included absorption lines coming from the metal electrodes but also absorption lines that were due to the presence of the gas. These absorption lines (when placed on the spectrum where the substance itself had absorbed some of the initial energy) could be used to identify unknown substances or trace elements of those substances. For example, constituent components of a gas could be determined, and light emissions from the Sun and other stars provided an indication of the gases that compose them.

With the advent of laser spectroscopy, Schawlow's work and that of his students and colleagues drastically refined levels of available precision, making possible molecular analysis. Their work enabled scientists to map out absorption lines of various gases, solids, and liquids with unprecedented detail, extending eventually down to the atomic level. As a result, the distribution of molecules and atoms within substances could be mapped. The spectra produced by this method can be used for chemical analyses, examining atomic and molecular energy levels, and determining molecular structures.

These advances enabled chemists, chemical engineers, and other scientists to obtain detailed evidence of reactions and changes within substances on scales that were previously impossible. The information obtained led to a rapid expansion of theory and a wide range of useful applications, as scientists and technologists created new materials by combining substances and both predicting and determining results from those combinations in a reasonable and accurate manner. Today, laser spectroscopy ranges from the submillimeter wavelengths of the infrared to the soft X-ray wavelengths at the other end of the spectrum. Interactions at the atomic level are now readily discernible that, prior to the advent of these approaches, were hidden from view. These developments have led to significant breakthroughs in understanding the physical world and to the design and implementation of various innovations based on these new insights.

The significance of Schawlow's work was recognized in 1981 by the award of the Nobel Prize in Physics, which he shared with Nicolaas Bloembergen, for their contribution to the development of laser spectroscopy, and with Kai M. Siegbahn, who helped develop high-resolution electron spectroscopy. Schawlow's numerous other awards include the National Medal of Science (1991), the Frederick Ives Medal from the Optical Society of America (1976), and the Liebmann Prize from the Institute of Electrical and Electronics Engineers (1964). The Laser Institute of America named its highest award for him, giving him the first Arthur Schawlow medal in 1982. He served as president of both the American Physical Society and the Optical Society of America, one of only two people to hold both positions. Diagnosed with leukemia from which he died on April 28, 1999, Schawlow spent his last few months accepting the visits of family and friends from his wheelchair and ensured that happy music from one of his beloved jazz bands was played at his funeral.

Impact

The range of contributions Schawlow made to physics was legion. Most important, perhaps, was his decades-long work on creating adjustable-frequency lasers. These can be tuned to desired lengths in order to be applied effectively to a range of applications, including noninvasive surgery, precise cutting of metals and other materials, measurement, and characterization of materials. Beginning in the early 1960's, Schawlow was also a major contributor to laser spectroscopy, using this tool precisely to measure and categorize spectra of molecules and individual atoms.

Schawlow also performed breakthrough work developing techniques to cancel the effects of the random thermal motions of atoms and molecules. These techniques allowed for very precise results to be obtained and became the basis for modern metrology (the science of measurement) and atomic chemistry. It was this work in particular that the Nobel Committee cited in awarding Schawlow the physics prize. In addition to his personal achievements, Schawlow instructed students who also contributed substantially to physics. One of his more famous students, Theodor Hänsch of the University of Munich, worked with him in high-precision spectroscopy and created the first continuous-beam atom laser.

Schawlow's speculations and intuition proved correct on numerous occasions. An early insight that laser light could be used to cool atoms and slow atomic motions led to several subsequent Nobel Prizes being awarded for this type of work. He was one of the first people to appreciate the importance of the different absorption properties of materials that would allow laser light to harmlessly pass through some substances while heating and destroying others. These properties led him to realize that lasers could be used for delicate, noninvasive surgical purposes, such as eye surgery.

Jacob Schick

American businessman

Schick spent most of his inventive efforts on developing the first successful electric razor, which could perform its operation dry, without the use of hot water, creams, or lotions.

Born: September 16, 1877; Ottumwa, Iowa
Died: July 3, 1937; Montreal, Quebec, Canada
Primary fields: Household products; manufacturing
Primary inventions: Electric razor; magazine repeating razor

Early Life

Jacob Schick was born in Ottumwa, Iowa, in 1877 and grew up in the southwestern United States. His father was a coal mine operator. By the time Jacob was sixteen, he was entrusted with the operation of a rail line that ran from Los Corrillos, New Mexico, to a coal mine his father had opened. The responsibility for this mechanical system no doubt helped him with his inventive efforts later in life. In 1898, Schick enlisted in the Fourteenth U.S. Infantry, where his close observations of repeating rifles would later be applied to one of his first commercially successful inventions.

Life's Work

After enlisting in the Army, Schick was shipped to the Philippines with the First Division, Eighth Army Corps, a few months later. He was commissioned second lieutenant and, after stateside service, returned to the Philippines, where he served from 1903 to 1905. Suffering from an attack of dysentery, he returned to the United States, where he was promoted to first lieutenant. He spent the next year recovering from his intestinal ailment.

Schick's doctor suggested that a colder climate would be good for his health, and he went to Fort Collins in Alaska to join the Twenty-second Infantry. While helping to construct one thousand miles of telegraph lines in the Alaskan interior, Schick invented the General Jacobs Boat, which was said to be well suited for use in shallow water.

Schick retired from this first stint in the Army in 1910 and went prospecting in Alaska and British Columbia. It was during this time that he became inspired to design improved shaving devices. Not realizing any commercial success from his ideas, Schick was drawn back into

Jacob Schick. (AP/Wide World Photos)

THE ELECTRIC RAZOR

Today, the electric razor enjoys a multimillion-dollar market, and the name Schick is a universally recognized name identified with the razor. The story of how the idea came to Jacob Schick has several variations, but they all agree on the general location: in Alaska and British Columbia while Schick was exploring for gold in 1910.

In one variation of the story, Schick was suffering from dysentery and, finding the trip to the sink for his daily shave a difficult task, was motivated to find a simpler method. Another variation tells of Schick exploring for gold in the cold climate with a sprained ankle and with only a moose to eat during temperatures of –40° Fahrenheit. This setting motivated him to find a way to shave without the use of hot water and shaving cream. The idea that occurred to him was a shaving head driven by an external motor, but his idea was not immediately accepted by manufacturers. During World War I, he returned to active duty as a captain, putting on hold further developments of his electric device.

Schick left the Army in 1919 and concentrated on developing his Magazine Repeating Razor, which used replacement blades that were stored in a clip in the handle. In 1926, he began selling the razor, which was successful enough that he was able to sell the company to American Chain and Cable in 1928 to develop his electric shaver. In 1931, Schick introduced the handheld electric razor, considered by many to be the beginning of the modern shaving industry. The razor sold for $25, and more than three thousand were made that year. Through refinements and advertising, by 1937 there were more than 1.5 million units in use, and Schick commanded a $20 million market. The electric razor had evolved from a device that had a separate head and electric motor that required the use of two hands to a single unit that could be operated easily by one hand.

service during World War I. He returned to active duty as a captain and was placed in charge of the U.S. embassy in London. By the end of the war, he was promoted to lieutenant colonel, a title he often used for the remainder of this life.

By 1921, Schick was ready for his first business venture. He patented a shaver of standard design, except that it incorporated a feature whereby the blades could be replaced without touching them. Inspired by the Army's repeating rifles, Schick's Magazine Repeating Razor had replacement blades, stored in a clip in the handle, that could be fed in by pivoting the head and pushing a built-in lever. The razors were produced in three models between 1926 and 1935 and were the forerunners to the modern Schick Injector Razor. A drawback of these razors was that their blades required occasional replacement and had to be used with water and lotion. In 1928, Schick sold his interests in the Magazine Repeating Razor and focused on pursuing his real passion—creating an electric razor that could be used dry. Schick introduced his first model in 1931, and as the concept of dry shaving increased in popularity, a multimillion-dollar industry was born.

Success brings competition, and competition brings disagreements and patent arguments. Schick had his share of both: From price wars to distribution rights, his business was always plagued with turmoil. One example was Schick's involvement in 1933 with promoter Archie Moulton Andrews, chairman of Dictograph Products. Andrews received permission from Schick to sell Schick's dry shaver at the Chicago World's Fair. The trouble started after the fair, when Andrews continued to sell the shaver without Schick's consent. Shortly after, Andrews started to manufacture a rival electric shaver called the Packard Lektro-Shaver, which Schick saw as a direct patent infringement. Schick sued but lost. He continued to patent many improvements to his electric shavers and was able to become a millionaire despite fierce competition from several other manufacturers.

Schick's career, with a few minor exceptions, centered on shaving devices. One invention not related to shaving was an improved pencil sharpener (he called it a "pencil knife"), which was patented on April 29, 1924. The sharpener was shaped like a tube into which one could insert the pencil. On November 24, 1931, Schick obtained a patent for an improved engine for cars or airplanes, but the device was never commercially produced.

Schick had some unusual ideas regarding shaving and age, believing that a man could extend his life by 120 years by proper everyday shaving. His theory was that a long life involved losing the ordinary mortal awareness of time. Unfortunately for Schick, his theory did not hold true for him: He died in 1937 at the age of fifty-nine from complications after a kidney operation. He was buried in Canada at Mount Royal Cemetery in Montreal, Quebec.

IMPACT

Every day, millions of men and women use electric shavers. The electric shaver has secured a permanent place in technological history. The name Schick will be long remembered, in part because of brand-name recognition. Like Coca-Cola and Budweiser, Schick became a dominant player in its market.

Schick was very determined to make his electrically powered razor a success. At one point, he had to mortgage his home for $10,000 to continue his efforts. He also was one of the early pioneers in the world market. He took the ideas of capitalism to heart, and he chose to incorporate his patent-holding company, Schick Industries, in Nassau, Bahamas, so as to minimize income taxes and corporate taxes. When the Joint Congressional Committee on Tax Evasion and Avoidance looked into his arrangements, he moved to Montreal and became a Canadian citizen in 1935. For this reason, he is sometimes listed as a Canadian inventor.

Bernhard Voldemar Schmidt

Estonian German optical instrument designer

Schmidt invented a revolutionary telescope design that allowed a large field of view without the off-axis image distortion that characterized traditional reflecting telescopes.

Born: March 30, 1879; Island of Naissaar, Estonia
Died: December 1, 1935; Hamburg, Germany
Primary fields: Astronomy; optics
Primary invention: Schmidt telescope

Early Life

Bernhard Voldemar Schmidt (BEWRN-hahrd VOHL-deh-mahr SHMIHT) was born on an island called Naissaar (also spelled Nais Saar), located in the Gulf of Finland twelve miles north of the port of Tallinn, Estonia. His parents were Karl Konstantin Schmidt and Maria Helene Christine, née Rosen. Although they had German names and spoke German at home, they were ethnically Estonian, being embedded in a Swedish-Estonian culture. The country's complex history involved conquest by virtually all of its neighbors at one time or another, including Russia, Sweden, Poland, and Germany. The island of Naissaar was inhabited mainly by Swedish-speaking Estonians, and the Schmidts were bilingual.

Bernhard Schmidt was the oldest of six children. His father was a writer who also supported his family as a farmer and fisherman. Bernhard and his brother August were close as children, and their adventures were the subject of many (possibly apocryphal) stories. One example is the story about their attempt to create their own meteor shower by using slingshots to fling hot embers into the sky. The experiment is said to have ended when one of the "meteors" set fire to the roof of their house.

Another adventure, one that is certainly not apocryphal, involved experiments with gunpowder. Bernhard's right hand was severely damaged and, in spite of attempts to save it, doctors in Tallinn amputated the hand as well as the forearm. This loss seems to have affected his personality, but amazingly it did not affect his agility: Later in his life, he became one of Europe's most skilled opticians and lens makers.

Early evidence that Schmidt was unusually enterprising is the story that even in the year following his accident he built himself a camera with which he photographed local scenes and neighbors. He learned how to process the photographic plates and printed and sold them to locals on the island. At the same time, he became interested in astronomy, an interest that would be with him for the rest of his life.

When he was sixteen years old, Schmidt moved to Tallinn, where he was employed in a photographic studio and where his skill in retouching photos was very useful. Later, he found employment at an electric motor company. However, by 1901 he decided to improve his education. Following a brief stay at Sweden's Chalmers University of Technology, he went to Germany, where he studied at the Hochschule Mittweida.

Life's Work

Schmidt's years at Mittweida were devoted to studies of physics, especially practical and theoretical optics. At the same time, he helped support himself by making high-precision lenses and mirrors for astronomical telescopes, which he sold to local astronomy enthusiasts. By the time he had completed his studies, his reputation as a maker of fine telescope optics had spread throughout Germany, and he established a thriving business serving both professional and amateur astronomers.

Schmidt's first place of business was a small house in Mittweida, but as business grew he moved to larger quarters and hired several assistants. His shop not only made high-quality new optics but also reworked existing optics for telescopes manufactured by others. An example is the famous case in 1913 when the lens of Potsdam Observatory's twenty-inch refractor was refigured by Schmidt, resulting in much-improved performance, as demonstrated when the well-known astronomer Ejnar Hertzsprung used it to resolve and measure extremely difficult close double stars.

The optical company was soon recognized as the source of some of the world's most precise astronomical lenses and mirrors. Its reputation spread beyond Germany. For example, the University of Prague obtained two telescope mirrors from Schmidt, one that was twenty-four inches in diameter and another that was twelve inches. Business prospered, but the cloud on the horizon was the world war. Because Schmidt was from Estonia, which at that time belonged to Russia, he was arrested and confined in a prisoner-of-war camp. When the government eventually released him, he found that some of his equipment had been confiscated, making it very difficult to restart his business. Furthermore, the economy was in ruins. Germany's defeat and its following financial debacle spelled disaster for many businesses, especially for telescope makers, as German astronomers were unable to buy any equipment.

After years of declining activity, Schmidt's optical company finally had to be closed in 1926. He found refuge at the Hamburg Observatory, whose director, Richard Schorr, had corresponded with Schmidt, having recognized his genius as an optician. A laboratory and apartment were provided for him in the basement of the observatory, located near the country town of Bergedorf, southeast of Hamburg. Schmidt's duties were to maintain and improve the various telescopes of the

The Schmidt Telescope

Bernhard Voldemar Schmidt's most important invention is his only surviving invention, namely, the Schmidt telescope design. Although it took more than a decade for astronomers to fully appreciate its importance, the telescope eventually became a powerful new tool for astronomical research. The new design could be realized only by a revolutionary new process, which was the result of Schmidt's genius in both engineering and optics.

The most productive Schmidt telescope is the one at the Palomar Observatory in California. It has a seventy-two-inch principal mirror and a forty-eight-inch correcting lens. Built as a companion to the Palomar two-hundred-inch telescope, for many years the world's largest, the forty-eight-inch Schmidt was a workhorse that mapped large areas of sky, while the two-hundred-inch photographed small, interesting fields to fainter limits and higher resolution. In addition to various specific investigations, such as for the study of Milky Way structure and star clusters, the Palomar Schmidt carried out a massive survey of the entire sky accessible from Palomar, the Palomar-National Geographic Sky Survey. This immense atlas, completed in the 1950's, continues to be used for support of research. A second survey using the forty-eight-inch Schmidt with reworked optics was begun in the 1980's.

Other Schmidt telescopes are found at many observatories. The two-meter Schmidt at the Karl Schwarzschild Observatory in Germany is the world's largest. Others, in addition to Palomar's, are the large Schmidts at the Kitt Peak (United States), Cerro Tololo (Chile), La Silla (Chile), Tonantzintla (Mexico), Siding Springs (Australia), and Boyden (South Africa) observatories. Most Schmidt telescopes now use electronic detectors rather than photographic film or plates. Thousands of smaller Schmidt telescopes, used with a Cassegrain (two-mirror) optical design, have been produced for sale to amateur astronomers.

Although Schmidt's invention was intended as a boon to astronomy, the design has been found to be important in many other optical applications. Schmidt cameras have the advantage of great speed and clarity, and small examples have found widespread use in special-purpose photography.

observatory. The relatively free access he had to the observatory's equipment and the supportive attitude of Schorr are probably the reasons for Schmidt's crowning achievement, the invention of the Schmidt telescope.

Before 1930, astronomers were limited in their ability to photograph large areas of sky with large telescopes. Refractors (telescopes using large lenses to gather the light) could not be made very large, and reflectors (telescopes using large curved mirrors to gather the light) produced sharp images only at the center of the image. Very large mirrors could be ground and polished, but the resulting telescopes suffered from coma, the distortion of the star images off from the optical axis. Thus, only very small sections of the sky could be imaged at a time.

From the 1920's, Schmidt had determined that some solution to the problem of coma ought to be possible. He tried at least one possibility that failed before he hit on the idea of formulating a specially shaped correcting lens to be placed at the top of a telescope that would correct for the spherical aberration of a spherical mirror without introducing coma. This was a revolutionary idea, but it was difficult to make such a lens. His knowledge of optical design showed him that he needed a lens that was convex in the center and concave in the outer parts. Schmidt solved that problem in an ingenious way—using a vacuum method to pull a section of the glass into a shape that enabled him to grind it so that, when the vacuum was turned off, the glass would bounce into the shape desired. In 1930, he succeeded in making the first Schmidt telescope. It had a mirror of seventeen inches and a correcting lens fourteen inches in diameter, and it worked just as he had desired. With a fast focal ratio (f/1.75, compared to large reflectors' values of f/5 or larger), the Schmidt telescope achieved sharp images over a wide swath of the sky.

Unfortunately, the new design was too unusual for astronomers to recognize its advantages at first. Also, the worldwide depression at that time resulted in there being little opportunity for anyone to buy new telescopes. Schmidt was unable to sell his new design. He died of pneumonia in 1935 without knowing that his revolutionary telescope would one day be a supremely successful new tool for astronomical surveys of the heavens.

Impact

Schmidt was a skilled and inventive optician whose knowledge of both practical and theoretical optics placed him to be the creator of a revolutionary new astronomical instrument. The Schmidt telescope design had a multifaceted impact on optics. It produced a new tool that made it possible for astronomers to obtain sharp images of stars for wide areas of sky at a time, opening up powerful means for surveying the cosmos. Also, his telescope introduced a new concept: combining the power of concave mirrors with the addition of specially designed, unusually shaped lenses to achieve superior resolution for optical systems, not only for astronomy but also for many other applications in which clear, sharp imaging is the desired product.

The impact of Schmidt's invention did not occur until a few years after his death. He had discussed the Schmidt telescope design with the Germen astronomer Walter Baade in 1929, when both were on an expedition to the Philippines to observe a solar eclipse. Baade was intrigued by the possibilities that the new design would open up. A few years later, when Baade moved to the Mount Wilson Observatory in California, he had the opportunity to instigate the building of an eighteen-inch Schmidt telescope, which was a brilliant success and which led to the building of many larger Schmidt telescopes around the world.

Ignaz Schwinn

German American mechanical engineer

Through his own innate ability, hard work, and hardheadedness, Schwinn advanced from a poor German immigrant to the head of a bicycle manufacturing company that became an exemplar for bicycle makers in the United States for nearly a century.

Born: April 1, 1860; Hardheim, Baden (now in Germany)
Died: 1948; Chicago, Illinois
Primary fields: Automotive technology; manufacturing; mechanical engineering
Primary invention: Streamline Aerocycle (Schwinn bicycle)

Early Life

Ignaz Schwinn (IHG-nahts SHVIHN), born April 1, 1860, in Hardheim, Baden (now in Germany), was the son of a piano and organ factory owner, who died when young Schwinn was eleven years old. Being next to the oldest in a family of seven children, Schwinn was required to leave school and help support the large family. He began an apprenticeship to a machinist, showing remarkable talent in this endeavor, and later began looking for work repairing high-wheeled bicycles and bicycle parts.

Life's Work

While working in bicycle factories, Schwinn learned about the new "safety," a rear-wheel, chain-driven bicycle with two wheels of similar size that was invented in 1885 by John Starley in England. Seeing possibilities in the new design, Schwinn set out to interest bicycle makers in it, but they preferred to continue producing the older high-wheel bicycles. Schwinn also saw advantages in the new pneumatic tire, which had a softer rubber than the hard tire, but most factories rejected it as an unrealistic novelty.

In Frankfurt, Schwinn worked in a machine shop that supplied parts to Heinrich Kleyer, a high-wheel bicycle manufacturer, who met and hired Schwinn. Kleyer was pleased with Schwinn's designs for the improved safety bicycle that Schwinn had worked on privately, and he gave Schwinn the opportunity to develop the bicycle. Schwinn soon became designer and works manager for the company, which produced some of the first safety bicycles in Germany. Schwinn supervised the building and equipping of a new factory for Kleyer's prospering business, which later became Adler Works of Germany.

In 1889, Schwinn arrived in the United States, settling in Chicago, where he hoped to observe the latest technical advances at the World's Fair in 1893. He worked briefly for a company that made Fowler bicycles; later, he designed the bicycles and established the bicycle factory of the International Manufacturing Company. Dissatisfied with the management, he left there in 1894 and formed a partnership with Adolph Arnold—Arnold, Schwinn & Company—in 1895. Arnold, the president of a meatpacking business and the Haymarket Produce Bank, provided the capital but allowed Schwinn to design the products and the tools, purchase machinery and equipment, hire personnel, and essentially set up the factory.

Schwinn's new bicycle factory took its place alongside thirty other bicycle factories on Lake Street and began to turn out superior merchandise. In 1896, bicycle racing was a sport sensation, and riding the Schwinn-built World Racers that weighed nineteen pounds complete, the Arnold, Schwinn & Company's team set numerous records. The world racing team won races in Italy, France, and England and set new records for the half mile and the kilometer. By the year's end, Schwinn's factory had more winners than any other bicycle factory. Racing clubs for prosperous Americans were quite popular, and tracks were built quickly. In 1902, the racing bicycle sold for $150, about $27,450 in 2000 dollars.

In the early years of the century, largely because of overexpansion and overproduction, the bicycle boom collapsed. Bicycle sales dropped to a fraction of those sold even five years earlier. Only twelve bicycle factories remained on Lake Street, as competition for parts and sales outlets was fierce. In the process of building a new factory in western Chicago, Arnold and Schwinn bought out failing factories and continued business. In 1902, Schwinn designed and built four experimental motorcars; the last one, in 1905, featured a four-cylinder, water-cooled, four-cycle engine—all furthered by the great strides of the company's forerunner, the bicycle.

In 1908, Schwinn bought out Arnold's share of the company, and although the company retained its name, Schwinn became its sole owner from that point. Schwinn's first child, Frank, was born that same year. In 1911, Schwinn bought the Chicago-owned Excelsior Motorcycle Company that, under his direction, soon became ranked with Indian and Harley-Davidson as the top three

American motorcycle manufacturers. Schwinn's company sponsored famous racing stars until World War I, sending Schwinn sales skyward. Schwinn purchased the Henderson Motorcycle Company in 1917, continuing to make motorcycles until the Great Depression, when he was forced, in 1931, to discontinue his motorcycle line.

When the advent of the automobile decimated bicycle sales, Schwinn turned his attention to the manufacture of bicycles for children. The lighter, more expensive bicycles of the 1890's were neglected in favor of the sturdier bicycles required for children and for delivery services. Mud flaps were added to the bicycles to attract youngsters, but the bicycle industry was devastated. In the early 1930's, Schwinn created a new department in his factory, one filled with workers from his defunct motorcycle line, whose duties were to search for possible improvements in the bicycle that would not include a large increase in price. In this attempt to break away from standardization, Schwinn not only weathered the Depression but also established himself as an innovative leader in the American bicycle industry.

In 1933, Schwinn introduced the first balloon-tire bicycle—with a double tube more than two inches wide—which was considered practical and durable. Although balloon tires had been used on automobiles for years, the bicycle industry was slow to accept the new design. Schwinn persisted in its adaptation, and within a few years balloon tires were standard features on all bicycles. Continuing the emphasis on innovations affecting quality, comfort, and appearance, Schwinn developed the Streamline Aerocycle in 1934. The following year, he introduced the Cycleplane, streamlined in appearance. In 1936, the Autocycle appeared, a fully streamlined bicycle featuring a full-floating saddle that brought new comfort to riders, better reflectors for night riding, double headlights, and an improved frame. In the remaining years of the 1930's, Schwinn introduced a bicycle with forewheel brakes, the spring fork for more riding comfort, and the bicycle truck made expressly for deliveries.

The beginning of World War II brought an abrupt end to the production of Schwinn bicycles as Ignaz Schwinn shifted to the production of war materials, for which his company received the Army and Navy "E" award for excellence. In 1947, Schwinn sales soared with the postwar economy's growth, reaching more than 400,000 bicycles that year. The following year, at the age of eighty-eight, Schwinn died of a stroke, leaving the Schwinn Company in the capable hands of his son, Frank, who continued to enhance the Schwinn image. As an engineer and marketing genius, Frank persisted with streamlined innovations. The Black Phantom (1949); the Panther (1950); the Starlet (1951) for girls; the Paramount (1952), said to be the best-built bicycle in America; the Wasp (1954); and the Corvette (1954) were stylish classics of the 1950's.

Frank W. Schwinn died in 1963. The company man-

The Streamline Aerocycle

Toward the end of the Great Depression, when Ignaz Schwinn and other bicycle manufacturers were struggling to survive, Schwinn employees worked doggedly to ensure Schwinn quality, to introduce new accessories, and to modernize existing bicycles. Schwinn and his son, however, were determined to take a bold step. They introduced the Streamline Aerocycle in 1934, the first departure from the standardized bicycle appearance in forty years. Influenced by the streamlined look of the airplane, the standard of design during the 1930's, Schwinn promoted the bicycle as having the "grace and beauty of the newest airliner." It featured the balloon tires that Schwinn had challenged the tire industry to produce and that had previously drawn the scorn of other bicycle makers, despite the tires' extensive use in Germany.

Balloon tires were associated with motorcycles and automobiles and were widely publicized—a fact that provided Schwinn with an image of improved durability. Moreover, the Aerocycle's teardrop-shaped tank over the crossbar, along with handlebars, grips, and accessories including headlight, taillight, and horn, all suggested the radical look of a sleek, streamlined motorcycle.

Although the Aerocycle was priced beyond the reach of most bicyclists at that time, it produced the desired effects. Imaginations were inspired, other companies began designing bicycles with new looks, and Schwinn's business improved, propelling the company into leadership during the Depression recovery. A huge sales stimulator, the Aerocycle marked a significant change in the history of the bicycle, as the bicycle market showed new signs of life and the demand for Schwinn bicycles increased. Despite its high price, the Aerocycle, one of the early "cruiser" bicycles, remained one of the most sought-after bicycles. It was replaced by Schwinn the following year with a more affordable model, the Cycleplane, which featured many of the Aerocycle's accessories and became one of Schwinn's best-selling bicycles. The Aerocycle eventually became a collector's item, a prized reminder of the innovation that kept Schwinn at the top of the bicycle industry.

agement devolved over time to his son and other family members, each less competent than the last. After a long decline, and amid family rancor and squabbling, the Schwinn Bicycle Company went into bankruptcy in 1992.

Impact

With the opening of his factory in 1895, Schwinn began to realize his dream, which was to build excellent bicycles. Possessing abundant knowledge about bicycles, having worked on them for many years in Germany, Schwinn began a conservatively managed company with the best machinery, equipment, and precision tools money could buy—one that could build bicycles that would last. "Schwinn-built" signs appeared in salesrooms to distinguish the bicycles with the latest innovations and accessories, and with the sturdiest frames, deemed the safest and the most durable. Schwinn went so far as to issue a lifetime guarantee with each bicycle, an astounding gesture that demonstrated Schwinn's confidence in his products. Soon, at the request of salesmen, the "lifetime guarantee" was placed on the handlebars, as the bicycling public had begun to equate Schwinn with quality.

While Schwinn's stratagems served his purpose well, his advertising methods may have reaped even greater benefits. Schwinn seemed to know what children wanted and targeted them with his advertisements. Because American youth understood from advertisements, their own observations, and by word of mouth that Schwinn bicycles were the "best," they beseeched their parents not for generic bicycles but for Schwinns. Schwinn also engaged famous actors and actresses to endorse his bicycles and to have their pictures taken while riding his bicycles. The association of the name Schwinn with quality continued for decades.

Glenn Theodore Seaborg

American nuclear chemist

Seaborg, the 1951 Nobel laureate in chemistry, was a leading participant in the Manhattan Project that created the nuclear bomb. A dedicated public servant, he was adviser to ten presidents, the first scientist to chair the Atomic Energy Commission, and a leading pioneer in the creation of new radioisotopes.

Born: April 19, 1912; Ishpeming, Michigan
Died: February 25, 1999; Lafayette, California

Primary fields: Chemistry; military technology and weaponry
Primary inventions: Transuranium elements; nuclear bomb; plutonium synthesis

Early Life

Glenn Theodore Seaborg (SEE-bohrg) was born in the small iron-mining town of Ishpeming, Michigan, the son of Herman Theodore Seaborg (originally Sjöberg), a first-generation Swedish immigrant, and Swedish-born Selma O. Seaborg, née Erickson. His first language was Swedish (he began his Nobel address in that language), and he was active in Swedish and Swedish American organizations.

When Glenn was ten, the family moved to a Los Angeles suburb, Home Gardens (now in South Gate), where his father unsuccessfully sought a permanent position during the Great Depression, and financial difficulties plagued the family. To earn money, Glenn mowed lawns and delivered newspapers. He and his sister Jeanette attended elementary school in Watts but finished their primary education in Home Gardens. While attending high school in Watts, Glenn took his first science course, chemistry, as a junior and decided on a career in science.

In 1929, Seaborg enrolled in the University of California, Los Angeles. He earned money by working as a graveyard-shift control chemist at the Firestone Tire and Rubber Company, as a stevedore, as an apricot picker, and as an apprentice Linotype machinist at the *Los Angeles Herald*. He preferred to major in physics but selected chemistry, thinking that it offered more job opportunities in industry.

After graduating in February, 1934, Seaborg entered the University of California, Berkeley, supporting himself with a $50 monthly teaching assistantship. In 1936, nuclear physicist Jack Livingood asked Seaborg to separate and identify radioactive isotopes from a “hot” target that had been bombarded in Ernest Orlando Lawrence’s particle accelerator, the cyclotron. During the next five years, the pair isolated many isotopes used in medicine, biology, and industry. Among these was iodine 131, now used more than half a million times annually in the United States to diagnose and treat thyroid diseases. It later saved Seaborg’s mother’s life. Seaborg and Livingood also discovered iron 59 and characterized cobalt 60, later used in metallurgy, radiotherapy, and materials testing. In 1938, Seaborg and Emilio G. Segrè discovered technetium 99m, the most-used diagnostic radioisotope.

In May, 1937, Seaborg received his Ph.D. for research that yielded the first unequivocal evidence for the inelastic scattering of fast neutrons and established a minimum cross section for this reaction in the region of lead and bismuth in the periodic table. He remained in Berkeley as personal assistant to the College of Chemistry’s dean, Gilbert Newton Lewis, with whom he coauthored several articles on acid-base chemistry.

Glenn Theodore Seaborg. (©The Nobel Foundation)

nium with neutrons stimulated Berkeley scientists to confirm or extend their results. In May, 1940, physicists Edwin Mattison McMillan and Philip Hauge Abelson produced the first transuranium (heavier than uranium) element, atomic number 93, by a similar process. They named it neptunium for the next planet beyond Uranus. In November, 1940, McMillan was suddenly called to the Massachusetts Institute of Technology (MIT) to work on radar; Seaborg obtained his permission to continue the search, and he synthesized element 94, plutonium.

Seaborg was one of the six scientists who signed the Franck Report urging that the nuclear bombs that he helped to develop be demonstrated to the Japanese rather than employed against a civilian population. The suggestion was disregarded, but Seaborg, until his death, thought that the control of nuclear weapons was the most critical problem of the time, and he was a leading figure in the campaign for nuclear disarmament.

After Seaborg finished his wartime studies of plutonium, he returned to Berkeley, where he and his coworkers, Albert Ghiorso, Ralph James, and Leon O. ("Tom") Morgan, continued their search for additional transuranium elements. Their use of chemical isolation methods, based on the assumption that the next elements (atomic numbers 95 and 96) were similar to plutonium, were unsuccessful. However, when they carried out their search according to Seaborg's actinide concept, they rapidly synthesized and identified these elements, named americium (now used in tiny amounts in every home smoke detector) and curium. Seaborg held patents on these elements, becoming the only person to hold a patent on a chemical element.

In summer, 1944, Seaborg proposed a new format for the periodic table incorporating his revolutionary actinide concept, considered the most important change in the table since Dimitry Ivanovich Mendeleyev's original design. Several inorganic chemists warned Seaborg against publishing it because doing so would destroy his reputation. He quipped, "I didn't *have* any scientific reputation, so I published it anyway."

Seaborg suggested that a new series begins with thorium (atomic number 90) and continues through all the elements beyond actinium (atomic number 89), including all the following fourteen elements, ending with element 103. He moved thorium, protactinium, and uranium (elements 90, 91, and 92) from the seventh period (horizontal row) to a new period, called actinide, parallel and similar to the so-called lanthanide (rare earth) series, cerium through lutetium (elements 58 through 71). The new actinide period was accommodated as a row of elements under the lanthanide period below the main portion of the table. Seaborg considered his new concept "the key to the subsequent discovery of a number of transuranium elements."

Seaborg announced his discovery of americium and curium on November 11, 1945, in response to a youth's question about whether any new elements had been discovered, while a guest on the *Quiz Kids* radio program. According to Seaborg, "this was the first time in the history of the world that the announcement of the discovery of chemical elements was sponsored by Alka-Seltzer."

Seaborg returned to Berkeley in 1946. Using his actinide concept and the ion-exchange technique (widely used to soften water), he and his team synthesized berkelium (element 97), californium (element 98, only a few thousand atoms isolated), einsteinium (element 99), fermium (element 100),

Plutonium

Glenn Theodore Seaborg is best known for his synthesis, identification, and characterization of plutonium (atomic number 94), the second of the transuranium elements ("Plutonium Isolation," U.S. Patent number 3,000,695). He was posthumously inducted into the National Inventors Hall of Fame in 2005. He described his discovery as "the first realization of the alchemist's dream of large-scale transmutation."

On December 14, 1940, with graduate student Arthur Wahl and instructor Joseph Kennedy, Seaborg produced and identified element 94 by bombarding uranium with deuterons (heavy hydrogen nuclei) in the sixty-inch cyclotron. They submitted the announcement of their discovery, which included Edwin Mattison McMillan as coauthor, to the *Physical Review* on January 28, 1940, but for national security reasons, it remained unpublished until 1946. Their critical and unequivocal chemical identification of what they called plutonium (for Pluto, the dwarf planet after Neptune) was carried out during a stormy night on February 23, 1941, in room 307 of Gilman Hall at the University of California, Berkeley, now a National Historic Landmark designated with a metal plaque.

Like uranium 235, plutonium 239 was fissionable with thermal neutrons. Large amounts of plutonium were required for a nuclear bomb. Therefore, a crash program was initiated by the Manhattan Project at the University of Chicago's Metallurgical Laboratory. Seaborg, who was placed in charge, arrived there on his thirtieth birthday. In what he called "the most exciting and most challenging period of my life," he developed an extraction process that was used in what he described as "surely the greatest scale-up factor [ten billion] ever attempted" at the newly constructed Hanford Engineer Works in Washington State. Subsequently, when large amounts of plutonium became available, the usual chemical methods could be used, but at the time all manipulations needed to be performed in enclosed areas because of the intense radiation.

Plutonium is produced in much greater amounts than any other synthetic element. Forty percent of the energy in the nuclear reactors producing electricity in the United States is produced from plutonium 239. In fact, more energy is produced from plutonium fuel than by burning natural gas. Another isotope, plutonium 238, has numerous applications as an easily transportable source of electrical power. Transmission of information from the space probes that flew by the planets Jupiter, Uranus, and Neptune to Earth would have been impossible without plutonium.

mendelevium (element 101, only five atoms isolated), nobelium (element 102), and seaborgium (element 106). Seaborg is the only person to have an element named after him during his lifetime. In 1951, Seaborg and McMillan shared the Nobel Prize in Chemistry "for their discoveries in the chemistry of the transuranium elements."

From 1946 to 1958 and 1972 to 1975, Seaborg served as director of the nuclear chemistry division of the Radiation Laboratory (now the Lawrence Berkeley National Laboratory). He was professor of chemistry from 1971 until his death. He served as chairman of the steering committee for the Chemical Education Material (CHEM) Study, which revolutionized high school curricula in the United States and abroad, and he served on many national and state educational studies.

Seaborg died at the age of eighty-six in his home, while convalescing from a massive stroke suffered while exercising on a flight of stairs at the Boston meeting of the American Chemical Society (August, 1998). He had been the society's president in 1976.

Impact

Seaborg was one of the central figures in the Manhattan Project, the highly secret American program that developed the two nuclear bombs—the uranium-235 bomb (code-named "Little Boy") dropped on Hiroshima on August 6, 1945, and the plutonium bomb (code-named "Fat Man") dropped on Nagasaki on August 9, 1945. Whether the bombs needed to be used to end World War II is still a debated question.

In 1961, President John F. Kennedy appointed Seaborg the first scientist to chair the Atomic Energy Commission (AEC), a position that he occupied for ten years (1961-1971), during the Kennedy, Lyndon B. Johnson, and Richard M. Nixon administrations, where he oversaw a broad range of activities, including developing nuclear weapons and finding peaceful uses for nuclear energy. He served as an adviser to ten U.S. presidents, from Franklin D. Roosevelt to George H. W. Bush, and was an active participant in national and international policy making at the highest levels of government. He was personally opposed to deployment of antiballistic missiles (ABMs) and lobbied for the Limited Test Ban and Comprehensive Test Ban treaties. A dedicated public servant and educator as well as a pioneer in nuclear science, medicine, and energy, he was so multifaceted that the *Guinness Book of World Records* cited him for having the longest entry in *Who's Who in America*.

Claude Elwood Shannon

American mathematician and electrical engineer

Though a prolific inventor, Shannon is best known for two contributions. The first dealt with electronic switching, laying the groundwork for the digital computer. The second dealt with information theory, outlining the basic requirements for transmitting data.

Born: April 30, 1916; Petoskey, Michigan
Died: February 24, 2001; Medford, Massachusetts
Primary fields: Communications; electronics and electrical engineering; mathematics
Primary inventions: Electronic switching theory; information theory

Early Life

Claude Elwood Shannon was born in Petoskey, Michigan, and grew up in the nearby town of Gaylord—about 160 miles north of Detroit—far from education centers of the state. Consequently, he was not exposed to academia. His father was a judge in the city, and his mother was the principal of the local high school.

In grade school, Shannon was a typical boy: He made model airplanes and a radio-controlled boat, delivered newspapers, and once used the barbed wire around a neighbor's pasture to string a telegraph line to a friend's house half a mile away. The only activity that might pertain to his future career was his job repairing radios for a local department store. (This was in the early 1930's, when every component in a vacuum tube radio was readily identifiable.) After grade school and high school, Shannon entered the University of Michigan, and in 1936 he obtained bachelor of science degrees in electrical engineering and mathematics. That year, he accepted a research assistant position in the Department of Electrical Engineering at the Massachusetts Institute of Technology (MIT), where he worked toward his master's degree.

Life's Work

Shannon was assigned to Vannevar Bush, who at that time was building a mechanical computer, the differential analyzer. It was not an easy job; this device solved differential equations by analog means, which required translating differential equations into mechanical terms, setting up the device, and running through the needed solutions for various initial values.

Also associated with this very complex device was a relay circuit consisting of more than one hundred relays. The circuit using these relays had been designed piece by piece, and Shannon wondered if it had been done in the most efficient manner. He recalled a course he had taken as an undergraduate on what was then known as relay algebra, or Boolean algebra (named for its originator, George Boole). Shannon developed and applied these ideas during the summer of 1937, which he spent at Bell Telephone Laboratories in New York City. Back at MIT, he prepared his master's thesis, in which he showed that Boolean algebra could be used to design switching and computer circuits. He was right. Decades later, computer scientist Herman H. Goldstine called this work "one of the most important master's theses ever written . . . a landmark in that it helped to change digital circuit design from an art to a science."

In 1938, at the suggestion of Bush, Shannon changed his major from engineering to mathematics. Shannon's doctoral thesis was "An Algebra for Theoretical Genetics" (1940). Shannon's work on switching theory now led him to think in terms of time, bandwidth, noise, and distortion in communications systems, and he wrote to Bush about his ideas. Shannon spent the next fifteen years at Bell Labs, associating with many talented scientists and engineers, including Harry Nyquist, a key contributor to signal theory; Hendrik Wade Bode, known for his feedback work; William H. Brattain, John Bardeen, and William Shockley, the inventors of the transistor; John R. Pierce, who made contributions to satellite communication; and many others.

Shannon's work on switching theory and on the application of Boolean algebra to computers led him to think in terms of transmitting the developed digital data over communications channels. This field has been called information theory. Shannon noted that a communications system consists of a few basic elements: a source of information (the sender), a channel over which the information is sent (wire, fiber optics, radio), a receiver, and noise (interference will always creep in and distort or smother the information being transmitted). All is well if the information being sent is loud enough, the channel is good enough, and the noise is low enough. In the case that one or more of these conditions does not exist, the obvious solution (and one that inevitably causes problems) is to increase the power of the transmitter. A better solution, but one not always possible, is to lower the noise. Shannon concluded that, given the bandwidth of the channel and the level of noise on the circuit, it is possible to mathematically determine how much information can be transmitted over a channel. He further pointed out that the information being transmitted has the best chance of being received accurately if it is kept to a minimum—that is, prepared with a minimum of redundancy.

Shannon was known by his peers as a true genius, but he was also quite playful. Adept at using a pogo stick, he developed a motorized one. He was also adept at using the unicycle, and he developed one with an eccentric wheel, so that the rider moved up and down as he pedaled. One of his hobbies was juggling, and he decided that bounce juggling was easier than conventional toss juggling because the balls were moving at their slowest speed when captured. Shannon was an unpretentious man and was frequently seen rolling down the hallowed halls of Bell Labs on his unicycle while juggling three balls. Taking an interest in artificial intelligence, he built what he called the "ultimate machine," described by futurist Arthur C. Clarke as a wooden box with a single switch on one face. When the switch was thrown, the lid slowly opened, a hand reached out, turned the switch off, and retreated into the box. The machine did nothing except switch itself off.

More in line with Shannon's life's work was the mechanical maze-solving mouse Theseus, built in 1950. It was controlled by a circuit of some one hundred relays that moved the mouse around a maze of twenty-five squares. The maze could be altered at will, and the mouse would then search through the passageways until it found the designated destination. Most important, the mouse could remember where it had been; when re-placed in the maze (at any point), it would quickly move to the destination.

Shannon held honorary degrees from a number of universities, including Yale, Michigan, Princeton, Edinburgh, Pittsburgh, Northwestern, Oxford, East Anglia, Carnegie-Mellon, and Tufts. Throughout his career, he received numerous awards, and he was named a fellow at half a dozen universities. Shannon retired from Bell

Switching Theory

Although Claude Elwood Shannon invented dozens of products and systems—including a motorized pogo stick, a chess-playing machine, and a juggling robot—he is best known for his work on switching theory, primarily utilizing Boolean algebra, and his work on information theory, which defined mathematically the capacity of a transmission channel under varying conditions.

Shannon's work on the process of using switching theory in the design of telephone switching circuits and computer circuits took place while he was a graduate student at the Massachusetts Institute of Technology (MIT). He had been assigned to Vannevar Bush to assist in the maintenance of Bush's differential analyzer, an analog computer. Associated with this device was a circuit of some one hundred relays. Shannon wondered if this circuitry could have been designed more simply, and he thought back to his study of Boolean algebra at the University of Michigan. (George Boole's work was purely mathematical; neither telephones nor computers existed in his day.) Boolean algebra has to do with the manipulation of logic functions. In the simplest form—the binary system—something either "is" or "is not;" it is a "yes" or a "no." From a mathematical standpoint, it is a 1 or a 0. A relay (an electronic logic circuit), therefore, can be on or off, 1 or 0. Shannon called this condition of being on or off a "bit," short for "binary digit."

When huge numbers of logic functions are pieced together, it is of course advantageous to do so in the most efficient manner. By representing each of these functions mathematically and then putting them together in a mathematical equation, it is possible to simplify the equation, and therefore the equivalent circuit. This action can save huge expenses in the design of computers or telephone switching circuits.

Shannon made this effort the basis of his master's thesis, which is considered one of the most important master's theses ever written, in part because it laid the foundation for the digital age. In later years, Shannon downplayed his contribution: "It just happened that no one else was familiar with both fields [mathematics and electrical engineering] at the same time." His work earned Shannon the title of the "father of the information age."

Telephone Laboratories at the age of fifty. He succumbed to Alzheimer's disease and died in 2001.

Impact

Shannon is credited with two extremely important contributions to information technology. The first, developed while a graduate student at MIT, dealt with the application of Boolean theory to electronic switching, thus laying the groundwork for the digital revolution. His second contribution, a paper titled "A Mathematical Theory of Communications" and published in 1948 in the *Bell Systems Technical Journal*, described in mathematical detail the amount of information that could be transmitted over a particular channel. The maximum information transfer rate over a channel was identified as the "Shannon limit." The paper has been lauded as "The Magna Carta of the information age."

John C. Sheehan

American chemist

Sheehan developed the first total synthesis of penicillin, opening the way for the production of the antibiotic in a pure form and for the production of specialized penicillins for a wide range of diseases.

Born: September 23, 1915; Battle Creek, Michigan
Died: March 21, 1992; Key Biscayne, Florida
Also known as: John Clark Sheehan (full name)
Primary fields: Chemistry; medicine and medical technology
Primary invention: Synthetic penicillin

Early Life

John Clark Sheehan was one of three boys born to Leo C. and Florence Sheehan. Leo was the sports editor and political writer for the *Battle Creek Enquirer*, where he later became managing editor. He died of cancer at age fifty. Florence worked as a genealogist. John was interested in chemistry at an early age and had a traditional chemistry kit, which grew into a basement laboratory. His other interests included rocketry, model airplanes, yo-yos (he was a champion), tennis, and the Boy Scouts of America. He received awards in tennis, both in singles and in doubles with his brother Joseph. He attended St. Philip High School in Battle Creek and then Battle Creek College, graduating with honors with degrees in chemistry and political science. As valedictorian of the 1937 class, he was awarded a scholarship to attend the graduate school of his choice. He received his master's and doctoral degrees from the University of Michigan in 1938 and 1941, respectively. His doctoral research was in the synthesis of phenanthrene derivatives.

In 1941, Sheehan married a high school classmate, Marion Jennings, and began postdoctoral work with his mentor, Werner E. Bachmann. Bachmann had a national defense grant to develop a synthesis for an explosive, cyclotrimethylenetrinitroamine, code-named RDX and called cyclonite. Bachmann and Sheehan developed a method to synthesize large quantities of RDX by nitration of hexamethylenetetramine. RDX was a very useful explosive, replacing trinitrotoluene (TNT) as the main explosive in rockets, bombs, and torpedoes. Sheehan also isolated another explosive, cyclotetramethylenetetranitramine (HMX), as a by-product of the RDX project.

Sheehan went to work for Merck and Company in Rahway, New Jersey, in 1941. While at Merck, Sheehan was involved in several outstanding projects, including the new synthesis of calcium pantothenate, the purification of streptomycin, and the purification of penicillin. In 1946, he became an assistant professor at the Massachusetts Institute of Technology (MIT) for half his salary at Merck. By 1950, Sheehan had proven that he was one of the most capable scientists in the field of organic synthesis. He was promoted to associate professor in 1948 and full professor in 1952.

Life's Work

Sheehan worked on many projects besides penicillin. He developed a new method to synthesize peptides—the carbodiimide method for forming amides. Further studies with the carbodiimides (molecules with a carbon double-bonded to two nitrogen atoms) led Sheehan to develop a gelatin that would not melt at room temperature. Gelatin, a form of collagen, is held together by weak hydrogen bonds and will remain semisolid at low temperature. The carbodiimide caused amide bonds to form, making the gelatin more stable at room temperature. Sheehan also proved that carbodiimides will cure leather. He developed three new methods to synthesize beta-lactam rings, and he did research in amino acids, alkaloids, steroids, and the synthesis of high explosives.

Sheehan began working on the synthesis of penicillin in 1948, receiving funding from Bristol Laboratories in Syracuse, New York. Nine years later, he and his team successfully synthesized penicillin V. Among his most important discoveries was ampicillin, a penicillin derivative that could be taken orally. Unlike ampicillin, penicillin is acid-sensitive and so cannot be taken orally. Ampicillin became an important antibiotic, as it had broad-spectrum antibacterial activity. For many years, Sheehan and MIT fought over the patent rights to penicillin synthesis. The rights were finally granted to MIT and generated millions of dollars for the institute. In 1992, the year Sheehan died, MIT named a professorship for him.

Synthetic Penicillin

John C. Sheehan took on the challenge of synthesizing penicillin in 1948. He approached the task in a systematic way, developing methods to make one part of the molecule at a time. While working on synthesizing penicillin, he learned enough about the reactions of the different chemical groups of penicillin to be able to form new synthetic derivatives of penicillin that could be used to treat particular diseases.

The beta-lactam ring of penicillin plays a key role in the antibiotic. It is also a chemical structure that, if opened, deactivates penicillin. One of the major problems Sheehan faced in the synthesis of penicillin was putting together the elements of penicillin's two rings and then closing the beta-lactam ring. Adding the remainder of the molecule without opening the beta-lactam ring was another problem for Sheehan and his research team.

Sheehan first worked on forming amide bonds. Two amino acids can be connected by an amide bond to form a peptide. The systems of humans and animals do this to form proteins. Though there were ways to do this chemically, all of the methods available at the time harmed the remainder of a penicillin molecule. Sheehan found a new way to form the amide bond by using a carbodiimide, a molecule with a carbon doubled-bonded to two nitrogen atoms. This was a revolutionary way to form amide bonds under mild conditions. This discovery set the stage for the synthesis of penicillin. If Sheehan could put all of the elements in place, the carbodiimide reaction would close the beta-lactam ring by forming an amide bond.

The first step of the synthesis was to form the five-element ring. Next, scientists either closed the beta-lactam ring and added the amide with a side chain attached, or attached the amide with a side chain and then used a carbodiimide to close the beta-lactam ring. One important consideration was the groups attached to the first compounds used to form the five-element ring. Those groups were to protect the ring and the nitrogen and carbonyl groups so that they would be active at the time to close the beta-lactam ring. The protecting groups also had to be easy to remove after their task was accomplished. Sheehan found several protecting groups that worked. One bulky group also helped close the beta-lactam ring. New derivatives of penicillin are formed by changing the side-chain group.

Penicillin derivatives such as ampicillin were found to be more effective than original penicillins in treating a wide range of bacterial infections.

Although penicillin is not a large molecule, it is unstable, with a beta-lactam ring that can be easily opened. A beta-lactam ring has a carbonyl group: a carbon double-bonded to an oxygen atom, which is bonded to a nitrogen atom, forming an amide bond. Two additional carbons make up the remainder of the ring. In the penicillin molecule, the nitrogen and one carbon are also part of a second five-element ring consisting of the nitrogen and carbon in the beta-lactam ring, a sulfur atom, and two carbons. One carbon has a carboxylic acid group attached to it; the other has two methyl groups attached. The carbon in the beta-lactam ring that is not part of both rings has a nitrogen atom attached to it that is part of an amide group. A side-chain group is then attached to the carbonyl carbon of the amide group. Penicillin works by attaching to an OH group in an enzyme that forms cell walls for bacteria. Human cells do not have the same type of cell walls and are not attacked by penicillin. The amide bond in the beta-lactam ring breaks to allow the carbonyl group to attach to the oxygen of the OH group on the enzyme. Thus, the beta-lactam ring is the key to the action of penicillin.

Besides his work at MIT, Sheehan headed a research group at the Research Institute for Medicine and Chemistry in Cambridge, Massachusetts, where he researched water-soluble carbodiimides and the synthesis of aldosterone. He also set up the nonprofit John C. Sheehan Research Institute, funded by research grants. Though initially successful, it later suffered from poor management. During 1953-1954, Sheehan served as scientific liaison officer for the Office of Naval Research with the U.S. embassy in London. He was a scientific adviser to Presidents John F. Kennedy and Lyndon B. Johnson from 1961 to 1965.

Sheehan received many awards for his work. He was awarded honorary doctorates from the University of Notre Dame and the Stevens Institute of Technology and was a member of the National Academy of Sciences. The American Chemical Society presented him the Award in Pure Chemistry (1951) and the Award for Creative Work in Pure Chemistry (1959). In 1964, the city of Philadelphia awarded Sheehan the John Scott Award and Medal, crediting him with "saving millions of lives." Elias James Corey, who won a Nobel Prize in Chemistry (1990) for developing the theory and methods of chemical synthesis, credited Sheehan and his colleagues at MIT with beginning the work for which Corey won the Nobel Prize.

Sheehan published more than 150 research papers and was granted some forty patents during his career. In 1977, he retired and was named professor emeritus and senior lecturer. Sheehan died of congestive heart failure at his home in Key Biscayne, Florida, on March 21, 1992. He was survived by his wife and three children.

Impact

During World War II, about eleven hundred scientists in thirty-nine labs in Great Britain and the United States worked unsuccessfully (at a cost of $20 million) to synthesize penicillin. Sheehan undertook the task after the war and succeeded in 1957. The synthesis led to commercial mass production of purer and improved penicillin at a lower cost than fermentation penicillin. People could afford penicillin to treat their particular ailment. By changing the side-chain groups of penicillin, scientists could alter the penicillin to treat different strains of bacteria. Different penicillins could treat diseases for which there had been no antibiotic treatment before.

Fermentation penicillin could treat only gram-positive microorganisms such as staphylococci, but not gram-negative microorganisms such as salmonellae. A derivative of penicillin, ampicillin attacks both gram-positive and gram-negative microorganisms. Also, fermentation penicillin is deactivated by acid and cannot be taken orally. Ampicillin can be taken orally. Some microorganisms are resistant to penicillin because they deactivate penicillin by opening the beta-lactam ring. By adding molecular groups to protect the beta-lactam ring, scientists have been able to develop penicillins such as staphcillin, methicillin, and oxacillin that are less likely to be deactivated. The method of modifying a drug to treat a specific problem is still used today.

Patsy O'Connell Sherman

American chemist

Sherman was a Minnesota Mining and Manufacturing Company (3M) chemist best known for her role in the development of 3M's successful line of Scotchgard textile-protector products.

Born: September 15, 1930; Minneapolis, Minnesota
Died: February 11, 2008; Minneapolis, Minnesota
Also known as: Patsy O'Connell (birth name)
Primary fields: Chemistry; household products
Primary invention: Scotchgard

Early Life

Patsy O'Connell Sherman was born Patsy O'Connell in 1930 in Minneapolis, Minnesota. Her father was interested in science, and he encouraged and challenged his daughter to develop her own scientific curiosity about the world around her. She attended Minneapolis North High School. She once told a teacher that she was interested in becoming a nuclear physicist, an aspiration that won her the class title of "Most Confused Person." In 1947, she and her classmates were given an aptitude test, one for boys and one for girls. Her results suggested that she would make a good housewife. She demanded to take the boys' test instead. The retest results indicated that she should pursue a career as a chemist. She had never so much as taken a high school chemistry course. Still, she found the idea of a science career compelling, and she decided to study chemistry once she entered college.

In 1948, she graduated high school and began her undergraduate studies at Gustavus Adolphus College in St. Peter, Minnesota. She received bachelor's degrees in chemistry and mathematics in 1952. From college, she went to work as a chemist for the Minnesota Mining and Manufacturing Company, or 3M, in St. Paul, Minnesota. She was one of the first female chemists to be employed there. Her position was considered temporary; the expectation was that, being a woman, she would eventually marry and leave her scientific work behind to raise a family. The young chemist married Hubert T. Sherman the year after she began her job at 3M, but she did not abandon her new career.

Life's Work

It did not take long for Sherman to distinguish herself at 3M—thanks to a fortuitous accident and her response to it. Initially, she was assigned to work on a government contract to develop rubber hoses that could withstand exposure to jet aircraft fuel without decomposing. In 1953, she and colleague Samuel Smith were experimenting with a fluorochemical rubber. A small vial of the sticky experimental mixture fell on the floor and splashed on a laboratory associate's canvas tennis shoes. Attempts to clean the shoes failed; the rubbery substance resisted water, soap, various solvents, and scrubbing. Seeing how the fluorochemical mixture stood up to water and oily liquids made Sherman and Smith wonder whether a similar material could be created that would protect fabrics from spills and stains. With permission from 3M, the two chemists turned the focus of their research from jet fuel hoses to stain-proof textiles.

The original fluorochemical mixture was too sticky for use as a fabric treatment, so the team worked to synthesize something new. Their first attempts yielded a material so gummy that it left behind a sticky residue when the treated fabric was run through mill machinery. Subsequent formulations were too hard and brittle, so that the material became powdery when passed through mill rollers. Sherman was unable to be present during this testing phase, as women were not allowed inside the textile mills.

Eventually, Sherman and Smith hit upon an effective and commercially viable formulation. The first Scotchgard product, a stain repellent for wool, reached the mar-

Scotchgard

Scotchgard protectors are fluorochemical treatments that coat a fabric or other surface to render it impenetrable to dry soil, water-based soils, and oils. The treatment may be applied by the consumer (typically from a spray can), by a professional applicator, or by the manufacturer. The product consists of a fluorochemical surfactant chemically bound to a polymer. Fluorochemicals are the most effective class of materials for repelling soils and stains found to date. The rigid carbon-fluoride structure of the surfactant keeps liquids from penetrating textile fibers and makes it difficult for dirt particles to cling to the fibers.

Today, upholstery, carpets, and other interior-design textiles are routinely pretreated by the manufacturer to make them stain-resistant, as are many items of clothing. The Scotchgard family of products has expanded to include easy-to-clean flooring, paints with built-in stain resistance, an algae-resistant roofing system, automobile care products, high-gloss waxes for boats, waterproofing for outdoor recreational equipment, and even antistatic eyewear lenses that resist smudges and scratches. All of the products in the Scotchgard line are intended to make items look newer longer, so that they need not be replaced as frequently.

Unfortunately, the popularity and ubiquity of these products during the latter half of the twentieth century has had unexpected environmental implications. Perfluorooctanyl sulfonate (PFOS), a fluorochemical used in the production of the original Scotchgard formulation, has spread throughout the environment. It is estimated that 95 percent of the people living in the United States would test positive for PFOS or related compounds. Once in the body, the chemical persists for years. Its presence in the environment is not limited to areas where PFOS is manufactured or used: It has been detected in dolphins and Arctic wildlife.

The impact on health and the environment is still being studied. According to the Minnesota Mining and Manufacturing Company (3M), research has shown no adverse human health effects even in workers exposed to higher concentrations of PFOS than the general public. Some adverse affects have been noted in animal studies involving significantly higher doses.

It is believed that, before 3M's 2000 phaseout of products having perfluorooctanyl chemistry, precursor chemicals to PFOS were released into the air during product manufacturing or application (industrial and home). Unbound residues could also escape from newly treated surfaces. Another suspected source is older treated surfaces, in which wear has broken the bonds between surfactant and polymer. Once airborne, the fluorochemicals are carried aloft, where they disperse and break down into the persistent PFOS that finds its way into wildlife and people.

Scotchgard stain protectors are not the only culprits in the worldwide spread of PFOS. Other PFOS-related fluorochemical products have included firefighting foams and food wrappers. 3M's reformulated Scotchgard products use perfluorobutane sulfonate (PFBS), a fluorochemical with a shorter carbon-fluorine chain length than PFOS. While it demonstrates some environmental persistence, PFBS has minimal toxicity and does not bioaccumulate.

ket in 1956. By that point, the two chemists had realized how well they worked together, and they continued to collaborate in expanding the Scotchgard line. Over the next several years, products for protecting upholstery, carpets, clothing, and household linens followed. In the late 1960's, Sherman and Smith created a product that not only repelled stains but also permitted the removal of oily soils from permanent-press fabrics and other synthetics. By then, Scotchgard was a trusted household name: When the product was made available to the public, quantities the manufacturer expected would last a year were sold out in a matter of days. The Scotchgard family of stain repellants and soil removers would ultimately include a hundred commercially applied and six consumer-applied products and bring in more than $300 million a year for 3M. Sherman and Smith were the corecipients of thirteen U.S. patents in fluorochemical polymers and polymerization processes. The chemist team was not issued a patent for Scotchgard until 1971.

During her four decades at 3M, Sherman served variously as a product development manager, a research specialist, and a research manager in the company's chemical resources division. In 1974, she became the first woman inducted into 3M's prestigious Carlton Society, an honorary organization for outstanding technical employees. In the mid-1980's, she created and headed 3M's technical education department, which provided continuing technical education for the company's staff.

Colleagues regarded Sherman as a great scientist who was open-minded, innovative, quick-thinking, and witty. She retired from 3M in 1992 (as did lab partner Smith, who had begun working at 3M a year before her). After retirement, Sherman channeled her love for chemistry into mentoring those interested in science careers. She often gave lectures on science, invention, and innovation.

In 2000, 3M announced that it would be phasing out production of products having perfluorooctanyl chemistry. Scotchgard, which was manufactured using perfluorooctanyl sulfonate (PFOS), was among these products. Low levels of the environmentally and biologically persistent PFOS had been detected in wildlife and people worldwide. Human health and ecological implications are still being evaluated. 3M is now manufacturing a reformulated Scotchgard using a fluorochemical that does not bioaccumulate.

Sherman was a member of the American Chemical Society for over half a century. She served on the Minnesota State Board of Inventors and the board of the National Inventors Hall of Fame. She and her husband had two daughters. One of them, Sharilyn Loushin, is a 3M chemist like her mother; the other, Wendy Heil, is a biologist who runs a precision optics company. Sherman outlived both her husband, who died in 1996, and her lab partner Smith, who died in 2005. She died in 2008 at the age of seventy-seven, a few months after suffering a stroke.

Impact

Sherman entered the workforce at a time when relatively few women were employed in the sciences and even fewer were trying to build a career there. Defying expectations, she succeeded as a chemist and as an inventor. She transformed an accidental spill into a serendipitous discovery, which ultimately translated into an important, popular, and long-lived product line for a major corporation.

Sherman was an excellent role model for young people—particularly girls—interested in science. She loved her work and was eager to share that enthusiasm with others. She stressed the importance of following discoveries wherever they might lead, even if they went in unexpected directions. She advocated remaining open to the accidental and the unanticipated, observing carefully, asking questions, working collaboratively, and thinking creatively.

Her importance as an inventor is reflected in the many awards and distinctions conferred upon her. She was inducted into the Minnesota Inventors Hall of Fame in 1989 and the National Inventors Hall of Fame (along with Samuel Smith) in 2001. She received the Distinguished Alumni Citation from Gustavus Adolphus College (1975) and the Joseph M. Biedenbach Distinguished Service Award from the American Society for Engineering Education (1991). She was one of the female inventors featured in the U.S. Patent Office's 1990 special exhibit, "A Woman's Place Is in the Patent Office." In 2002, she was one of thirty-seven American inventors invited to speak about the process of invention at the U.S. Patent Office's bicentennial celebration.

William Shockley

American engineer

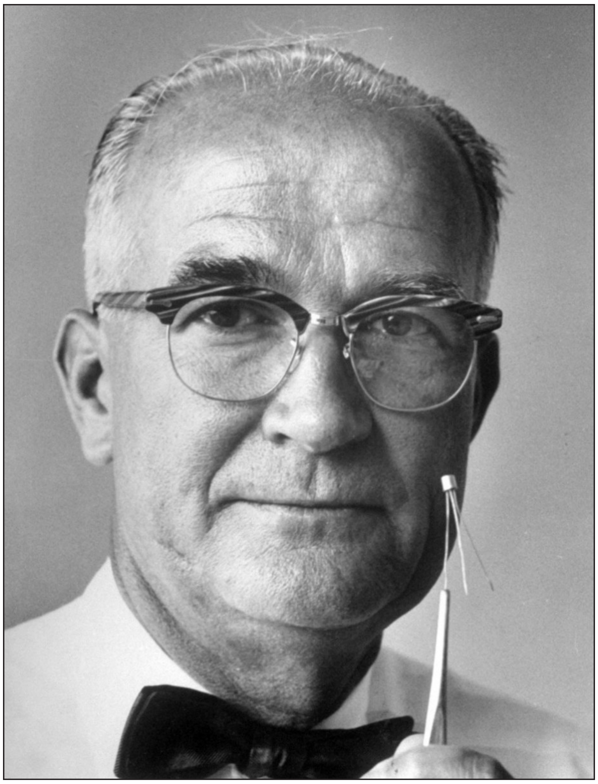
Shockley invented the junction transistor, a device that revolutionized the electronics industry. For their invention of the transistor, Shockley, William H. Brattain, and John Bardeen were awarded the 1956 Nobel Prize in Physics.

Born: February 13, 1910; London, England
Died: August 12, 1989; Stanford, California
Also known as: William Bradford Shockley (full name)
Primary fields: Electronics and electrical engineering; physics
Primary invention: Junction transistor

Early Life

William Bradford Shockley was born on February 13, 1910, in London, England, to American citizens: William Hillman Shockley and May Bradford Shockley. In 1913, the Shockleys moved from London to Palo Alto, California, near the Stanford University campus. Coping with William's frequent tantrums, his parents taught him at home before enrolling him in a private school in 1918. In 1920, concerned that their son was insufficiently disciplined, they enrolled him in a military academy. In 1923, the Shockleys moved to Los Angeles, where William entered Hollywood High School and where, in 1925, his father died. In high school, young Shockley excelled in mathematics and science, tending to find faster ways to solve problems than those his teachers presented.

In 1927, Shockley attended the University of California, Los Angeles, but he enrolled the next year at the California Institute of Technology, where he majored in physics and avidly studied quantum mechanics. Having received a bachelor's degree in June, 1932, Shockley entered graduate school three months later at the Massachusetts Institute of Technology (MIT). During the summer of 1933, he married Jean Bailey, and their daughter, Alison, was born the next year. In June, 1936, with a dissertation on the movement of electrons through sodium chloride, Shockley received his doctorate in physics.



William Shockley uses tweezers to hold up one of the early models of the junction transistor. (Time & Life Pictures/Getty Images)

Life's Work

In that year, Bell Telephone Laboratories hired Shockley. In 1938, he joined a research team studying solid-state physics. Late in 1939, he realized that in theory there could be solid-state amplifiers that used semiconductors, which would replace vacuum tubes, which needed warm-up time and were energy-inefficient, short-lived, fragile, voluminous, and costly.

Early in 1940, Shockley used a piece of weathered copper screen to try to build a copper-oxide amplifier. Delicately, he placed a wire on either side of the screen so that the wire barely touched the copper-oxide exterior. His intent was to control the current between the two wires by controlling the voltage on the screen, but he failed. Then Shockley turned to Walter H. Brattain, a physicist with better laboratory skills than Shockley. Brattain worked under Shockley's supervision to cut grooves into sheets of copper and then oxidize the surface to bury the copper itself beneath the copper oxide. Again, the result was failure.

By then, the United States seemed headed toward World War II, which had already started in Europe, and Shockley turned to military research. Late in October, 1940, he was working at Bell Labs on improving radar, but in May, 1942, he took a leave of absence so that, as a civilian, he could conduct operations research for the U.S. Navy. In addition to explaining why American depth charges dropped from airplanes were not sinking German submarines, he used statistics to tell the Navy how it could more efficiently search for submarines and how its convoys might better avoid bombers. Shifting his civilian work entirely to the Army Air Forces (direct precursor to the U.S. Air Force) by January, 1944, Shockley worked around the world to develop training methods for airmen who would use radar bombsights.

In 1945, with the end of the war approaching, Shockley returned to Bell Labs, while maintaining his military ties. The company picked him to lead a team to research semiconductors at the laboratory in Murray Hill, New Jersey. Among his teammates were Brattain and eventually John Bardeen, another physicist. Building on a discovery at another laboratory, Shockley tried to develop a solid-state amplifier with silicon or germanium as the semiconductor and with an external electric field to control the current within the semiconductor. In a series of experiments in 1945, he expected a big increase in current in the circuits he had designed, but there was no change. Bewildered by his failure, Shockley turned to other work and left the development of a solid-state amplifier to scientists whom he supervised.

On December 16, 1947, Brattain and Bardeen invented a working semiconductor amplifier—specifically, a point-contact transistor, although Bell Labs had not yet coined the word "transistor." That invention marked a decline in group harmony. While happy about the invention, Shockley felt angry that he had not closely participated in what Brattain and Bardeen had done and felt driven to improve on their accomplishment. On December 12, 1947, and again two weeks later, Gerald Pearson of Bell Labs obtained the field effect that Shockley had failed to obtain in 1945. Drawing from what Pearson had achieved, as well as from what Brattain and Bardeen had invented, Shockley worked intently during a professional visit to Chicago from late December, 1947, to early January, 1948, and designed a sandwich arrangement in which a layer of positive-type (P-type) germanium would be on either side of a layer of negative-type (N-type) germanium. Thus, two PN junctions would replace Brattain and Bardeen's delicate point contacts.

Back at Murray Hill, Brattain and Bardeen had considered a patent. When Shockley returned from Chicago, he dismayed them by saying that there should be a broad patent in his name alone, because of his idea in 1945 about the field effect. The lawyers in the patent office would likely have filed for a patent in Shockley's name only, but they discovered something he had not known: In 1930, an obscure physicist named Julius Lilienfeld had received a patent for essentially the same idea. Bell Labs would therefore file for a patent on the point-contact transistor in the names of only Brattain and Bardeen.

Intensely competitive, Shockley suffered from sleeplessness because he felt defeated by two colleagues. On January 23, 1948, he had an idea of immense technologi-

The Junction Transistor

A semiconductor is a solid that ordinarily conducts electricity slightly but not much. Originally, the semiconductor in the junction transistor was germanium, which was eventually largely replaced by silicon. As William Shockley realized, his transistor looked a little like a sandwich but worked like a faucet.

In its simplest form, the junction transistor has a positive (P) charge layer sandwiched between two negative (N) charge layers. Whether the layer is P or N depends on the substance used to make it impure—that is, to dope it. In the negatively charged layers, there are excessive electrons, while in the positive layer there are excessive "holes," which are absences of electrons in the bonds between atoms. In his book *Electrons and Holes in Semiconductors* (1950), Shockley acknowledges that holes, in this sense, are abstractions, but remarks that they are experimentally useful.

Because opposite charges attract each other, holes will flow toward electrons. More important, in the junction transistor, electrons will flow toward holes; electrons, in other words, will be the majority carrier in the NPN arrangement. If there are electrical contacts on each layer of the sandwich, a little added positive voltage on the P layer (the base) will cause, within limits, a large flow of electrons from one N layer (the emitter) to the other N layer (the collector); a small decrease in that voltage on the P layer will greatly reduce the flow of electrons. Thus, the P layer works with electrons in the junction transistor as, in a sink, the handle of a faucet works to increase or decrease the flow of pressured water through the faucet.

Transistors are the building blocks of modern solid-state electronic devices. They replaced vacuum tubes, which were bulky, energy-inefficient, and unreliable; thus, transistors led to the development of computers that were smaller, more efficient, and less expensive than the previous generation.

cal consequence. Instead of the PNP sandwich-style amplifier, which he had designed in Chicago, Shockley secretly designed a solid-state amplifier, still in sandwich style, with an NPN arrangement—one in which electrons would be the main carriers of charge. It was not until February 18 that Shockley revealed his new idea to his surprised colleagues, including Brattain and Bardeen.

The invention of the junction transistor marked the peak of Shockley's scientific career. Meanwhile, as discord within Bell Labs led to Bardeen's departure and Brattain's reassignment, there was discord in Shockley's family. Even before World War II, his marriage was troubled, and his frequent absences from home during the war and an episode of severe depression in 1943 made his family life even worse. His relationships with his sons—Billy, born in 1942, and Dick, born in 1947—were emotionally distant at best. Characteristically honest, Shockley acknowledged, despite his employer's publicity, that Brattain and Bardeen had beaten him to the invention of a solid-state amplifier. On leave again from Bell Labs, Shockley taught at the California Institute of Technology, but he wanted to run his own company to develop electronic devices.

In 1955, after Jean Shockley seemed to be recovering from cancer, he asked her for a divorce and, receiving it, married Emmy Lanning, a psychiatric nurse whom he had met the year before. Furthermore, with the support of Arnold Beckman, Shockley resigned from Bell Labs and founded the Shockley Semiconductor Laboratory as a subsidiary of Beckman Instruments; he chose the Stanford area as his workplace. He hired a group of young scientists who he thought would make the business successful. Shockley, however, showed again the abrasiveness that had offended colleagues at Bell Labs. In 1957, eight scientists left the company because of Shockley's mismanagement. He hired others, but his company never made a profit. Before his company's eventual demise, his interest had turned to teaching at Stanford.

Surprisingly, in the light of his difficult personality, Shockley was a successful teacher. Few persons could solve problems in science and engineering as well as Shockley, and he taught students his methods. However, in the opinion of many observers, Shockley tarnished his reputation, beginning in the 1960's, by his self-publicized pronouncements about what he considered the dysgenic effect in developed countries of excessive reproduction among people with low intelligence. An expert in statistics, if not in genetics, Shockley made enemies by claiming that, despite brilliant individuals within the African American population, the mean intelligence quotient (IQ) among blacks was significantly lower than that among European Americans and that this disparity was largely the result of genetic differences. Actually adding little of substance to the scientific debate about the relative contributions of heredity and environment to human intelligence, Shockley nevertheless brought to the public a topic about which many other scientists feared to talk.

As Shockley focused on eugenics and exposed himself to verbal attacks, he became distrustful of almost everyone except his second wife. After his mother died in 1977 (the same year Jean Shockley died), he was emotionally close only to Emmy Shockley. When diagnosed with metastasized prostate cancer, he refused to let anyone call his children, and he ordered his wife not to notify them upon his death, which came on August 12, 1989.

Impact

Despite being likened to a Nazi in his later years, Shockley helped defeat Germany and Japan in World War II and saved thousands of Allied lives through his work with the U.S. military. Furthermore, he took part, though indirectly, in the invention of the first transistor—Brattain and Bardeen's point-contact device—and won with them the 1956 Nobel Prize in Physics. Although the point-contact transistor was used awhile in such machines as hearing aids, it was Shockley's junction transistor, made first at Bell Labs by Morgan Sparks and Robert Mikulyak, that led to an age of electronics, an age of miniature radios, pocket calculators, laptop computers, cellular telephones, and numerous other devices that depend on transistors deriving from Shockley's great invention. Finally, Shockley in effect chose where Silicon Valley would be when he chose Northern California as the location of his laboratory. As a result of his inability to work with his employees, he inadvertently led several of them to form another company, Fairchild Semiconductor, which prospered and became an ancestor of most of the other companies in Silicon Valley. Often selfish, sometimes arrogant, Shockley massively changed the world.

Christopher Latham Sholes

American newspaper editor and mechanical engineer

Sholes is the inventor of the first commercially viable typewriter and the developer of the QWERTY keyboard, the system that is still in use today on word processors and computers.

Born: February 14, 1819; Mooresburg, Pennsylvania
Died: February 17, 1890; Milwaukee, Wisconsin
Primary fields: Mechanical engineering; printing
Primary inventions: QWERTY keyboard; practical typewriter

Early Life

Christopher Latham Sholes was born on February 14, 1819, in Mooresburg, Pennsylvania. As a teenager, he moved to Danville, where he apprenticed to a printer. He joined his brothers Henry and Charles in Green Bay, Wisconsin, when he was eighteen. There his experience as a printer landed him the position of editor of the *Wisconsin Enquirer*, where he worked for about a year. He relocated again, this time to Kenosha, where in 1845 he became the publisher and editor of the *Southport Telegraph*. He continued to publish the newspaper for seventeen years.

Sholes decided to enter politics, and he was elected to the Wisconsin senate for two terms—first from 1848 to 1849 and then from 1856 to 1857. In the years between these terms, he served in the Wisconsin State Assembly, from 1852 to 1853. In 1860, he became the editor of the *Milwaukee News*, but he soon left the newspaper to become editor of the *Milwaukee Sentinel*. During the Civil War years, Sholes was the Milwaukee postmaster until he was appointed by President Abraham Lincoln to be the Milwaukee port collector. As port collector, he had some free time to pursue his other interests, one of which was developing mechanical typing machines.

Life's Work

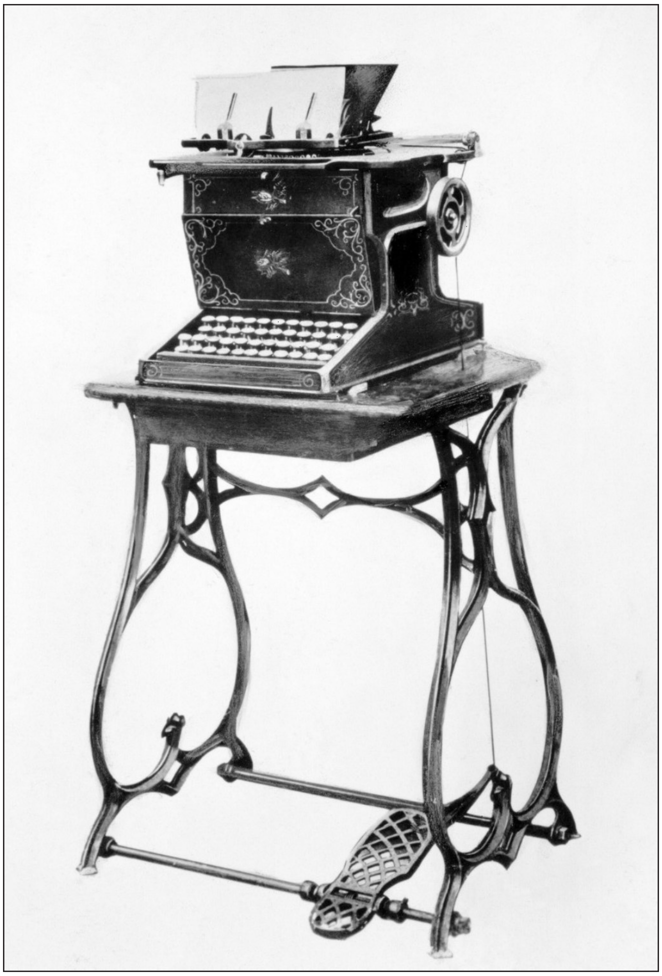
In 1864, Sholes and fellow inventor Carlos Glidden collaborated on developing a machine that could sequentially number pages in book folios. They based this new design on a machine that Sholes and another inventor, Samuel Soulé, had built to sequentially number railroad tickets. One day, Glidden read an article in *Scientific American* that described the Pterotype, a writing machine built by John Pratt in London, and showed it to Sholes. The two men resolved to attempt to rework their numbering machine to make a writing machine.

Sholes, Soulé, and Glidden began work on their writing machine in 1867 in a local machine shop owned by C. F. Kleinsteuber. Their first prototype used a bar attached to a telegraph key to move the type up when the key was pressed down. They filed for a patent for this design on October 11, 1857. Sholes parted ways with Glidden and Soulé after filing the patent. Needing financial support for his enterprise, Sholes entered into a partnership with James Densmore, who, for 25 percent of the patent rights, agreed to pay off Sholes's debts and to provide future financing. Densmore saw the commercial potential of the writing machine and hoped to profit from his partnership with Sholes.

Densmore filed a patent application on May 1, 1868, for an improved model of the writing machine that used a modified piano keyboard to move the type bars. Sholes continued working on improvements to the machine and by 1872 had constructed more than twenty-five prototypes. In 1870, Densmore made his first attempt to sell

Sholes's writing machine. He offered it exclusively to the Automatic Telegraph Company for $50,000. Thomas Alva Edison told the company that he could make a better machine for less money, so the company declined Densmore's offer. Edison was never able to make good on his offer.

Densmore then partnered with George Washington Newton Yost, an entrepreneur who sold petroleum and invented farm machinery. Together they sold the writing machine to E. Remington and Sons in March, 1873, for $12,000. Since the end of the Civil War and hence a decreased demand for their firearms, Remington had begun manufacturing farm implements and sewing machines and was interested in other inventions that it could profitably manufacture. The first typewriter that Remington produced, dubbed the Sholes and Glidden typewriter, had problems with jamming. The bars that held the type moved slowly enough that if the typist typed too quickly, they would jam up against each other. The first typists used the "hunt and peck" method of typing, so Sholes thought that if the most commonly typed pairs of letters were positioned far apart from each other, typists would take longer to move their index fingers the distance from one letter key to the next and therefore have less of a chance of typing too rapidly and jamming the bars. (Sholes at first thought that no one would ever type faster than about twenty words per minute, the equivalent of writing by hand.) Sholes's first keyboard had the keys arranged alphabetically, based on the way newspaper printers' letters were arranged. The new arrangement earned the name "QWERTY," for the first six letters on the top row of the keyboard. Only the middle row kept a semblance of the original alphabetical arrangement minus the vowels—*D F G H J K L*. Sholes's QWERTY system is still used today.



The first modern typewriter, designed by Christopher Latham Sholes, Carlos Glidden, and Samuel Soulé. (The Granger Collection, New York)

Sholes is credited with coining the name "typewriter" for his writing machine. Some researchers have suggested that part of Sholes's rationale for selecting the letters for the top line of his QWERTY keyboard was that the line then included all the letters in the word "typewriter." Salesmen demonstrating the new writing machine could show how they could type "typewriter" just using the top line of the keyboard.

The first Remington typewriters typed only capital letters. In 1878, Sholes added a shift key to his design and had both a capital and lowercase letter on each type head. His new keyboard did not have a key for the number 1, as Sholes thought that typing the small letter *L*, *l*, would suffice.

The mass production of the Remington typewriters was assigned to the treasurer of the Remington sewing machine department, H. H. Benedict. At first, the typewriter was morphed with sewing machine technology; it was mounted on a sewing machine base complete with a treadle that, when moved, returned the typewriter's carriage. The first typewriters were also festooned with the same decorative flowers that were painted on the sewing machines. It may be that the feminizing of the appearance of the first commercially produced typewriters led to the association between women and the career of typing.

Sholes spent his retirement years in Milwaukee, Wisconsin. He died on February 17, 1890, and is buried in Forest Home Cemetery in Milwaukee.

Impact

The typewriter has proven to be an invaluable tool since its invention and commercial production. It increased business productivity, gave writers a more rapid method for writing books and manuscripts, provided students with a means to neatly write their school papers, and gave newspaper reporters an implement for writing their articles. Perhaps the area in which it had the greatest impact was women's employment. Before the typewriter's development and subsequent demand for typists, women had few options for employment. Sholes commented several times that his invention had proved to be a blessing for women, as it enabled them to earn a decent living. Today, word processors and computers have largely replaced the typewriter, but all major computer manufacturers use Sholes's QWERTY keyboard.

—*Polly D. Steenhagen*

The QWERTY Keyboard

Since Christopher Latham Sholes's development of the QWERTY keyboard, many others have proposed improved configurations. Because Sholes designed his keyboard to separate the most often typed pairs of letters to prevent the keys from jamming, his critics have said that the keyboard has built-in inefficiency. However, Sholes envisioned people typing with only one finger, using the "hunt and peck" method, not touch typing, which was not developed until 1888 by law clerk Frank E. McGurrin. With touch typing, the QWERTY keyboard favors use of the left hand and requires many movements of the fingers to the upper and lower levels of the keyboard. The various new keyboard designs were intended to correct the perceived inefficiencies of Sholes's keyboard.

The biggest contender for an improved keyboard was developed and patented by August Dvorak in 1936. His keyboard was touted for favoring the right hand, using the middle row keys more often than the upper and lower rows, and minimizing inefficient fingering sequences. Supporters of the Dvorak keyboard claimed that it could be learned more quickly than QWERTY and typists using it would make fewer errors.

Dvorak was a lieutenant commander in the U.S. Navy during World War II, and he convinced the Navy to allow him to perform tests on his keyboard against the QWERTY keyboard to demonstrate its superiority and to persuade the Navy to adopt his keyboard. One study had fourteen typists who averaged thirty-two words per minute on QWERTY retrain on Dvorak. After eighty-three hours of training, the participants achieved a speed of fifty-two words per minute on the Dvorak keyboard. Another of his experiments was similar, except that some of the participants could not type at all before being trained on Dvorak, thereby having no baseline to which to compare their Dvorak speeds. August Dvorak used the results of his tests to argue for the superiority of his keyboard.

Earle Strong, a professor at Pennsylvania State University, conducted less biased tests comparing QWERTY and Dvorak keyboards. He compared two groups of typists who at first all typed at the same speed, but one group used QWERTY and one Dvorak. Strong then had both groups go through skill improvement training and found the QWERTY users actually improved more than the Dvorak typists. Other studies showed that QWERTY is comparable to any of the other keyboards, including the Dvorak, and that so far no one has made a keyboard superior to Sholes's QWERTY design.

Alan Shugart

American computer engineer

Shugart helped develop the first disk drive at an IBM research laboratory in 1955, creating the digital storage industry that allowed for smaller computers that could store more data. He was also an entrepreneur, a restaurateur, and a political gadfly.

Born: September 27, 1930; Los Angeles, California
Died: December 12, 2006; San Jose, California
Also known as: Alan Field Shugart (full name)
Primary fields: Computer science; electronics and electrical engineering
Primary inventions: Floppy disk; disk drive

Early Life

Alan Field Shugart (SHEW-gahrt) was born in Los Angeles in 1930 to Donald F. and Elizabeth Shugart. His parents divorced when he was about five years old. He and his sister were raised by a single mother who taught elementary school in the farming community of Chino, California, east of Los Angeles. As a child, he exhibited an entrepreneurial spirit, partly as a result of a perceived need to support his family. He had several newspaper routes and even published a newspaper in his home. He also ran a small bicycle repair shop under a tree in his backyard. During harvest season, he worked on several area farms. His mother taught him many life lessons, including an adage: "All work and no play makes Jack a dull boy, all play and no work makes Jack unemployed."

Shugart's father, a structural engineer, remarried when the boy was quite young. While Shugart maintained a good relationship with his father, Donald spent very little time with his son. It was through one of his father's contacts that Shugart obtained a scholarship to the University of Redlands. At Redlands, he studied four different majors, but he still graduated after four years with a degree in engineering physics. The day after graduation in 1951, he started work with International Business Machines (IBM) in Santa Monica, California, as a customer engineer. He needed the job because he was married with one child.

Life's Work

By 1955, Shugart transferred to a small IBM research and development lab in downtown San Jose, California. The lab was tasked with developing technology to replace the stacks of punch cards used to store computer data. The research team of fifty people tested various methods for storing data on media such as magnetic tape and rotating drums. They settled on a design using twenty-four-inch magnetized disks stored on a rotating spindle. The data were stored on the disks using an arm, like those on record players, which also found and retrieved the data for the computer operator. Introduced on September 4, 1956, this first disk drive was called Random Access Method of Accounting and Control (RAMAC). It weighed about twenty pounds and was two feet high. IBM leased computers with the device for about $3,200 per month. It had very limited storage compared to more modern computers, but it could hold the same amount of data as fifty thousand punch cards.

In 1957, IBM promoted Shugart to a position managing a research team to build a better disk drive. His team developed a drive that had multiple arms for reading and writing data on magnetic disks. The new drive, the IBM 1301 disk storage unit, was about the same size as RAMAC but stored 50 million bytes of data. Due to the multiple reading and writing arms, it also could access the data at a much faster rate. The first 1301 disk storage units were introduced in June, 1961.

Shugart was eventually promoted to a higher management position, a promotion that required him to move to IBM's headquarters in Harrison, New York. A native and lifelong Californian, he originally refused the promotion but was told he had to take it. In 1969, after spending slightly more than a week in New York, Shugart resigned as director of engineering for the Systems Development Division of IBM. Several days after Shugart resigned, Memorex hired him and he returned to California. The company wanted him to direct an engineering division to create computer peripherals. About two hundred IBM employees followed Shugart to Memorex. In 1972, he left Memorex to start his own company, Shugart Associates. The goal of this new company was to design and build floppy disk drives to allow for more portability in data storage. By 1974, the company had no product to show investors, and it ran out of money. Shugart was asked to resign, but rather than return to the computer industry, he bought a fishing boat and opened a restaurant. He also did some consulting.

Shugart returned to data storage in 1979 with the founding of Shugart Technology, later renamed Seagate Technology. With $1.5 million in funding, the company sought to produce the first hard disk drives to be used in personal computers (PCs). In May, 1980, the company introduced a 5-megabyte, 5.25-inch disk drive. The company's first customer was Apple Computer, but in 1983 IBM included the hard disks with its PC/XT. Selling disk drives at $600 per unit, Seagate Technology earned $300 million in revenue by the end of its fifth year in operation.

In 1998, the board of directors of Seagate Technology fired Shugart as the company's chief executive officer (CEO). The firing was the result of a restructuring at Seagate in response to a downturn in the computer industry. He founded Al Shugart International, a venture capital company that invested in technology start-ups.

In addition to his work as an entrepreneurial engineer in the computer industry, Shugart worked as a political activist. In 1996, he ran his dog Ernest for a seat in the U.S. House of Representatives as a protest against the frustrating political system. He was the major financial backer of California Proposition 23 in 2000. Had it been approved by voters, the proposition would have allowed citizens the option of voting for "none of these candidates" in statewide elections. Shugart died of complications from heart surgery on December 12, 2006.

Impact

It is difficult to envision the widespread use of personal computers without the invention of the disk drive. When IBM introduced the first disk drive in 1956, the storage device used fifty 24-inch disks and had limited storage capacity. Almost twenty-five years later, Shugart's Seagate Technology introduced the 5.25-inch drive, and customers such as Apple Computer purchased the device for its computers sold to businesses and homes.

Though he was a pioneer in the computer industry, Shugart never accepted the word "visionary" as a descriptor. He shrugged off accolades. Some of Shugart's contemporaries called him a maverick of California's Silicon Valley. He regularly wore Hawaiian shirts to the office, and he remarked that he felt most comfortable when working on his fishing boat or at the restaurant he co-owned. Shugart's success came in part from an entrepreneurial drive that started in his youth. Guided by his mother, he learned the values of hard work, honesty, and humility. He also learned how to have fun, an important aspect of life as the CEO of a growing corporation. As a manager, he was respected by the members of his team. Shugart believed that personal relationships with customers, suppliers, and employees were important in building a successful company. He remarked that hiring people to

The Floppy Disk

The floppy disk, or memory disk, as it was officially known, was introduced by International Business Machines (IBM) in 1971 and was invented by a team of IBM engineers under the direction of Alan Shugart. The disks initially were components in the Merlin (IBM 3330) disk pack file, a 100-megabyte storage device attached to IBM computers. The first floppy disks were used as the medium to store data in another device.

Early floppy disks were eight-inch flexible (hence "floppy") plastic disks coated with magnetic iron oxide. The disks were encased in a plastic housing called an envelope. One or both sides of the disk could be used for recording data. The disk was inserted into a disk drive. The drive spun the disk inside its protective envelope. The read-write head contacted the disk through an opening in the envelope. The first floppy disk created by the Shugart team could hold up to 100 kilobytes of data. Providing portability, the disk could be used to transport data from one computer to another.

In 1976, Shugart developed a floppy disk for Wang Laboratories that was only 5.25 inches. Wang wanted to use smaller floppy disks in its new desktop computers. By 1978, floppy disks could store up to 1.2 megabytes of data. Sony introduced the first 3.5-inch floppy disks in 1981. Even though these disks were housed in hard plastic, they retained the name "floppies." Despite their smaller physical size, their relative rigidity allowed them to store more data. Double-density disks stored 720 kilobytes of data while high-density disks stored 1.44 megabytes.

Floppy disks and their associated drives were gradually replaced in many personal computers by hard disk drives, also pioneered by Alan Shugart and manufactured by Seagate Technology. Early hard drives could store up to 5 megabytes of data after formatting. Similar in concept to floppy disks, hard disk drives stored data on a rigid platter connected to the computer by a data cable. Hard disks were used primarily for storage and easy access, not for moving data from computer to computer. For portability, floppy disks were eventually replaced by recordable compact discs (CDs) and digital video discs (DVDs) as well as flash drives.

Shugart's work with computer disk drives helped launch the personal computer industry. Without small, reliable, inexpensive data storage, computers would have been too large and expensive for many businesses and homes to purchase. The growth of the Internet would have been slowed without the server technology built on the advances of Shugart's work with disk drives.

staff his companies was easy and that he always tried to hire people smarter than himself.

Werner Siemens

German electrical engineer

Siemens's development of diverse applications of electricity to telegraphy, combined with engineering schemes to lay underwater telegraph lines, became the basis for an international network of business contracts.

Born: December 13, 1816; Lenthe, Prussia (now in Germany)
Died: December 6, 1892; Berlin, Germany
Also known as: Ernst Werner von Siemens (full name)
Primary fields: Communications; electronics and electrical engineering
Primary invention: Telegraphy applications

Early Life

Ernst Werner von Siemens (SEE-muhnz) was born to Christian Ferdinand and Eleonore Siemens, née Deichmann, on December 13, 1816, in the Prussian town of Lenthe, near Hanover. The couple would have eight surviving boys and two daughters. The Siemens family's history could be traced back to the mid-seventeenth century Harz mountain region. By the early nineteenth century, a number of prominent individuals had left their mark in a variety of callings ranging from public service through professional careers as doctors and lawyers. Werner's father had studied agricultural science at the University of Göttingen. The generation of Werner and several of his siblings seems to have been the first to pursue educations preparing them for technical vocations.

Werner Siemens attended the Katharineum in Lübeck. He was not attracted to the traditional curriculum at this well-known school, preferring mathematics and science over humanities. He supplemented his school courses with private lessons, mainly in mathematics, and left the *Gymnasium* in 1834 without completing the final examination. He acquired training as an engineer by volunteering for military service in the Prussian Engineering Corps. After some difficulty gaining passing knowledge of subjects that had were not included in his classical *Gymnasium*'s offerings, he moved from regular service in an artillery brigade in Magdeburg to the Artillery and Engineering Academy in Berlin. There he was exposed to both theoretical and practical training under several of the best-known mathematicians and chemists of his time, including Georg Simon Ohm (1789-1854), who had developed what became the standard theory of electrical conductivity that bears his name.

Life's Work

After completing his officer training in 1838, Werner returned for a short period to his family's farm near Hanover. Apparently, it was at this time that he took particular notice of his younger brother William (born in 1823), who had hopes of leaving family farming responsibilities to two other brothers (Hans and Ferdinand) to follow a career in commerce. Werner undertook to help William attend a business and trade school in Magdeburg and even offered him additional instruction in mathematics. This close association between the two young men would have a major impact on the future of the famous company that Werner founded in 1847 under the name Siemens and Halske. When Werner Siemens joined with Johann Georg Halske to found Siemens and Halske (S and H), he would be building on the importance of his own initial work in silver and gold electroplating as well as on contributions made by other well-known figures in the field of electrical engineering. These contributions included the work of his teacher Georg Ohm and Michael Faraday's formulation in 1831 of the law of electromagnetic induction.

In 1834, the year Werner Siemens entered the Berlin academy, Moritz von Jacobi (1801-1874) made history through his invention of the first electric motor. Werner's first patent using electrolytes for silver and gold electroplating was registered in 1842, just as William decided to leave the University of Göttingen to try his hand at engineering in Magdeburg. In 1843 and 1844, William visited England, where he struck a business deal with the English firm Elkington, which was interested in using Werner's electroplating process. This was the first step that would lead to a lifelong collaboration between William and Werner, as the latter's vital inventions opened business prospects not only in England but also (through the efforts of another Siemens brother, Karl) in places as far away as St. Petersburg, Russia.

Werner Siemens's work took a major new direction when he became interested in electrical telegraphy, a new field first pioneered by André-Marie Ampère in the 1820's. By 1837, the Englishman Sir Charles Wheatstone (1802-1875) had advanced Ampère's work by inventing a pointer telegraph. Early systems sent electric current to magnetic needles at the end of a system of wires, causing the needles to indicate letters of the alphabet. Even though Wheatstone achieved higher levels of efficiency by using direct-current batteries and electromagnetic devices, his telegraph was unwieldy, given that five needles were used.

By 1847, Siemens had developed significant improvements over such early telegraphic techniques, and he succeeded in inviting Halske, head of a precision equipment company, to leave his firm to form Siemens

The Siemens Unit

Although the name Siemens is most commonly associated with the company originally founded by Werner Siemens, those familiar with special nomenclature used by electrical engineers associate the same name with the Siemens unit. Siemens developed this measurement of electrical conductance in 1860. It was initially termed the *mho*, the reverse order of letters signifying its relevance to the earlier work of Georg Simon Ohm, who in the 1820's pioneered methods of measuring electrical resistance. What Siemens aimed at in carrying Ohm's calculations forward was to determine how easily electricity flows through each segment of a potentially very complex path carrying an identifiable input, or voltage. Different levels of resistance in such a path will vary depending on, for example, materials used in each stage, from the source of electric charge to the "final destination" of the current.

Eventually, the term "Siemens unit" would be used widely in calculations relating to electrical current, whereas *mho* is now reserved for electronic applications. Despite its widespread use by electrical engineers for several generations (using as its symbol the Greek letter omega, ω, turned upside down), actual official designation of the symbol SI and adoption of the Siemens unit by the General Conference on Weights and Measures came in 1971. The Siemens unit allows calculation of the conductance of a given electrical device by a quite simple formula. Siemens defined the value of his unit of resistance (which is about .953 ohm) based on the resistance of a mercury column one meter long and one square millimeter in cross section at 0 degree Celsius. One Siemens unit of conductance would occur when one volt of electric current produces one ampere, or electric charge measured in coulombs per second. Added (or decreased) voltage in actual testing of electrical devices allows precision calculation of conductance in terms of multiples of, and fractions of, the Siemens unit. In the simplest of terms, and using integral numbers, increasing electrical voltage by one unit (one volt) produces one added ampere of electrical current. When any electrical apparatus, whether a simple household appliance or a very powerful machine, is being designed for production, use of the Siemens unit is essential in order to avoid dangerous overloading of current at any point in the circuits carrying electricity through the particular apparatus.

and Halske, headquartered in Berlin. Siemens had the rare advantage at the time of dividing his efforts between finishing the last year of his military service obligation (which involved participation in the Prussian Telegraph Commission) and the task of founding a new private company. Within a year, despite the wave of political disturbances that struck many areas of Europe, especially the German region in 1848, S and H was awarded a contract to build (in the short span of one year) Europe's first region-to-region electric telegraph, between Berlin and Frankfurt am Main. By this date, two other Siemens brothers—Karl and Friedrich—had joined Werner and William in what was becoming a broad family business enterprise.

In 1850, the year in which Friedrich became director of S and H activities in England, a significant breakthrough in international communications occurred that would have a major impact on the direction of the firm's research: The first submarine telegraph cable was laid from England to France, under the English Channel. This feat was accomplished only after an essential technical issue had been addressed: encasement of bundles of electric wires in an insulated sheath made out of latex produced from the sap of the Southeast Asian gutta-percha tree. This natural latex substance, which had been used to insulate electric cables since the mid-1840's, was superior to (unvulcanized) rubber because it did not become brittle when exposed to different temperature levels. An equally important characteristic of natural latex was its chemical composition, which actually repulsed marine plants and animals—the main cause of damage to earlier submarine cables.

By the time of Werner Siemens's marriage in 1852 to Mathilde Drumann, daughter of a Königsberg professor and mother to two children by Siemens (Arnold, born in 1853; William, in 1885), S and H had begun to expand its telegraph construction services to Russia. Activities that started with a telegraph line from St. Petersburg to Moscow in 1851 were followed by the appointment of Karl Siemens to oversee the first stages of a larger project: construction of the Russian state telegraph network. Russia's involvement in the Crimean War (against Britain, France, and the Ottoman Empire) in 1853-1856 increased the importance of S and H's work, leading to the establishment of a company subsidiary in St. Petersburg.

Despite what might have seemed a shift in "business loyalties," in 1859 Werner and William Siemens welcomed an offer from London naming them the primary submarine telegraph advisers to the British government. Their contribution to British strategic interests was already taking shape when the first telegraph line to India was completed in 1860: The imperial government would soon assume full political responsibility for India and sought to increase the efficiency of communications that would come with the opening of the Suez Canal in 1869. By 1868, Werner was engaged in construction of a state-of-the-art Indo-European telegraph line from London to Calcutta, completed in 1870.

In the meantime, S and H faced its first serious setback in 1864, only a year after establishing the first Siemens cable factory in Woolwich, England. The firm lost half its capital when it failed to complete a contract with the French government to lay a cable (using its own materials) from the coast of Spain to Algeria. This setback played a role in Halske's decision to end his participation in the English subsidiary of the company, which was restructured under the name Siemens Brothers. Halske retired from the internal direction of S and H in 1867.

During the 1870's, the Siemens company would rank among the top contractors involved in laying long-distance underwater telegraph cables. The zenith of its accomplishments in this field came in 1875, when the transatlantic cable linking Ireland to the United States was inaugurated. By this date, however, results of research undertaken by Werner Siemens and several of his colleagues at S and H pointed to new directions for the company. Siemens's long-standing interest in electric motors would be applied to electrical transport systems, a branch of company operations launched in 1879, when the company's model for an electric railway system powered by an external source of current was unveiled at the Berlin Industrial Exhibition. This new technology was put to work as early as 1881, when the first electric tramway built by Siemens began operations in the suburbs of Berlin. Soon after this, the company proved that large electrical locomotives pulling heavy loads could increase efficiency in the German coal mining industry.

Beyond his activities in the Siemens company, Werner also had a publicly recognized career. He voiced strong support for the emerging field of electrical engineering by urging introduction of this subfield as part of the curriculum in all German technical universities. From 1862 to 1866, he was an elected member of the Prussian parliament, and he helped cofound the German Progressive Party. Although his opinions led to disagreements (and withdrawal from politics) in the politically charged years that led to the founding of the German Empire (in 1870-1871), he continued to receive public recognition from the highest institutions of the new empire.

In 1873, he became a member of the prestigious Royal Prussian Academy of Sciences in Berlin, and fifteen years later Kaiser Friedrich III raised him to the ranks of the Prussian nobility (thus adding the noble particle "von" to his surname). One year before Werner handed the direction of S and H over to his brother Karl and his two sons, Arnold and William (in 1890, two years before his death), a second giant responsible for the expanding use of electricity both in domestic life and in industry shared a personal meeting with Siemens in Berlin—Thomas Alva Edison.

Impact

It is difficult to determine whether Siemens's impact should be measured in terms of the technical advances made possible by his discoveries or in terms of the development of the firm he founded, which became a world leader in the field of electronics. Just in terms of the expanding volume and diversity of the company's activities only a few years after his death, one could have predicted that the Siemens company was going to count among the top international firms in the twentieth century. The rapidly changing electrical and electronic advances of that century would, of course, pose new parameters for the company's activities. World demand for more and more sophisticated applications in electronics became so extensive that none of the founding members of the Siemens family could have imagined how important their company would become.

In the thirty-year period from 1872, when S and H had 1,386 employees (a large number for that time), to 1902, the company's workforce (including several subsidiaries) grew to more than 25,000. By 1872, the company was selling its products in fourteen European countries and in North and South America. By the end of the century, two new zones of operations—Australia and Africa—had been added. By 1900, Siemens was distributing an impressive range of products throughout the world. These included not only telephonic and telegraphic equipment but also cables, incandescent lamps, and dynamos.

Igor Sikorsky

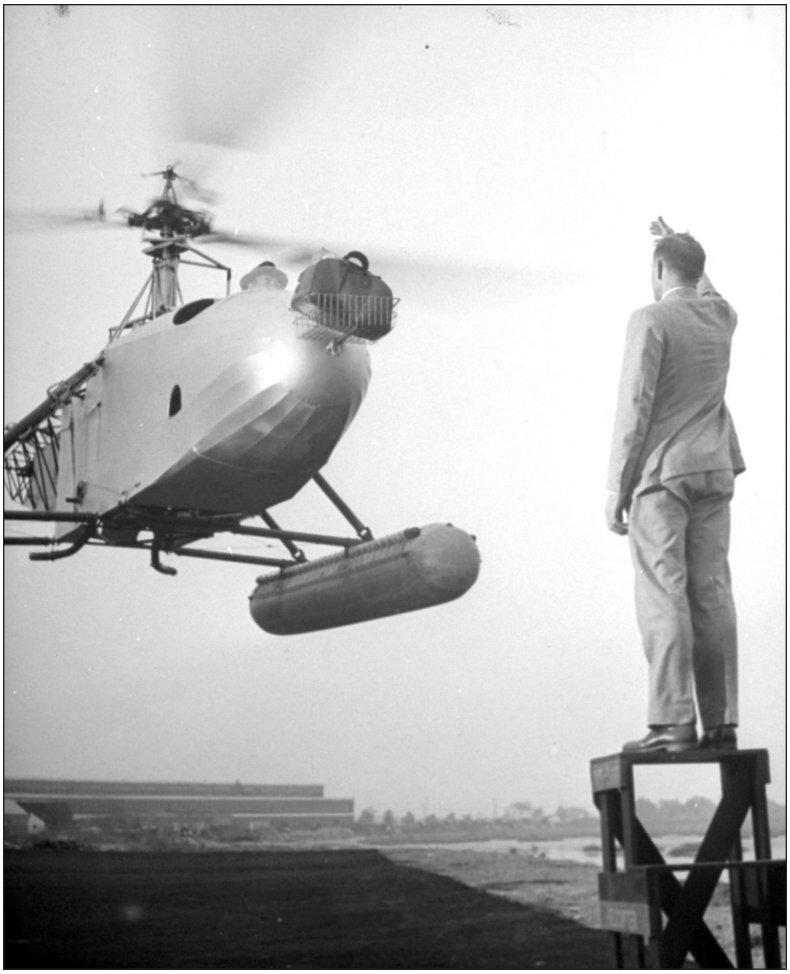
Russian American aerospace engineer

Igor Sikorsky made pioneering contributions to the design of aircraft in Russia and then in the United States, designed and flew the world's first multiengine fixed-wing aircraft, and was instrumental in the development of the helicopter industry.

Born: May 25, 1889; Kiev, Russia
Died: October 26, 1972; Easton, Connecticut
Also known as: Igor Ivanovich Sikorsky (full name)
Primary fields: Aeronautics and aerospace technology; manufacturing
Primary inventions: Helicopter; multiengine fixed-wing aircraft

Early Life

Igor Sikorsky's (EE-gohr sih-KOHR-skee) father, Ivan Alexis Sikorsky, was a professor of psychology at the University of Kiev, and his mother, Mariya Stefanovna,



Igor Sikorsky, left, takes off in the VS-300, the first practical helicopter. (Time & Life Pictures/Getty Images)

was a physician who did not practice professionally. The youngest of five children, Sikorsky grew up in Kiev, attended the Russian Naval Academy in St. Petersburg, studied engineering in Paris, and returned to Kiev to enroll in the Polytechnic Institute in 1907. Inspired by Count Ferdinand von Zeppelin's flights in his first dirigibles in Germany as well as the Wright brothers' flights at about the same time, Sikorsky returned to Paris, then the aeronautical capital of Europe. His mother had homeschooled Igor, and she developed in him a great love of art, including the life and work of Leonardo da Vinci and the fantastic stories of Jules Verne.

By the age of twelve, Sikorsky had made a small rubber band-powered helicopter, and by twenty he had built his first helicopter, although it never left the ground. Undiscouraged, Sikorsky turned his attention to fixed-wing aircraft; his second design, the S-2, was successful, and later, the S-5 won national recognition when Sikorsky flew it for thirty minutes at seventy miles per hour. The S-6A soon followed, and it won first place at the 1912 Moscow Aviation Exhibition. His success led him to be named head of the aviation division of the Russian Baltic Railroad Car Works, where he designed and built the S-21, "The Grand," the world's first successful four-engine plane. Sikorsky was the test pilot for its maiden flight on May 13, 1913. This accomplishment led to the design of an even bigger aircraft, the Ilia Mourometz, and more than seventy versions of this plane were built for use as bombers during the World War I.

The Bolshevik Revolution of 1917 disrupted life in Russia and prompted Sikorsky to leave. He first moved to France, where he began designing bombers for the Allied war effort, but the Armistice that ended World War I was signed soon after he arrived in France. Sikorsky left for the United States, arriving in New York on March 30, 1919.

LIFE'S WORK

Sikorsky struggled for several years to gain a foothold in the United States. Finally, on March 23, 1923, the Sikorsky Aero Engineering Corporation was formed in New York, with the help of friends who knew his talents, and Sikorsky began his aviation career all over again. On a chicken farm on Long Island, using spare parts and handmade tools, Sikorsky and his colleagues designed and built the twin-engine, fourteen-passenger S-29A (the *A* stood for "America") in 1924. This first prototype was made possible only because of a last-minute contribution of $5,000 from the famous Russian pianist and composer Sergei Rachmaninoff. This original S-29A was later sold to Howard Hughes, who used the plane in his early aviation epic, *Hell's Angels*, in 1930.

Sikorsky's first important commercial success was the design of the twin-engine S-38 amphibian plane in 1928. Orders soon rolled in, most notably from Pan

American World Airways (Pan Am), which used the plane to open air routes to Central and South America, and the Sikorsky Corporation moved its headquarters to Stratford, Connecticut, and continued production of the S-38. In the same year, the company became a subsidiary and then a division of United Aircraft Corporation (later known as United Technologies Corporation). Its next model was the four-engine S-40 and then the S-42, with engines built by nearby Pratt and Whitney, the "flying boat" used by Pan Am to pioneer transoceanic flights across the Atlantic and the Pacific. The S-44, developed at the end of the 1930's, was the last fixed-wing aircraft built by Sikorsky.

Having succeeded in careers designing and building aircraft in both Russia and the United States, Sikorsky now returned to his first love, helicopters, which he had tried unsuccessfully to build nearly thirty years before. On September 14, 1939, he piloted his VS-300 a few feet off the ground in a demonstration of the first practical helicopter design. By 1940, the VS-300 (for "Vought-Sikorsky," a joint venture of two divisions of United Aircraft) had become the first of the single-rotor configuration that would emerge in the future as the world standard in helicopter design. On May 6, 1941, the VS-300 set a world endurance record of over an hour and a half in the air, again with Sikorsky at the controls. Military contracts followed the success of the VS-300, and by 1943 large-scale manufacture of the Sikorsky R-4 made it the world's first mass-produced helicopter. Thus, the helicopter industry—and the helicopter age—was born.

Sikorsky continued to be a vital part of the company even after his 1957 retirement at the age of sixty-eight, and he was at his desk at the Sikorsky plant, on the Housatonic River at the Merritt Parkway in Stratford, on the day before his death at the age of eighty-three. He was buried not far from the plant, in Easton. A short-lived marriage in Russia had produced a daughter, Tania, and Sikorsky's marriage to another Russian émigré, Elizabeth Semion, in 1924 produced four sons. Their eldest, Sergei, continued in the aviation field, eventually becoming a vice president at Sikorsky Aircraft.

Sikorsky won numerous awards during his lifetime, and he is enshrined in both the International Aerospace and the Aviation Halls of Fame. In addition to his multiple aviation careers, Sikorsky produced three books. His autobiography, *The Story of the Winged-S* (1938), chronicled his development as an aircraft designer and builder, and his two religious works, *The Message of the Lord's Prayer* (1942) and *The Invisible Encounter* (1947), revealed his more spiritual side.

The Helicopter

Of all Igor Sikorsky's achievements, none was more important than his development of the helicopter. Humans had dreamed of the helicopter—a craft that could move vertically without forward speed—from as far back as the Renaissance, when the notebooks of Leonardo da Vinci showed an early helicopter design. It was Sikorsky, as much as any man, who made that form of flight possible. It is noteworthy that Sikorsky was always proudest of his role in this development of an aircraft that would be so important in saving lives, in peacetime as in war, on land and on sea. The first recorded mercy mission by helicopter occurred on January 3, 1944, when a Coast Guard helicopter braved a snowstorm to get blood plasma to crewmen badly burned in an explosion aboard a U.S. destroyer off the New Jersey coast. A year later, it was a helicopter that was used to make the first wartime rescue of three British commandos and their American medevac pilot behind Japanese lines in Burma. Since that time, hundreds of thousands of people have been rescued thanks to helicopters, and the account of every national or international disaster is highlighted by images of the arrival of helicopters, plucking people from floods or storms, off rooftops or out of trees.

If anyone can be credited with that success, it would be Igor Sikorsky. He pioneered the single-rotor configuration that would become the standard world helicopter design, a rotorcraft with a single controlled-pitch, three-blade main rotor and a smaller vertical tail rotor to counteract the torque of the main rotor. His first flight of the VS-300 in 1939—a machine powered by a 65-horsepower (50-kilowatt) engine with Sikorsky sitting in an exposed pilot's seat—would lead to the rapid development of the helicopter during and after World War II, eventually producing crafts like the Sikorsky "flying cranes," the cargo helicopters used to carry heavier loads (such as trucks and prefab houses). Under his direction, Sikorsky laboratories developed numerous high-lift and control devices for this and other aircraft.

No one person invented the helicopter. It evolved from the contributions of hundreds of inventors and aeronautical engineers over decades, but only Sikorsky had all the engineering skills to develop this amazing craft, the entrepreneurial skills to bring it to production, and the spiritual vision to understand its importance.

Impact

Sikorsky had three almost separate careers, in Russia and the United States, and his impact on aviation history is immeasurable. As a scientist, engineer, pilot, and aircraft manufacturer, he influenced the design and development of both fixed-wing aircraft and helicopters. In a career spanning more than six decades, Sikorsky designed and flew the first four-engine airliners, developed the airplanes that would open the world to air travel, and drafted the first practical helicopter design and helped to launch the helicopter age in the United States. His accomplishments would change the faces of both war and peace. His designs for bombers altered the way warfare would be conducted from World War I on, his design of transoceanic aircraft opened up the world for travel and business, and his development of the helicopter changed the nature of flight and the pace and speed of modern life.

Sikorsky was awarded more than eighty honors during his lifetime, including the National Medal of Science presented in 1967 by President Lyndon B. Johnson, and the Royal Aeronautical Society of England's Silver Medal. The achievements of Igor Sikorsky and Sikorsky Aircraft take more than seven pages to list, and they include more than 120 firsts, from the world's record for flight duration in the S-21 in Russia, to the first airmail service between the United States and Panama (in an S-38 piloted by Charles Lindbergh), to the first helicopter (the S-55) to fly across the Atlantic Ocean (1955), to the first helicopter (the S-58) to retrieve a U.S. astronaut, Commander Alan Shepard, America's first man in space. No one has had a greater impact in a wider range of aeronautical fields.

Isaac Merrit Singer

American machinist

While Singer did not invent the sewing machine, he made improvements to the machine that made it more practical and adaptable for home use. He then, through clever marketing and the first installment payment plan, made a fortune selling his machines around the world.

Born: October 27, 1811; Pittstown, New York
Died: July 23, 1875; Torquay, Devon, England
Also known as: Isaac Merrit
Primary field: Manufacturing
Primary invention: Sewing machine improvements

Early Life

Isaac Merrit Singer was the youngest child of Adam Singer and Ruth Benson. Adam was a German immigrant from Saxony who had changed his surname from Reisinger to Singer. When Isaac was ten years old, his parents divorced and his father remarried. Isaac did not get along with his new stepmother, so at the age of twelve he left home. At first, the young Singer lived with his older brother in Oswego, New York, and worked in his brother's machine shop. It was there that he learned the machinist's trade.

In 1830, Singer married Catharine Maria Haley, and the newlyweds moved to New York City to live with her parents. Then, in the summer of 1833, the couple moved to Fly Creek in Otsego County, New York, where Singer went to work in a machine shop owned by George Pomeroy. After the birth of his first son, William, Singer moved his family back to New York City and found employment in a press shop.

Singer had long been interested in acting, and in 1836 he left his family and joined a company of traveling players. When they went to Baltimore, Singer met eighteen-year-old Mary Ann Sponseler. The next year, Mary Ann gave birth to his son Isaac while Catharine bore him a daughter, Lillian. Singer lived with Mary Ann in Baltimore, his marriage to Catharine effectively over, but he and his wife did not divorce until 1860.

Life's Work

In 1839, Singer received his first patent for a rock-drilling machine that he developed while working with one of his older brothers digging the Illinois waterway. He sold the patent for $2,000. He used the money to form his own acting company, which he called the Merrit

RAIL-ROAD NEWS.

Railroads in Europe.

We have rather been consoling ourselves with the idea that our recent railroad enterprise was greater than that of all other nations together. This seems to be a mistake, for the Continent of Europe, mixed up with despotic governments, appears to be as truly alive to the importance of railroad communication, as the most go ahead of all our States. The London Times has recently been publishing statistics of the progress of the different countries, which exhibit these results:—Belgium has 532 miles of railways, 353 of which have been constructed and worked by the State, the remainder by different private companies. The expense of constructing the whole has been £9,576,000, or £18,000 per mile. The annual expenses are 63 per cent. of the receipts, and the profits three and a half per. cent. on the capital. In France there are 1,818 miles of railway under traffic, 1,178 miles in progress, and 577 miles projected. The cost of construction per mile has been £26,832, and the whole expenditure requisite for the completion of the 3,573 miles is estimated at £95,-870,735. The average annual net profit on the capital employed does not exceed two and seven-tenths per cent.

In Germany there are 5,342 miles of railway in actual operation, 700 in progress, and 2,414 miles projected. Of the railways in operation, 1,812 miles were within the Prussian territories, and 771 miles in the Dutch Netherlands, the Danish Duchies, and the ex-German Austrian provinces, and therefore only 4,571 miles can be considered as strictly within the Germanic confederation. Two-fifths of these 4,571 miles were constructed and worked by the State, the remainder by private companies. Those in Prussia, however, are all the result of private enterprise. The expense of construction of the 5,342 miles is estimated at £12,500 per mile, being single track only. The working expenses are about fifty per cent. of the receipts, and the net profits are nearly three per cent. In Russia a railway from Warsaw to Cracow, 168 miles in length, is in operation; one connecting Warsaw with St. Petersburg, 683 miles in length; and one of about 400 miles, from St. Petersburg to Moscow, is in progress. A railway for goods from the Wolga to the Don, 105 miles in length, is also contemplated. In Southern Russia a line of railway between Kief and Odessa has been surveyed. In Italy no extensive system of railway has yet been executed. A few lines, diverging from the principal cities, such as Naples, Milan, Venice, Leghorn, and Florence, are alone in operation. In the kingdoms of Sardinia, Spain, and Portugal, railways are only in prospective.

By multiplying £1 by $4,85 we can arrive at the cost per mile of some of these roads. It will be observed that the French lines—the highest—cost $130.135,20 per mile, or nearly three times as much as those of Massachusetts, the cost of which averages $43,781.00, or about £9,000. If the European lines pay at such an enormous cost, need we be afraid?

SINGER'S SEWING MACHINE.—Fig. 1.

The accompanying engravings represent a perspective view, figure 1, and a side elevation, figure 2, of Isaac M. Singer's Sewing Machine, which was patented on the 12th of last August. A is the frame, made of cast-iron, and B is a cast-iron standard to support part of the working machinery. C is a large driving wheel, worked by the handle, D. E is a small second wheel, driven by C, and works the shaft that vibrates the needle; E' is another wheel to work the shuttle shaft, e, hung in the bearing straps, b b, fig. 2. F is a round plate on the revolving shaft of E: it has a small roller stud on its inner face fitting into a plate, G, slotted of a heart-shape, to answer the purpose of a cam. This plate, G, is secured to the vibrating arm, H, to which the needle, I, is fastened. The needle performs three strokes up and down during one revolution of the large wheel, C. The thread, J, of the needle is supplied by a bobbin, K, and goes through an eye in the needle, near its point. The cloth is laid flat on the table on the top of a small rough-faced roller S, with the edge to be sewn under the needle. The cloth is held down by a pad, R, acted upon by a coiled spring, P.

Figure 2.

this pad is raised by a pin, O, and kept fixed by a catch bar, N, which presses against a shoulder piece, M. There is another shoulder piece, M, to secure the arm, L, of the pad, R, in its place. When the cloth is laid on the table, on the wheel, S, the catch, N, is thrown out, and the pad, R, is pressed on the cloth by the spring, P, and is retained firmly in its place but still allowed to be carried forward as it is stitched. The way in which the stitch is performed is by two threads, one supplied with a shuttle, X, the other by the needle, I. Without two threads, no good stitch has yet been made by any sewing machine. X is the shuttle carrying a thread which passes from a pirn inside through a small eye on the side next the needle. Now, to form the stitch, which is just like the lock or link of a chain, the thread in the needle, after having passed through the cloth, opens, and the shuttle passes through this loop, therefore, when the needle is drawn back, and the shuttle also to the end of its raceway, the two threads are drawn tight, forming a link drawn on the cloth, and thus link after link of these threads form the seam. The drawing of the threads tight, and the forming of the loop on the end of the needle for the shuttle is an essential feature to the successful working of these sewing machines. For this purpose the shuttle, X, has a motion to coincide with that of the needle, I, and it is imparted by the same devices, d, fig. 2, being like plate, F, and Y like cam G, only the shuttle runs horizontally at right angles to the needle; c, fig. 2, is the shuttle arm, and Z is the guide or raceway, in which it runs. Thus the motions of the needle and shuttle are explained. The other lettered devices not explained are those belonging to the cloth-feeding motion. The roller, S, that moves the cloth has a rough face, and rotates, but moves round slowly, only making its movements forward the length of a stitch for every stitch taken; this is done by catches or pallets, a well known way to do so. These pallets are vibrated by a rocking shaft, f, having a bar, g, on it, which is moved by a cam, c, on the shaft, a. To the small rocking shaft, f, there is secured a suspended lever, h, having a collar, h surrounding said shaft, near its bearing end, i. This lever has a hook, V, on its lower end, to which is affixed a setting screw, W. The hook, V, catches on the hand of an arm, T, which has pallets or catches in a box, that catch into notches on the shaft of the feed wheel, S; every time, therefore, the lever, h, is vibrated, the feed wheel, S, moves the cloth the exact length of a stitch forward; the set screw, W, is for regulating the length of feeding the cloth forward to make short or long stitches.

This machine does good work. The patent claim will be found on page 390, Vol. 6, Sci. Am. The agent of this machine is W. H. Shepard, No. 256 Broadway this city.

Things to be Invented.

Among the things that are wanted by every body is a substitute for pen and ink. It seems that a single instrument ought to perform the function, and that fluid ink may be dispensed with. Cannot some substance be found, simple or compound, that will make an indelible mark upon paper, being hard enough also to hold a fine point? Or cannot paper be so prepared, without great addition of expense, as to aid the purpose?

The Christian Hat.—The improvements of the age have reached almost every thing except the abominable flower-pot hat, that so much needs the kindly attention of reformers. We are glad to notice that attention is being directed by some of our public journals to the unreasonableness of a stiff and perspiration-proof covering for the head. The flower-pot hat cannot pretend to beauty; it is certainly uncomfortable and unhealthy. Why then shall we not seek a substitute? The hat should be very light and porous, and by all means soft or elastic; and if any article of our dress calls for especial ornament, the covering of the head speaks most loudly for something to set off the front that slightly distinguishes one man from another. The Turban is probably most susceptible of such modifications as would be most easily adjusted to the purposes required; and we think some such change of the head-dress would require little urgency to get into general favor.

The November 1, 1851, cover of Scientific American *detailing Isaac Merrit Singer's improved sewing machine.* (Time & Life Pictures/Getty Images)

THE SEWING MACHINE

Several inventors worked on developing sewing machines; Isaac Merrit Singer incorporated many of their ideas and designs into his functional model. The first patent for a sewing machine design was issued in 1790 to a British inventor, Thomas Saint. He never built a working model of his design. The first working model was invented by Barthélemy Thimonnier, a French tailor. He patented a machine in 1830 that sewed a chain stitch in a straight line. In 1841, Thimonnier's factory sewed French military uniforms using eighty of his machines, but the building was destroyed by a mob of angry French tailors who thought their jobs were being threatened by mechanized sewing.

These early machines used a chain stitch, which was formed using either one or two threads. The first or only thread passed through an eye in a needle, and if there was a second thread, it moved back and forth over the fabric carried by a looper. Either way, the machine formed a series of linked loops that looked much like a chain. The major drawback of this stitch is that if the thread is broken, the chain easily unravels, much in the way a stocking will run if one thread is broken. This stitch, however, is still used today in applications such as sewing together the tops of large sacks that hold seed, grain, or dog food. The stitch keeps the bags closed but allows for quick and easy opening by just pulling the thread.

Walter Hunt developed the lockstitch in 1834, using a thread on a curved needle that passed through fabric horizontally, thus forming a loop on the underside of the fabric. A shuttle then passed another thread through this loop, locking the stitch. It is much more difficult to rip out a seam sewn with a lockstitch, so the seams in clothing sewn in this way will not unravel. Howe sold his machine without patenting it. Elias Howe then produced and patented a machine very similar to Hunt's in 1845.

Singer's machine combined design features of these first machines. He added a presser foot to anchor the fabric being sewn in place, a tensioning system to adjust the tension of the thread for sewing different weight fabrics, and a fixed arm to hold the sewing needle vertically. Some of the earlier machines were operated with a hand crank, but Singer used a foot treadle that left the sewer's hands free to manipulate the fabric. The machine as designed by Singer remained the standard until 1889, when the Singer Sewing Company introduced electric machines. At this point, however, the electric model was simply the same design, but with an electric motor attached to the side to turn the sewing wheel.

Players. He and Mary Ann, who now went by the names of Isaac Merrit and Mrs. Merrit, toured for five years until their money ran out. The couple eventually had ten children together.

When his money ran out, Singer found himself in Fredericksburg, Ohio, where he found employment in a print shop. His work inspired him to design a machine to cut wood and metal printing blocks. He moved on to Pittsburgh, Pennsylvania, where on April 10, 1849, he patented his machine for carving wood and metal. He then moved back to New York City and built a working prototype of his machine at A. B. Taylor and Company, but when the shop's boiler exploded, his machine was destroyed. Orson C. Phelps heard about Singer's machine and asked him to come to Boston and build another one.

While there, Phelps asked Singer if he could improve the Lerow and Blodgett sewing machines that were being manufactured at Phelps's shop. At first, Singer refused, thinking the machine mundane and beneath him, but he eventually agreed. In eleven days, Singer was able to make over the difficult, impractical machine. Singer patented his new design (patent number 8,294) on August 12, 1851. With financing from George B. Zieber, Singer, along with partners Zieber and Phelps, formed the Jenny Lind Sewing Machine Company, soon renamed I. M. Singer and Company.

By the time Singer filed his patent, several others had already independently developed sewing machines. Elias Howe had filed for a patent for his machine on September 10, 1846. Like Singer's machine, Howe's was an improved model of another machine—in this case, one invented by Walter Hunt. A lawsuit between Hunt and Howe was decided in Howe's favor. Subsequently, Howe sued Singer.

By 1856, Singer, Baker, Grover, Watson, and Wheeler, all sewing machine manufacturers, were each accusing the others of patent infringement. The president of the Grover and Baker Company, Orlando B. Potter, suggested that the companies would fare better by sharing their patents. Together they brought Howe into their patent pool and formed the Sewing Machine Combination. I. M. Singer and Company was now free to mass-produce machines without fear of lawsuits.

Singer now faced the task of creating a market for his machines. Up to this point, sewing machines had only been used commercially by tailors and harness makers. Singer embarked on huge advertising campaigns aimed at housewives, and he provided an installment payment plan to make the machines affordable to all. I. M. Singer and Company manufactured and sold 2,564 machines in 1856 and built a factory in Scotland to produce machines for the European market.

Singer prospered financially, but his personal life was thorny. He moved to a mansion on Fifth Avenue in New York City with Mary Ann and their children, and in 1860 he divorced Catharine, accusing her of adultery. However, in 1862, when Mary Ann discovered that Singer had started another family with Mary McGonigal, with whom he now had five children, Mary Ann had him arrested for bigamy. Singer, disgraced, moved with McGonigal to London. Later, a fourth wife and daughter, Mary Eastwood Walters and Alice, surfaced in New York. In Europe, Singer left McGonigal, rekindled a relationship with Isabella Eugenie Boyer, and married her, pregnant, in 1863. They moved to Paris and eventually had six children.

In 1863, the I. M. Singer and Company was disbanded and then reorganized as the Singer Manufacturing Company. Singer continued to be a major stockholder, but he no longer was involved with the company's operation. Singer later moved back to England with Isabella and built Oldway Mansion in Paignton. He died there in 1875 and was buried in the Torquay Cemetery.

Impact

In many ways, Singer is the epitome of the nineteenth century American self-made man. Born into an impoverished, immigrant family and on his own at age twelve, Singer learned the machinist's trade through his various odd jobs while pursuing his love of acting. Singer had the uncanny abilities to look at a need for a machine or an existing but impractical device and see how to design or improve it, to be at the right place at the right time, to surround himself with lawyers and financial bankers who could help him achieve his goals, and to use his ingenuity to develop the installment plan and his flair for the dramatic to sell his product.

While Singer did not invent the sewing machine, he improved it so that it could be used reliably and be manufactured at a reasonable cost. These two qualities made it practical to sell the machine to housewives and thus revolutionized sewing in America. The sewing machine could now be used both by commercial entities to sew clothing, harnesses, and even hydrogen balloons, and by domestic housewives to produce family clothing much more rapidly than by hand sewing.

James Murray Spangler

American janitor and entrepreneur

Spangler's electric suction sweeper revolutionized household cleaning in the United States and abroad. His Electric Suction Sweeper Company became the Hoover Company, which grew to be the largest vacuum cleaner company in the world and a leader in innovative marketing techniques.

Born: November 20, 1848; Plainfield, Pennsylvania
Died: January 22, 1915; Chicago, Illinois
Primary field: Household products
Primary invention: Vacuum cleaner

Early Life

James Murray Spangler was born in Plainfield, Pennsylvania, the son of William and Elizabeth Lind Spangler. He came from a large family with five brothers and four sisters. On May 21, 1874, he married Elestra Amanda Holtz. They had three children: two sons, Clarence and Francis, and a daughter, Jennie.

In 1880, Spangler moved his family to Akron, Ohio, where he operated a men's clothing business with one of his brothers. He also worked as a salesman for the Aultman Company, which manufactured portable and traction steam engines. Interested in how things worked and how they could be improved, Spangler invented a grain harvester and a combined hay rake and tedder. He received patents for the equipment in 1887 and 1895, respectively. He then founded a company to manufacture and sell his inventions but was unsuccessful in this business venture.

Despite this setback, Spangler's interest in inventing was not dampened. His next invention was a velocipede wagon. In 1897, he received a patent for it and promptly sold his invention to a Springfield, Ohio, company. Unfortunately, about this time bicycles gained immense popularity and overshadowed the velocipede wagon, resulting in disappointing sales.

Life's Work

Eventually, Spangler took a janitorial job at the Zollinger Department Store in Canton, Ohio. He suffered from asthma, which was severely aggravated when he swept the dusty floors. Spangler became convinced that there was a better way to clean the dust and dirt from floors. Observing a rotary street sweeper in operation, he got the idea for a vacuum cleaner or, as he called it, an electric suction sweeper. Spangler attached a sewing machine motor to a carpet sweeper. He cut a hole in the back of the sweeper and attached fan blades that would blow dust into the attached sweeper bag (a pillowcase). He attached one end of a leather belt to the motor shaft and the other end to a wooden cylinder with a brush roller. He used a broomstick for a handle and a wooden box for the main body of the sweeper. Spangler's invention proved very successful, and he was ready to go back into business.

In September of 1907, he filed for a patent for his electric suction sweeper. Later that fall, he entered into a partnership with Ray Harned, the nephew of F. G. Folwell and W. H. Folwell, the owners of the building in which the Zollinger Department Store was located. Spangler and Harned named their business the Electric Suction Sweeper Company, financed by the Folwells. Spangler was granted a patent on the sweeper in June of 1908. Dissatisfied with the amount of financial backing from the Folwells, Spangler began to search for additional assistance.

Spangler soon found his investor. His first cousin was married to William Henry "Boss" Hoover, a saddle and harness manufacturer. At the time, Hoover was looking for a new product to sell. (With the invention of the automobile, demand for his leather goods was severely diminished.) Hoover's wife had bought one of Spangler's sweepers, which her husband found fascinating. Hoover promptly invested in the Electric Suction Sweeper Company, which started with just six employees who assembled the sweepers in Hoover's saddle and harness shop. By August of 1908, the company had been reorganized, with Hoover as president and treasurer and his son as secretary and general manager, with responsibility for sales and marketing. The firm was headquartered in Canton, but as early as 1911 Hoover began to expand the company by opening a factory in Canada. The first sweeper sold by the company was the Model O, which retailed for $60.

Hoover and his son were instrumental in making the electric suction sweeper a success. They developed innovative marketing techniques to convince consumers to buy this new type of sweeper. The first advertisement for the sweeper appeared in *The Saturday Evening Post* in 1908. It offered potential buyers a free ten-day in-home trial of the sweeper. The sweepers were not, however, sent directly to consumers. Instead, Hoover made them available at reputable stores, thus developing a dealer network for the product. The following year, the company placed a full-page ad in *Collier's*.

The Spangler family was still very involved in the Electric Suction Sweeper Company. Spangler became superintendent and continued to work at the company for a salary. He also received royalties for his invention. Both Spangler's wife and his daughter Jennie made all the bags for the sweepers until 1914, when that work was moved to New Berlin, Ohio. Spangler's son Clarence also worked at the company for a short time. He contracted a terminal disease and died in December, 1911. On January 22, 1915, James Spangler died in Chicago.

The company continued to prosper under Hoover. In 1919, he opened a factory in England, and in 1922 he renamed the company the Hoover Company. He continued to pay royalties to the Spangler family until June 2, 1935, when Spangler's patent expired.

The Electric Suction Sweeper

The electric suction sweeper invented by James Murray Spangler was the first practical portable vacuum cleaner. As early as 1868, Ives W. McGaffey had invented a manually powered cleaner. It was difficult to operate, however, because the user had to turn a hand crank while pushing the device. Other types of vacuum cleaners, including a pneumatic one, were invented during the nineteenth and early twentieth centuries, but none was practical for use as a household cleaner. H. Cecil Booth's Puffing Billy was very efficient at removing dust and dirt, but it was so large that it had to be drawn by horses and parked in the street outside the building to be cleaned.

With his electric suction sweeper, Spangler solved many of the problems associated with the early vacuum cleaners. His cleaner was portable, could be used easily by one person, and had a brush roller to loosen dirt that the cleaner sucked into a bag. The first cleaner that he assembled consisted of a sewing machine motor with fan blades attached to blow dust and dirt into a pillowcase, which served as a bag. He attached the brush roller to the motor with a leather belt. The sweeper was an upright unit with a broomstick handle. The body of the prototype was a hand carpet sweeper with a hole cut in it to permit the dust and dirt to pass into the bag. He soon replaced the carpet sweeper with a wooden box. Spangler continued to improve his sweeper by improving the design. In 1908, the Electric Suction Sweeper Company introduced its first vacuum cleaner, the Model O, which had a sheet-steel body and iron castings. The sweeper was heavily decorated in the Art Nouveau style. The following year, the Senior model was introduced. It had aluminum castings and no decorations.

Although Spangler died just eight years after founding his company, the firm (renamed the Hoover Company in 1922) continued to improve its product and play a significant role in the development and manufacture of vacuum cleaners. In 1926, Hoover engineers developed the metal beater bar, which lightly struck the carpet to loosen deeply trapped dirt. This was a significant improvement to the wooden cylinder with the brush roller of the original electric suction sweeper. The company also introduced innovative designs, including the Constellation, a canister vacuum that hovered on its exhaust. Hoover was the first vacuum cleaner company to make disposable bags. The steam cleaner and the self-propelled cleaner also were first developed by the Hoover Company.

Impact

Spangler's electric suction sweeper made household cleaning easier, more efficient, and healthier, as his vacuum cleaner sucked up dust and debris into a bag. Spangler played a significant role in launching the vacuum cleaner manufacturing industry with the founding of the Electric Suction Sweeper Company. William Hoover's successful marketing of the sweepers under the Hoover name in England resulted in "hoovering" becoming a synonym for "vacuuming" in British English. Spangler's invention also led to new advertising and marketing strategies, particularly in the United States. In-home demonstrations, door-to-door selling, and free home trials were introduced by the Hoover Company.

PERCY L. SPENCER

American electrical engineer

Spencer is best known as the inventor of the microwave oven, one of the most popular household time-, labor-, and energy-saving devices of the twentieth century.

Born: July 9, 1894; Howland, Maine
Died: September 8, 1970; Newton, Massachusetts
Also known as: Percy Lebaron Spencer (full name)
Primary fields: Electronics and electrical engineering; household products
Primary invention: Microwave oven

A chef prepares food with the Raytheon Radarange, the first commercial microwave oven. (Time & Life Pictures/Getty Images)

EARLY LIFE

The childhood of Percy Lebaron Spencer was one of tragedy and deprivation. He was born in a Maine farming community in 1894. His father died when he was eighteen months old, and his mother abandoned him soon afterward, leaving the young Spencer with an impoverished aunt and uncle. At age twelve, Spencer left elementary school to work in a local paper mill to bring much-needed extra income into his household. Four years later, after learning that the mill was to become electrified, he volunteered to assist with installing the electrical system, which provided him with a practical education in electrical engineering.

Inspired by reports of the efforts of wireless telegraphers to rescue victims of the *Titanic* disaster in 1912, Spencer developed an interest in radio, a technology then in its infancy. Joining the Navy as a teenager, he feigned a formal education by teaching himself from textbooks in order to gain admission to radio school. Spencer excelled as a radio engineer and was appointed supervisor of a crew of naval radio operators during World War I. Following his discharge from the Navy, Spencer went to work in the burgeoning radio industry, taking a job with the Radio Corporation of America (RCA) in 1918. In 1922, the Raytheon Company, an early manufacturer of radio components, hired Spencer at the suggestion of his brother John, an engineer with the company.

LIFE'S WORK

During his time at Raytheon, Spencer worked extensively with vacuum tubes, an essential component of early radios. In 1925, after leading radio manufacturer RCA increased the operating voltage of its radios, rendering Raytheon tubes obsolete, Spencer quickly developed a tube compatible with the new radios, saving the most profitable product manufactured by the company and

The Microwave Oven

The small, relatively inexpensive microwave oven so familiar to Americans of the late twentieth century took decades to evolve from early prototypes. The first microwave oven, introduced by Raytheon in 1947 and dubbed the Radarange, was much too cumbersome for household use, standing over five feet tall and weighing more than 750 pounds. The device also required a constant water supply for cooling. The first Radaranges marketed to the public retailed for around $5,000 (more than $48,000 in 2008 dollars), rendering them further out of reach of the average consumer. The first Radaranges were used for cooking on ships and trains and in a small number of restaurants, as well as for other nonculinary commercial purposes such as drying paper and leather. Eventually, mass producers of food realized the potential of microwave ovens and began using them for a variety of industrial and food service applications, such as drying potato chips and roasting coffee beans and peanuts.

Realizing the potential of the microwave oven for household use, Raytheon continued to work toward manufacturing smaller and less expensive microwave ovens throughout the 1950's and 1960's as competitors entered the market. The Tappan Corporation introduced the first home microwave oven in 1952, but this model was still larger than a conventional oven and expensive—at $1,295 (around $10,500 in 2008 dollars)—and thus sold poorly. In the mid-1960's, Litton Industries, another defense contractor with experience in the manufacture of magnetrons, began marketing microwave ovens for household use utilizing a short, wide design that became an industry standard. In 1967, Amana, a subsidiary of Raytheon, introduced a household version of the Radarange with a compact design similar to that of the Litton oven, further increasing the choices available to consumers. Yet the relatively high retail prices of microwave ovens still limited their use to affluent households, and many consumers were still wary of using microwave ovens because of fears of radioactive contamination. Nevertheless, by the early 1970's, a steady decrease in prices had made microwave ovens available to a wider range of consumers. As prices continued to drop throughout the 1970's and 1980's, consumers around the world, attracted by the time- and labor-saving potential of microwave ovens, purchased them in increasing numbers. By the mid-1980's, roughly one-fourth of all American households owned a microwave oven.

By the 1990's, relaxed international trade standards and the availability of cheaper parts had lowered prices to levels far below those of conventional ovens, and American consumers enjoyed access to microwave ovens in a variety of sizes and price ranges. Fears of the potential harmful effects of microwave cooking had largely abated as decades of use yielded no discernible evidence of such effects. At the end of the twentieth century, microwave ovens were more common than conventional ovens, appearing in more than 93 percent of American households and in settings where conventional ovens were impractical, such as offices, college dormitories, and motel rooms.

facilitating Raytheon's growth during the 1920's. During the 1930's, he developed a more efficient vacuum tube for radios that helped sustain the company during the Great Depression. Driven by a seemingly insatiable curiosity, Spencer developed a reputation as a tireless worker who often spent hours in the laboratory dismantling and reassembling parts and devices to familiarize himself with their inner workings and to devise ways of improving them. Devices or materials that other engineers discarded as waste were often a source of inspiration and knowledge for Spencer, who in the course of his research discovered that broken vacuum tubes were capable of emitting large amounts of concentrated photoelectric energy, a discovery that aided the development of cathode-ray tubes for televisions in the 1930's.

During World War II, Spencer worked extensively with radar, a technology still in its experimental stages that involved long-distance detection of airplanes, artillery, and other objects through the use of concentrated electromagnetic waves fired over long distances that would reflect from the objects and reveal them as images on a display screen. The key component of these radar devices was a magnetron, a high-powered vacuum tube from which electromagnetic waves were emitted. As the war intensified, an increasingly urgent demand for the deployment of radar units in the field went unfulfilled because of the slow nature of the production process. At the behest of U.S. and British military forces, Spencer developed a method of mass-producing magnetrons through an innovative laminating process that enabled the tubes to be fashioned rapidly from thin sheets of metal. This process resulted in a dramatic increase in the use of radar units by Allied forces toward the end of the war. In the process of improving production techniques, Spencer also made several improvements to radar devices that rendered them more accurate and effective. In addition, he drew upon his knowledge of radar to develop the proximity fuse, a small radarlike device that could be placed in artillery shells to ensure their detonation at the proper distance from their targets. For his efforts, the Navy presented Spencer with its highest civilian honor, the Distinguished Public Service Award.

Spencer continued experiments with the new technology following the end of the war, winning critical peacetime defense contracts that helped to keep his company afloat during the postwar era. In 1945, Spencer, working to develop an improved radar device, conducted an experiment using a high-powered magnetron. During the experiment, he discovered that the candy bar that he was carrying in the pocket of his lab coat had melted. Intrigued, Spencer subsequently placed a quantity of popcorn in front of the magnetron and watched as it quickly popped. He later placed the magnetron inside a metal box to concentrate the waves further and placed an egg beside the box; the egg reportedly exploded in the face of his assistant as the magnetron heated it from within. Spencer had demonstrated that the radio waves capable of detecting metal objects from a distance by bouncing off them were absorbed by most nonmetallic substances, producing heat from within the substances through a process known as dielectric heating, in which microwave radiation accelerates the motion of molecules within a substance and heat is produced by friction from the contact between the molecules.

Intrigued by the promise of his initial experiments, Spencer began working toward development of a workable device for cooking food with microwave radiation. The primary obstacle to developing this device was devising a means of controlling the power emitted by the magnetron to avoid overheating the food being cooked, a problem that Spencer resolved with characteristic resolve and urgency. Having devised a suitable prototype, Spencer filed for a patent for the microwave oven on October 8, 1945. In 1947, Raytheon introduced the Radarange, the first microwave oven marketed to the public. The company paid Spencer a token fee of two dollars for rights to the patent but soon promoted him to vice president, a position that he would hold for the remainder of his life. In 1958, Raytheon honored Spencer by dedicating a research laboratory to him in Burlington, Massachusetts. Spencer Laboratory remained an active research facility until 1965 and was still owned and occupied by Raytheon at the end of the twentieth century.

The holder of more than 150 patents by the end of his career, Spencer remained active in his field following his retirement from full-time research, continuing as a vice president and senior consultant at Raytheon until his death in 1970 at age seventy-six. Many of his obituaries scarcely mentioned his invention of the microwave, citing instead his relatively obscure work in defense and vacuum tube technology. In 1999, Spencer was inducted into the National Inventors Hall of Fame.

Impact

Despite lacking a high school education, Spencer became recognized worldwide as one of the leading experts in microwave technology and the inventor of the most widely known and frequently used device to utilize the technology, the microwave oven. As a self-taught inventor who developed his inventions in corporate laboratories, Spencer is also symbolic of the shift in focus from the individual to the corporation that characterized technological research in the developed world during the early twentieth century. His invention of the microwave oven is an early example of the adaptation of military technology to consumer applications that would become a dominant force in the U.S. economy during the latter half of the twentieth century. By providing humans with an alternative means of preparing food, the microwave oven produced changes in cuisine, diet, and eating habits, creating demand for new products geared toward the new technology such as microwave-safe cookware and foods prepared and packaged for microwave cooking.

Elmer Ambrose Sperry

American engineer

One of the most prolific inventors in U.S. history, Sperry invented an improved gyrocompass and contributed to significant military projects in the lead-up to World War I. He also possessed the business acumen to turn his inventions into lucrative investments.

Born: October 12, 1860 (baptized); Cortland, New York
Died: June 16, 1930; Brooklyn, New York
Primary fields: Mechanical engineering; military technology and weaponry; navigation
Primary inventions: Gyrocompass; gyrostabilizer; flying bomb

Early Life

Born in Cortland, New York, Elmer Ambrose Sperry tinkered with mechanical devices from an early age. He was fascinated by the machine shops in his hometown and spent many days learning how machines worked. Recognizing the young boy's potential talents, the local YMCA sponsored Sperry on a trip to the 1876 Centennial Exposition in Philadelphia. The central feature of the exposition was Machinery Hall, a massive building filled with all the mechanical and technological achievements of America's industrial age. Amid the massive machines and whirring cogs, Sperry discovered where his future lay.

Sperry subsequently attended two years at Cortland Normal School (now State University of New York College at Cortland), followed by a year at Cornell University. At Cornell, he concentrated on electrical engineering. In 1880, he moved to Chicago, where he founded the Sperry Electric Company to manufacture dynamos and arc lamps.

Life's Work

Sperry's new firm specialized in urban lighting systems, and Sperry designed the electric street lighting for a number of large American cities, earning him a fortune in contracts. In 1887, Sperry married Zula Goodman, with whom he had four children. The next year, he established the Sperry Electric Mining Machine Company to manufacture machines for mining. After observing many American mines still using obsolete steam machinery or even brute manpower, Sperry began to design systems to electrify the mines. Starting with electric lighting to illuminate deep shafts, he followed with electric drills, hoists, and sorters that sped up the pace of production and improved safety.

Sperry next turned his attention toward electric streetcars. In 1890, he organized the Sperry Electric Railway Company, and he designed a streetcar that used electricity more efficiently and could run longer on a single charge than other models. He first sold the design to the city of Cleveland, Ohio, and other cities purchased his design after seeing its success. Sperry would continue to develop railroad technology for the rest of his life. In 1911, he established the Sperry Rail Service, which developed devices for testing railroad lines and locating rail defects to reduce accidents.

Sperry also improved on existing searchlights, using better lens design to increase their brightness without increasing their weight. The searchlight was adapted to serve as a beacon in a number of lighthouses and airfields in the early twentieth century, giving Sperry still more public exposure.

His greatest achievement came in 1911, when he received a U.S. patent for his gyrocompass, a nonmagnetic compass that indicates true north. In 1910, Sperry founded the Sperry Gyroscope Company in Brooklyn, New York, and his gyrocompass underwent its first trial in 1911, when it was installed on the U.S. battleship *Delaware*. Before Sperry's invention, ships relied on magnetic compasses. These devices do not point to true north; instead, they point to magnetic north. The true North Pole is the axis around which the Earth revolves, while the magnetic North Pole is the positive pole of the Earth's magnetic field, which is some distance from the North Pole. Thus, while magnetic compasses are generally accurate and practical for most basic purposes, they are not precise enough when speed and efficiency are of the essence.

Magnetic compasses were useful on ships made of wood, but they were practically worthless on iron ships, which appeared in the nineteenth century. The metal hull of the ship affected the magnetic field around the vessel, degrading the accuracy of the magnetic compass. Electrical systems on the ship also hampered the compass's accuracy. Sperry's compass, harnessing the gyroscope, solved the problem. The spinning gyroscope aligned itself to the spinning of the Earth, maintaining a north-south orientation. With the gyrocompass locked onto the north-south line, any relative movement could be measured to determine course direction, measured as degrees off the north-south alignment. Consequently, not only were north and south determined accurately, but relative movement east-west also was very precise.

Sperry's gyrocompass design was an improvement on German scientist Hermann Anschütz-Kaempfe's gyrocompass. When Sperry tried to sell his version to the German navy, Anschütz-Kaempfe sued Sperry for patent infringement. In 1915, a German court ruled in Anschütz-Kaempfe's favor, largely because, with World War I going on, Sperry refused to risk his life to go to Germany to defend himself. The U.S. Patent Office upheld his U.S. patent, however, and Sperry continued to produce gyrocompasses. Gyrocompasses can still be found on ships today, although satellite navigation has largely supplanted them.

Sperry found other applications for the gyroscope. In 1913, he received a patent for a gyrostabilizer, a device to control the roll, pitch, and yaw of a moving ship. Before Sperry's invention, even the largest ships were at the mercy of the sea. Sperry's gyrostabilizer was a powered gyroscope mounted in the center of the ship's hull and attached by linkages to fins mounted on the sides of the ship. At sea, the gyrostabilizer measured the movement of the hull relative to the stable gyroscope. By accurately measuring how much the ship moved, the gyrostabilizer could then actuate the external fins to dampen the roll, pitch, or yaw. The device could not completely compensate for a ship's movement, but it smoothed out the ride considerably. Moreover, as an automatic device, it acted more quickly and more precisely than could a human at the fin controls. In the 1920's, Sperry invented "Metal Mike," the first automatic pilot for ships. Sperry's autopilot allowed a ship to follow a straight course and to maintain a set speed without direct intervention. This made it easier to steer a ship because helmsmen no longer had to constantly make minute adjustments to the ship's wheel and throttle.

Like many scientists and inventors, Sperry worked on military projects during World War I. His most prominent invention was a precursor to the cruise missile. Sperry, working with his son Charles and Peter Cooper Hewitt, developed the "flying bomb," an unmanned aerial vehicle also known as an aerial torpedo. Hewitt was a pioneer in radio technology, and Sperry believed that Hewitt could provide the expertise to use radio waves to control a gyrostabilizer by remote control. Glenn H. Curtiss, the famed aircraft designer, aided with the aircraft components. After a number of failed flights in 1917, the group found success on March 6, 1918. The flying bomb flew more than half a mile under radio control and struck its intended target. Using a modified Curtiss N-9 airframe, the flying bomb flew for nearly eight miles in a test in October, 1918. However, the war ended a month later, the flying bomb project was canceled, and

The Gyrocompass

Elmer Ambrose Sperry's gyrocompass consists of an electrically driven gyroscope whose wheel is mounted within two gimbal rings attached to a base. This design allows the wheel to move in any direction. Employing the principle of angular momentum, the constantly spinning wheel remains in the same location and attitude unless acted upon by an external force. The angular momentum of the device interacts with the rotational force of the Earth to maintain orientation to the north-south line. The heavy base prevents the mount from shifting and also serves to isolate the gyrocompass from any outside magnetic influence. This is one of the great weaknesses of magnetic compasses on an iron ship, whose own magnetic field throws off the compass. Isolated from magnetic force, the gyrocompass has no such interference. Also, unlike the magnetic compass, the gyrocompass points to true north rather than magnetic north, a crucial feature for precise navigation.

Other factors that might affect a magnetic compass—electricity, inert metals, or the temperature of the device—have no effect on the gyrocompass. An electric motor powers the gyrocompass to ensure that the wheel continues spinning, and a metal housing usually covers the gyrocompass to prevent any outside effect on the gyroscope. Its tolerance for all types of weather makes the gyrocompass a popular means of navigation in many hostile environments.

the world would have to wait for the emergence of the cruise missile. The project got Sperry interested in automatic control for airplanes, and he developed several basic designs based on his ship autopilots. Sperry was still working on the project when he died in 1930 at the age of sixty-nine.

Impact

During his lifetime, Sperry founded eight companies and received some four hundred patents. His inventions made rail and sea travel safer, opening the world for exploration by common people. Many of his inventions, including his autopilot designs, utilized gyroscopic principles. His most famous invention, the gyrocompass, was used by Allied navies during the two world wars. In his will, Sperry left a large portion of his estate to the YMCA, the organization that opened his eyes to the future of mechanical engineering.

Frank J. Sprague

American electrical engineer

Often called the "father of electric traction" for his development of the first commercially successfully electric railway system, Sprague was also well known for his inventions related to the electric elevator and the multiple-unit system of automatic control of electric railways.

Born: July 25, 1857; Milford, Connecticut
Died: October 25, 1934; New York, New York
Also known as: Frank Julian Sprague (full name)
Primary field: Electronics and electrical engineering
Primary inventions: Electric elevator; electric motor; electric traction system

Early Life

Frank Julian Sprague (sprayg) was the second of three sons of David Cummings Sprague, a hat-factory superintendent, and Frances Julia (King) Sprague. Born in 1857, he grew up and began grammar school in Milford, Connecticut, but after his mother died in 1866, he was sent to be cared for by an aunt in North Adams, Massachusetts. Here he completed his elementary education and then attended Drury High School, where he excelled in his science and mathematics courses. Seeking to further his scientific and technological training, he entered the competition for the limited number of slots at the United States Naval Academy. Although he won an appointment to the 1874 class, he needed to borrow $400 to pay for his travel to Annapolis, Maryland, and for his initial expenses.

During his four-year education at the Academy, he was always among the leading midshipmen in his classes, but especially in physics and chemistry. He passionately enjoyed laboratory work, even spending Saturday afternoons in experimental studies. His commanding officers later noted that it was through these courses that Sprague discovered his true vocation as an engineer and inventor. At the commencement ceremonies, attended by President Rutherford B. Hayes, Sprague graduated seventh in his class of thirty-six.

Life's Work

Commissioned as an ensign, Sprague experienced his first naval service aboard the USS *Richmond*, the flag-

The First Commercial Electric Traction System

Just as there had been numerous incandescent lamps before Thomas Alva Edison, so too had there existed numerous experimental electric traction systems before Frank J. Sprague. During his naval career and his short time with Edison, Sprague had developed a versatile electric motor along with ideas of how to use it to power vehicles on tracks (so-called electric traction). When he formed his company and signed a contract with Richmond, Virginia, to install a twelve-mile electric railway, he had the chance to turn his dream into a reality.

Sprague approached the project as if it were a wartime task, and he in fact hired some former military engineers to help him. The contractor responsible for the track had been forced to include several steep grades and sharp curves along the route, which meant that Sprague had to redesign his electric motor to provide the variable power that would be needed. He mounted his motor so that it was geared directly to the axle, in a "wheelbarrow" arrangement that was widely adopted, since it helped to maintain motor-axle alignment no matter how irregular the car's motion. By experimenting with many different ways of bringing electricity to the moving cars, Sprague and his team found a satisfactory swiveling trolley pole that maintained contact with the overhead electrical wire even around sharp curves. When the system began service, other problems arose—for example, the brass brushes bringing current to the rotating part of the motor created a metallic dust (a "golden road") that contributed significantly to operational costs. This and additional problems were later solved by Sprague and others, but he was already beyond the time constraints of the project. He did lose $75,000 of his contracted fee, but the line was so successful that, during the next decades, cities using Sprague's system proliferated all over the world. Soon horse- and mule-powered streetcars were things of the past.

ship of the Asiatic fleet, part of whose mission was to facilitate newly retired president Ulysses S. Grant's triumphal world tour. From his letters and notebooks, historians learned that Sprague was keeping abreast of advances in the new electric lighting and telephone industries, and that he began designing, on paper, his own electric motors and telegraph systems. On his return to the United States, he used his leave to perform experiments at Stevens Institute, where he met William Wallace, an inventor who had developed dynamos for arc-lighting systems, and Moses G. Farmer, an inventor whose electric lighting system antedated Thomas Alva Edison's.

In 1881, Sprague was assigned to the USS *Minnesota*, and when his ship docked in Rhode Island, he was able to visit Farmer, who was then official electrician at the U.S. Torpedo Station in Newport. Sprague was able to gain valuable experience working with Farmer on a new kind of dynamo, and this "inverted" type of dynamo became one of his first inventions. In 1882, when he was transferred to the USS *Lancaster*, the flagship of the European fleet, he was able, during the ship's tour of the Mediterranean, to install an electric call-bell system, the first of its kind in the U.S. Navy. He obtained permission to visit electrical exhibitions in Paris and London. While traveling on London's steam-powered underground railway, he began to think of the benefits of using electricity instead of steam. At the Crystal Palace site, he served as a secretary on a jury whose duty was to confer awards on the most innovative gas engines, dynamos, and incandescent lamps. Even though his leave was up, he remained in England to present a paper to the British Association for the Advancement of Science on Edison's new method of delivering electricity. When he finally returned to his ship, he prepared a report on his experiences, which was later published by the Navy Department in Washington and probably saved him from a court-martial.

By this time, it had become clear to Sprague that his future was as an electrical engineer rather than a naval officer, and when, in 1883, Edward H. Johnson, an Edison associate he had met in London, urged him to resign from the Navy and work for Edison, he did just that. A few years earlier, Edison had built an experimental electric railway line at his facilities in Menlo Park, New Jersey, and Sprague thought he would be put to work on that project, but he became the electrical expert in Edison's new Construction Department. He helped install the central station and overhead distribution system for electric lights in Sunbury, Pennsylvania. He also invented a formula for determining the optimum ratio of wire size to electric current, and he created an improved electric motor readily adaptable to various industrial machines. However, Sprague chafed as an Edison subordinate, and in his 1884 letter of resignation he stated that what Edison had done for the electric light he wanted to do for the electric railway.

Together with Johnson, Sprague founded the Sprague Electric Railway and Motor Company, which had an early success with Sprague's constant-speed motor, which was mainly manufactured by the Edison Machine Works. Sprague now felt financially secure enough to marry Mary A. Keating in New Orleans, Louisiana. (The couple would have one son before eventually divorcing.) Sprague then spent time developing a generating (and regenerating) electric power system that he would later use to propel railway cars up steep grades and elevators in high buildings. He signed what he once called "a foolish contract" to furnish Richmond, Virginia, with an electric railway system in only ninety days, for which his company would receive $110,000. Because the route involved hills and curves, Sprague had to devise a motor that could efficiently respond to these demands and an electrical delivery system that involved an overhead trolley. Because of the time needed to solve these problems, Sprague missed the deadline and was penalized, but the Richmond trolley line proved to be so successful that, within two years, more than one hundred electric railroads that used Sprague's innovations were in existence in many U.S. and European cities and towns.

During his work on the Richmond system, Sprague purchased most of his company's equipment from the Edison General Electric Company, and in 1890 this company took over Sprague's. He was willing to let this happen because his attention had turned from horizontal transportation to a new venture, the vertical transportation of an electric elevator. In 1892, he founded the Sprague Electric Elevator Company to capitalize on the need for safe and swift transport in the increasingly taller buildings that were being built in American cities. With Charles R. Pratt, he designed an electric elevator that could travel faster and lift heavier loads than hydraulic and steam elevators. He proved the feasibility of his invention by constructing six elevators for the New York headquarters of the Postal Telegraph Company. After building hundreds of elevators for the tallest buildings in the world, Sprague sold his business to the Otis Elevator Company and focused his attention on developing a multiple-unit control system for electric trains.

In 1897, Sprague was able to convince Chicago officials that his new company could electrify the city's sole steam-powered elevated railway via a new system, in which each car had its own electric motor, though all were controllable by master switches in every car. This made possible long trains, with a concomitant gain in efficiency and revenue. Sprague oversaw the construction of the first multiple-unit system for the Chicago South Side Elevated Railway, and its great success led to similar installations in Manhattan, Brooklyn, and Boston. Buoyed by his new prosperity, he married Harriet Chapman Jones, a happy marriage that resulted in three children and lasted until his death. Repeating a pattern from his past, he sold his company to General Electric in 1902, and he then went on to found the Sprague Safety Control and Signal Corporation to make railway travel safer by designing automatic controls that necessitated compliance with trackside signals.

During Sprague's later career, he and his family lived in New York with a summer home in Connecticut, and his successes in fostering electric power led to his serving, in various roles, the electrical engineering profession as well as several cities, states, and the federal government. He continued to invent; for example, he created small electric power units suitable for machine tools, printing presses, dentists' drills, and home appliances. During World War I, he was a member of the Naval Consulting Board and helped develop the depth charges that were used against German U-boats. He received medals from the Franklin Institute and the American Institute of Electrical Engineers, an organization that he had served as president. In 1934, while he was terminally ill with pneumonia, he learned that he had been awarded the John Fritz Medal, and he was also able to examine a model of his latest invention. After his death in New York, he was buried in the National Cemetery in Arlington, Virginia.

Impact

Sprague was a pivotal figure in helping to transform the United States and much of the world from steam to electrical power. He was a leading innovator in a revolution in urban horizontal and vertical transportation. He was a member of a new breed of mathematically and scientifically trained engineers whose methods of discovery were more efficient than the trial-and-error techniques employed by such early inventors as Edison. In his lifetime, Sprague was often linked with Edison and Alexander Graham Bell as the "remarkable trio" of American inventors whose discoveries made possible modern electric-powered civilization. Unfortunately, since Sprague's death and the growth of what some have called the "Edison myth," the reputation of Edison has grown while that of Sprague has dwindled.

With the publication of Edison's private papers and notebooks, scholars now see that Edison had a propensity for claiming the innovations of his associates as his own. Sprague was particularly irked by Edison's assertion that he (Edison) had pioneered electric railways. Sprague had a nimble-witted mind, bubbling over with imaginative new ideas, and his assiduous energy propelled the best of his ideas into successful industries. His ideas facilitated the growth and prosperity of cities, and modern environmentalists note with sadness that his energy-efficient electric transportation system went into decline because of the aggressive marketing of less-efficient gasoline-powered automobiles, buses, and trucks. Although he never achieved the lasting fame of Edison, and although his inventions were not as many or as varied, his contributions to the expansion of electric-powered civilization rivaled, if not surpassed, those of his first employer.

RANGASWAMY SRINIVASAN

Indian research scientist

Srinivasan pioneered ablative photodecomposition (APD) of organic materials using ultraviolet radiation. APD is extensively used in etching microcircuits and in laser-assisted in situ keratomileusis (LASIK), the surgical correction of myopia and astigmatism of the human eye.

Born: February 28, 1929; Madras, India
Primary fields: Chemistry; physics
Primary invention: Ablative photodecomposition

EARLY LIFE

Rangaswamy Srinivasan (RAHN-gah-swah-mee SHREE-nih-vah-sahn) was born in Madras, India, the youngest of four children born to Vedammal Rangaswamy and Rangaswamy Iyengar of the Iyengar community of southern India. He studied at the Pennathur Subramaniam (P.S.) High School in Mylapore, Madras, and Loyola College, Madras. He received a B.Sc. in chemistry (1949) and M.Sc. in physical chemistry (1950) from the University of Madras. Arriving in the United States in 1953, he received his Ph.D. in physical chemistry from the University of Southern California (USC) in 1956. He did postdoctoral research at USC (1956) and the University of Rochester, New York (1957-1961), before joining International Business Machines's research center in Yorktown Heights, New York. He won a Guggenheim Fellowship in 1965-1966. Srinivasan's early work on organic photochemical syntheses led to a book coauthored with Thomas Roberts in 1971.

LIFE'S WORK

Srinivasan's subsequent work focused on what he termed ablative photodecomposition (APD), a phenomenon of etching or drilling of organic solids such as plastics or tissue without any thermal damage to the surrounding substrate. The first lasers generated power in the infrared and later the visible part of the spectrum, but

Rangaswamy Srinivasan was inducted into the National Inventors Hall of Fame in 2002 for his pioneering work in the field of LASIK eye surgery. (AP/Wide World Photos)

very little in the ultraviolet (UV). IBM reports in 1974 and 1975 discussed Srinivasan's team's photochemical studies on organic dye lasers to generate tunable UV power. In 1970, Nikolay Gennadiyevich Basov and colleagues at the Lebedev Institute of Physics in Moscow invented the pulsed excited-state complex (exciplex) excimer laser. In the late 1970's, high-power excimer lasers became available in the United States as spin-offs from CO_2 laser research by Northrop Corporation inventors (Manilal Bhaumik, U.S. Patent number 4,063,192, 1977). This opened opportunities for precise cutting applications in making microcircuits. Intense pulses of several different wavelengths in the far UV could be produced by using different gases.

Dr. Srinivasan's discovery of ablative photodecomposition set off a flurry of research and led to the development of the LASIK eye surgery procedure. He authored more than 220 publications in refereed journals and a large number of conference papers and other presentations. A 1983 paper reported on depositing metal films on polymer surfaces photo-oxidized with UV radiation at 185 nanometers (nm). Several other papers in 1983-1985 discussed etching polymers using APD, indicating a drive toward better microcircuits. Publications on APD with organic tissue appeared in 1986, and on the dynamics of UV laser ablation of corneal tissue in 1987. Studies on laser pulses in the 100-femtosecond regime continued with different wavelengths and organic materials. A 1990 paper reported on using two simultaneous, coincident pulses of different wavelengths to ablate organic polymers. The emphasis then appeared to shift back toward longer (10-400 microseconds) pulses and then to continuous-wave (cw) radiation.

Srinivasan has twenty-two patents. U.S. Patent number 3,986,140, "2,4,6 Trisubstituted Pyridine Dye Lasers" (1976), by Channabasappa Angadiyavar and Srinivasan of IBM, describes an acidic dye solution and a pumping energy source combined into a dye laser operating between 410-nm (violet) and 570-nm (green) wavelengths. The maximum power of the output pulse is around 70 kilowatts. U.S. Patent number 4,414,059, "Far UV Patterning of Resist Materials" (1983), by Samuel E. Blum, Karen Brown, and Srinivasan, describes a technique to fabricate devices and circuits using multiple layers of materials, where material in the resist layer is selectively removed by APD. Energy at wavelengths below 220 nanometers is delivered in pulses exceeding 10 millijoules (mJ) per square centimeter, enough to fragment polymer chains and ablate the material, with no further processing required to make the desired pattern.

U.S. Patent number 4,417,948 (1983), issued to Veronica Mayne-Banton and Srinivasan, describes a self-developing technique for photoetching polyesters such as polyethylene teraphthalate (PET) by UV irradiation, removing material to at least 1,000 angstrom depth without degrading or heating the bulk of the PET material. This technique could be done in the presence of oxygen or air. U.S. Patent number 4,440,801 (1984), by Ari Aviram, Mayne-Banton, and Srinivasan, describes how to achieve electroless deposition of metals such as copper, silver, or gold onto a polymer substrate by preparing the areas to be deposited and then treating those areas with UV. Another patent (number 4,451,503, 1984), issued to Blum, Brown, and Srinivasan, shows how to deposit metals by UV photodecomposition of metal vapor rather than the substrate: A tungsten layer is deposited on a gallium arsenide substrate to form a Schottky diode. U.S. Patent number 4,568,632 (1986), by Blum, Karen L. Holloway, and Srinivasan, describes photoetching of polyimides with pulses of 60 mJ per square centimeter, with oxygen enhancing the etching rate. Another patent issued in 1986 extended the invention to a multilayer glass-metallized structure interconnected to multilayered metallized ceramic substrate. The UV laser was now used as a construction tool, drilling holes and forming the attachment points between layers.

Srinivasan's most important patent, shared with Blum and James E. Wynne, is "Far Ultraviolet Surgical and Dental Procedures" (number 4,784,135). Issued in 1988, the patent details the method and apparatus for removing organic biological matter using pulsed or cw radiation, specifically at 193 nanometers. U.S. Patent number 4,925,523 (1990) describes the use of a second pulse with a 308-nm xenon-chloride laser that follows the initial etching pulse with a 193-nm argon-fluoride laser, delayed by about twenty to thirty nanoseconds. This combination greatly improved the rate of etching while keeping the heating effects minimal. Typically, five hundred pulse pairs of this type were used for each etching. U.S. Patent number 5,246,885, issued to Bodil Braren, Brown, and Srinivasan in 1993, describes a method of superior fill of features in semiconductor processing using laser ablation.

Srinivasan has worked as a visiting research professor at the Edward S. Harkness Eye Institute of the Columbia-Presbyterian Medical Center (1984-1990); the Wellman Laser Lab, Harvard Medical School (1987-1989); and the City University of New York. Since 1990, he has headed UVTech Associates, a New York consulting firm. He is a fellow of the American Institute of Physics, the New York Academy of Sciences, the Association for the Advancement of Science, the American Physical Society, the Inter-American Photochemical Society, and the American Society for Laser Medicine and Surgery.

Ablative Photodecomposition for LASIK

How does an engineer dig a neat trench just a few micrometers deep to lay microcircuits? The traditional approach was to etch the trench through a mask using a solvent such as an acid. This messy and expensive process involved many complex steps. In the 1970's, researchers at International Business Machines (IBM) were looking for a method for etching neat trenches. They found that lasers could be precisely focused to very high intensity but that infrared or visible lasers caused intense heating, destroying the material around the trench. Physical chemists such as Rangaswamy Srinivasan discovered ultraviolet (UV) wavelengths that would be absorbed directly into the chemical bonds of certain substances, causing them to ablate (vaporize and leave the surface) and losing little heat to the surrounding material. This was ablative photodecomposition (APD). The problem was finding a strong, precise UV source.

With the introduction of the excimer laser in the late 1970's, a solution was found. The nanosecond (ns) lifetimes of the excited-state molecules that released the laser energy produced intense nanosecond-long pulses compared to the microsecond pulses of dye lasers. (A nanosecond is one-thousandth of a microsecond.) It is helpful to note that a 1-millijoule (mJ) pulse delivered in 1 ns is equivalent to 1 megawatt, whereas the same pulse delivered in 1 microsecond is equivalent to only 1 kilowatt, which is one-thousandth of a megawatt.

In 1981, Srinivasan and IBM colleagues Samuel E. Blum and James E. Wynne conducted APD experiments on various materials. The ablated cells could be washed or would blow away at supersonic speed without damage to the surrounding substrate. Using a turkey bone from that year's Thanksgiving dinner, the researchers discovered that 193-nanometer (nm) UV pulses from an excimer laser would cut away the surface layer of organic tissue precisely and neatly, compared to incisions made with a continuous-wave green laser. Given the well-known heat sensitivity of human hair, electron micrographs of the IBM logo made by APD on a human hair powerfully demonstrated APD as a method for surgery as well as for micromachining of polymers and plastics.

The most famous surgical application of APD improves the keratomileusis procedure, in which thin flaps are cut from the cornea of the human eye to change lens curvature. Spanish opthalmologist Jose Barraquer had developed a thin knife called a microkeratome around 1950. Starting in 1983, opthalmologists in New York tested APD using lasers provided by the IBM group. The surgical reshaping of the cornea using APD won approval from the Food and Drug Administration (FDA) in 1995. Thus was born laser-assisted in situ keratomileusis (LASIK).

Blum, Srinivasan, and Wynne's 1988 patent, titled "Far Ultraviolet Surgical and Dental Procedures," describes the method and apparatus for removing organic biological matter using pulsed or continuous-wave radiation, specifically at 193 nanometers. The technique is "a method for removing selected areas of a biological layer comprised of organic material" by irradiating with several pulses of UV below 200 nanometers. The pulse intensity is about 10 mJ per square centimeter. Today, more than five million people worldwide have undergone LASIK surgery to improve their vision.

He was elected to the U.S. National Academy of Engineering (NAE) in 1999 and inducted into the National Inventors Hall of Fame in 2002. He has won numerous prizes and medals from professional societies. He has pursued his interest in history and archaeology to write a book on events in nineteenth century British-ruled southern India, where his grandfather served as a public prosecutor.

Impact

As Srinivasan's patents and papers demonstrate, the applications of ablative photodecomposition have multiplied over the years, ranging from microcircuit manufacture to dentistry to ophthalmology and other fields of surgery, down to the single-molecule level. Srinivasan's NAE citation reads: "For ultraviolet laser processing of polymers and its extension to refractive surgery of the cornea." LASIK surgery, which uses APD, has improved the eyesight of more than five million people worldwide.

Charles Proteus Steinmetz

German electrical engineer

Steinmetz made the everyday use of alternating electrical current practical by developing the mathematics necessary to calculate answers to practical problems. He was also instrumental in producing the techniques of transmission of electricity over long distances.

Born: April 6, 1865; Breslau, Prussia (now Wrocław, Poland)
Died: October 26, 1923; Schenectady, New York
Also known as: Karl August Rudolf Steinmetz (full name)
Primary field: Electronics and electrical engineering
Primary invention: Alternating-current calculations

Early Life

Named Karl August Rudolf Steinmetz at birth, Charles Proteus Steinmetz was born in 1865 in Prussia to German Protestant parents. His father, Carl Heinrich, worked for the railroad as a lithographer; he was later promoted to preparing train orders. His mother, Caroline Neubert Steinmetz, had two daughters by a previous marriage. Like both his father and grandfather, Steinmetz was afflicted with dwarfism, kyphosis ("hunchbackism"), and hip dysplasia. When he was only one year old, his mother died of cholera. His father then asked his own mother to live with his family. Steinmetz grew up in a home with his father and four women: his paternal grandmother, his father's sister, and his mother's two daughters by her first husband. As the youngest child and only boy in a house full of women, Steinmetz was spoiled by his family, especially his grandmother.

Steinmetz began his schooling at the age of five and a half. At first, he was a slow student, but he soon began to excel. He eventually graduated from high school with honors and entered the University of Breslau, where he

Charles Proteus Steinmetz. (Library of Congress)

studied for six years. In contrast to the behavior of many European university students of his era, he faithfully attended his classes and did all the suggested work. Although he completed all the work necessary for a doctoral degree, including a thesis, his studies did not prevent him from participating in social activities. He was particularly interested in the university students' socialist club. After the editor of the student socialist newspaper was jailed, he became its editor. However, this was a time when the Prussian government was building an empire and frowned upon socialism, and Steinmetz's political activities led to the government issuing a warrant for his arrest in 1888. Warned by friends that his arrest was imminent, Steinmetz fled to Austria and then to Zurich, Switzerland. He left Prussia without receiving his doctoral degree and without even being able to tell his family he was going. During half the year he remained in Zurich, he studied mechanical engineering at Zurich Polytechnic School.

Through his socialist friends, Steinmetz met a man named Oscar Asmussen, who invited him to return to the United States with him. Steinmetz had no money for the voyage, but Asmussen offered to pay his passage if they both traveled by steerage, the cheapest form of shipboard travel. When they arrived in the United States, Asmussen vouched for Steinmetz to immigration officials, who were reluctant to admit a dwarf who spoke little English into the United States. Within two weeks of his arrival, Steinmetz used a letter of introduction to American electrical engineer Rudolf Eickemeyer to obtain a job as a draftsman with Eickemeyer's company, Osterheld and Eickemeyer. In an effort to sound more American, Steinmetz changed his name from Karl to Charles and dropped August Rudolf. Noting that gentlemen generally had middle initials, he chose *P* for "Proteus," a nickname he had picked up during his university days. (Proteus was a Greek god who could take on any shape or form.)

Life's Work

Shortly after taking up his new position at the Osterheld and Eickemeyer company in Yonkers, New York, Steinmetz attended a lecture on alternating current in which a paper titled "Armature Reaction of Alternators" was presented. When he pointed out that the paper had failed to discuss the third harmonic, he was told that inclusion of the third harmonic would have made the presentation overly complicated. Steinmetz could not tolerate that omission, however, and worked out his own presentation—encompassing the third harmonic—which he presented three weeks later.

Any engineer designing an electrical apparatus using alternating current confronts the problem of hysteresis—the diminution of electrical power caused by changing magnetizing force. When electric current alternates, the north and south poles change places, but they do not do so instantaneously. The delay is called hysteresis. Steinmetz determined that hysteresis is proportional to the magnetism generated by the current. This causes a power loss that generates heat. In fact, a poorly designed apparatus can become red-hot. Steinmetz presented his law of hysteresis in the journal *Electrical Engineer* on December 8, 1891. His theory was immediately recognized as an important contribution to understanding electricity and remains an important part of electrical engineering to the present day.

The subject of Steinmetz's greatest success, alternating current, was less expensive to use and safer than direct current (such as that used by batteries), but no one knew how to calculate values for alternating current circuits. By this time, Eickemeyer's company had been bought by the new conglomerate known as General Electric, which wanted not only the patents Eickemeyer's company owned but also Steinmetz himself. So greatly did Steinmetz respect Eickemeyer that when the latter advised him to work for General Electric, Steinmetz went without hesitation. In Schenectady, New York, where General Electric eventually located him, Steinmetz conquered the problem of calculating alternating-current values. To do this, he devised a new way to express the problems in what he called a symbolic system.

Steinmetz believed that his three most important achievements were his mastery of electromagnetism, his invention of a practical way to calculate values for alternating current, and his research into lightning. His research on lightning would eventually be cut short by his comparatively early death, but he managed to develop a lightning arrester that senses lightning, opens a line to ground, and then stops electricity from following the lightning to the ground.

Steinmetz also invented devices to protect high-voltage power lines from lightning strikes, new types of electrical transmission cables, improvements to electrical transformers, and new methods of operating transmission systems. He designed an electric car and organized a company to produce it, but his company folded after his death. Before he died, he registered nearly two hundred patents and published several books, including works on alternating current, a history book, and a collection of lectures on relativity and space, in which he tried to explain Albert Einstein's theories to lay readers.

During his last ten years, Steinmetz taught at Schenectady's prestigious Union College without pay while working at General Electric part time. He became dean of the college's engineering school, whose curriculum he revamped. He also helped to reform the public schools of Schenectady and gave every orphan in the town a gift every Christmas. Universally well liked, Steinmetz was a bit of a prankster. He enjoyed weekly poker games and smoked cigars almost constantly. Although he never married, he was an outgoing, social person and took a young engineer, J. L. Hayden, and his family into his own household. On October 26, 1923, shortly after a Pacific Coast trip with Hayden, and his family Steinmetz died of a heart attack in Schenectady at the age of fifty-eight.

Alternating-Current Calculations

Charles Proteus Steinmetz once noted that "absolutely all the success I have had has been due to my thorough study of mathematics." Possibly the most outstanding invention of Steinmetz's mathematical mind was his ability to visualize an entirely new way to describe alternating current (AC). To see AC as a single number—even a complex number—was a concept that no one else had grasped. To simplify AC calculations, Steinmetz devised a new method. Before his time, AC had been described with a time-dependent equation that required graphical methods to show values of current at particular moments. Recognizing that this was not a practical way to make calculations, Steinmetz developed a system of symbols to use in AC calculations.

Steinmetz's method of making AC calculations was important because it made it possible for electrical engineers to design electrical devices and systems, such as machinery and power lines, so that their performance would be predictable. Prior to Steinmetz's calculations, an electrical system would have to be built first, then tested for efficiency—a very expensive and time-consuming approach. Steinmetz's system made it possible for electrical engineers to understand and work with alternating current and proved critical in the building of electric infrastructure at the turn of the century.

In 1893, Steinmetz presented his new method to the International Electrical Congress; its proceedings were not published until four years later. In the interim, Steinmetz's work could be used only by those whom he taught himself. His complete system filled three volumes and was understood by only a few people at that time. Moreover, only scientists with outstanding mathematical abilities could follow what Steinmetz had done and understand his symbols. Steinmetz explained his system again in *Theory and Calculation of Alternating Current Phenomena*, a book he published in 1897 with the help of Ernst Julius Berg. Steinmetz also wrote a textbook for college students, *Theoretical Elements of Electrical Engineering* (1902), and one for high school students, *Engineering Mathematics* (1911).

As dry and technical as these texts seem today, Steinmetz was not simply a mathematical genius. He put his abilities to sound practical use. Ignoring and overcoming the social obstacles his dwarfism may initially have provoked, he was loved by many and legendary for his sense of humor. On one occasion in 1902, when General Electric hired him to fix a system that no other technician had been able to repair, he billed the company ten thousand dollars—an enormous sum in 1902—for placing a chalk mark at the point where the system was broken. Balking at this fee, General Electric's managers requested an itemization. Steinmetz responded with the following list: "Making the chalk mark, $1. Knowing where to place the chalk mark, $9,999."

Impact

All engineers who work with electricity owe Steinmetz a debt of thanks. Without his new methods of calculating values of alternating current, electrical power would have spread more slowly, and fewer applications for it would have been developed. Electrical motors, kitchen appliances, power tools, televisions, computers, and hundreds of other devices would not have evolved as they have.

Until Steinmetz developed the law of hysteresis, the amount of hysteresis and power loss could not be calculated for electrical apparatuses, which had to be designed, built, and tested to determine how they would work with alternating current. Devices that lost too much power and became too hot were discarded and new apparatuses were designed. Thanks to Steinmetz's mathematical equations, engineers could calculate and predict power losses and heat gains due to magnetism before the apparatuses were built. This foreknowledge enabled them to design apparatuses that generated less magnetism and thereby experienced less power loss.

Steinmetz became aware that many engineers did not have the mathematical background to understand the theories and calculations that he was publishing. His textbooks on mathematics, which start very simply and build to what the engineers need, are still copied today, as is his text on electrical engineering. He even provided the mathematical background needed by electrical engineers, starting at the high school level.

George Stephenson

English mechanical engineer

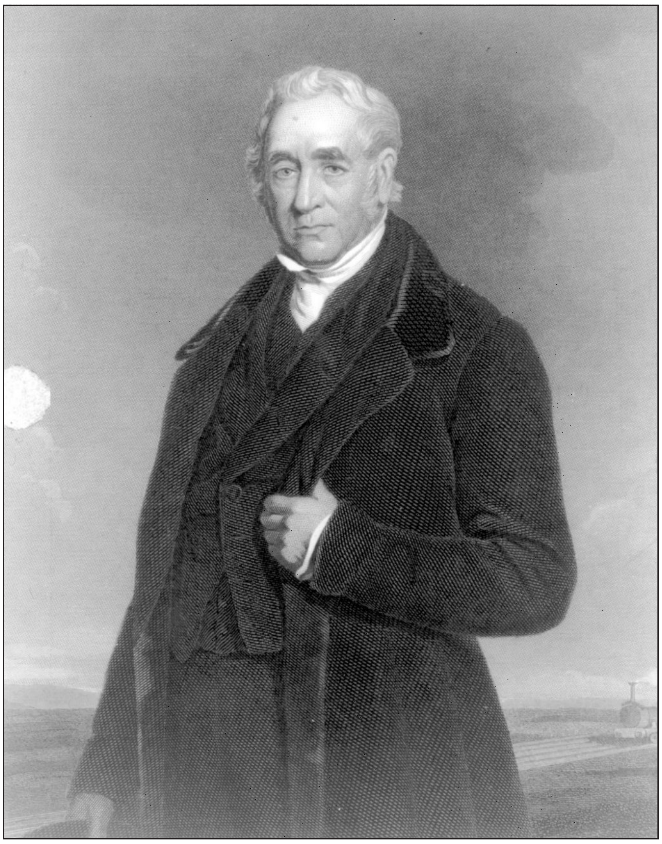
Stephenson built the world's first railway line to use steam locomotives. His Rocket *is considered the world's first successful steam locomotive, and his railroad track gauge became the world's standard gauge. Stephenson also invented the miner's safety lamp, used widely in northeastern England.*

Born: June 9, 1781; Wylam, Northumberland, England
Died: August 12, 1848; Chesterfield, Derbyshire, England
Primary field: Railway engineering
Primary inventions: Safety lamp; *Rocket* (steam locomotive)

Early Life

Born in the mining town of Wylam, England, George Stephenson spent his early life in poverty. By the age of ten, George was working in the mining pits sorting and breaking coal. His father, Robert, was a fireman for Wylam Colliery who supported his family on the meager salary of twelve shillings per week. Neither of his parents could read or write, and neither could George until he decided, at age seventeen, to attend night school. Also at this time, he became an engineman at a local mine. Three years later, he worked as a brakeman at Black Callerton Colliery, operating the winding gear of the mine. In 1802, he married and moved into one room of a cottage. A year later, his son, Robert (1803-1859), was born. To supplement his meager income, George mended shoes and fixed clocks. In 1804, he transferred to the Killingworth pit to obtain a slightly higher brakeman's salary. A daughter was born the following year but died three weeks after birth. In 1806, his wife, Fanny, died of consumption.

Life offered no opportunities for Stephenson until 1811, when the steam-driven pumping station at the Killingworth mine broke down and he volunteered to fix it. Success in this venture led to an engineering position with responsibilities for maintaining and repairing steam-driven machinery in neighboring mines. Two years later, Stephenson learned that efforts were being made in his native Wylam to design a steam-driven engine to run on tracks and haul coal out of the mine. Joining forces with John Thorswall, a skilled coal mine blacksmith, and Lord Ravensworth, the main owner of the Killingworth mine, Stephenson designed the *Blücher*, an engine that could pull on an upward incline eight cars loaded with thirty tons of coal at four miles per hour. Its major innovation was using flanged wheels to achieve adhesion and traction on iron rails. Although the engine was a success, Stephenson improved the *Blücher*'s power by introducing a blast of steam that increased the draft. He also began work to strengthen the iron rails needed to handle the tremendous weight produced by the coal. Joining forces with William Losh, who owned an ironworks in Newcastle, Stephenson patented an economical method for making cast-iron rails. Also in 1818, he helped alleviate one of the causes of mine explosions by developing the miner's safety lamp—though the discovery resulted in a fifteen-year patent dispute with the scientist Sir Humphry Davy. Ultimately, Parliament judged the discovery to be jointly shared and independently arrived at by both men.



George Stephenson. (Smithsonian Institution)

The Great Race at Rainhill

On October 6, 1829, a large crowd journeyed to Rainhill, England, to witness a competition among railroad engines. The crowd was drawn by what promised to be a revolutionary new technology for transportation of freight and passengers. Only four engines were entered in the competition. Many others under construction could not be entered because they were not completed in time. One was disqualified because it consisted only of a horse in a metal frame. The race was to take place on two miles of track. Each entry needed to make twenty trips during a single day at a speed of not less than ten miles per hour.

The first day consisted of trial runs. George and Robert Stephenson's *Rocket* completed twelve miles in fifty-three minutes. The second engine, the *Novelty*, made a far shorter trip but was able to reach a maximum speed of twenty-four miles per hour. The third engine, *Sans Pareil*, made an even shorter but successful trip. The fourth engine, *Perseverance*, was not ready for a trial run. The following day, when the race was supposed to begin, both the *Novelty* and *Sans Pareil* had to be repaired because of damage done in the trial run, and the *Perseverance* was still not ready. To entertain the spectators, George Stephenson brought out the *Rocket*, attached a thirty-passenger coach to it, and ran it on the track at a speed of between twenty-four and thirty miles per hour.

The great race finally began on October 8. Hauling about thirteen tons, the *Rocket* easily completed the twenty-mile course, reaching a top speed of twenty-nine miles per hour and an average speed of fifteen miles per hour, which was five miles over the minimum. All of the other competitors' engines broke down. The *Perseverance* finally got started but was able to achieve a speed of only five miles per hour before breaking down. Stephenson had won not only the prize but also the contract for building engines for the Liverpool-Manchester Line.

As for the *Rocket*, after service on the Liverpool and Manchester Railway it was used on Lord Carlisle's Railway in London. In 1862, it was donated to the Patent Office Museum in London, but in very modified form. It is housed today in the Science Museum in London. A replica of the *Rocket* was built to celebrate the 150th anniversary of the Rainhill trials. It is housed in the National Railway exhibit in York.

Life's Work

In 1821, Parliament permitted a twenty-five-mile line of track to be built to connect a number of mines between Darlington and Stockton. Since Edward Pease, the company director for the newly planned Stockton and Darlington Railway, was a partner in Stephenson's locomotive manufacturing company at Newcastle, Stephenson was contracted to build both the line and the locomotives. The line was completed in late September, 1825. Its wrought-iron tracks set at a 4-foot, 8.5-inch gauge became the worldwide standard. It was the first line to carry passengers (at the speed of fifteen miles per hour). Because of power issues with inclines, heavy freight could be hauled at an average of only five miles per hour. Still, the line was a success, and when plans were made to build a forty-mile line of track between Liverpool and Manchester, Stephenson was awarded the contract. In 1829, as the line was nearing completion, the Liverpool and Manchester Railway offered a prize of 550 pounds sterling for a locomotive weighing less than six tons that could pull a load of twenty tons at a minimum speed of ten miles per hour. The completion date was set for October 1, 1829.

For Stephenson, this was a challenge that could not be ignored. He worked with his son, Robert, trained in engineering work and educated at Edinburgh University, to build a steam locomotive called *Rocket*. Instead of a boiler with one large tube surrounded by water, the *Rocket* had twenty-five small copper tubes to significantly increase the heating surface. The system produced large volumes of steam while rapidly expelling exhaust gases. The *Rocket* also used a blast pipe that produced a partial vacuum that pulled large amounts of air into the boiler fire. The *Rocket* had two cylinders, set at 35-degree angles, driving the wheels. (Most previous engines had vertical cylinders.) The end result was an engine with a multitubular boiler that had far more power and less sway than anything produced before. When tested on the Killingworth Railway, the *Rocket* worked flawlessly. The engine was sent by wagon to Carlisle and then shipped to Liverpool to take part in the competition to be held at Rainhill.

Of the four engines entered at the Rainhill Trials, only Stephenson's *Rocket* was able to complete all requirements of the competition. While most thought the *Rocket* ran flawlessly, Stephenson knew that modifications needed to be made. The two cylinders were lowered eight degrees to provide a smoother ride, and the smokestack was immediately enlarged. The *Rocket* was sold to the Liverpool-Manchester Line, and four more engines were ordered from Stephenson. The opening of the world's first passenger line on September 15, 1830, was a major national event attended by the prime minister.

Having achieved national recognition, Stephenson became chief engineer for a wide variety of other railway construction projects, including lines from Derby to Leeds, Normanton to York, Birmingham to Derby, and Sheffield to Rotherham. Realizing that these lines would someday link up, Stephenson used the same railway gauge as his other lines. When the Institution of Mechanical Engineers was founded in 1847, he was elected its first president. A year later, the sixty-seven-year-old Stephenson contracted pleurisy. He died on August 12, 1848, and was buried at Holy Trinity Church in Chesterfield. Railroad construction, especially the building of tubular bridges of unprecedented size, was continued by his son, Robert, until the latter's death in 1859.

Impact

Stephenson was a pioneer of railroad engineering, helping to produce a transportation revolution in England that spread over the rest of Europe and worldwide. He was a creative force who helped make England the center of the First Industrial Revolution.

Stephenson did not build the first steam locomotive to run on tracks. This was accomplished on an experimental level by another Englishman, Richard Trevithick (1771-1833), twenty-five years earlier. What Stephenson accomplished was the design of an engine that made railroad transportation practical. The basic design of his *Rocket*—with its multitubular boiler to maximize heat transfer, blast pipe to draw air through the firebox, and direct coupling of pistons to driver wheels by connecting rods to maximize power transfer—was used in most steam locomotives up to modern times. Moreover, the laying of track throughout England at a gauge of 4 feet, 8.5 inches helped produce a national train network in Europe and became the worldwide standard gauge. It is often termed Stephenson's gauge.

Stephenson's rise from poverty to wealth and national recognition was used as a model for the work ethic of Victorian England. He became a figure of importance to Samuel Smiles, one of the most influential "self-help" writers of his day. The fact that Stephenson's national significance continues to modern times is symbolized by his portrait on the Bank of England's five-pound notes between 1990 and 2003.

John Stevens

American engineer

A pioneer of steamboat design and of the American railroad, Stevens invented the first steamship that sailed on the ocean and the first working American steam locomotive. Because of his advocacy of railroads over canals, he is called the "father of American railroads."

Born: 1749; New York, New York
Died: March 6, 1838; Hoboken, New Jersey
Also known as: John Stevens III (full name)
Primary fields: Mechanical engineering; naval engineering
Primary inventions: Steam-powered locomotive; steamship

Early Life

John Stevens was born in New York City in 1749. He was the son of the Honorable John Stevens, a wealthy landowner, shipowner, and merchant, who served as a New Jersey delegate to the Continental Congress, and Elizabeth Alexander, daughter of James Alexander, surveyor general of New York and New Jersey. The Stevens family had homes in both Perth Amboy, New Jersey, where the young John Stevens was raised, and in New York City. Stevens was educated largely by tutors, and later attended Kings College (later renamed Columbia University) in New York. Stevens graduated from Kings with a B.A. in 1768 and prepared for a career as a lawyer. He was admitted to the bar in 1771. Instead of practicing law, Stevens went to work with his father.

During the American Revolution, Stevens was granted a commission in the Continental Army, and it was in this period that he began his interest in inventing. In 1776, Stevens became treasurer of New Jersey, eventually rising to the rank of colonel, and for the rest of his life he was popularly known as Colonel Stevens. On October 17, 1782, he married Rachel Cox, daughter of Colonel John R. Cox, the deputy quartermaster general to General George Washington. After the revolution, Stevens and his wife moved first to the Stevens family home in New York City, and then on March 16, 1784, he bought a 689-acre piece of land that had been confiscated from a British Loyalist across from New York City, in what is now Hoboken, New Jersey. The Stevenses built a villa in Hoboken that was completed in 1787. They eventually had eleven children. In 1787, Stevens supported the ratification of the U.S. Constitution, writing a number of articles to this purpose, and in a pamphlet (signed "A Farmer of New Jersey") he even critiqued some of John Adams's constitutional ideas. Beginning in 1788, Stevens focused his creative mind on the subject that would captivate him for the rest of his life—steam power.

Life's Work

Stevens's attention was first drawn to the subject of steam power when, in the latter part of 1787, he viewed one of America's earliest steam ships operating on the Delaware River. He followed the ship to its berth and then studied its design. This was a ship built by John Fitch, with whom Stevens would soon be in competition.

Stevens turned his imagination to the problem of steam engine design after reading a series of pamphlets that appeared in 1788. The pamphlets were written by two American inventors who both claimed to have invented the steamboat. The first was James Rumsey, an inventor from Bath, Virginia, who began work on a steam-powered ship in 1785. Rumsey's first trial run in April, 1786, was disappointing. In December, 1787, he made his first successful trial run on the Potomac River. The other inventor was John Fitch, who also began his work on a steam-powered ship in 1785, and in August of 1787 Fitch successfully ran his steamship on the Delaware River. After reading these publications, with their conflicting claims of precedence for the creation of the steamboat, Stevens wrote to Rumsey with suggestions to improve the design of his engine and to increase its speed.

As a man of business, Stevens needed to commute between New York and New Jersey, and he appreciated the potential commercial benefits of this new steam technology. Such innovations could greatly increase the speed of commerce and industry. Stevens believed he could improve upon the designs of Rumsey and Fitch. With some innovative ideas of his own, Stevens decided to go into the steamship business himself. Stevens, along with Rumsey and Fitch, and a few others seeking federal protection of their steamboat designs, were granted federal patents under the new U.S. patent law on August 26, 1791.

Stevens's first partners were his brother-in-law, Robert R. Livingston (chancellor of New York State and later negotiator of the Louisiana Purchase), and Nicholas I. Roosevelt (inventor and ancestor of Presidents Theodore and Franklin D. Roosevelt). Livingston provided political influence and financial backing, and Roosevelt provided assistance in the building and design areas. Eventually, both Livingston and Roosevelt teamed up with Robert Fulton, a later competitor of Stevens. Stevens's sons eventually joined their father in the family business.

The Steam Waggon

In 1825, John Stevens built the first working steam-powered locomotive in the United States. Neither the original "steam waggon" nor any detailed plans exist. Nonetheless, the original boiler is in the Smithsonian Institution, and contemporary descriptions of Stevens's steam waggon do exist. The locomotive used an upright boiler similar to one Stevens had patented in 1803 for use on his steamboats. The steam waggon is thought to have operated with a boiler pressure of no more than fifty pounds. At just over sixteen feet long, the steam waggon had four wheels (with a diameter of around fifty-seven inches) that supported a flatbed wagon. The steam waggon was 6.25 feet wide, and from the top of the boiler to the bottom of the wheels, the locomotive was just under ten feet high. There were wooden benches for seats in the rear of the locomotive. It weighed 5,125 pounds and used a five-by-twelve-inch cylinder. To propel the railroad, Stevens used several gear wheels mounted in the middle of the wagon, the lowest of which fitted into a rack rail beneath the engine and which ran between and parallel to the tracks. The wheels themselves ran on a circular track, 660 feet in circumference, on Stevens's estate in Hoboken, New Jersey.

Stevens demonstrated his steam waggon for visitors who traveled from New York on his ferryboats. The steam waggon is said to have traveled at a speed of up to twelve miles per hour, even with passengers. While Stevens did not run his steam engine in Hoboken for financial gain, the visual demonstration of the first working American steam railroad proved to be a major step in the building of the American railroad. Stevens's steam waggon did not win over financial backers for his projected railroad projects, but within five years, the Stevens family would secure the charter for the Camden and Amboy Railroad in New Jersey. In 1831, Stevens's son Robert brought the *Stevens* (later the *John Bull*) from England as the first steam locomotive to run on the Camden and Amboy line. Within two years, the Camden and Amboy Railroad had fifteen additional steam locomotives running on their rail line, all built in New Jersey. Stevens's steam waggon was the first of its kind in the United States, and it helped give birth to a whole industry.

Beginning in 1798, Stevens made trial runs of various engine and propulsion designs. Among the design innovations that he and his colleagues tested were low- and high-pressure steam engines and single- and twin-screw propellers. In 1804, Stevens launched the *Little Juliana*, with a high-pressure tube boiler and a twin-screw propeller. In 1809, he ran the first steamship to sail on the ocean, the *Phoenix*, at a speed of 5.5 miles per hour. In this same year, he began steamship service between Philadelphia and Trenton, New Jersey. In 1811, he launched the *Juliana*, which was the world's first steam ferryboat, sailing between Hoboken and New York City. In 1812, he launched the *Philadelphia*, a 136.5-foot-long steamship with a speed of twelve miles per hour.

With an eye to facilitating the speed of business and travel on land as well as on water, in 1802 Stevens planned and later became the president of the Bergen Turnpike Company. He even proposed building bridges and tunnels connecting New Jersey with New York. In 1812, Stevens authored a very important document that has been called the "birth certificate of American railroads." His piece, titled "Documents Tending to Prove the Superior Advantages of Railways and Steam Carriages over Canal Navigation," applied the idea of steam technology to the railroad.

Stevens was a vocal proponent of railroads. In later years, he was recognized as a man ahead of his time in his advocacy of the benefits of rail transportation. Stevens proposed building railroads throughout the burgeoning United States, and in 1815 he obtained the first railroad charter in the country. This railroad was not built, but in 1825 Stevens built the first steam-powered locomotive in the United States, running up to twelve miles per hour. The locomotive, which Stevens called a "steam waggon," ran on a circular track on his estate in Hoboken. A replica of this engine is now on display at the Railroad Museum of Pennsylvania in Strasburg, Pennsylvania.

Stevens was the first to suggest building a railroad between Philadelphia and Columbia, Pennsylvania. Eventually, a railroad was built between those cities, the Philadelphia and Columbia Railroad, which was taken over by the Pennsylvania Railroad in 1857. In 1830, Stevens and his sons obtained a charter for the first railroad in New Jersey, the Camden and Amboy Railroad, one of earliest railroads in the country. It successfully carried passengers and cargo throughout the state. Stevens's son Robert Livingston Stevens became its president.

Impact

Stevens has been recognized as an inventor ahead of his age. He saw the possibilities of bridges and tunnels spanning rivers many years before these things became a reality, and he saw the potential of steam power to unite the economic resources of the American republic. Even as he advocated for railroads, he continued working on steamboats. Stevens's ferryboat service between Hoboken and New York helped spur the development of Hoboken. Passengers were transported to his Elysian Fields parkland on his Hoboken estate, where on June 19, 1846, the first recorded baseball game was conducted. The ferryboat service continued to remain in family hands into the early twentieth century.

Stevens lived to see the vindication of his arguments for the "superior advantages" of the railroad. His advocacy of railroads over canals encouraged the development of railroads throughout the United States. By the time Stevens died in 1838, the Camden and Amboy Railroad was just one of a growing number of railroads that were successfully operating in the United States. Stevens's son Robert invented the modern metal T-rail, the "hook-headed" spike, and the cowcatcher. He also designed the boiler for the Camden and Amboy's first locomotive, named *Stevens* (later known as the *John Bull*), which came from the shop of English railroad builder Robert Stephenson.

Prior to Stevens's death, he had hoped that a portion of his property could be used for a school of science. When his son Edwin died in 1868, he left an endowment and a city block to open the Stevens Institute of Technology, opened in 1870. The institute remains to this day a testament to the impact of John Stevens on American technology and engineering.

George Stibitz

American mathematician

Widely considered the "father of the modern digital computer," Stibitz was a visionary in the world of electronics who foresaw a number of uses for the computer. In 1940, he demonstrated the first long-distance transfer of computer data.

Born: April 20, 1904; York, Pennsylvania
Died: January 31, 1995; Hanover, New Hampshire
Also known as: George Robert Stibitz (full name)
Primary fields: Computer science; electronics and electrical engineering; mathematics
Primary invention: Model K (computer)

Early Life

George Robert Stibitz was born in the industrial town of York, Pennsylvania. At a young age, he showed intellectual promise, and his parents looked for opportunities to give their son an advanced education. Stibitz gained entrance into Moraine Park, an experimental secondary school in Dayton, Ohio. After graduating in 1922, he attended Denison University in Granville, Ohio, where he received a bachelor of philosophy degree in 1926. The following year, he received his master's degree from Union College in Schenectady, New York. In 1930, he earned a doctorate in mathematical physics from Cornell

University in Ithaca, New York. After earning his Ph.D., Stibitz accepted a job as a mathematical consultant to Bell Telephone Laboratories, the leading telecommunications company of the day, and began designing electronic circuitry to improve the nation's telephone systems.

Stibitz spent most of his earlier years at Bell Labs doing fairly conventional work relating to the company's key industry. Bell required a great deal of scientific effort to keep its telephone network functioning and was constantly looking for innovative ways to make its systems more efficient and cost-effective. Stibitz quickly earned a reputation for innovative thinking and was rapidly promoted for his efforts. He helped to develop phone circuits that could communicate with other circuits more efficiently. There were limits, however, to what Stibitz could do. Bell Labs was wary of technology that might make its own product obsolete, so innovative projects and concepts had to conform to the company's expectations. Stibitz began to turn his attention toward company projects unrelated to the telephone. He sought ways to use electronics in new ways that would expand Bell Labs' business opportunities without threatening its dominance of the telephone industry.

Life's Work

Starting with his graduate work at Cornell, Stibitz was interested in the practical application of electronic impulses other than to transmit a telephone message. The problem was how to make electronic devices, which had no intrinsic intelligence, "talk" to each other via a common language. However, even if a common language existed, these machines had to make "decisions" as a result of two or more instructions. Essentially, Stibitz's problem was how to get a machine that had no previous experience or knowledge to reach an outcome. If Stibitz was going to "teach" machines to perform, he had to teach them how to "think." The answer came in the form of Boolean logic and its use of switches. Using constant commands, such as "if," "then," and "not," Boolean logic allows outcomes from abstract or unintelligent processes. From a mathematical viewpoint, Boolean algebra allows the production of outcomes from uncertain or incomplete data. The same process, Stibitz realized, could also be applied to multiple electrical impulses moving through electronic gates to produce a result. The gates served as the "language" that allowed the machine to "learn." Stibitz set out to prove his process before he revealed it to the scientific world.

Working with salvaged parts, Stibitz in 1937 began constructing his first calculating device in his home. Because he was designing something completely new, he had to make some parts himself. For instance, he cut metal strips from tin cans to make electrical connectors. Stibitz called his first calculating device the Model K (for the kitchen table on which he assembled the computer). Despite its crude origins, the device could perform basic addition correctly every time. Though it was not the first computer (geared computers could calculate numbers through mechanical processes), the Model K was the prototype of the digital computer: Its calculations were performed entirely by electrical impulses moving through Boolean gates.

Demonstrating his device to his colleagues and supervisors at Bell Labs, Stibitz found a receptive audience. Bell Labs saw the commercial applications for the computer and placed Stibitz in charge of a project to improve the Model K. In 1940, Stibitz's Complex Number Calcu-

The Binary Adder Circuit

The innovation that made George Stibitz's digital computer possible was the binary adder circuit, the "brain" that allowed the computer to perform complex mathematical functions. When Stibitz began his work on his computer, the only circuits available were simple two-way circuits, capable of sending two impulses (inputs) and receiving two responses (outputs). These circuits became known as half-adder circuits, and they were the circuitry on radios of the day.

A half-adder circuit can send elemental bursts of data and is therefore suitable only for basic mathematical functions: It can add or subtract but cannot perform the higher math functions of multiplication and division, which require the extrapolation of data beyond mere linear sums. To make his Model K computer, Stibitz had to create an improved circuit. He designed the full-adder circuit, which has three inputs—the two available on the half-adder circuit, plus a "carry" function for higher-magnitude computations. This third function allows circuits to do multiplication and division by adding a third abstract variable. Technicians had to run the multiplication and division tables through the circuit to "teach" the circuit the outcome, but the circuit could "remember" the information. The encoding of the circuit to multiply and divide is an early example of computer programming. While outwardly the two types of circuits looked the same, the addition of the carry function expanded the capabilities of the digital computer.

lator (CNC), later renamed the Bell Labs Model Relay Computer, was introduced to the other scientists and engineers at Bell Labs. It was the the first true digital computer. The CNC could add, subtract, multiply, and divide complex numbers instantaneously and correctly every time. A few months later, in September, 1940, Stibitz demonstrated the CNC at the American Mathematical Society's national conference at Dartmouth College in New Hampshire. Besides its computational ability, Stibitz showed that it was possible to operate the computer from remote control. Using a Teletype machine to send a mathematical problem to the CNC in New York (250 miles away), he received a computed answer a fraction of a second later. Stibitz had performed the first long-distance transfer of computer data. Although the full realization of the potential of this function was still decades away, Stibitz's transmission was, in essence, a primitive form of the Internet. Stibitz had relayed data from one location, the data was processed at a second location, and an outcome was returned to the original sender. Stibitz's message heralded the age of mass information transfer.

During World War II, Stibitz became a member of the National Defense Research Committee (NDRC). Responsible for identifying, funding, and promoting scientific achievements to aid the war effort, the NDRC supported Stibitz's effort to expand on his computational theories first demonstrated with the CNC. His efforts helped expand the use of digital computers in the war effort in such areas as gunnery calculation, intelligence gathering, and secure communications. After the war, Stibitz returned to Bell Labs to work further on his calculating devices, but he perceived more uses for computers than those promoted by Bell Labs. He left Bell Labs in 1945 to work as a private consultant, and by the 1950's he had designed a prototype portable computer, though it did not have the power of the larger computers.

Stibitz's career took the computer in different directions in 1964, when he joined the faculty of Dartmouth College. There he pioneered the science of biomedicine, demonstrating that computers could measure and diagnose biological functions, such as generating computer models of blood circulation, airflow in the lungs, and reaction of organs to treatment. Combining computers with medicine revolutionized medical care since the 1960's, as computers made computed tomography (CT), magnetic resonance imaging (MRI), and other forms of remote diagnosis possible.

Stibitz retired from Dartmouth in 1983 but did not stop looking for applications for the digital computer. In his later years, he began to view the computer as a means of personal expression. Using the increasingly powerful personal computers available in the 1980's and 1990's, he explored the potential of computers to generate art and electronic music. Stibitz believed that, instead of merely expressing the direct vision of the artist, a computer could decipher the vision of the artist and generate its own image based on general inputs. Stibitz continued to work on this new application for the computer until his death in 1995.

Impact

Stibitz introduced the world to the digital computer, but he also demonstrated its vast potential. His computer had an immediate impact on science, technology, and communications. Thanks to his pioneering work, the Internet became a possibility and computer technology became an increasingly significant part of daily life. Computers now pervade nearly every aspect of modern life, from business to entertainment to shopping for groceries. Just as Stibitz stepped beyond the basic electronic, mathematical, and scientific uses of computers to introduce the technology to the medical field, other innovators followed his lead in applying digital computers in new ways.

Robert Stirling

Scottish clergyman

A Church of Scotland minister, Stirling invented the Stirling hot-air engine, which he and his brother, civil engineer James Stirling, refined throughout their lives. Although never widely adopted, the Stirling engine is based on remarkable thermodynamic principles that promise great efficiency and energy conservation.

Born: October 25, 1790; Methven, Perthshire, Scotland
Died: June 6, 1878; Galston, Ayrshire, England
Primary field: Mechanical engineering
Primary invention: Stirling engine

Early Life

Robert Stirling was born in 1790 at Cloag Farm in the parish of Methven, Perthshire, in central Scotland. His father, Patrick Stirling, was a farmer. His mother was Agnis Stirling. The couple had eight children. Robert's grandfather, Michael Stirling, had invented a threshing machine in 1758. Robert attended Edinburgh University from 1805 to 1808, studying a wide range of classical subjects. In November, 1809, he enrolled as a divinity student at Glasgow University. On November 15, 1814, he returned to Edinburgh to continue his divinity studies. The following year, he was licensed as a minister in the Presbyterian Established Church of Scotland. On September 19, 1816, he was ordained as a minister in second charge of the Laigh Kirk parish in the prosperous town of Kilmarnock.

On July 10, Stirling married Jane Rankin, daughter of the local wine merchant. Their first child, Patrick, was born on June 29, 1820. Patrick would become an inventor and engineer in his own right. Robert and Jane would go on to have four additional sons (three of whom became engineers, and one of whom became a minister) and two daughters.

Life's Work

Stirling came from a line of industrious farmers who diligently worked to improve their mechanical implements. Stirling apparently showed mechanical aptitude from youth and was carrying out practical experiments while studying for the ministry. On September 27, 1816, only eight days after his ordination, Stirling applied for his first patent, for a fuel-efficient air engine. This was the first version of what would become the famous Stirling hot-air engine. Stirling was motivated to develop it both to save fuel and to design a safe alternative to boiler engines, which were prone to explosions. It is also possible that he was inspired by the investigations into the transmission of heat by Edinburgh professor of mathematics John Leslie. (It is unclear how much Stirling knew of earlier proposals to obtain power from heated air such as the 1794 heated-air engine of Thomas Mead and the 1807 open-cycle engine of George Cayley.)

Stirling's engine represented an improved method of storing and exchanging heat. It essentially worked by the alternative expansion and contraction of enclosed air acting upon a piston. To emphasize its fuel efficiency, Stirling called the central component of his engine the "economiser," although it would soon take the name of a "regenerator." It was the economiser that stored and released heat as the air circulated. With the promising start of his engine design, Stirling was able to acquire laboratory facilities from Thomas Morton, an inventor and the town industrialist. It would be a very productive partnership. In his Morton workshop, Stirling built numerous optical and scientific instruments, including the object glass of telescopes, which he ingeniously constructed from the bottoms of tumbler glasses. In 1818, he constructed an engine based on his economiser design to pump water from a stone quarry. The engine worked well, generating about two horsepower, until the air vessel became overheated and was crushed by the pressure of the heated air. Morton and Stirling later founded a free school in Kilmarnock to educate orphans and neglected children.

In 1823, Stirling took up a post as minister of the Galston parish. Although Stirling was involved in a dispute over the power of the established Church of Scotland over the local presbytery, his work on improving his engine designs continued unabated. In 1824, Robert and his brother James, a mechanical engineer, tried to improve the efficiency of the economiser with the use of high-pressure air by using metal sheets to subdivide the air into multiple layers. They received a patent for this improved engine in 1827. Although the patent application listed four improvements to Robert's original design, the new hot-air engine was not a success. James built an engine at the local ironworks, but it failed to produce the more efficient use of heat that was expected.

In 1840, Robert Stirling received an honorary doctorate in divinity degree from the University of St. Andrews for his erudition in classical languages and devoted ministry. In that same year, the brothers received another patent, for a new version of their engine. The patent application again listed four improvements, including forming materials into rods, employing these rods for receiving and imparting heat, passing the air through extensive systems of surfaces, and applying cupped leathered collars around the piston rods. James Stirling built two new engines based on these improvements for the iron foundry he managed in Dundee. These engines operated on coal and proved more successful, one running continuously for a period of two years and nine months until an air vessel failed. The new engines were able to generate about forty-five horsepower. However, the cylinders were prone to burn out quickly, a problem the Stirling brothers never solved. Robert blamed the failure of the engines on the imperfections of the materials used in their construction, an unlikely explanation. He continued to express hope that his engine would become the mainstay in production of the new Bessemer iron.

James Thomson, the brother of Lord Kelvin, claimed that Robert Stirling did not fully understand the principles of his own engine. Nevertheless, the regenerative principles demonstrated in Stirling's engine were successfully used by the inventor John Ericsson in his 1833 patented caloric engine; by Julius Jeffreys in his patented 1836 medical respirator; by industrialist brothers William and Frederick Siemens in their 1856 patented regenerative steam engine, condenser, and furnaces; by Edward Cooper in his 1857 patented hot-blast furnaces; and by F. T. Botta and G. B. Normand in their 1855 and 1856 patented chimney regenerators for use in marine boilers. For the remainder of their lives, Robert and James Stirling took out no new patents on the hot-air engine and apparently worked on it only sporadically. In 1878, after fifty-five years as minister of the Galston parish and continual refining of his hot-air engine, Stirling died on June 6.

STIRLING'S HOT-AIR ENGINE

In simplest terms, Robert Stirling invented an engine that heats air to obtain power. The Stirling hot-air engine is a closed-cycle, external combustion engine. In other words, the working fuel is designed to stay within the engine. Although Stirling originally named the innovative design of his engine the "economiser" to emphasize its fuel economy, it soon came to be called a "regenerator" because it uses an internal heat exchanger to increase the engine's thermal efficiency. With this heat exchange, the engine can reuse heat that would otherwise be dissipated. Because it operates under low pressure, the hot-air engine does not cause steam burns and is unlikely to explode. Stirling hoped that his hot-air engine would be adopted by iron foundries, making the smelting process safer and cheaper. However, it never proved fully satisfactory for either iron or steel production.

Stirling's engine combines numerous parts in its operation. The heater burns fuel in an external combustion chamber. Almost any fuel source can be used. Because the fuel is burned continuously, the Stirling engine tends to operate smoothly. The heater is connected to a gas-filled cylinder. Two opposing pistons compress the gas as it is heated and push the gas through the engine's heat exchanger and cooler. The cycle is then started again as the gas enters the heater. The heat exchanger stores the thermal energy emitted as the gas is compressed. The energy is then recaptured by the system, as explained by Nicolas Léonard Sadi Carnot's thermodynamic theory.

As Robert and James Stirling had mixed results with the engine, it never achieved wide popularity. Steam engines, greatly improved by the 1850's, continued to power England's industrial revolution. Nevertheless Stirling engines continued to be manufactured until the 1920's. After a period of nonuse, industrial interest in the Stirling engine was revived around World War II. Companies such as Dutch NV Philips experimented with a Stirling engine to generate radio power, and Ford Motor Company sought to use the engine in a fuel-efficient automobile. The Stirling engine's theoretical promise of almost complete efficiency without pollution continues to intrigue engineers. Even now, it is being proposed for hybrid-electric drive automobiles. However, the use of the Stirling engine remains to this day quite limited, confined mostly to specialized engines, cryogenic refrigerators, heat pumps, and small generators.

Impact

Robert Stirling lived the life of a distinguished country parson, becoming learned in biblical languages, arranging for charitable enterprises, succoring townspeople during a cholera epidemic, and pastoring his Church of Scotland flocks in the parishes of Laigh Kirk and Galston. During this life of religious duty, he and his brother James were working ambitiously on perfecting the design of the hot-air engine that had come to Robert as a youth.

Robert Stirling's idea for a hot-air engine had to some extent a charitable origin. He wanted to design an engine less susceptible to dangerous accidental explosions than the steam engine. With his mechanical mind, he focused on a design that centered on the efficient exchange of heat. How much of this design flowed from his understanding of thermodynamics is not certain, but the Stirling engine would in fact take advantage of scientific principles that were explained by the scientist Nicolas Léonard Sadi Carnot, who introduced the theory of the thermodynamic cycle. On April 21, 1847, William Thomson, better known as Lord Kelvin, the famed scientist who helped develop the laws of thermodynamics, delivered his first address to the Glasgow Philosophical Society on the subject of "Stirling's Air Engine." Thomson would also use the Stirling engine for demonstration purposes in his lectures at Edinburgh University.

The Stirling engine has intrigued engineers ever since, because of its theoretical possibilities for enormous efficiency and suggestion of a perpetual motion machine. However, no working Stirling engine has yet to come close to achieving this ideal. Although its use in industry remains limited, there are numerous researchers and Stirling engine societies convinced that its fundamental principles will one day provide a great breakthrough in the ability to generate clean, safe, and self-perpetuating power. Ingenious uses of these principles have been made over the last century. An engineer from Tyneside, England, John Malone, followed the Stirling model to invent a heat engine that used liquid at the critical point. Engineers at the Los Alamos National Laboratory have been experimenting with a Stirling engine that is powered by sound waves, and engineers from the National Aeronautics and Space Administration (NASA) have studied the use of Stirling engines with solar energy. Thus far, however, the Stirling hot-air engine remains more promise than reality.

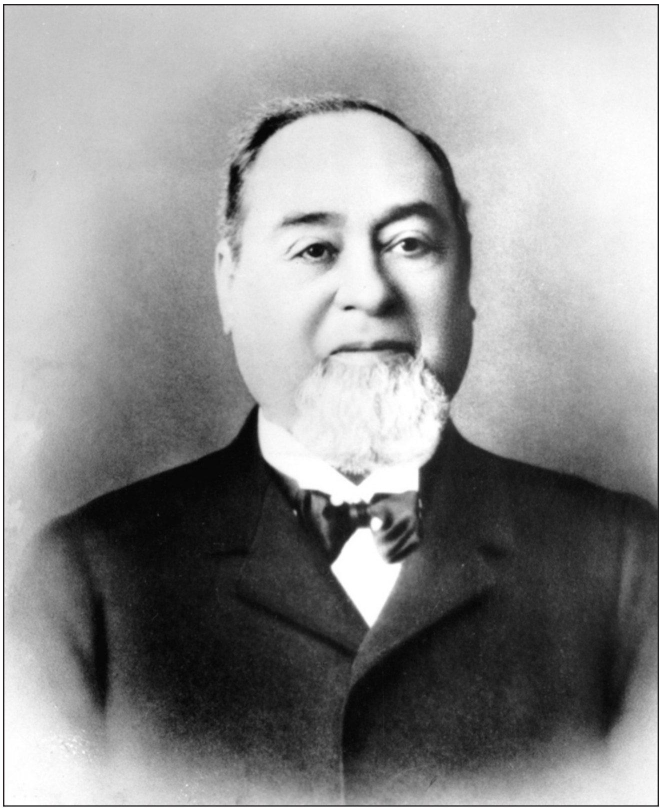
LEVI STRAUSS
German American garment manufacturer

Strauss is responsible for the creation and production of blue jeans, a type of pants that became a staple in American fashion and across the world.

Born: February 26, 1829; Buttenheim, Bavaria (now in Germany)
Died: September 26, 1902; San Francisco, California
Also known as: Löb Strauss (birth name)
Primary field: Manufacturing
Primary invention: Blue jeans

EARLY LIFE
Levi Strauss was born Löb Strauss to German Jewish parents, Hirsch and Rebecca Strauss, in Buttenheim, Bavaria. He had four older siblings: Jonas, Louis, Fanny, and Mathilde. His father was a dry goods peddler who succumbed to tuberculosis in 1845. After his father's death, young Strauss traveled to the United States with Fanny, Mathilde, and their mother. They settled in New York, where they lived with Strauss's two older brothers, Jonas and Louis, who had previously arrived and set up a prosperous wholesale textile and tailoring business. Once in the United States, Strauss Americanized his name by changing it to Levi.

Strauss worked with his brothers during his brief stay in New York. He relocated to Louisville, Kentucky, where he lived on his uncle Daniel Goldman's ranch and learned the language. In Kentucky, Strauss worked as a door-to-door salesman peddling various goods, while dreaming of becoming an independent businessman. When the California gold rush hit in 1849, Strauss saw the opportunity to set up a business in the burgeoning region that would fulfill the needs of the miners and others who were flocking west to find their fortunes. In January, 1853, Strauss became an American citizen, and in February he traveled west to set up a dry goods business in San Francisco. He established Levi Strauss and Company with his sister Fanny's husband, David Stern. Strauss's business primarily sold materials that the mining community would need, such as scissors, buttons, thread, fabrics, and linens, but also carried household and specialty items imported from Europe and sent via ship from his brothers' business in New York.



Levi Strauss. (AP/Wide World Photos)

Receiving goods via ship was often unpredictable and time-consuming. Although Strauss relied heavily on this method of shipment, he also purchased goods whenever they presented themselves at auctions at the docks, and from other salesmen traveling through the area. Strauss would often load his horse with supplies and travel into the mountain ranges where men would clamor to purchase his wares.

LIFE'S WORK
Strauss, along with Stern, had created a successful business and was well established in the community. Strauss worked closely with the miners, selling them needed supplies, and with other businesses that catered to the community. He sold fabric to local tailors and seamstresses who would turn the bolts into pants and outerwear for miners, who were very hard on their clothing. As his business began to prosper, Strauss also began buying real estate in Northern California, amassing a fair bit of wealth. A generous man, Strauss helped fund

the construction of Temple Emanu-El, the first synagogue in San Francisco, and also belonged and donated to several organizations, including the Eureka Benevolent Society, the Pacific Hebrew Orphans Asylum and Home, and the Hebrew Board of Relief, which helped orphans, widows, and others in need. He also donated to several academic institutions.

By 1872, Strauss's reputation as a bright businessman and a philanthropist preceded him. That year, Strauss received a letter from Jacob Davis, a Reno, Nevada-based tailor who bought much of his fabric from Strauss. The poorly written letter explained that he frequently heard miners complain that their jeans were not able to withstand the rigorous work. The primary complaints were that the pockets would split apart at the seams when stuffed with ore and other materials. In the letter, Davis explained that he had developed a solution: reinforcing the corners of the seams around the pockets and at the tip of the fly with metal rivets. He wrote, "The secratt of them Pants is the Rivits that I put in those Pockots and I found the demand so large that I cannot make them up fast enough." The metal gave the jean pockets the extra strength necessary to withstand the rugged mining conditions. Davis wanted to file a patent for his design but did not have the capital. Knowing that Strauss was quite successful, and always looking for a good business opportunity, Davis offered to share the rights to the invention if he would fund the patent registration and legal fees. Strauss agreed, and the two men applied for their patent for an "Improvement in Fastening Pocket-Openings" in August of 1872. On May 20, 1873, they received their patent, and blue jeans were born.

Davis came to work for Strauss in 1873, overseeing the company's West Coast manufacturing operations. Stern died the following year at the age of fifty-one, and his four sons, Jacob, Luis, Sigmund, and Abraham, went to work for their uncle.

The jeans, then called "waist overalls," were an immediate success. They came in two styles—dark indigo blue denim and dark brown cotton duck. The denim products were much more popular, since the denim softened with washing, whereas the duck remained stiff. The duck was eventually dropped from the line altogether. In addition to making waist overalls, the company manufactured jackets and other durable outerwear articles, eventually producing solid-colored and patterned muslin button-up shirts.

Because of the overwhelming demand for the jeans, it quickly became clear to Strauss and his nephews that they would need to find a new distributor for denim. The company had been purchasing its denim from the Amoskeag Manufacturing Company in Manchester, New Hampshire, one of the oldest and most established textile mills in the country. In 1875, Strauss purchased the Mission and Pacific Woolen Mills to ensure that his company would always have a ready supply of material for its pants.

Although lack of railroad lines made national distribution of the jeans impossible, sales in the West were staggering. In 1886, the company introduced its trademark leather patch on the back waistband that depicted two horses attempting to pull apart a pair of the jeans. The original jean design was called XX but was changed to 501 in the 1890 catalog, the same year that the riveted pants patent expired. With the name and the logo in place, the jeans were positioned to become the cultural icon that they are today. Strauss incorporated his business in 1890, retaining a 55 percent share in the company and dividing the remainder between the seven Stern children. He had no children of his own.

Levi's Jeans

Levi Strauss was an American businessman who saw a good business opportunity, created a product to fill a need, and in doing so invented what became a quintessential American garment. The original Levi's 501 button-fly jeans were designed to be both durable and comfortable. Their material, denim, softened and conformed to the body with every wash, yet the resilient fabric did not fray. The seams were well constructed and strong. The secret to the success of the jeans was Strauss's patented metal rivets, which reinforced the pockets and button fly. The reinforcing rivets were created by a Nevada tailor, Jacob Davis, after he received frequent complaints from miners about their waist overalls (jeans) falling apart at the pockets and crotch. The extra support provided by the rivets allowed miners to use a single pair of jeans for years. The jeans' material and construction allowed them to withstand the rugged conditions of mining.

The innovation that Davis and Strauss employed in their product ensured their success, but the comfort and style of their jeans made the denim pants a fixture in the fashion world as well. Levi's jeans were worn by silver-screen icons such as John Wayne and James Dean, sparking demand for the jeans. Levi's jeans for women were first featured in *Vogue* magazine in 1935. Media attention further propelled Levi's jeans into the international spotlight.

Strauss began to suffer from a heart condition in his seventies. Although his company was in the able hands of his nephews, he continued to go into the office regularly to attend meetings and make decisions until his doctor insisted upon bed rest. Strauss died peacefully at his family estate on September 26, 1902, at the age of seventy-three.

Impact

The death of Strauss rocked the community, which felt that it had lost a civic leader and philanthropist. On the day of the funeral, many businesses were closed so that their owners could attend the services. The San Francisco Board of Trade passed a special resolution stating that "the great causes of education and charity have likewise suffered a signal loss in the death of Mr. Strauss, whose splendid endowments to the University of California will be an enduring testimonial of his worth as a liberal, public-minded citizen and whose numberless unostentatious acts of charity in which neither race nor creed were recognized, exemplified his broad and generous love for and sympathy with humanity."

Levi's 501 jeans became an American staple because of their unique and durable design and their comfort and easy care. Originally designed for miners, who needed rugged pants for their work, Levi's jeans have long been associated with cowboys and ranchers. With the explosion of cinema, however, the jeans took on a new role during the 1950's—the trademark of the rebel—as actors such as James Dean and Marlon Brando donned their blue jeans on the silver screen. The movie industry also helped to promote an association between Levi's jeans and youth and a carefree attitude. By the 1960's, Levi's jeans and other brands had become popular worldwide. Calvin Klein and other designers introduced their lines of "designer jeans" in the late 1970's, and these high-fashion jeans were popular through the 1980's. In 1986, Levi's introduced its Dockers line of casual pants, helping to establish the "business casual" style.

William Sturgeon

English electrical engineer

Sturgeon, a self-educated scientist, is credited with inventing the first electromagnet. He also invented the electric motor, a galvanometer, and a long-lasting battery cell. He was an energetic participator in the amateur scientific and learned societies of nineteenth century London.

Born: May 22, 1783; Whittington, Lancashire, England
Died: December 4, 1850; Prestwich, Lancashire, England
Primary fields: Electronics and electrical engineering; physics
Primary invention: Electromagnet

Early Life

William Sturgeon was born in Whittington, Lancashire, England, in 1783. His father, John Sturgeon, was a shoemaker of unsavory character and harsh with William. William's mother, Betsy Adcock Sturgeon, died when he was ten. At thirteen, William was apprenticed to a shoemaker, who was also known to treat the boy harshly. As a youth, Sturgeon, like many future inventors, showed mechanical skill, learning to clean clocks and watches. When his apprenticeship ended in 1802, he enlisted in the army, becoming an artilleryman. Sometime thereafter, he married Mary Hutton. Sadly, all three of their children died in infancy and Mary herself died in the 1820's.

Sturgeon told his friend John Leigh that his scientific interest in electricity was aroused while he was stationed in a military post in Newfoundland. Fascinated in watching a violent thunderstorm, he found no one who could explain to him the scientific causes of lightning. He therefore embarked on an impressive course of self-education. An artillery sergeant friend had a small collection of books, which Sturgeon borrowed, learning basic principles of Latin, mathematics, and science at night, after finishing his guard duty. He also studied optics and improved his mechanical skills. In 1820, Sturgeon retired from the military to reside in Woolwich, England. He supported himself with his former trade as a shoemaker, devoting his spare time to making his way in science. He also helped form the Woolwich Literary Society and began writing articles for the popular press.

Life's Work

With his unusual and self-taught learning, Sturgeon would always remain an outsider to the established British scientific community, despite his impressive accomplishments. Nevertheless, his scientific successes came quickly upon his 1820 return to England. With his tradesman background, Sturgeon began making his own instruments with a lathe he had purchased. Hans Christian Ørsted and André-Marie Ampère had recently discovered the fundamental principles of electromagnetism, and Sturgeon followed in their footsteps. He conducted experiments in magnetism and thermoelectricity and published his results in the scientific journal the *Philosophical Magazine*.

In the early 1820's, Sturgeon constructed a variety of apparatuses that demonstrated a range of electromagnetic effects. These dozen or so electromagnetic instruments were compact enough to be displayed on a tabletop. They were thus easily shown and demonstrated to an audience. One of the devices was a soft iron bar in the shape of a horseshoe. A coil of varnished copper wire was wrapped around the bar. When a voltaic current was passed through coil wire, the bar became magnetic. Sturgeon's iron bar is now considered the first working electromagnet, although Michael Faraday was never willing to credit Sturgeon for its invention. On the basis of this work, Sturgeon was awarded a silver medal and thirty guineas by the British Society of Arts. He was also appointed lecturer in experimental philosophy at the East India Company's Royal Military Academy at Addiscombe in Surrey. In addition, he gave paid lectures in other London scientific institutes, including the Adelaide Gallery, the Lowther Arcade at the Laboratory of Science, and the Western Literary and Scientific Institution.

Electromagnet

An electromagnet is a magnet that is generated by electricity. William Sturgeon built the first practical electromagnet in the 1820's. André-Marie Ampère had earlier proposed the idea of electrifying iron; François Arago had experimented with altering the magnetic properties of iron through rotation. Among the array of tabletop devices that Sturgeon built and exhibited in the early 1820's was the first workable electromagnet. It was generated by a single-cell battery. In a dramatic presentation on May 23, 1825, Sturgeon showed that his electromagnet, although weighing less than three-fourths of a pound, was capable of lifting a nine-pound object. The practical and industrial ramifications were obvious, and Sturgeon was awarded a valuable prize for his apparatus. Sturgeon's display demonstrated that solenoids—cylindrical coiled wires that produce a magnetic field when electrified—are strengthened when wrapped around an iron core. Sturgeon's electromagnet led to the invention of the telegraph in 1837 and the telephone in 1875. As a theoretical matter, it can even be said that Sturgeon's primitive electromagnet contributed to a line of inquiry that would eventually result in the great scientific achievement of James Clerk Maxwell's unified theory of electromagnetism.

Sturgeon's electromagnet consisted of a soft one-foot, seven-ounce iron bar in the shape of a horseshoe, around which Sturgeon wrapped eighteen turns of copper wire, the turns not touching each other. (The U shape of the electromagnet brings the poles together, concentrating the magnetic field.) When the wire was connected to a voltaic cell, the iron became magnetic and capable of lifting weights as heavy as nine pounds. Each wrapped coil reinforced the next, as they formed a set of parallel wires with the current moving in the same direction. The core of the iron was varnished so as to be insulated and not short-circuit the wires. When Sturgeon turned off the electric current, the iron's magnetic field disappeared. Sturgeon also demonstrated a straight bar electromagnet.

Within a few years, Joseph Henry was improving on Sturgeon's instrument, constructing electromagnets capable of lifting more than one thousand pounds. Electromagnets would become a vital generator of power in a wide range of uses. Their strength can be changed by altering the quantity of electric current, and is also dependent on the mass and structure of the iron core and copper wire. Electromagnets have been useful for many devices, including motors, bells, and various electronic instruments, and in industrial lifting.

He could now give up shoemaking for his scientific pursuits.

Sturgeon's success followed from his decision, as he explained it, to increase the magnetic, rather than the galvanic, power of his electromagnetic inventions. He designed his experiments such that they could be witnessed and understood by the emerging English middle class, who were transfixed by this amazing new force called electricity. A religious man, Sturgeon saw his new apparatuses as symbolic of the workings of the universe, actuated by the electriclike powers of the Creator. In 1826, he experimented with the firing of gunpowder by electrical discharges. In 1829, Sturgeon married Mary Bromley. In 1832, he invented an electric motor capable of turning machinery. The motor included a direct-current (DC) commutator. Over the next few years, Sturgeon invented the moving-coil galvanometer, improved the battery cell by amalgamating zinc plates with mercury, and discovered the unequal heating effects at the two poles of the voltaic arc. Making more than five hundred observations of experimental kites, Sturgeon published a meteorological study establishing that when weather is calm, the atmosphere is charged positively with respect to the earth, with the charge becoming more positive as the altitude increases. Joseph Henry, the American inventor and scientist of electricity, sought out Sturgeon on a trip to England to discuss their scientific work.

In 1836, Sturgeon launched a journal of experimental science, the *Annals of Electricity*, the first English journal devoted to electricity. Although the *Annals of Electricity* would publish important papers of Sturgeon and other inventors during its seven-year span, the contentious Sturgeon would also use its pages to critique rival scientists, particularly Faraday. Disdaining Great Britain's established Royal Society, chartered in 1662, and the Royal Institution, chartered in 1800, Sturgeon helped found a rival London Electrical Society in 1837. After a tenuous existence, the London Electrical Society disbanded in 1843 because of its accumulated debt. At the time, Sturgeon and Faraday had something of a rivalry. They both came from humble beginnings, but Faraday was well established as a fellow of the Royal Society. Faraday was, of course, the greater scientist and indeed was the leading experimenter of his day. Sturgeon's greatest talent lay perhaps not in theoretical work but in fashioning instruments demonstrating the latest scientific advances. In the invention of electromagnetic devices, he was hardly surpassed.

In 1840, Sturgeon became superintendent of the Royal Victoria Gallery of Practical Science in Manchester, leaving his London appointments. As superintendent, Sturgeon continued his lectures on electromagnetism. However, the gallery too had difficulty supporting itself, and it closed in 1842. Sturgeon started the Manchester Institute of Natural and Experimental Science in 1843, but it hardly got off the ground. Likewise, his new *Annals of Philosophical Discovery* folded after six issues.

For the rest of his life, Sturgeon supported himself as an itinerant lecturer with occasional bounties: two hundred pounds from the Royal Bounty Fund in 1847 and a fifty-pound annual pension from the British government in 1849. In his career, Sturgeon published sixty-nine papers cataloged by the Royal Society. He was able to collect and publish his major papers in an attractive volume titled *Scientific Researches*, funded by subscription. He was debilitated from a severe case of bronchitis in 1847. In 1850, he died at Prestwich, Manchester, possibly of influenza. He was survived by his wife, Mary.

Impact

Sturgeon is important to the world of invention and science on several fronts. He was a member of the remarkable group of scientists such as Ørsted, Ampère, and Faraday who discovered and advanced the basic principles of electromagnetism in the 1820's and 1830's. Although each of these scientists experimented with some form of charged magnet, Sturgeon's horseshoe-shaped "Improved Electro-Magnetic Apparatus" has a good claim to be the world's first workable electromagnet. Sturgeon's successful demonstration influenced Peter Barlow to attempt to apply the electromagnet to telegraphy and Joseph Henry to intensify the electromagnet, eventually leading to an electromagnetic telegraph as well as magnets capable of lifting three thousand pounds. In addition, Sturgeon invented the first electric motor capable of turning machinery.

Sturgeon was an active member in scientific societies, which helped to disseminate scientific ideas in early nineteenth century London and its surroundings. With scientific figures such as Barlow, Samuel Hunter Christie, Olinthus Gilbert Gregory, and James Marsh, London had an impressive number of learned men at the time, several of whom assisted Sturgeon with his career. An important element of Britain's industrial and scientific revolution, these societies also represent perhaps the first direct involvement of a prosperous middle class in the workings and publications of scientists. Sturgeon was tireless and hopeful in forming new societies and journals supported by popular subscription. Their existence was precarious and rarely survived a decade, but they did represent an alternative to the haughty royal societies, long the sole dispenser of scientific prestige and patronage in Britain. Sturgeon's efforts to publicize the details of his experiments were not only learned; they can now also be seen as an effort to democratize scientific effort.

With his mean upbringing and idiosyncratic education, Sturgeon stood outside the often aristocratic world of self-supporting, gentleman scientists. Sturgeon's journals reflect his grudge against Faraday, the most famous scientist of electromagnetism, and of the learned royal societies. Sturgeon appealed to his subscribers to validate his results, as opposed to Faraday, who presented his science as correct in itself and not dependent on wider acclaim. This is perhaps the reason Sturgeon was so eager to lay his instruments and the workings of his theories before a larger public. Sturgeon was not only making a rival claim about scientific discourse but also anticipating the competitive, journal-based and resource-driven nature of modern science.

Theodor Svedberg

Swedish chemist

Svedberg made extensive contributions to physical chemistry, especially to the subfield of colloid chemistry. He invented the ultracentrifuge, a device for determining the sizes, densities, and distribution of very small particles. He also invented a balance for measuring low osmotic pressures.

Born: August 30, 1884; Fleräng, Valbo, Sweden
Died: February 25, 1971; Örebro, Sweden
Also known as: The Svedberg
Primary field: Chemistry
Primary invention: Ultracentrifuge

Early Life

Theodor Svedberg (TAY-oh-dahr SVEHD-bahryuh) was born in Fleräng, a small town in Sweden northeast of Stockholm, to Elias Svedberg and Augusta Alstermark Svedberg. His father, a civil engineer who managed different ironworks in Sweden and Norway, strongly influenced his only child by fostering an interest in science and an enduring love of nature. Theodor sometimes performed experiments in a laboratory at his father's workplace, and he regularly joined his father in long outings in the country.

Svedberg first attended the Köping School, then the

Karolinska School in Örebro as well as the Gothenburg Modern School. Two teachers let him use the school laboratories after classes. He built a radio transmitter and a Tesla transformer and gave public demonstrations at the school. He also prepared chemicals at home. Svedberg's love of nature drew him to botany, but he enjoyed physics and chemistry as well. He finally resolved to study chemistry, viewing it as a means to understand biological processes.

In 1904, Svedberg entered Uppsala University, where he received his bachelor's degree in 1905, after only a year and a half of study. His first publication, on a new method for creating organic compounds of metals in colloidal form, appeared the same year. He presented his doctoral dissertation in 1907 and accepted an appointment as lecturer in Uppsala's chemistry department.

Life's Work

As a student, Svedberg became interested in the new field of colloid chemistry. Colloids are mixtures containing particles intermediate in size between ordinary molecules and larger particles visible with a microscope. These substances include the materials necessary for life (such as starch, cellulose, and proteins) and countless natural and manufactured materials (foods, paints, gels, soaps, alloys, rubber, fog). Though invisible to the eye, colloidal particles can be viewed indirectly by reflected light with an ultramicroscope, a device for studying particles too small to be seen with an ordinary microscope. Svedberg built an ultramicroscope and published several papers on the production and motion of colloidal particles before completing his dissertation on colloidal solutions. He believed his observations verified theories of Albert Einstein and Marian Smoluchowski about the chaotic movements of small particles, known as Brownian motion. Svedberg's theoretical analyses were criticized by Einstein and Smoluchowski as well as by chemist Jean Perrin.

Theodor Svedberg. (©The Nobel Foundation)

Radioactivity was also a new and exciting field at this time. Svedberg decided to determine where new radioactive substances might fit in the periodic table. Working with his colleague Daniel Strömholm, he found that corresponding members of the three radioactive series were extremely similar chemically. In 1909, Strömholm and Svedberg proposed that the periodic table based on atomic weight was only an approximation. Rather than being completely uniform in weight, elements were mixtures of chemically identical substances having slightly different weights. This was the earliest formulation of the concept of isotopes, a conceptual breakthrough with profound theoretical and practical consequences.

In 1912, Svedberg became the first professor of physical chemistry at Uppsala, a position that the university instituted for him. Colloids remained his main interest. Contrary to expectations, his research showed that colloids lacked properties that sharply distinguished them from other types of matter. Such findings eventually erased the distinction between colloid and physical chemistry.

Svedberg needed to use a centrifuge to progress in his work. This apparatus would apply extra force to the particles he was studying and cause them to sediment more rapidly. Since research funds were scarce after World War I, he became discouraged.

A visiting position at the University of Wisconsin at Madison in 1923 was a godsend. Svedberg thrived in Madison's stimulating atmosphere. With J. B. Nichols, he built a centrifuge in which the sedimentation process could be recorded by photography. However, technical problems precluded useful measurements.

Rejuvenated by the Wisconsin experience, Svedberg returned to Sweden full of ideas and enthusiasm. In 1924, he and Hermann Rinde built the first working centrifuge for investigating colloids. They named this device the "ultracentrifuge," following the pattern used for the terms "ultramicroscope" and "ultrafiltration." Driven by an electric motor, this machine could rotate up to 8,700 times per minute and create a force up to 5,000 times the gravitational field.

Svedberg decided to use the ultracentrifuge to find the size distribution and molecular weights of proteins, which chemists believed were not uniform in size. To his surprise, tests with hemoglobin showed that all the particles were the same size. Just as amazing was the result that the molecular weight of hemoglobin was four times that predicted from its composition.

The first ultracentrifuge was unstable and unreliable, and it exhibited numerous problems. Explosions and breakage were common occurrences. Svedberg and his coworkers redesigned this device many times. Though it was suitable for many purposes, a different mechanism was needed to speed the centrifugation process and to enable researchers to distinguish components in a complex mixture.

In 1926, Svedberg and others constructed a high-speed ultracentrifuge powered by an oil-driven turbine instead of an electric motor. Early versions could rotate approximately 45,000 times per minute, producing a force approximately 100,000 times that of gravity. While working on this machine, Svedberg was awarded the 1926 Nobel Prize in Chemistry for his work on colloidal systems.

The award enhanced Svedberg's status. The Swedish legislature agreed to fund a physical chemistry laboratory, which was completed in 1931. Privately, Svedberg felt that the award was premature. The Nobel Committee had thought that his early incorrect theoretical work corroborated the existence of molecules. He resolved to prove himself worthy of the award and threw himself into a whirlwind of activity. He concentrated on improving the ultracentrifuge and using it to study proteins and other large molecules.

During World War II Svedberg worked on synthetic rubber production. With a coworker, he invented a bal-

The Ultracentrifuge

A centrifuge is a rotating device that can be used to separate different materials. This machine creates a force along its axis of rotation that causes the denser particles to move outward, while the less dense particles collect near the center. The design, dimensions, and materials for a centrifuge depend on the kinds of substances to be separated.

Different types of particles in a suspension can sometimes be separated by allowing them to settle. Under the influence of gravity, denser particles will fall toward the bottom of a container, while the lighter particles will rise to the top. Settling does not work well with very small particles because the gravitational forces will be overwhelmed by other factors that affect the particles' behavior. In these cases, the increased force provided by a centrifuge is essential for separation and for measuring the speeds, concentration variations, and other properties of suspended particles.

Theodor Svedberg and Hermann Rinde built the first ultracentrifuge with parts from a machine used for separating cream from milk. An electric motor connected to a gear drive drove a brass shaft (the rotor) that rapidly rotated the samples, which were enclosed between glass plates in compartments, or cells. A prism reflected light into the centrifuge from a bright lamp to illuminate the materials so that their behaviors could be observed. Svedberg suspended a camera over the apparatus to record the progress of changes in a sample by photographing it through a window in the apparatus. Rubber plates and tubing were used to isolate the apparatus and to reduce vibrations. Oil lubricated the centrifuge's moving parts, while water and hydrogen cooled areas subject to friction.

Svedberg and others first constructed a centrifuge driven by an oil turbine in 1926. This machine reduced the operating time required and made it possible to analyze many more substances. During the late 1920's and the 1930's, other scientists developed a high-speed ultracentrifuge propelled by an air turbine.

The ultracentrifuge revolutionized the study of colloids by enabling chemists to determine particle sizes and molecular weights of particles too small to be seen directly in an optical microscope. The ultracentrifuge made it possible to study proteins and other macromolecules, leading to the development of molecular biology and modern biochemistry and biophysics, with applications in medicine and industry. The ultracentrifuge became a standard fixture in well-equipped laboratories, essential for determining molecular weights of large molecules and linear polymers and desirable for gleaning thermodynamic and hydrodynamic data. Now often coupled with computer software, this device provides a simple, nondestructive method for gaining quantitative information about complex systems.

ance for finding molecular weights of polymers by osmosis in 1944. He also investigated the actions of radiations on proteins and built a neutron generator for such tests and to prepare radioactive tracers.

Svedberg was interested in relationships between academia and industry, and he was instrumental in founding the Research Council for Technology. He obtained funding from an industrialist to build a large cyclotron for research and medical applications. This machine was ready in the new Gustaf Werner Institute in 1949, the year of Svedberg's mandatory retirement. Svedberg became head of the institute, where he continued research and collaborations with Swedish industries until his second retirement in 1967.

So closely was Svedberg associated with the ultracentrifuge and the researches this invention made possible that his peers named a measurement unit after him. The svedberg (S or Sv) equals 10^{-13} seconds. It is used to measure the sedimentation rate of a suspended particle moving at constant speed.

Svedberg received numerous awards and honorary degrees, and he was elected to more than thirty learned societies, including the Royal Society in London and the American National Academy of Sciences. He died in Örebro on February 25, 1971.

Impact

Svedberg was a brilliant, innovative, and indefatigable researcher whose research and inventions advanced several scientific areas and contributed to the birth of a new field, molecular biology. His work had far-reaching consequences for areas as diverse as chemistry, biology, medicine, metallurgy, manufacturing, nuclear science, agriculture, and food processing.

Svedberg's radiochemical investigations helped establish the existence of isotopes, which have had extensive applications in research, medicine, archaeology, technology, and industry. Radioactive isotopes are widely employed as tracers to mark nonradioactive elements, allowing researchers to follow physiological and industrial processes and chemical reactions.

Svedberg made his most significant contributions to the field of colloid chemistry. Directly and through his students, Svedberg established the existence of macromolecules, found the weight of many proteins and other substances, and determined that proteins were well defined in size. Svedberg's research and invention of the ultracentrifuge sparked an explosion of research on the large molecules that compose living things, facilitating the identification of viruses and the development of modern biochemistry. He contributed to conceptual change in chemistry by showing that colloids lacked unique properties and establishing the existence of macromolecules, which became the new disciplinary focus.

Svedberg transformed physical chemistry in Sweden by building up the University of Uppsala's chemical laboratories and mentoring numerous students. He created a fruitful exchange between academic and industrial research in Sweden by his individual efforts and through his work with the Research Council for Technology. Under Svedberg's leadership, the Gustaf Werner Institute advanced research on radiation, its effects on macromolecules, and its applications to medicine.

Joseph Wilson Swan

English physicist and chemist

Swan made several important contributions to the early development of photographic printing and was the first person to patent an electric incandescent lamp, whose manufacture and refinement led to further significant technological discoveries.

Born: October 31, 1828; Sunderland, County Durham, England
Died: May 27, 1914; Warlingham, Surrey, England
Also known as: Sir Joseph Wilson Swan
Primary fields: Chemistry; photography; physics
Primary inventions: Electric incandescent lamp; dry photographic plate

Early Life

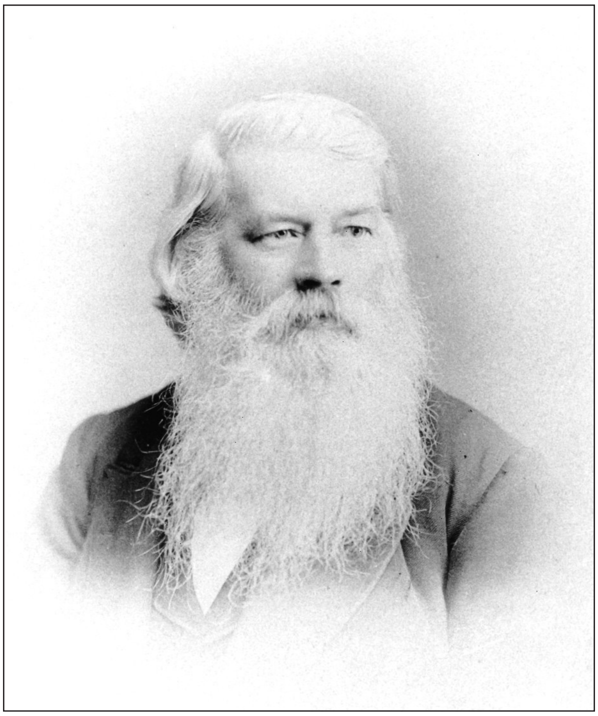
Joseph Wilson Swan was the third of eight children born to John Swan and his wife Isabella, née Cameron, who were both of Scottish descent. The family had been fairly prosperous in previous generations but had declined into an uncomfortable poverty. Joseph attended schools in Sunderland before being apprenticed at the age of thirteen to a firm of druggists in that town, Hudson and Osbaldiston. Both the partners died within three years, liberating Joseph from his obligation, and he went to join a family friend, John Mawson, in operating a druggist's shop in Newcastle upon Tyne. There he became a pillar of the local Literary and Philosophical Society.

Mawson subsequently married one of Swan's sisters before dying in an accident in 1867, leaving Swan as sole proprietor of their business. Swan subsequently took on another partner in order to concentrate his own efforts on research work. The druggist's shop continued to operate from the same premises in Grey Street when Swan eventually moved to London, and it functioned under the name Mawson, Swan, and Morgan until it finally closed its doors in 1973.

Swan married Frances White, the daughter of a Liverpool merchant, on July 31, 1862; three of their five children survived to adulthood (two twins perishing in infancy), but Frances died in 1868. Swan subsequently married her sister Hannah in 1871; that second marriage produced five children, all of whom survived to adulthood, although the youngest daughter predeceased her father, dying at twenty-nine. From 1869 until he moved south, Swan and his family were resident at Low Fell, near Gateshead.

Life's Work

While working with John Mawson, Swan became very interested in photography, and the shop's facilities provided him with a suitable environment for exploring its chemistry and technology. Their business expanded to market a number of products originated by Swan, including an improved collodion—a viscous solution of pyrox-



Joseph Wilson Swan. (Smithsonian Institution)

The Electric Incandescent Lamp

Two vital problems had to be solved before the phenomenon of electrically induced incandescence could be adapted to serve in a viable lamp: finding a filament that would produce an adequate amount of radiation over a long period of time without fracturing or burning out, and successfully maintaining that filament in a vacuum for a similar length of time. The crucial breakthrough came when Hermann Sprengel developed an improved vacuum pump, which facilitated the evacuation of glass bulbs that could be sealed without significant inward leakage; Joseph Wilson Swan was quick to realize this, as was Thomas Alva Edison in the United States.

The solutions to the former problem found by Edison and Swan were almost exactly the same, both involving carbonized filaments. The main difference was that Edison initially preferred a bamboo filament to Swan's weaker thread filament, but any superiority the Edison product temporarily enjoyed was lost when Swan developed the superior extruded cellulose filament, which Edison was slow to adopt. (Both filaments eventually became redundant when coiled tungsten filaments were developed.) The careful shaping of the containing glass bulb so as to secure its tensile strength, and the seal binding it to the housing of the electrical contacts, were also crucial to the success of the technology.

Electrical lighting was a far more efficient means of lighting streets and homes than gaslight or candlelight. It completed a revolution against the tyranny of night that made the streets infinitely safer, initiating the era of modern policing, and made reading so much easier as to institute revolutions in both popular fiction and education. The technology's abundant spin-offs included the entire realm of practical electronics.

ylin in a mixture of organic solvents, including alcohol, ether, and acetone, used as a coating for photographic surfaces. "Mawson's collodion" became a famous local product in northeast England.

Swan went on to devise a refined version of the carbon process for producing permanent photographic prints, which he perfected in 1864. This technology, considerably more significant than the previous one, became the basis of photogravure printing, and he continued to work on the improvement of that application by producing and marketing half-tone blocks for use in printing. He began producing bromide dry plates in 1877, and Mawson and Swan's bromide plates (Swan maintained his brother-in-law's name on their produce although Mawson was long dead by then) also became celebrated as a commercial product. He followed up this discovery by adapting it in 1879 to the production of bromide paper.

In 1845, when he was only sixteen, Swan had been present at a demonstration of electrically induced incandescence at Sunderland Atheneum. The phenomenon was already well known, and the prospect of adapting it for use in lamps was clearly visible on the technological horizon, but the practicalities of developing such a lamp proved awkward. Swan began experimenting with electrical incandescence in 1860, twenty years before Thomas Alva Edison took up the problem in the United States. Swan actually took out a patent on an incandescent bulb, but his prototypes were unsatisfactory, partly because the vacuum within his bulbs could not be effectively sustained and partly because the incandescent material could not be refined to the point at which the lamps were sufficiently long-lived for commercial exploitation. Swan therefore set the problem aside to concentrate on his experiments with photography.

The existence of the Swan patent was something of an inconvenience to Edison when he set out to develop an electric lamp of his own in the late 1870's. Swan also resumed work on his electric lamp at about the same time. Both men had been encouraged to do so by Hermann Sprengel's invention in 1875 of a new vacuum pump, which opened up the possibility of producing efficiently evacuated sealed bulbs to contain incandescent filaments. Swan substituted carbonized thread for the bulkier slivers of wood that he had earlier used as filaments, while Edison applied for a new patent employing a bamboo filament.

Swan demonstrated his electric lamp privately for the first time in December, 1878, and then gave a public demonstration at a meeting of the Newcastle Literary and Philosophical Society in February, 1879. A further eighteen months of development produced a product that was technically and commercially viable, which was demonstrated at another meeting of the Literary and Philosophical Society on October 20, 1880. The room was entirely lit for the occasion by Swan lamps. Swan went on to demonstrate his lamp at the Institute of Electrical Engineers, and it was shown at a Paris Exhibition in the following year.

Swan's own house was the first to be lit by electricity, but a fellow member of the Newcastle Literary and Philosophical Society, Lord Armstrong, soon commissioned him to install electric lighting at his home, Cragside, near Rothbury. More domestic installations followed, but the lamp's first great publicity coup was at the Savoy Theatre in London, where the D'Oyly Carte company had a set installed as a component of its stage lighting, using the lamps for the first time to light the fairy scenes in W. S. Gilbert and Arthur Sullivan's *Iolanthe* (1882).

Swan set up a company to market his electric lamp before the end of 1880, but it was superseded by a larger company in 1882; it was at that point that the Edison Company initiated legal action for patent infringement. Given that an English court was highly likely to uphold Swan's original patent, the action might have been a nuisance suit intended to tie up Swan's finances. The case, however, never came to court, because the two companies agreed to combine their operations in England as the Edison and Swan United Electric Light Company, while Edison continued to enjoy a monopoly in the United States. By this time, Swan had further improved his design, using an extruded cellulose filament, and all the lamps sold in Great Britain thereafter were made to Swan's design, while Edison continued to use his own filaments in the United States for several more years.

Because the Edison and Swan United Electric Light Company took over the Edison Company's former local headquarters in London, Swan moved his family south from Low Fell, initially settling in Bromley, Kent, in 1883. The company moved to Ponders End in 1886, where it expanded considerably, eventually establishing a factory to make thermionic valves in 1916, thus becoming the foundation stone of the British electronics industry. Swan subsequently bought a house in Holland Park in 1894, the year in which he was elected as a fellow of the Royal Society. In 1898, he became president of the Institute of Electrical Engineers. In 1900, he received an honorary doctorate from the University of Durham, which had previously presented him with an honorary M.A. He subsequently served as president of the Faraday Society and—perhaps somewhat belatedly—as president of the Literary and Philosophical Society of Newcastle upon Tyne. He was knighted in 1904.

Although the electric lamp made his fortune, Swan did not rest on his laurels; he continued to seek innovations in various fields as he had throughout his career. His other major achievements included the chrome tanning process for leather and the cellular lead plate for use in rechargeable batteries, for which he had obtained a patent in 1881. The method by which he eventually produced extruded cellulose filaments for use in electric lamps also proved adaptable to other purposes, the most notable being the manufacture of artificial silk, another of his discoveries. His activity was eventually curtailed by health problems, and in 1908 he moved to Overhill, near Warlingham in Surrey, when heart trouble made it impossible for him any longer to take an active role in his business. He died six years later.

Impact

Swan was a typical technological entrepreneur of the Victorian era: a "self-made man" who rose from poverty by virtue of his ingenuity and business acumen to win wealth and social advancement. Most of his innovations were relatively unspectacular and were lost to sight when they were superseded, and the one that made him rich and famous was overshadowed by the enormous reputation of a rival claimant. To this day, it is Edison rather than Swan who is almost universally, but somewhat unjustly, regarded as *the* inventor of the electric light bulb. It was Swan, however, who took out the first patent and subsequently matched his rival in terms of the redevelopment of the technology; his decision to join the Edison Company rather than attempting to beat it must be reckoned generous, especially as it left the United States entirely at Edison's disposal.

Although his fame and wealth arrived belatedly, partly because he labored so long in the unfashionable northeast corner of England, Swan was enabled to enjoy them by living to a ripe old age—which also enabled him to see many of London's streets and homes lit by his most celebrated invention. That presumably gave him a great deal of satisfaction, and justifiably so. The crucial role he played in facilitating the incorporation of photographic illustrations in books and magazines also made his influence widely felt, albeit indirectly, in Victorian public and private life.

Leo Szilard

Hungarian American nuclear physicist

Szilard conceived the chain reaction necessary for a nuclear reactor or an atomic bomb. Szilard was a contributor to the Manhattan Project, which produced the first atomic bombs, used to end World War II.

Born: February 11, 1898; Budapest, Austro-Hungarian Empire (now in Hungary)
Died: May 30, 1964; La Jolla, California
Primary field: Physics
Primary inventions: Nuclear chain reaction; atomic bomb

Early Life

Leo Szilard (LEH-oh SEE-lahrd) was born to Louis and Tekla Spitz, a Hungarian Jewish couple. They changed their last name in 1900 to Szilard, meaning "solid," because of governmental pressure to change foreign-sounding names. Leo had a brother, Bela Szilard (later to be known as Bela Silard) and a sister, Rose Szilard. Since their father, Louis, was an engineer, the boys received solid training in mathematics and the sciences. Leo Szilard attended what would become the Budapest Technical University. During World War I, he was drafted into the army. As a college student, he was trained as an officer but was at home, sick with the Spanish flu, when his unit was sent to the front and demolished. The war ended before he recovered.

In 1919, Szilard went to Berlin to study electrical engineering but found physics so intriguing that he began to work toward a doctorate with Max von Laue. Although it was not the problem that he was assigned, Szilard worked out the mathematical proof that Maxwell's demon could not violate the second law of thermodynamics. One outcome of the second law is that it is impossible to create a perpetual motion machine. Maxwell's demon had to have knowledge (a "bit" of information) of the particles to sort them. This extra information would allow the sorting of particles. Szilard proved that because the information cannot be known, Maxwell's demon cannot generate a perpetual motion machine. This proof earned him a doctoral degree and was the cornerstone to the field of information theory that developed later.

Szilard became von Laue's assistant and later an assistant professor at the University of Berlin. During this time Szilard collaborated with Albert Einstein to invent a refrigerator with no moving parts. Although in seven years they designed three different types of refrigerators and received several patents, none of the refrigerators made it into public use. From this work, however, did come the Einstein-Szilard electromagnetic pump. The pump had no moving parts but instead used an electromagnetic field to push a liquid metal. In 1933, Szilard fled Nazism and Berlin for Vienna and then England. In 1937, he moved permanently to the United States.

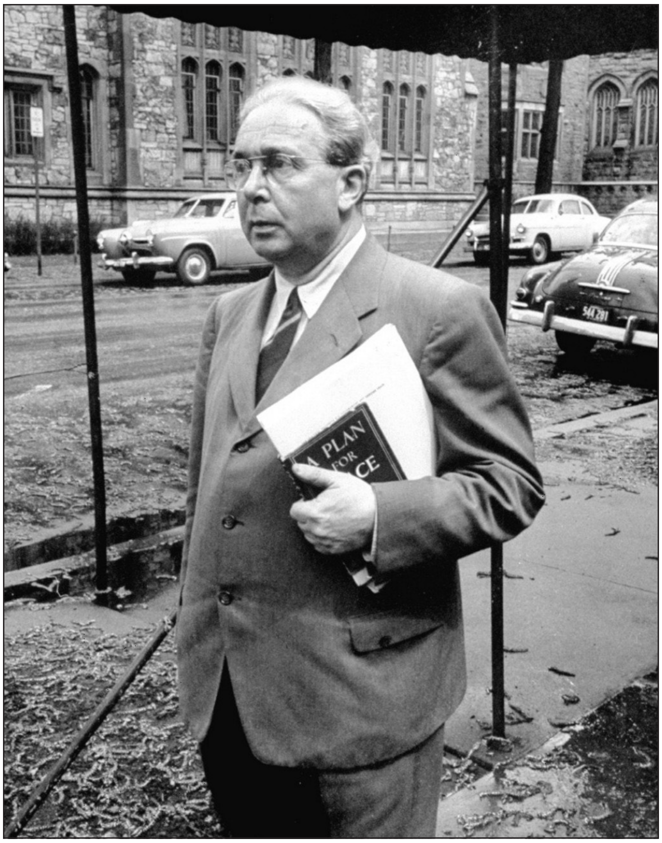
Life's Work

In 1933, Szilard conceived of the concept of a nuclear chain reaction. His thoughts were that it would produce the power needed for the modern world. He first considered beryllium and actually tested it and a few other elements to see if they would produce the chain reaction. In 1939, Szilard thought uranium would produce such a reaction after he heard of the fission of uranium reported by Otto Hahn, Fritz Strassman, and Lise Meitner. After testing the idea and hearing of the work by German scientists, he convinced Einstein to sign a letter that he wrote to President Franklin D. Roosevelt warning the president that German scientists were doing experiments that could lead to making a bomb of dramatic proportion. The letter resulted in a committee being formed and eventually the start of the Manhattan Project to build a bomb.

Szilard worked with Enrico Fermi in building the first nuclear reactor, which proved the concept of nuclear chain reaction. He was the person who arranged for boron-free graphite to be used as a component of the reactor. Normal graphite contains boron, which absorbs neutrons and slows the chain reaction. He continued to contribute to the Manhattan Project until the atomic bombs were completed.

After Germany surrendered, Szilard did not want the bomb to be dropped on Japan. He felt that a demonstration of its power would be enough. After the war, he worked for peace. He had always feared the power of nuclear weapons. He even tried to start peace talks with the Soviet Union. He wrote books such as *How to Live with the Bomb and Survive* (1960) and *The Voice of the Dolphin* (1961), a science-fiction look at how dangerous nuclear weapons can be. Szilard also began to work in 1946 on antibodies and on the regulation of enzymes.

On October 13, 1951, he married Gertrud "Trude" Weiss; however, they did not live together until his health began to fail in 1959. Szilard had met the Viennese woman in 1929 and was her mentor and longtime friend. He suggested that she attend medical school because he thought that she was, in his words, too dumb to be a physicist. They had traveled together in England in 1936 and several times in the United States. In the years before their marriage, he had often visited Trude. She worked as a medical doctor in New York, and after 1950, she taught at the University of Colorado Medical School. When Szilard was stricken with bladder cancer in 1959, he arranged for a new type of radiation treatment with Trude as his doctor. The radiation treatment was successful. In February, 1964, they moved to La Jolla, California, for Szilard to take a position at the Salk Institute. He died May 30, 1964, in his sleep, of a heart attack.



Leo Szilard. (Time & Life Pictures/Getty Images)

Szilard was a brilliant man who enjoyed exchanging ideas with others more than he enjoyed mundane everyday research. He knew how to do research but he wanted to supply the idea and sometimes the advice, yet have someone else do the day-to-day routine work. He liked to sit for hours in a bathtub, where he did some of his best work. His work schedule, or in some views, lack of work schedule, often meant that he had difficulty holding a paying position that offered the freedom that he wanted. His desire was to be able to travel to talk with other scientists. His position at the Salk Institute was his dream job.

The list of ideas that Szilard had is astounding. In 1923, he designed an X-ray sensor element. He next developed an improvement for mercury-vapor lamps for which the Siemens Company bought the licenses. In 1928, he patented a linear accelerator, independent of the design of Rolf Wideroe. A year before Ernest Lawrence built his cyclotron in 1929, Szilard patented a cyclotron and a betatron. All modern accelerators except for electrostatic machines are based on a combination of several ideas: multiple acceleration, focusing, frequency modulation, and phase stability. All of these were theories conceived by Szilard between 1928 and 1934. He also foresaw the electron microscope by 1928. While Szilard was in Berlin (1920-1933), he was granted thirty-one patents. The only patent that actually came to fruition was the "Discharge Tube to Be Used as an Electron Source." Szilard and Einstein designed and received several patents for three types of refrigerators: absorption, diffusion, and electromagnetic. The most successful idea in terms of use of the early collaboration of Szilard and Einstein was the Einstein-Szilard pump. Its inherent safety makes it valuable in cooling breeder reactors. In 1933, he conceived his most famous idea, the nuclear chain reaction. Shortly afterward, he worked with Thomas Chalmers using a neutron source to irradiate different samples. The results from this work became known as the Szilard-Chalmers reactions, or hot atom chemistry. His work with Chalmers allowed him to eliminate beryllium

Hot Atom Chemistry

In 1934, Leo Szilard and Thomas Chalmers developed the Szilard-Chalmers reactions, a method for concentrating artificially produced radioactive isotopes. The Szilard-Chalmers reactions are now often called "hot atom chemistry." By bombarding ethyl iodide with neutrons, the iodide absorbs a neutron, causing stable I-127 to become radioactive I-128, which emits a gamma ray. The recoil energy of the atom from the gamma ray is enough to break the chemical bonds and allow the I-128 to escape the compound. The separated I-128 can then be extracted with water and precipitated with silver ions. In this way, Szilard established a method to separate isotopes. If the right extraction is used, the method can produce a carrier-free isotope. If the temperature of the recoil energy is calculated, it is close to a million degrees, thus the term "hot atom" chemistry. A second advantage is that not all of the I-128 is extracted from the sample so it can be used as a medical tracer.

The Szilard-Chalmers reactions have been used with carbon 11 to study mechanisms of organic reactions. Carbon 11 has also been used extensively in diagnostic medicine. For example, the use of L-dopamine in the treatment of Parkinson's disease could be researched because of these reactions. The chemistry of germanium and silicon has been studied by using "hot atom" techniques.

and a few other elements as chain reaction candidates. In 1935, Szilard conducted a series of experiments on slow neutron absorption that proved him to be competent as a nuclear physicist. In 1939, he went to Columbia and worked with Walter Zinn to prove that neutron-induced fission of uranium did produce enough product neutrons, at least two, to make a chain reaction possible. Szilard and Fermi designed and helped build the first nuclear reactor. Szilard later designed a breeder reactor that would produce plutonium 239. Plutonium 239 could also be used to produce a nuclear chain reaction.

Impact

Without Szilard, the world might not have nuclear power. In the United States, 20 percent of all electricity is generated by nuclear power plants. In other countries, the use of nuclear power is even greater, producing 70 percent of the electricity for France. One-third of the electricity for Belgium, Sweden, Spain, and Switzerland is from nuclear power.

The breeder reactor is used more in other countries than in the United States. The breeder reactor produces new fuel for the next round of energy production while making energy to produce electricity. It uses the neutrons from the fissioning of uranium 235 to change uranium 238 to plutonium 239. This method was used to produce the plutonium for the atomic bomb tested at White Sands, New Mexico, and the atomic bomb dropped on Nagasaki, Japan.

Toyoichi Tanaka

Japanese American biophysicist

Tanaka's discovery of the phase transition of polymer gels initiated a new field of research, making it possible for scientists to see microscopic changes in a macroscopic way. Because the "smart gels" respond to stimuli by expanding and contracting exponentially, they are valuable for use in a wide variety of applications.

Born: January 4, 1946; Nagaoka, Niigata Prefecture, Japan
Died: May 20, 2000; Wellesley, Massachusetts
Also known as: Toyo Tanaka
Primary field: Physics
Primary invention: Smart gels

Early Life

Toyoichi Tanaka (to-yo-ee-chee tah-nah-kah) was born in Nagaoka, Niigata Prefecture, Japan, on January 4, 1946, to Toyosuke and Shizu Tanaka. As a child, he enjoyed athletics and was competitive in swordplay, racing, and sumo wrestling. He played baseball in junior high school for a time before stopping to devote time to preparing for entrance examinations into a good high school. He graduated from the elite Hibiya High School in 1964 before entering the University of Tokyo. His growing interest in the sciences was due in part to the influence of his father, a chemistry professor. In 1968, Tanaka received a bachelor of science degree in physics, followed two years later by a master's degree, and in 1973 a doctor of science degree, all from the University of Tokyo. In 1970, Tanaka married Tomoko Tahira. The following year a son, Kazunori, a graduate student in physics at the Massachusetts Institute of Technology (MIT) at the time of his father's death, was born. In 1972, Tanaka began postdoctoral work in physics at MIT, working with Professor George Benedek. A daughter, Ayako, was born in 1974. In 1975, he joined the physics faculty at MIT, rising to the rank of professor (1982) and becoming the Morningstar Professor of Science (1997). During the 1980-1981 academic year, Tanaka was visiting professor at the Pasteur Institute in Strasbourg, France, and was the Rashmer lecturer at the University of Washington in 1987. He also contributed a number of articles to professional journals and was editor in chief of the periodical *Polymer Gels and Networks* in 1992.

Life's Work

Tanaka was only in his thirties when he made his first big discovery, that of the phase transition of polymer gels. Through his experimentation, he was able to make important theoretical predictions about polymers; in so doing, he gave birth to a new field of research. In the mid-1970's, he found that polyacrylamide gels had the ability to respond to minute changes in their environment—variations of temperature, light, magnetism, or electricity—by changing color or by expanding or contracting exponentially. Tanaka fine-tuned gels to undergo radical changes, or phase transitions, when they came in contact with chemicals or environmental variations. This ability to react radically to these environmental changes resulted in the polymer gels with which he worked being labeled "smart" gels.

Because of the properties of expansion and contraction, Tanaka's gels are ideal for a number of practical applications in varied fields, such as in medicine, industry, and agriculture. In medicine, for example, when the appropriate gels are exposed to electricity, they may undergo a thousandfold increase in volume that allows them to function as artificial muscles when they are set in motion by a particular electrical pulse. They can also be programmed to release insulin when glucose levels drop below a certain point and used in other controlled drug release products. The gels are also being used in such products as long-lasting sunscreen and eyedrops. In industry, the smart gels have proven to be effective in the cleanup of oil spills and in the absorption and immobilization of toxic waste because they act as giant sponges. They may also act as molecular filters of various kinds. The gels are useful in personal care items such as diapers and certain cosmetic products in which they can hold and then release ingredients such as fragrances in response to the pH level of the skin. Agricultural applications are numerous as well.

As Tanaka's research continued, he was able to elucidate the roles of the various chemical and physical forces found in natural and artificial polymers involved in the phenomenon of polymer folding, the process whereby a polymer's linear chair of molecules crumple, or fold, into more solid shapes so that they can perform their microscopic functions within living organisms. Putting this knowledge to practical use, Tanaka helped many scientists and companies to realize the practical applications of his work. In fact, in 1992, he cofounded GelMed, Inc.,

Smart Gels

Toyoichi Tanaka was recognized worldwide for his revolutionary discovery of smart gels, which is the phase transition in polymer gels. A gel is a polymer, a long chain of molecules, or monomers, which is cross-linked much like a web of fibers, giving it elasticity and fluidity. These links allow a gel to capture water. Smart gels are called "smart" because of their ability to expand, contract, or change color when they are exposed to even the slightest of variations of temperature, magnetism, light, or electricity. This ability of the gels to experience very large but reversible changes in volume make the gels ideal for a number of important applications in a number of fields, such as in chemistry, agriculture, medicine, and engineering. What material a gel interacts with determines what its behavior will be.

Thanks to Tanaka's pioneering research, experimentation with smart gels, which are stimuli-responsive polymers, continues to search for practical applications in a wide variety of fields. Biomedical applications include such things as controlled drug release, ocular devices, and the synthesis of products by artificial mechanisms that mimic those in nature (biometrics). Agricultural applications include soil additives to conserve water, the coating of plant roots to increase water availability, and seed coating to increase germination rates. In industry, smart gel applications are numerous, and the future may well find many more.

Understanding the phase transitions of gels enables one to better understand the functions of proteins, which are the molecular basis of life. Proteins are made up of different sequences of twenty amino acids. Amazingly, these proteins can twist themselves into various shapes that they can "remember." They are able to recognize particular molecules that they can store or release as needed, and, as such, they can assist in effecting life-sustaining chemical reactions. Scientists are able to determine the sequence of amino acids that make up a specific protein, but it remains for future research to determine how to make one from scratch.

At the time of Dr. Tanaka's death in 2000, he was working on synthesizing a gel that possessed characteristics similar to those of proteins that could recognize a target molecule. His hypothesis was that this research could possibly produce a model, even if a crude one, of pre-biotic polymerization, a key step in the origin of life. The current theory, that in the early days of Earth amino acids in some primordial soup came together randomly in a sequence capable of sustaining life, was unsatisfactory to Tanaka. Given the possible working sequences of amino acids, he held that not all the possible combinations could have been tried, given the age of the universe. It remains for future scientists to discover all the potential applications of Tanaka's smart gels.

and a sister company, Gel Sciences, Inc. These companies explored medical, cosmetic, commercial, and industrial applications for polymer gels. Tanaka later cofounded Buyo-Buyo, Inc., a company that concentrates on finding medical solutions for enhancing and extending human life. Of particular interest to him was the idea of using smart gels to build artificial muscles. In the latter years of his life, Tanaka focused his energies on trying to unravel the mysteries of the origin of life, with which he saw a direct connection with his gel research.

Tanaka was honored with a number of awards before his untimely death. While still in his thirties, Tanaka received the Nishima Memorial Prize in 1985, and the following year the Award of the Polymer Society of Japan. He became a fellow of the American Physical Society in 1992, and in 1993 he was awarded the Vinci d'Excellence in France. In 1994, he received the Inoue Prize for Science, awarded for his outstanding achievement in basic science and given annually to a scientist under age fifty. In 1996, he won both the R&D 100 Award and *Discover* magazine's Editor's Choice for Emerging Technology Award. In 1997, he was the winner of the Thirty-eighth Toray Science and Technology Prize from the Toray Science Foundation in Japan. He was a Nobel Prize nominee and was considered one of the frontrunners among Japanese scientists to win one in the future, had his life not been cut short.

Tanaka's hobbies included jazz piano, guitar, shogi (Japanese chess), watching movies, reading, and tennis. On Saturday, May 20, 2000, he died of an acute myocardial infarction at age fifty-four, while he was playing tennis.

Impact

While the general public may have heard about Tanaka through his inventions and applications of his polymer gel research, especially that having to do with smart gels, it was his scientific research and discovery that may prove to have been his greatest contribution. Because of that research, countless numbers of later researchers, scientists, and inventors whom Tanaka himself never met may well benefit from his work for years to come. Nevertheless, it is undoubtedly his work with polymers, and his revolutionary discovery of smart gels in particular, that have assured him a lasting place in scientific discovery. The sheer number of practical applications as diverse as pollution-cleanup materials and cosmetics make his work important to an immensely wide variety of products.

In addition to Tanaka's work with polymer gels, he also contributed to the body of knowledge regarding the still-elusive process of polymer folding, the process by which polymers do not stay in the lengthened forms in which they begin but instead break into various solid shapes so that they can perform their microscopic functions within living organisms. Tanaka's elucidation of the roles, in polymer folding, of the various chemical and physical forces found in natural and artificial polymers led to numerous practical applications.

Not the least of Tanaka's impact on the world of science was his work with students; many of them considered themselves fortunate to be able to work in Dr. Tanaka's laboratory at MIT. He had the reputation of being a superb teacher who could hold students spellbound with his demonstrations.

In the final years before his death, Tanaka focused his energies on trying to unravel the mysteries of the origin of life. He could not accept the then current theory of the origin of life, and he died while pioneering a new frontier of science.

Charles E. Taylor

American machinist and airplane mechanic

Taylor manufactured the aircraft engine used by the Wright brothers in 1903. He also built engines that powered their 1904 and 1905 airplanes and was the mechanic for the Wright Flying School at Huffman Prairie, Ohio.

Born: May 24, 1868; Cerro Gordo, Illinois
Died: June 30, 1956; Los Angeles, California
Also known as: Charles Edward Taylor (full name)
Primary field: Aeronautics and aerospace technology
Primary invention: Aircraft engine

Early Life

Charles Edward Taylor was born in the small town of Cerro Gordo, Illinois, to hog farmers Willet and Elmira Taylor. A hog cholera epidemic forced the family to move to Lincoln, Nebraska, in 1878. Taylor worked in a bakery and quit school after the seventh grade. At age twelve, he began work for the *Nevada State Journal* and worked his way into the bindery. It was here that he began his lifelong love affair with machinery. Taylor later claimed that the hog cholera epidemic was responsible for his career as a machinist.

As a young man, Taylor moved to California and worked briefly as a surveyor. Returning to Nebraska, he opened a machine shop. In 1892, he met Henrietta Webbert, and they were married two years later. In 1896, the Taylors moved to Dayton, Ohio, where Charles took a job with the Stoddard Manufacturing Company, a producer of farm machinery and bicycles. In 1898, he opened another machine shop where he did some subcontract work for Wilbur and Orville Wright. Coincidentally, Henrietta's family was familiar with the Wrights, and Henrietta's uncle owned the building in which the Wrights' bicycle shop was located.

Taylor sold his machine shop and accepted a job with the Dayton Electric Company but was soon hired as a full-time machinist by the Wrights. Taylor was aware that the Wrights were interested in gliders and flight, but he knew very little about airplanes or the brothers' flying activities. Taylor would later claim that he was hired as much for his management skills as for his machinist skills. Indeed, he managed the day-to-day affairs of the bicycle shop as the Wrights spent more time with their experiments, making trips to Kitty Hawk, North Carolina. This was to change when they returned from Kitty Hawk in 1901 and began construction of a wind tunnel for aerodynamic testing. Thus began Taylor's aviation career.

Life's Work

When the Wright brothers returned from Kitty Hawk in 1901, they recruited Taylor to assist in the construction of a wind tunnel to verify lift and drag calculations. He constructed balances for the machine by grinding down old hacksaw blades. After completion and testing of the wind tunnel, Taylor returned to managing the bicycle shop, leaving the aviation experiments to the Wrights. In 1902, the brothers announced that they were finished with glider experiments and desired to conduct powered flights. However, they met total resistance from engine manufacturers, who were unwilling or unable to construct an engine to meet the Wrights' specifications. The Wrights again turned to Taylor to manufacture an engine that would be light enough and powerful enough for their aircraft. Taylor was confident that he could manufacture such an engine, even though his only experience with engines up to that time was an attempt to repair an automobile engine in 1901. In six weeks, without any blueprints, and using only the limited machinery in the bicycle shop, he proceeded to manufacture the first successful aircraft engine.

The design and construction of this engine was critical to the Wrights' success. They calculated that the engine must weigh less than 180 pounds and develop at least eight horsepower. Working from hand-drawn sketches tacked to the machinery, Taylor constructed the engine. Since he kept no personal records, there is only limited information available about exactly how he manufactured the various parts. None of the original sketches have survived. What is known is that the original crankshaft was machined out of a hundred-pound block of tool steel and that the pistons and cylinder barrels were cast from a fine-grained iron. Taylor manufactured a number of duplicates for each part for constructing what he called a "skeleton model." This was a nonfunctional engine that was hooked up to the shop power system to verify the fit and proper operation of all the parts. Once Taylor was satisfied that everything fit and worked as expected, the actual engine was constructed.

Taylor's engine significantly exceeded the Wright brothers' specifications. It weighed 170 pounds, including all of the accessories, and produced twelve horsepower at 1,025 revolutions per minute (RPM). Taylor made use of readily available materials for construction. He built the radiator from metal speaking tubes commonly used in apartment houses, the ignition from components manufactured by Dayton Electric Company, and the fuel valve from a gas lamp. Taylor's vision and ingenuity was instrumental in the Wrights's historic flight on December 17, 1903, when they successfully flew a heavier-than-air plane at Kitty Hawk.

Taylor continued to design and build engines for the Wright brothers as their aircraft designs evolved. His 1904 engine developed eighteen horsepower. He integrated an automatic oiling system to prevent engine seizure. His 1905 engine was the first engine powerful enough to allow the carriage of a passenger. He built a thirty-two-horsepower engine for Army tests in 1907, and his successful 1909 military engine produced thirty-five horsepower. In addition to constructing engines, he machined metal fittings and helped assemble and rig the airplanes for flight. He accompanied the brothers to the military trials and accompanied Wilbur to France in 1907. Taylor was the only full-time employee of the Wrights until 1909, when they formed the Wright Company. At this point, Taylor was placed in charge of the engine shop.

Taylor apparently experienced some difficulty in the changing environment, and friction with the shop manager developed. This may have prompted him to accept a job with Cal Rogers in 1910. Rogers offered him $10 per day plus expenses to serve as his mechanic on a proposed cross-country flight. The Wright brothers wanted him to stay and convinced him to take a leave of absence rather than quit. Taylor accompanied Rogers to California, repairing the airplane after each of the many crashes en route. Because of his wife's ill health, Taylor decided to stay in California, where he worked for a number of early aviation pioneers, including Glenn Martin. After Wilbur Wright died in 1912, Taylor returned to Dayton and continued to work for Orville even after the company was sold. In 1919, Taylor accepted a job with the new Dayton Wright Company. He continued his association with the Wright Company and Orville, working with the company intermittently until 1928, when he moved back to California and virtually disappeared from the public eye.

Taylor did not reappear until he was approached by Henry Ford in 1937 to reconstruct the original Wright shop in Dearborn, Michigan. In this capacity, Taylor tracked down the original equipment, built a replica of the 1903 engine, and reconstructed the original shop. In 1941, he moved back to California, where he again seemingly disappeared. Taylor suffered a heart attack in 1945 and died in 1956 at the age of eighty-eight.

Impact

Taylor was a self-taught machinist with the ability to visualize how to manufacture an engine that could do what had never been done. Although he had limited experience with engines, he built the engine that made aviation possible. Without his insight and ability, the Wright brothers would not have flown successfully in 1903. He not only built the first successful aircraft engine but also improved it every year, allowing the Wright brothers to reach a level of performance that astonished the world. He is recognized by the Federal Aviation Administration as the world's first aircraft mechanic.

Due to his work managing the operations and flight school established by the Wrights at Huffman Prairie, Ohio, Taylor is also recognized as the first airport manager. He worked with many of the early pilots who flew for the Wright Exhibition Team. He was also instrumental in the success of the first transcontinental flight by Cal Rogers in 1911. During his sixty-year career as a machinist, he worked for a number of major aviation companies, including the Glenn L. Martin Company and North American Aviation.

Taylor is sometimes called aviation's forgotten man. He was a very private person, and many segments of his life remain undocumented. He did not seek the limelight or claim credit for the Wright brothers' success. He kept no personal records, and his essential contributions re-

The First Aircraft Engine

Charles E. Taylor was the first person to successfully address the problem of producing a satisfactory engine for powered flight. With no previous designs or experience on which to rely, and working with simple tools, he helped design, construct, and test the first practical aircraft engine. In six weeks, Taylor constructed an engine for aviators Wilbur and Orville Wright, exceeding their specifications. He produced virtually all the components himself in the brothers' bicycle shop.

Taylor claimed that this engine was the first four-cylinder aluminum block engine ever built. The crankcase was cast aluminum, and Taylor bored the cylinders on the shop lathe. Because of the limitations of the tools available, the water-cooled engine was mounted horizontally rather than vertically. The crankshaft was machined from a hundred-pound block of high carbon steel on which Taylor traced the outline of the shape he desired, drilled holes with the drill press, and knocked out the extra metal with a hammer. The engine had no throttle and employed a very simple carburetor system that vaporized the fuel, utilizing heat generated by the engine itself. This vaporized fuel was drawn into the cylinders through the open intake valve. Ignition was supplied by inducing a high-tension arc across platinum contacts within the cylinders. Initial ignition was supplied by a dry-cell battery, while a simple magneto supplied the current when the engine was running. Taylor incorporated a spark advance that actually retarded the ignition timing for ease of starting and a "kill switch" for grounding the magneto to shut down the engine. While these systems appear very primitive by today's standards, they were a giant step forward in 1903. Every component of the engine was designed to minimize weight without sacrificing the required power. The final product weighed 170 pounds and produced twelve horsepower.

While Taylor is remembered primarily for his 1903 engine, he continued to produce improved versions for the Wright brothers. He estimated that he built about six engines specifically for the Wrights, culminating with the 1909 "military version" that produced thirty-five horsepower. The Wright brothers recognized their debt to Taylor, and Orville Wright publicly credited Taylor for doing all of the machine work on the original as well as the succeeding experimental engines. Taylor's engine revolutionized the world of aviation on December 17, 1903, when the Wright brothers flew the first powered airplane at Kitty Hawk, North Carolina.

ceived little attention until the death of Orville Wright in 1948. After Orville's death, Taylor was awarded a number of honors in recognition of his lifelong contributions to aviation. In 1965, he was inducted into the National Aviation Hall of Fame. More than a footnote in aviation history, Taylor was a major supporting character to more widely known actors. His contributions throughout his life were vital to the perfection of the design of the modern airplane.

Maria Telkes

Hungarian American biophysicist

Telkes made significant developments in the application of solar energy for practical use and is most notably attributed with designing the first solar home. Her primary research into phase-change thermal storage produced more than one hundred published papers, books, and numerous patents and inventions. The solar still and solar oven, two of her forward-looking inventions, are garnering renewed interest today in environmentally conscious circles.

Born: December 12, 1900; Budapest, Austro-Hungarian Empire (now in Hungary)
Died: December 2, 1995; Budapest, Hungary
Also known as: Maria de Telkes (birth name); Sun Queen
Primary fields: Electronics and electrical engineering; physics
Primary inventions: Solar home; solar oven; solar stills

Early Life

Like most active teenagers in Hungary in the early 1900's, Maria Telkes (TEHL-kehs) spent much of her free time outdoors. Born on December 12, 1900, in Budapest, Austro-Hungarian Empire, to Aladar and Maria Laban de Telkes, she lived an active and full life. Her favorite outdoor activities were swimming, ice-skating, and sledding. Her enthusiasm for the outdoors was equally matched by her interest in the classroom and for her studies, in which she showed an increasing aptitude in science.

In high school, Telkes's imagination was stirred by reading a book titled *Future Sources of Power*. Inspired by what she read, she sought out more information, reading all the literature she could find pertaining to the Sun. She did not stop at her own Hungarian language, however; she continued reading in French, German, and English. While the book introduced ideas surrounding solar energy, they were largely still theoretical in her day.

However, Telkes in due course made practical what many had only imagined possible. It is not too much of a stretch to claim, then, that Telkes's lifetime quest to harness solar energy began with the reading of a book.

After high school, Telkes pursued studies in physical chemistry, receiving a bachelor of arts degree in 1920 and a doctorate of philosophy in 1924 from the University of Budapest. In her last graduate year, she gained experience teaching physics at a local Budapest high school. Encouraged by her early teaching experience, Telkes would return to work in academia repeatedly throughout her life.

Maria Telkes adjusts the energy levels of the Dover House, the first solar-powered home, built in 1948. (Time & Life Pictures/Getty Images)

Life's Work

Shortly after receiving her doctorate, Telkes visited the United States and stayed with her uncle, the Hungarian consul to Cleveland, Ohio. During this visit, she accepted a position as a biophysicist at the Cleveland Clinic Foundation, often working alongside one of its founders, Dr. George Crile. Their collaboration produced a book, *The Phenomena of Life* (1926), and led to the invention of a photoelectric device that recorded the brain's energy waves. Telkes applied herself diligently for the next twelve years at this post, where she studied cellular transformation, particularly as it applied to carcinogenesis, the development of cancer.

In 1937, Telkes initiated the first of many changes for her future career. She became a naturalized citizen of the United States and swapped her job and research direction by moving to Westinghouse Electric, where she studied heat energy. Possibly her many research interests or her past fascination with the Sun compelled her to restlessness, but whatever the impetus, Telkes changed positions frequently after her long stint at the foundation. Although she stayed at Westinghouse but two years, significantly, her new focus set her firmly on a path to discover practical ways to harness the Sun's energy.

Her new research direction started in earnest when Telkes joined the Solar Energy Conversion Project at the Massachusetts Institute of Technology (MIT) in 1939. The project's goal—to study energy conversion—had considered more conventional responses to store solar energy by heating bricks, rocks, concrete, or water. However, as a physical chemist, Telkes offered a novel but more appropriate response. Her solution recommended transforming and storing energy using a common and abundant material: Glauber's salt (sodium sulphate decahydrate). Inexpensive, plentiful, and nontoxic, Glauber's salt is derived from natural sources as well as from common by-products of chemical manufacturing processes. Traditionally used in the making of detergents, glass, and paper, it has a high heat storage capacity and melts when heated and solidifies (crystallizes) when cooled. Telkes discovered it was ideal as an energy conversion material because, when mixed with water, salt hydrates have a range of temperatures appropriate for solar storage systems: 85°-120° Fahrenheit for active systems, 70°-75° for passive systems, and 40°-65° for cooling. Making use of the material's phase-change capability, she proposed drawing ambient temperatures from the Sun during the day and outside air during the night to heat or cool a house as needed. Her solution, then, was inventive as well as economically ideal. Telkes's idea culminated in the building of the first solar house: the Dover House.

Taking note of Telkes's growing expertise with solar power was the U.S. government. Recruited during World

War II to prevent downed pilots from dehydration, Telkes, while working at the New York University College of Engineering Research Division, developed a solar still. Installed on life rafts, the still desalinated and demineralized the seawater using solar energy, making it fit for consumption. The solar still, constructed with several frames, made use of a weatherable Mylar film, painted black on a front surface-facing plate to absorb the Sun's energy. Later, Telkes was able to expand on her idea to design a large-scale solar desalinator in the U.S. Virgin Islands—a place chronically short of fresh water.

Throughout her life, Telkes continued research and development into solar application with an eye always toward utilizing practical and inexpensive materials. She developed a solar oven, intrinsically valuable to developing countries, and helped design materials used in the Apollo and Polaris space ventures to protect instrumentation from extreme temperatures. Recognized for her achievements, Telkes received the Certificate of Merit in 1945 from the Office of Scientific Research and Development for her solar still design. In 1952, she accepted an Achievement Award from the Society of Women Engineers and was recognized with the Greely Abbot Award by the International Solar Energy Society. In 1958, the Ford Foundation awarded her a grant of $45,000 to develop her solar oven design. In 1977, for her pioneering work in solar-heated technology, Telkes joined the ranks of previous honorees such as Frank Lloyd Wright in being recognized by the National Academy of Sciences Building Research Advisory Board.

Telkes received emeritus status in her last academic post from the University of Delaware. Beginning and ending her career in academia, Telkes retired from active research in 1978 but continued to consult on solar energy matters into the 1990's. Telkes died in 1995 just shy of her ninety-fifth birthday, while visiting the place of her birth, Budapest.

The First Solar-Powered Home

In 1948, Maria Telkes's solar-heating and cooling system reached fruition in the building of the first solar-powered home. Commissioned by Amelia Peabody, designed by Telkes along with architect Eleanor Raymond, and named after its location on Peabody's property in Dover, Massachusetts, the Dover House was situated on the grounds to maximize the full potential of the Sun's rays. Incorporated within the building's walls was Telkes's phase-change thermal storage system. The home's black-painted glass walls concentrated the sunlight and directed the heat via air into bins that contained a mixture of sodium sulphate decahydrate, silica, and Borax. To maintain the viability of the energy storage system, and to prevent issues related to the gravitational settling of salts, Telkes added the agents of silica and Borax to the salt solution to inhibit its nucleating capability and decomposition by bacteria or enzyme action.

Telkes lived in the Dover House comfortably for a couple of months, and for several years records were kept to monitor the temperature of the five rooms. Relatives resided in the home for three years and claimed that the passive solar-heating and cooling system kept the home at a comfortable 70° Fahrenheit, even during the coldest and hottest season of the year. No auxiliary heating or cooling was required. After three years, the system failed, but her experimentation with solar energy continued on. In total, Telkes designed three solar-powered homes.

During the 1950's and 1960's, development of passive solar-heated house designs continued with homes pioneered in the United Kingdom, Canada, and Japan. In 1973, the University of Delaware built the first solar-powered demonstration house, Solar One. In her senior position at the university, Telkes developed the solar laboratory's heating system. Solar One, however, departed from previous solar house designs to use photovoltaics (PVs) to directly convert sunlight into both heat and electricity. Gradually, thin PV designs replaced passive solar-heated systems in research and development, funded largely by the government and prompted in part by the energy crisis of the 1970's. Around the world today, passive solar energy (radiant heat) designs outnumber PV implementations.

Impact

Today, with dwindling natural resources, appreciation of Telkes's early contributions to solar technologies may substantially increase, as her designs are proving to have far-reaching environmental application and relevance. The demand for solar stills and solar ovens has increased, particularly in developing countries and densely populated cities, where the availability of natural resources is becoming increasingly scarce.

The solar oven is in wide use and acceptance in parts of Africa. Recognized as an implement to help combat rampant deforestation, the inexpensive and practical functionality of the solar oven replaces traditional methods that employ wood fuel for cooking. Additionally, the device frees many people, typically women, from time-intensive chores. Where wood traditionally has been the only fuel available, its use leads to desertification of the surrounding area, and the resulting effects are often a dwindling water supply. Generally, when water becomes a limited commodity, conflict over rights of access normally follows. However, the solar still may help alleviate this problem in many areas as it makes available adjacent expanses of previously nonpotable seawater for consumption. In many ways, the applicability of Telkes's inventions promotes peaceful relations in a world that increasingly is finding that its available resources often outstrip its consumption.

Today, laws prohibit inequality in the workplace, but in Telkes's day women often had to overcome entrenched, patriarchal views concerning their role in science and engineering. Specifically, solar energy innovations often received less attention and funding than their nuclear counterpart because, as Telkes claimed, "Sunshine isn't lethal." Characteristically, then, women's contributions to science and innovative technologies were often ignored or given scant notice in gender-biased annals. However, thanks in large part to scholars in feminism, Telkes's contributions, and those of other women, are receiving current acknowledgment. In years to come, society may discover that it owes a further debt to Telkes's imagination and determination to harness the Sun's energy. For now, Telkes's lifetime commitment to solar application deservedly earns her the title of the "Sun Queen."

Edward Teller

Hungarian American physicist

Teller is frequently called "the father of the hydrogen bomb" because he played a major role in its design, development, and political acceptance.

Born: January 15, 1908; Budapest, Austro-Hungarian Empire (now in Hungary)
Died: September 9, 2003; Stanford, California
Also known as: Ede Teller
Primary field: Physics
Primary invention: Hydrogen bomb

Early Life

Edward Teller was born on January 15, 1908, to a Jewish family in Budapest, a major cultural center of the Austro-Hungarian Empire. His parents, Max Teller, a lawyer, and Ilona (Deutsch) Teller, a pianist, were well-educated and affluent. Edward was educated in private schools, and he showed talent in mathematics at a young age.

The breakup of the Austro-Hungarian Empire at the end of World War I happened when Teller was only ten years old. Political turmoil, as Hungary became indepen-

Edward Teller. (Lawrence Radiation Laboratory/AIP Niels Bohr Library)

dent, disrupted Teller's education. In 1926, Teller went to Karlsruhe, Germany, where he studied chemical engineering. He arrived in Germany just as a major new idea of physics, quantum mechanics, was developing. This highly mathematical technique to predict the behavior of microscopic particles appealed to Teller, who transferred to the University of Munich to study physics in 1928.

Teller's right foot was cut off in a streetcar accident later in 1928. After learning to walk with an artificial foot, he transferred to the University of Leipzig. Teller studied under Werner Heisenberg, one of the major figures in the development of quantum mechanics. In 1930, Teller was awarded a Ph.D. in physics. His thesis provided the first accurate quantum mechanical description of the "hydrogen molecular ion," a "three-particle system"—two hydrogen nuclei bound together by a single electron.

After receiving his Ph.D., Teller worked at the University of Göttingen, in Germany, for two years, but the rise of the Nazi Party made Germany unsafe for Jews. Assisted by the Jewish Rescue Committee, Teller left Germany in 1934. He went to London and then to Copenhagen, where he worked with Niels Bohr, another pioneer of quantum mechanics. George Gamow, a Russian physicist who Teller had met in Germany, persuaded George Washington University in Washington, D.C., to offer Teller a position in the Physics Department. Teller and his wife, "Mici" (Augusta Maria) Harkanyi, whom he married in February, 1934, moved to the United States. Teller worked with Gamow on problems in quantum, molecular, and nuclear physics until 1941. That year, Teller and his wife became naturalized American citizens.

Life's Work

In 1939, Teller and Hermann Arthur Jahn discovered the Jahn-Teller effect, which helps describe the chemical reactions of metals. The outbreak of World War II brought about a shift in Teller's interests from theoretical physics to the more applied areas of nuclear energy and weapons development.

In 1942, J. Robert Oppenheimer organized a meeting at the University of California, Berkeley, that resulted in the Manhattan Project, the code name for the U.S. effort to develop the atomic bomb. Research in Europe showed that a uranium atom could fission, breaking apart into two smaller atoms in a process that released energy. If enough energy was released in a short time, nuclear fission could be used in a powerful bomb.

Before Oppenheimer's meeting, Teller met with Enrico Fermi, who suggested that an atomic bomb might be used to produce the high temperature and pressure needed to fuse two very light atoms together, a process accompanied by an even bigger release of energy than could be achieved through fission. Although Teller first thought Fermi's idea would not work, he quickly became intrigued by this superbomb and described it at Oppenheimer's meeting.

A laboratory, directed by Oppenheimer, was established at Los Alamos, New Mexico, in 1943 to design and build an atomic bomb. Teller joined the Theoretical Physics Division of the Los Alamos National Laboratory in April of that year. He contributed to the understanding of implosion, a process that uses carefully shaped explosive charges placed around the outside of an object to compress the material inside. However, Teller's real interest was the superbomb. The first atomic bombs developed at Los Alamos were equivalent to about fifteen to twenty thousand tons of the chemical explosive trinitrotoluene (TNT), while Teller's superbomb, the hydrogen bomb, could have one thousand times that yield. The hydrogen bomb project was of low priority, however, at least until the atomic bomb was perfected.

In 1946, Teller again presented his idea for a hydrogen bomb. It used deuterium, a heavy isotope of hydrogen, as the fuel. However, other physicists thought Teller was too optimistic in assessing the feasibility of this design, which would require a very high temperature to initiate fusion. The suggestion that adding tritium, a heavier, radioactive isotope of hydrogen, to the deuterium would lower the required temperature was deemed reasonable. Unfortunately, the amount of tritium (which is very rare) required was unknown. Although Teller believed that the hydrogen bomb could be developed, the U.S. government did not proceed with the project. Disappointed, Teller left Los Alamos and accepted a position at the University of Chicago, where he worked with Fermi.

In 1948, after the Soviet Union tested its first atomic bomb, President Harry S. Truman decided to support the development of the hydrogen bomb. Teller went back to the Los Alamos laboratory in 1950, anxious to work on the development of his superbomb, but he soon became frustrated by the slow progress being made on the project. Calculations by mathematician Stanislaw Ulam showed that much more tritium would be needed than Teller had estimated, and the production of the isotope was slow and expensive.

In 1951, Ulam had an idea that allowed Teller to design a hydrogen bomb. With a feasible design, the Los Alamos group was able to test a hydrogen "device," technically not a bomb because it was too large and heavy (eighty-two tons) to be carried by any airplane. The test, code-named "Ivy Mike," was conducted on November 1, 1952, on the small island of Elugelab in the Enewetak Atoll in the Pacific Ocean. The bomb had a yield equivalent to 10.4 million tons of TNT, almost completely vaporizing Elugelab.

By then, Teller had left Los Alamos, disappointed that he had not been chosen to head the development effort. He moved to California, where the nation's second nuclear weapons laboratory, now the Lawrence Livermore National Laboratory, had just been established. Rather than viewing the blast from the test site in the Pacific, Teller observed the shock wave from Ivy Mike in Berkeley on a seismograph, a device usually used to record the ground tremors from earthquakes. He knew immediately that the test was successful. The first hydrogen bomb, code-named "Castle Bravo" and designed at Los Alamos, was tested at the Bikini Atoll in the Pacific Ocean

The Hydrogen Bomb

The hydrogen bomb generates energy by nuclear fusion, the same process that generates energy in the Sun. In nuclear fusion, two light ions come together to produce a single, heavier ion. If the heavier ion has a mass less than the sum of the masses of the two ions that came together, then the excess mass is given off as energy.

Nuclear fusion requires extremely high temperature and pressure, or else the two ions cannot come together because of the repulsive force of their positive charges. Edward Teller recognized in 1943 that a fission bomb could provide both heat and compression needed to trigger a fusion reaction. It took a decade to develop the idea into a practical design, so that the fission would trigger the reaction rather than just blowing the fusion fuel apart. Teller developed an idea from Stanislaw Ulam, who recognized that much of the energy from a fission bomb is released as X rays. He suggested the fission and fusion parts of the hydrogen bomb could be kept separate from one another, and the X rays from fission could produce the high temperature and pressure necessary to trigger the fusion reaction. X rays, which travel at the speed of light, would reach the fusion fuel faster than the shock from the fission explosion, providing the critical time needed for fusion reactions to release energy. To increase the X-ray intensity, those X rays emitted away from the fusion fuel would be reflected by a casing surrounding the bomb.

The Teller-Ulam design remains classified. It is believed to consist of a fission bomb located inside the reflector. Deuterium and tritium are generally used as the fuel for a fusion bomb, but both are gases at room temperature. For the "Ivy Mike" test in 1952, the gas was cooled to liquid helium temperature, so it was liquid. However, the fusion device was too heavy, so later tests combined deuterium with lithium, since lithium deuterate is solid at room temperature. Heat from the X rays exerts pressure on the lithium deuterate, compressing it to less than one-tenth its original volume. Neutrons, also produced in the fission bomb, react with the lithium, producing tritium, which lowers the temperature needed to initiate fusion. Tritium-deuterium and deuterium-deuterium fusion reactions produce additional heat, radiation, and neutrons, continuing the reaction for as long as fifty-billionths of a second, long enough to result in a large release of energy. The Ivy Mike device employed the Teller-Ulam design, producing about seven hundred times the explosive power of the first atom bomb test.

on March 1, 1954. The Livermore laboratory tested its first hydrogen bomb at Bikini a month later, on April 7, 1954.

Teller's testimony during congressional hearings on the renewal of Oppenheimer's security clearance, in 1954, alienated him from some of his colleagues. Although Teller testified that Oppenheimer had provided excellent leadership in developing the atomic bomb, he indicated that Oppenheimer hindered the effort to develop the hydrogen bomb. The Atomic Energy Commission (AEC) did not renew Oppenheimer's security clearance, citing in part his opposition to thermonuclear weapons.

Teller was named director of the Lawrence Livermore National Laboratory in 1958, but he resigned in 1960 so he could lobby against a proposed ban on testing nuclear weapons, testifying before congressional committees, appearing on television, and writing on the issue. Teller advocated the use of nuclear technology to solve a variety of military and civilian problems. He proposed excavating an artificial harbor by using nuclear explosions, to ship coal and oil from Cape Thompson, Alaska. The AEC adopted this plan, called Project Chariot, which would have exploded six hydrogen bombs in Alaskan waters. Project Chariot was canceled, however, because local residents and Alaskan political leaders were concerned about the possible radiation hazard.

Teller spoke out strongly in favor of President Ronald Reagan's Strategic Defense Initiative, a proposal to intercept and destroy intercontinental ballistic missiles using intense X-ray lasers, powered by nuclear explosions, which would have been deployed on orbiting satellites. He also advocated development of a system that would have used nuclear explosions to intercept and destroy asteroids on a collision course with Earth. Teller suffered a stroke and died in Stanford, California, on September 9, 2003.

Impact

Teller's work on implosion technology was important to the development of plutonium-based atomic bombs. This type was first tested in New Mexico in 1945 and dropped on Nagasaki, Japan, bringing an end to World War II.

Teller developed the first practical design for the hydrogen bomb and was instrumental in convincing the U.S. government to open a second nuclear weapons laboratory, Lawrence Livermore National Laboratory, to more rapidly develop that bomb. His hydrogen bomb ushered in a half century without world war, as the world's superpowers recognized that the use of hydrogen bombs would guarantee the destruction of both nations, a policy called "mutual assured destruction."

Teller exerted influence on defense and energy policies in the United States, writing more than a dozen books on these topics. As chair of the Reactor Safeguard Committee of the AEC in the late 1940's, he helped develop nuclear reactor safety standards. Teller lobbied against nuclear test bans, and for nuclear power, particularly nuclear fusion, and the Strategic Defense Initiative, but he never succeeded in overcoming public skepticism about nuclear power.

Nikola Tesla

Serbian American engineer

Tesla spent his life researching new ideas in theoretical physics, electricity, and magnetism in the late nineteenth and early twentieth centuries. Although his brilliance was later obscured by mental illness, Tesla's work has dubbed him the "inventor" of the twentieth century.

Born: July 9/10, 1856; Smiljan, Austro-Hungarian Empire (now in Croatia)
Died: January 7, 1943; New York, New York
Primary fields: Electronics and electrical engineering; physics
Primary inventions: Rotating magnetic field applications; induction motor; arc lighting; alternating-current transmission; transformer; wireless communication systems; power-transmission systems

Early Life

Nikola Tesla (NIH-koh-luh TEHS-luh) was one of five children born to the Reverend Milutin Tesla, a priest in the Serbian Orthodox Church Metropolitanate of Sremski Karlovci, and Đuka Mandić, herself a daughter of a Serbian Orthodox Church priest, in the village of Smiljan, Austro-Hungarian Empire (present-day Croatia). He was born at midnight between July 9 and 10, allegedly during an electrical storm.

As a child, Tesla was expected to become a minister like his father. His natural talents, however, caused Tesla to dream of pursuing a scientific career. He was born with a prodigious memory, could perform calculations in his head, and had the ability to visualize scenes, people, and objects vividly. This dream, however, seemed unreachable because of his father's expectations.

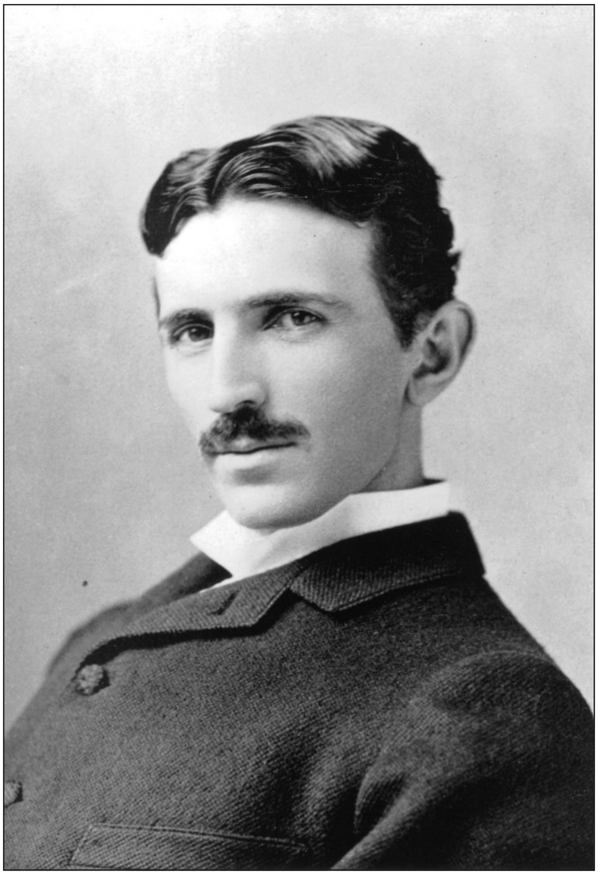
Fortunately, after graduating from the *Realgymnasium* in Austria, Tesla caught cholera and became gravely ill. Fearing that his son was dying, Milutin Tesla promised his son that he would allow him to attend engineering school if he would recover. Given Nikola Tesla's tremendous strength of will, it should not be a surprise that he survived, and he attended the Austrian Polytechnic School at Graz in 1875.

While at university, Tesla studied the uses of alternating current (AC), but a scholarship that had enabled him to attend classes was eventually terminated, a situation that Tesla exacerbated by a growing love of gambling. Tesla never officially returned to school beyond the first semester of his third year. In December of 1878, he left Graz.

By 1881, Tesla was working for a telegraph company in Budapest and finally able to begin his lifelong love of invention. He developed a type of telephone repeater or amplifier, a precursor to the modern loudspeaker. Although his work with Nebojša Petrović, a fellow inventor, resulted in several designs for a twin-turbine-powered engine, he wanted to work more definitively as an inventor and signed up with the Continental Edison Company in Paris, France. By the end of 1882, Tesla had conceived the earliest ancestors of what would become his most well-known invention, the induction motor, and began developing various devices using rotating magnetic fields.

Life's Work

On June 6, 1884, Tesla traveled to New York City with nothing in his pockets but a few cents and a letter of rec-



Nikola Tesla. (Library of Congress)

ommendation from his former manager Charles Batchelor addressed to American inventor Thomas Alva Edison. Impressed, Edison hired Tesla to work for the Edison Machine Works, beginning with simple electrical engineering and eventually becoming a troubleshooter for Edison's most complex engineering issues. Tesla's salary was a modest $18 per week; he was angered at Edison's dismissal of his value and promptly resigned when Edison would not offer him a raise.

After a brief stint digging ditches from 1886 to 1887, Tesla finally attracted the attention of wealthy inventor George Westinghouse and began the process of creating the initial brushless AC induction motor with his financial support. It was sufficiently ready in 1888 to demonstrate to the American Institute of Electrical Engineers (AIEE; later merged into the Institute of Electrical and Electronics Engineers, or IEEE). Tesla's design for a polyphase system transmitting electricity wirelessly further impressed Westinghouse, and he offered Tesla a position at the Pittsburgh laboratories at Westinghouse Electric and Manufacturing Company.

In 1891, while becoming a naturalized U.S. citizen, Tesla demonstrated what came to be called the "Tesla effect," the wireless transmission of electrical energy based on electrical conductivity. He moved his scientific experiments to 35 South Fifth Avenue in New York, and later to 46 E. Houston Street, much to the disgruntlement of his neighbors. Experimenting with sound resonances, Tesla accidentally discovered the vibrational frequency of his apartment building and several of the ones around it, causing them to violently shake on their foundations. Summoned by Tesla's terrified neighbors, the police encountered a calm Tesla surrounded by the crushed remains of his device; he had been forced to take a sledgehammer to his invention.

When he was thirty-six years old, Tesla's first patents for a polyphase power system were granted, encouraging him to further develop uses for alternating current. The 1893 World's Fair in Chicago showcased his wireless electric lights by allowing Tesla to illuminate the various buildings with his fluorescent lamps. His "Egg of Columbus," a sphere made of copper, stood on end as a demonstration of the rotating magnetic field principle. Despite his successes, however, Nikola Tesla's AC generator was made to directly compete with Edison's direct current (DC) motors for development funds. Because of this "War of Currents," Edison and Westinghouse suffered near financial ruin, forcing Tesla to tear apart his royalty contracts with Westinghouse.

By 1899, Tesla decided that his current quarters were inadequate to the task of housing his experiments with high voltage and high frequencies. He moved his research to Colorado Springs, Colorado, where he demonstrated the conductivity of the Earth and generated ball lightning. He was still researching wireless technology,

The Rotating Magnetic Field Principle

A magnetic field, as defined by physics, is a field produced by moving electric charges that form currents, or waves. The charges exert a force on other moving charges. A magnetic field associates with every point in space a vector that may vary in time; hence, it is a vector field. A magnetic field affects the movement of magnetic dipoles and electric charges. It permeates space, surrounding all electrically charged objects, and exerts a magnetic force. Magnetic fields can be generated in a variety of ways, both through natural and artificial processes, and have an energy density proportional to the square of the field intensity. Stationary dipoles generate magnetic fields that are constant. Changing electric fields, one of the basic principles of electromagnetism, generate rotating magnetic fields.

Nikola Tesla discovered the rotating magnetic field as a precursor to his work on devices using alternating current (AC). Alternating current is so named because its magnitude and direction change frequently in a cyclical motion, rather than remaining constant like the electrical currents generated by the stationary fields created by direct current (DC) generators. The rotation of magnetic fields creates an electric impulse that is both efficient and cost-effective to transmit as a sine wave. Tesla adapted this principle in order to realize his vision of his induction motor and a polyphase system that not only can create electrical energy but also can transmit it efficiently and over vast distances by both cable conduction and, potentially, without wires using energy generated by the movement of the molten center of the Earth's core and conducted through the magnetic lines that make up the Earth's magnetic poles.

The AC induction motor continues to be used as the basis of consumer electronics and industrial machines. It formed the basis for the Industrial Revolution, since the polyphasic AC system is a highly adaptable method of powering everything from toasters to table lamps. Some examples of the many uses of AC are audio and radio signals. These devices emphasize the importance of data integrity, since inefficient transmission would reduce an audio or radio signal to incomprehensible babble.

and he found that the resonant frequency of the Earth was approximately 8 hertz.

Despite his many patents, Tesla was continually troubled by the lack of funding. On January 7, 1900, he was forced to sell his laboratory equipment and leave Colorado Springs. Still hopeful of a more successful future, Tesla built the Wardenclyffe laboratory and its famous transmitting tower in Shoreham, Long Island. The tower, copper-domed and 187 feet high, was intended to transmit both signals and power without wires to any destination. Unsure of the profitability of such an invention, however, financier J. P. Morgan pulled his monetary support. The unfinished tower would remain standing until 1917, when the U.S. government decided that it was a national security risk and that the land it sat on would be more valuable without the tower.

Tesla's troubles continued to plague him. The rent on his two-room suite at the Waldorf-Astoria Hotel had been deferred because of a private agreement between Tesla and proprietor George Boldt, but mounting financial pressure forced Tesla to turn over his Wardenclyffe deed to pay the $20,000 he owed. Ironically, in 1917 Tesla established principles regarding frequency and power level for the first radio detection and ranging (radar) units and received AIEE's highest honor, the Edison Medal.

By 1943, Tesla was penniless and his life constricted by his ever-worsening phobias. His behavior, always marked by eccentricity, became bizarre. He became known for taking care of Central Park's pigeons, often taking injured ones home. He died of heart failure in Room 3327 of the New Yorker Hotel, but his reclusive nature made the exact day difficult to determine. One of the last times Tesla was seen alive, an assistant discovered Tesla standing in front of his open window in the middle of an electrical storm, feverish and claiming that he had made better lightning than God. It was later discovered that Tesla had died between the evening of January 5 and the morning of January 8, the constant effect of electricity upon his body having finally caused his heart to fail. Tesla never realized significant profits from the sale of his many patents, even though the ones describing AC electricity were extremely valuable. Nevertheless, his longtime feud with Guglielmo Marconi, who had successfully challenged Tesla's patent on the principles of radio and been awarded the Nobel Prize in Physics for radio in 1909, was ended with the U.S. Supreme Court establishing Tesla as the inventor of radio, recognizing the validity of Tesla's U.S. Patent number 645,576 (1893).

Tesla's funeral was held at Manhattan's Cathedral of St. John the Divine on January 12, 1943, and the inventor's remains were cremated and enshrined in a golden sphere. Immediately thereafter, in spite of Tesla's status as a naturalized citizen, the government's Alien Property Custodian Office was directed by the Federal Bureau of Investigation (FBI) to impound Tesla's possessions in the hopes of recovering a so-called death-ray based on Tesla's experiments with controllable ball lightning and plasma. Although no such device was found, Tesla's papers were taken, and the War Department decided to classify his research as "top secret." Tesla's family and the Yugoslav embassy struggled to prevent the confiscation. Eventually, his nephew, Sava Kosanović, was able to reclaim Tesla's cremated remains as well as some of Tesla's personal effects and placed them on permanent loan to the Nikola Tesla Museum in Belgrade, Serbia.

Impact

Tesla was one of those rare individuals whose contributions to society defy any attempt at summary. He acquired more than seven hundred patents both in the United States and in Europe on a wide variety of topics. Some of the consequences of his work were the creation of the Nikola Tesla Award by the IEEE and the naming of the SI unit for measuring magnetic flux density (or magnetic induction), the tesla. He has been extensively recognized in his homeland, even though he is relatively unknown in the United States outside the field of electrical engineering.

It is hard to imagine what the world would be like if Tesla had not survived cholera in 1875. He was directly responsible for so many "fixtures" of modern life—such as AC electricity, radio, radar, and X-ray photography—that one cannot really comprehend how differently modern technology might have arisen. There have been a few monuments created to honor this brilliant man; his close friend Ivan Meštrović made a bust of him when the sculptor was in the United States. The artwork, finished in 1952, became the centerpiece of the Tesla exhibit in the Nikola Tesla Museum in Belgrade. Another statue was placed on the aptly named Nikola Tesla Street in Zagreb's city center on the 150th anniversary of Tesla's birth, with a duplicate erected at the Ruđer Bošković Institute. Finally, in 1976, Niagara Falls commissioned a bronze statue of Tesla. It remains to be seen if Tesla's creative genius can overcome the obscurity to which his work has been condemned.

—Julia M. Meyers

Valerie L. Thomas

American aerospace administrator, analyst, and electronics designer

Inventor of the illusion transmitter, Thomas worked for NASA as a mathematical data analyst and as project manager for NASA's image-processing system on Landsat.

Born: February 1, 1943; Baltimore, Maryland
Primary fields: Aeronautics and aerospace technology; electronics and electrical engineering
Primary invention: Illusion transmitter

Early Life

Valerie L. Thomas showed an early interest in technology, and at age eight she checked out from the library *A First Electrical Book for Boys* (1935) with the idea that her father would help her build some of the models it provided. Although he did not aid her in this specific endeavor, she was not discouraged. Thomas's parents did encourage her interest, which she learned from her father. She continued to explore electronics during her childhood. Her father taught her how to take a radio apart and reassemble it, explaining the function of each part. She even worked on some of her neighbors' broken electronics in her youth. As electronics advanced, Thomas continued to learn, and she was able to work on early televisions as well.

Thomas pursued her interest in technology and science at her all-girls high school, where she ranked at the top of her class. Though the school did not offer electronics classes and she did not take the advanced math classes that were offered, teachers supported her with additional projects that would promote her interest in math and science. After high school, Thomas attended Morgan State College (now Morgan State University) in Baltimore, Maryland, where she was one of only two women to major in physics. She would later receive a doctorate in education at the University of Delaware in 2004. Her dissertation focused on a method to improve teaching mathematics to middle school students.

Life's Work

In 1964, Thomas was offered a job at the National Aeronautics and Space Administration (NASA). She began her career with NASA in mathematical and data analysis. From 1964 to 1970, she worked creating real-time, quick-look processor data systems for the Orbiting Geophysical Observatory (OGO) and Multi-satellite Operations Control Centers. Following this work, from 1970 to 1980, she filled many other roles for NASA, including serving as assistant director of the National Space Science Data Center (NSSDC). In this position, one of her jobs was to develop a pipeline-processing software data system; this work sustained the launch of three Landsat Earth-observing satellite systems.

Thomas became an international expert on Landsat digital products. From 1984 to 1985, she was assistant project manager for the Pilot Land Data System. She also worked at NASA's Goddard Space Flight Center (GSFC) in Greenbelt, Maryland, as leader for the multi-agency Large Area Crop Inventory Experiment (LACIE). This project included members from NASA, the National Oceanic and Atmospheric Administration (NOAA), and the United States Department of Agriculture (USDA). The LACIE project, comprising around fifty members, predicted global wheat crop yields based on weather patterns.

The years between 1986 and 1990 found Thomas managing the Space Physics Analysis Network (SPAN) and the NASA Automated Systems Incident Response Capability Team, as well as working at the Space Science Data Operations Office (SSDOO). She served as technical officer SSDOO's Hughes STX On/Offsite technical support contract and led the SSDOO's Education Committee. Her work on the creation of data and information systems for NASA was unequaled and led to her appointment as associate chief of the SSDOO. It was from this position that she retired in August, 1995. In addition to her work in these groups, Thomas designed computer programs that facilitate the study of astronomical phenomenon such as Halley's comet, supernova explosions, the ozone layer, and other planets.

Thomas received varied awards and honors during her career. In 1984, she served as president of the National Technical Association (NTA), the oldest predominantly African American technical association. She was awarded the GSFC Award of Merit and the NASA Equal Opportunity Medal for individual achievements. She also received the NASA Group Achievement Award on April 12, 1995, for her work on the LACIE project.

Thomas's work was so admired that she filled a managerial position in NASA's image-processing systems for Landsat. In this position, her inventions made it possible for pictures to be sent to Earth from space. The idea behind Thomas's illusion transmitter was to improve the space images being sent from Landsat. The illusion transmitter takes two-dimensional pictures seen on a screen and turns them into accurate three-dimensional images that are suspended in space. The basic concept of the invention is similar to that of television, employing signals that travel through the air.

The inspiration for the illusion transmitter came partially from an experiment Thomas saw on display at a scientific seminar in 1976. The display created the illusion that a light bulb remained lit after it had been turned off, using a system of mirrors to reflect another lit bulb. A year afterward, Thomas started working with various types of mirrors in an effort to create three-dimensional illusion effects, succeeding with a set of concave mirrors. Thomas believed that visual data presented through

The Illusion Transmitter

Valerie L. Thomas was inspired by a simple demonstration at a seminar she attended in the mid-1970's. The demonstration she observed used a system of mirrors to project an image of a lit light bulb. Her work experience with the National Aeronautics and Space Administration (NASA) gave her the insight to realize a version of this basic principle could become useful for other applications, including the satellite systems she had been working on for years. She quickly designed her concept, calling her invention the illusion transmitter. She applied for a patent on December 28, 1979, and received patent number 4,229,761 on October 21, 1980.

Thomas's machine goes beyond the idea of television's projection of two-dimensional pictures onto a screen. Instead, the illusion transmitter presents three-dimensional images. These projections, like holographs, can appear in varying spatial relations to a viewer, allowing them to appear to occupy the same physical location as their viewers. The image is generated through the use of a concave mirror system, which places one mirror next to the object being projected and one in the location where the projection is received. It is then transmitted electromagnetically in real time, either over the airwaves or by cable.

Though originally developed for NASA's Landsat system, the illusion transmitter has a number of potential functions. For example, it has been used by NASA for meteorological applications and crop mapping. In this project, Thomas worked with a number of other countries to predict global crop yields specifically for wheat production. Images sent from illusion transmitters on the Landsat satellites can help scientists understand the nature of astronomical phenomena, as well as of the earth itself. Another potential purpose is to simplify complicated medical procedures for surgeons.

three-dimensional models would be more precise and appealing, and she envisioned both commercial and NASA applications for the process.

Although similar to holographic imaging devices, the illusion transmitter is not strictly equal to such devices, which use coherent radiation and front-wave reconstruction methods that make them impractical for common use. The illusion transmitter provides a similar effect by using a concave mirror system. One mirror is located close to the object being projected, while another concave mirror is located at a distant location. As a result of the way the human eye perceives an object, the mirrors project three-dimensional illusions in real time. Thomas applied for a patent on December 28, 1978. It was granted almost two years later, on October 21, 1980.

After retiring from NASA, Thomas worked promoting the study of science in middle schools and high schools. She has presented papers at conferences and mentored and tutored students who are interested in mathematics and the sciences. She has also created a way to improve problem-solving performance for mathematics students, as well as a professional development model for implementing her program.

Impact

The illusion transmitter has a variety of both current and potential applications. It has been used by NASA and other groups to make crop predictions, to track weather patterns in relation to agricultural applications, and to transmit three-dimensional images from space. The ability to view spatial bodies in accurate, real-time images allows scientists to better understand their nature. The device may also save lives, as researchers are investigating its potential application in surgical procedures.

Thomas's work with NASA and other governmental agencies, her advances in scientific and analytical thought processes, and her body of achievements have made her a strong role model for young people everywhere. In an effort further to encourage interest in science and mathematics, she has worked with young people through the NTA and Science Mathematics Aerospace Research and Technology (SMART). She has also visited educational institutions from elementary schools through colleges, mentored student workers at the GSFC, judged science fair entries, and worked with Women in Science and Engineering (WISE). Her successes have opened doors for African Americans and women in many realms.

Benjamin Thompson

American physicist

Thompson's scientific studies greatly advanced understanding of heat and heat transfer. He invented the slow-roasting oven, improved oil lamps, improved double boilers and drip coffee makers, and the modern fireplace with a smoke shelf to prevent downdrafts.

Born: March 26, 1753; Woburn, Massachusetts
Died: August 21, 1814; Auteuil, France
Also known as: Count Rumford
Primary fields: Household products; physics
Primary inventions: Rumford stove; slow-roasting oven

Early Life

Benjamin Thompson was born to Benjamin Thompson, senior, and Ruth Simonds on March 26, 1753, in the town of Woburn, Massachusetts. His father, a farmer about whom little is known, died in November, 1754. His mother married again in March of 1756 to Josiah Pierce, Jr. Late in life, Thompson recalled his stepfather as a tyrant who virtually forced the child from the home, but this is not borne out by the historical evidence.

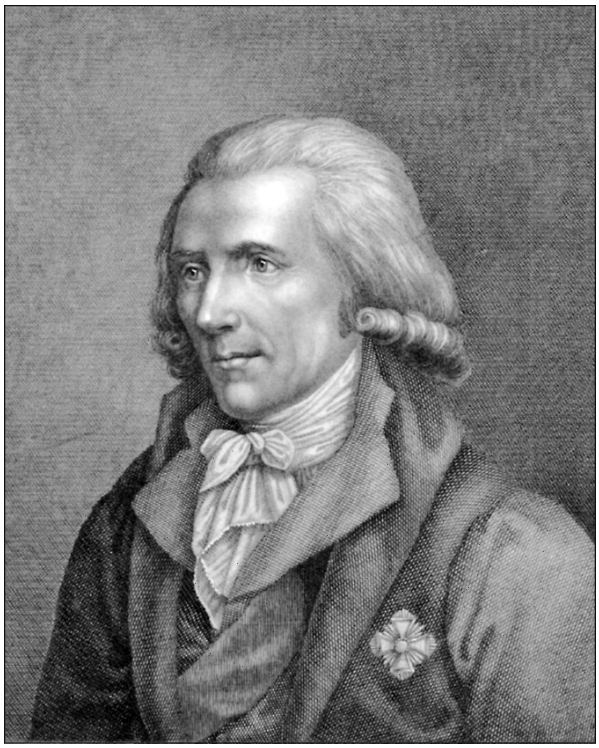
Schooling was hard to come by in colonial Massachusetts, but the young Thompson managed to attend three schools before the age of thirteen. Showing himself to be a bright boy deeply antagonistic to farmwork, he ended up an indentured apprentice to John Appleton, a successful retail merchant in the nearby town of Salem, in October, 1766. He continued his education on an informal, individual basis under the guidance of the Reverend Thomas Barnard, the Salem schoolmaster, with an emphasis on mathematics and astronomy.

Thompson's apprenticeship under Appleton ended dramatically when Thompson injured himself in an explosion while attempting to manufacture homemade fireworks. His injuries were so severe that he was sent home to Woburn to be cared for by his mother. In October, 1769, as soon as his injuries permitted, he returned to work in the employment of Hopestill Capen, the owner of a dry goods shop in Boston. Thompson continued to educate himself through self-study and experimentation to the extent that Capen fired him for neglecting his duties in the shop. He returned to Woburn in 1770 and supported himself cutting firewood.

While back in Woburn, Thompson befriended Loammi Baldwin, one of the leading engineers in the colony. Baldwin and Thompson remained in correspondence for the rest of Thompson's life, with Baldwin carefully preserving Thompson's letters. Thompson boarded with and studied medicine under the town physician, paying his way by teaching in the nearby towns of Wilmington and Bradford. The schoolmaster in Bradford helped Thompson obtain a position as schoolmaster in Concord, New Hampshire. He took up his duties there in the summer of 1772 at the age of nineteen.

Life's Work

Thompson's career as an inventor and scientist was secondary to, but an integral part of, his primary career as a social climber. He began by marrying Sarah Walker Rolfe, the widow of Colonel John Rolfe, a wealthy and prominent New Hampshire politician. Thompson was nineteen; she was thirty-three. Thompson and his bride dined on their wedding day with John Wentworth, the royal governor of the colony of New Hampshire, and Thompson quickly forged a bond with him. Wentworth was interested in science and technology and possessed one of the finest libraries in the American colonies.



Benjamin Thompson.

The Rumford Stove

The standard fireplace in 1795 consisted of a rectangular box recessed into the wall and opening directly into a full-throated chimney above it. The fire was built at the rear of the box. Hot air generated by the flames rose vertically upward, exiting the room without heating it. The room and its occupants were warmed only by radiant heat received directly from the flames, supplemented by whatever radiation reflected from the rear wall of the fireplace. Winds blowing across the chimney frequently forced smoke back into the room. The fireplace was dirty, smelly, ineffective, and expensive to fuel.

The Thompson fireplace (known at the time as the Rumford stove) was an elegant and economical improvement over the standard fireplace. Installation consisted of building a new firebox within the old so that existing homes could be retrofitted without tearing out the old firebox and chimney.

The new firebox had a rear wall built at the center of the old firebox. This brought the fire closer to the front of the hearth, where it could illuminate more of the room with its radiant heat. The rear wall was shorter than before, with the sides angled in to meet it obliquely. The footprint of the fireplace became a truncated triangle rather than a rectangle. The sides of the firebox no longer radiated uselessly toward each other, but out into the room.

This design narrowed the exhaust flue just over the fire. The hot gases then accelerated to high speed as they flowed through the narrow throat. This created a strong draft that kept the fire burning vigorously. The extra masonry needed support from behind; support bricks formed a shelf (the "smoke shelf") that deflected cold air attempting to infiltrate the firebox via the chimney. The increased efficiency was enough to permit a smaller fire to adequately heat the room, justifying the smaller firebox.

Kitchen fireplaces of that era had a separate brick box built in for baking. This chamber was preheated with a fire built directly into it. As soon as the brick interior was hot enough, the coals and ashes were swept out and the food inserted. Radiant heat from the hot bricks baked or roasted the food without tainting it with taste and smell of smoke.

Thompson's oven (not to be confused with his stove) replaced this brick chamber with an iron box in direct contact with the flue gases of the main fire. The iron box, with its high thermal conductivity, would quickly heat to the required temperature, bake or roast the food inside by radiant heat, and prevent smoke contamination. All of this was accomplished with less fuel and more convenience than the brick oven approach.

These inventions and others—including the slow-roasting oven, the double boiler, and the drip coffeemaker—after further improvements, still contribute to modern daily comfort. The modern fireplace is little changed from Thompson's original design.

Thompson had ready access to the governor's books and instruments, all of which he studied assiduously.

Thompson's climb to prominence and wealth began against the backdrop of the American Revolution. He acquired a commission as major in the Fifteenth Regiment of the New Hampshire Militia with duties of organization and recruitment. He proved to be naturally adept at both, acquiring skills there that would serve him well for many years. Thompson was particularly skilled at identifying and repatriating deserters from the British forces occupying Boston under General Thomas Gage. When this work became public knowledge in New Hampshire, Thompson became persona non grata in Concord and had to leave town precipitously. He fled to Boston to join General Gage's staff, abandoning his wife and newborn daughter.

Over the next twenty-four years, Thompson served as a spy for the British army in revolutionary New England; aide to secretary of state for the colonies during the revolution, Lord George Germain; undersecretary of state for the colonies; commandant of the King's American Dragoons, raised and based in South Carolina (retiring with the rank of colonel); and aide-de-camp to Carl Theodor, elector of Bavaria. Theodor eventually ennobled Thompson as Count Rumford. Along the way, Thompson raised and spent several fortunes, never hesitating to use his offices to enrich himself.

Thompson's duties for the Bavarian military began with reform of the army but expanded into the establishment of prison workhouses to produce military materiel, and poorhouses to house Bavaria's impoverished. Feeding all of these people in the cheapest, most efficient way possible inspired Thompson to improve the design and operation of institutional kitchens. His improved kitchen stove used many small fires with enclosed flames to keep the hot gases in contact with the cooking pans. The flue gases were used to cook additional foods before escaping up the chimney. During this time, he invented the first slow-roasting oven, a product that proved immensely popular throughout Europe and America.

While supervising the manufacture of cannons for the Bavarian army, Thompson observed that the production of heat while boring the cannons appeared to be inexhaustible. Inspired to perform detailed experiments, he showed that the heat produced was directly proportional to the length of the boring process and was quantitatively the same whether the bore was or was not cutting metal. These results were incompatible with the caloric theory of heat, which regarded heat as a material substance released from matter when it is cut, compressed, or otherwise stressed. Thompson explained the heat as a product of the work done in mechanical processes. His interpretation was later incorporated in the theory of heat as random molecular motion, and his results validated by James Prescott Joule's measurements of the mechanical equivalent of heat.

Thompson returned to London in October, 1795, hoping to publish his scientific papers and reingratiate himself with British society. Finding this difficult to do, Thompson threw himself into developing and marketing his kitchen stoves, roasters, and fireplaces. Appalled at the dirty and inefficient fireplaces prevalent in England, he set about to improve them. Thompson's new improved fireplaces were soon in much demand in England, Scotland, and Ireland and made him (once again) a wealthy man.

Thompson left England in September, 1802, to settle his affairs in Bavaria. On the way back to England, he passed through Paris, where he was seduced by the ladies of Parisian society and Napoleon Bonaparte, emperor of France. He consummated an ultimately unhappy marriage to the wealthy and socially prominent widow of Antoine Lavoisier, the founder of chemistry. During this period, he invented improved oil lamps and improved drip coffeemakers and experimented with new soap-making techniques. He remained in France until his death in Auteuil on August 21, 1814.

Impact

Thompson's innovations increased the efficiency and economy of heating, cooking, and lighting at a time when the cost of fuel was a large part of domestic expense. Thompson lived during the Industrial Revolution, when the business consumption of energy began to compete with and place economic pressure on domestic consumption. When wood became scarce, it was replaced by coal. However, much like the present day, continued expansion of the industrial economy without a corresponding decrease in standards of living demanded the energy available be used with the greatest possible efficiency. Households that adopted Thompson's improved fireplaces and ovens profited immediately from a significant drop in heating and cooking costs while also enjoying a warmer, cleaner home. Air pollution and the cost of fuel were both less than what they otherwise would have been.

Thompson is better known today as a scientist than as an inventor, remembered for his measurements of the amount of heat produced by mechanical action. His hypothesis that the heat produced is traceable to the work done during the boring process has proved to be correct. The new perspective these seminal experiments opened on the theory of heat eventually led to the recognition of heat as a form of energy, a fact not fully understood until the formulation of the law of conservation of energy and the development of the atomic theory of matter.

John T. Thompson

American army officer and businessman

Thompson, in collaboration with Theodore Eickhoff and Oscar Payne, conceived the American version of the submachine gun.

Born: December 31, 1860; Newport, Kentucky
Died: June 21, 1940; Great Neck, Long Island, New York
Also known as: John Taliaferro Thompson (full name)
Primary field: Military technology and weaponry
Primary invention: Thompson submachine gun

Early Life

John Taliaferro Thompson was born December 31, 1860, to Lieutenant Colonel James Thompson and Julia Maria Taliaferro. John had one older sister, Frances. James Thompson graduated from West Point in 1851 and was a distinguished artillery officer during the Civil War, but in 1869 he left the Army and began an academic career teaching military science at Indiana University. By age sixteen, John Thompson had decided to pursue a military career. He graduated from West Point in 1882, eleventh in his class. That same year, he married Juliet Estelle Hagans. Within a year their son, Marcellus Hagans Thompson, was born. Like his father and grandfather, Marcellus would graduate from West Point and enter the Army. Upon commissioning, John entered the Army artillery, and between 1882 and 1889 he was trained in engineering and artillery. In 1890, he transferred to the U.S. Army Ordnance Department.

Life's Work

In 1898, Thompson was promoted to lieutenant colonel and appointed chief ordnance officer for the U.S. Expeditionary Forces in the Spanish-American War. While chief ordnance officer, he recognized that the Army's small arms were obsolete and that there was a need for standardized weaponry and a need to increase the firepower of the individual soldier. This realization prompted his search for an efficient, rapid-fire personal small arm.

Thompson was appointed chief of the Small Arms Division of the Army Ordnance Department in 1907. In this capacity, he supervised development of the highly successful M1903 Springfield rifle. While with the Ordnance Department, Thompson carried out extensive tests on rifle and pistol cartridges, resulting in the U.S. armed forces adopting the standardized .30-caliber rifle cartridge and .45-caliber pistol cartridge, which remained service standards through the 1950's. Thompson was also an advocate of the Gatling gun as an infantry weapon because of its ability to concentrate firepower.

Because of his insistence on the need for sustained firepower and automatic weaponry, Thompson was considered a radical thinker within the Army, which at the start of the twentieth century was still dominated by aging nineteenth century cavalry commanders. Traditional military tacticians emphasized numerical superiority, whereas Thompson believed that firepower was a practical substitute for manpower. Because it was peacetime, the Army felt no need to pursue development of automatic weapons, though European nations were actively purchasing machine guns, automatic rifles, and semiautomatic pistols designed by Hiram Percy Maxim, John Moses Browning, Isaac Newton Lewis, Hugo Borchardt, Benjamin Hotchkiss, Georg Luger, and the German arms manufacturer Mauser. Thompson became frustrated with the Army, feeling that his military career was not allowing him the chance to design similar automatic weapons. In 1914, Thompson retired from the Army to become a consultant to the Remington Arms Corporation.

While the Remington job was interesting and challenging, Thompson used his evenings to design a simple, dependable, self-operating breech mechanism for an automatic weapon. In 1915, he contacted John Bell Blish, a retired naval officer who had designed and patented a blowback breech self-actuating mechanism. Thompson decided to design an automatic weapon around this delayed blowback system. In 1916, he founded the Auto-Ordnance Corporation, backed by money from Thomas Fortune Ryan, a supporter of the Irish Republican Army (IRA). Thompson, along with engineers Theodore Eickhoff and Oscar Payne, worked to develop a handheld automatic weapon during the course of World War I.

Thompson recognized the need for a handheld machine gun that could lay down sustained fire as a soldier advanced across open terrain or for use to clear enemy trenches. In 1917, as the United States entered the war, Thompson was recalled to active military duty and appointed director of arsenals. In 1918, he was promoted to brigadier general. Production of the first Auto-Ordnance automatic guns, nicknamed the "Persuader" and "Annihilator," arrived too late to be used in action during the war: The first shipments were dock-bound when the Armistice was signed. In 1919, Thompson was awarded the Distinguished Service Medal for his meritorious service

The Thompson Submachine Gun

The Thompson gun was designed as a sub-caliber machine gun, firing pistol-caliber ammunition rather than rifle-caliber ammunition of previous machine guns. A one-man, handheld weapon with a high rate of fire for close-in fighting, the Thompson gun was especially effective for clearing enemy troops from entrenched positions. The gun was known as the "Tommy gun," "trench broom," "chopper," "Irish sword," and "Chicago piano."

The Thompson submachine gun was designed to provide World War I soldiers with increased individual firepower. The first shipment of war-bound guns for American forces in Europe arrived at the New York docks on November 11, 1918, the day of the Armistice. The Thompson gun was then modified for nonmilitary use, and in 1921 the M1921 Thompson submachine gun entered the commercial market. Despite its high price of $200, the Thompson won approval among users. A Thompson submachine gun could be purchased by mail order or at sporting goods or hardware stores. Firing the .45 ACP (automatic Colt pistol) cartridge fed from box magazines of twenty and thirty rounds, or large-capacity fifty- and one-hundred-round drum magazines, the gun is a powerful weapon that fires fifteen hundred rounds per minute. A Cutts compensator at the muzzle keeps the gun under control during automatic fire. After the M1921's release, criminals and law-enforcement agencies took to the Thompson gun, and it was many years before the negative image associated with criminal use was overcome.

The Thompson submachine gun's basic operation is a delayed blowback (the delay initially provided by a brass Blish hesitation lock) consisting of two metal blocks sliding against each other at an oblique angle. The hesitation lock was found to be unnecessary, and later Thompson guns were produced without it. The M1921 and M1928 were the first Thompson guns to enter military service, being adopted in 1925 by the U.S. Coast Guard and Marine Corps, yet manufacture of Thompson guns did not reach substantial levels until the beginning of World War II, when France and Great Britain needed reliable small arms with high rates of fire. The Thompson M1928 is perhaps the most well known of the Thompson submachine gun models, though it actually differs little from the M1921, apart from having a reduced rate of fire (seven hundred rounds per minute) and some versions having different forearm furniture. Unfortunately, the M1928 required labor-intensive production processes involving many machined parts. The M1928 gave excellent service to many Allied troops and also continued to be a favorite weapon among criminal organizations for its small size and ease of disassembly for concealed carrying.

The Thompson M1 was the M1928 redesigned for wartime mass production by the Savage Arms Company. The M1 went into production in 1942 using a simplified blowback design and removed the M1928's compensator and barrel-cooling fins. The M1 went into widespread use by U.S. military forces but was eventually superseded by the M1A1, which had a set firing pin configuration rather than hammer type used in the M1 and M1928. The M1A1 remained in regular military and police use until the mid-1960's.

Vintage Thompson guns are highly sought after by collectors. Currently, a semiautomatic version of the Thompson gun is manufactured by Auto-Ordnance Corporation, a division of Kahr Arms. Kahr Arms purchased Auto-Ordnance in 1999, though it was not the original Auto-Ordnance founded by John T. Thompson, which changed hands several times after World War II before being sold in 1951 to Numrich Arms Corporation.

in design and production of arms and ammunition to the U.S. Army and released from service. That same year, his son, Marcellus, resigned from the Army and became vice president and general manager of Auto-Ordnance.

During 1919, the prototype Thompson submachine gun was produced and by 1920 was undergoing testing by the U.S. government. Test results were impressive, but no service recommended adopting the weapon. Auto-Ordnance realized that it was difficult to market submachine guns during peacetime, so the company began an extensive advertising campaign using the mottos "The most effective portable fire arm in existence" and "On the side of law and order." This marketing strategy resulted in mixed sales of the Colt-made M1921 Thompson submachine gun: While there were steady sales to law enforcement, many guns found their way into the hands of criminals, and a number of Thompson guns were smuggled into Ireland and used by revolutionaries against British forces.

The Thompson gun faced several additional peacetime marketing problems: The gun sold for around $200, at a time when postwar surplus machine guns sold for about $10. Also, the Thompson fired the .45 ACP (automatic Colt pistol), a pistol cartridge deemed obsolete as early as 1911 and used by no other military powers but the United States. During the 1920's, the gun was readily available to Prohibition Era gangsters, Irish rebels, anti-union mine owners, strikebreakers, and enforcers. By the economically depressed 1930's, the reputation of the Thompson gun's image was mythically linked to professional criminals and gunmen. By the late 1930's, Europe verged on war, and orders for the M1928 started to arrive from Great Britain and France. However, Colt refused to manufacture the M1928 because of its perceived criminal reputation. As a result, Auto-Ordnance signed a contract with Savage Arms Company to produce the first truly military Thompson submachine guns. Savage made its first delivery in April, 1940, and by late 1940 the war in Europe was fully engaged. Britain, France, and Russia ordered hundreds of thousands of Thompson guns.

For nearly twenty years, Thompson and his investors had been distressed and plagued by their submachine gun's scandalous reputation. On June 21, 1940, Thompson died; he would never see his invention help free the world from the terrors of World War II. Throughout the war, the Thompson submachine gun went through several redesigns to simplify manufacture, lower cost, and adapt it to combat conditions. The Thompson gun proved a solid, reliable weapon especially suited for European and Pacific battlefields: Though it was heavy and sand could clog it, the gun had excellent stopping power, one soldier could lay down immense firepower, and its distinct firing sound intimidated the enemy. The "Tommy gun" became a favorite of elite fighting forces such as rangers, paratroopers, and special operations groups, and it was issued in great numbers to infantry and armored groups. Numerous wartime stories relay how the Thompson gun's single-handed firepower saved the day.

Impact

Military historians credit Thompson with modernizing American infantry ordnance from 1900 through World War I. Thompson's M1921 gun is the first weapon deemed a "submachine gun," a term Thompson coined. The Thompson gun is considered to have one of the most distinct and recognizable designs in firearms history. The use of Thompson guns, and other automatic weapons such as the Browning automatic rifle (BAR), by criminals resulted in the National Firearms Act of 1934, which aimed to keep such weapons out of the hands of Depression Era bandits. During World War II, more than 1.5 million variations of Thompson submachine guns were produced. Many veterans consider it the best weapon of the war. The Thompson submachine gun remained in military and police use well into the 1960's.

Elihu Thomson

English electrical engineer

Inventor and entrepreneur Thomson was prominent in the field of electrical engineering because of his creation and skillful marketing of early electric light and power systems in the United States, the United Kingdom, and France.

Born: March 29, 1853; Manchester, England
Died: March 13, 1937; Swampscott, Massachusetts
Primary field: Electronics and electrical engineering
Primary inventions: Improved X-ray tubes; recording watt meter

Early Life

Elihu Thomson (ee-LI-hew TOM-suhn), the second of seven children born to Daniel Thomson and Mary Ann Rhodes, was born in Manchester, England, on March 29, 1853. Elihu's father was a mechanic specializing in the installation of factory machinery, but he had difficulty finding steady work in England. In 1858, Daniel immigrated with his family to the United States and settled in Philadelphia, taking a position with the Southwark Foundry owned by Merrick and Sons. His work entailed a great deal of travel, often to such distant places as Cuba, so the running of the household and Elihu's upbringing were mostly the responsibility of Elihu's mother. One of her favorite pastimes happened to be stargazing, and she demonstrated the patterns of constellations and stars to her son, sparking his lifelong love for astronomy.

Thomson began his education in a local Philadelphia elementary school, where he met his first mentor, teacher George Stuart, and began to take an interest in mathematics and engineering. Thomson's genius for invention and his quick-wittedness were remarked on by his instructors and his peers, leading to the early completion of his grammar school studies. At age eleven, Thomson passed the entrance exams for Philadelphia's premier public school, Central High School. Unfortunately, he could not matriculate until he was thirteen years old, so Stuart unsuccessfully tried to persuade the boy to take more interest in his physical development than in additional education for a few years. Distressed by the idea of several years without books, Thomson persuaded his parents to allow him to direct his own studies, involving, especially, the reading of his father's copies of *The Imperial Journal of Art, Science, Mechanics and Engineering*, published in Manchester in 1840 and 1841, which impressed upon the young Thomson the importance of inductive reasoning in scientific studies. He read and reread the articles, inspired by them to conduct early experiments on his own, one of which involved creating a crude electrostatic device from a wine bottle.

At Central High School, Thomson was such a talented student that, after graduating, he was appointed assistant professor of chemistry and mechanics at the Franklin Institute, spending more of his time building optical lenses and electrical motors than teaching classes and delivering lectures. In 1876, at twenty-three, he was promoted to chair of chemistry. Teaching, however, was not the career that fueled Thomson's imagination. In 1880, having become nearly obsessed with possible applications for electricity, Thomson resigned as chair in order to pursue electrical research full time.

Life's Work

The three-coil dynamo was one of Thomson's earliest inventions; along with an automatic regulator, the coil was

Elihu Thomson. (The Granger Collection, New York) the basis of his electric lighting system. In 1880, he and fellow science professor Edwin Houston established the Thomson-Houston Electric Company for the purpose of profitably manufacturing and selling arc lamp systems. When the company proved to be financially successful, Houston and Thomson bought into other electrical markets, which led to the founding in 1880 of the American Electric Company in New Britain, Connecticut. The purchase of the Sawyer-Man Electric Company in 1886 enabled them to begin the manufacture of incandescent lamps. In 1892, having sufficient capital, Thomson-Houston merged with former competitor Edison General Electric Company to become the General Electric Company. In 1893, a Parisian office of Thomson-Houston was opened and named the Compagnie Française Thomson-Houston (CFTH). From this company derived the modern Thomson SA Company, which still manufactures televisions and other multimedia devices.

In 1896, Elihu Thomson built electrical equipment for the production of X rays, improved X-ray tubes by designing one that used cathode rays to produce more intense radiation than had been previously possible, and was one of the earliest proponents of stereoscopic "Röntgen pictures" as a investigative tool for the diagnosis of bone fractures and to aid in the medical removal of foreign objects. However, despite his work in improving the field of X-ray technology, he was also one of the few working in the field of radiation who admitted the dangerous effects of overexposure to radiation. At a time when X-ray demonstrations were held at cocktail parties, Thomson wished caution to be observed by all technicians. To prove his point, in November of that year, Thomson intentionally allowed a finger on his left hand to be burned by overexposure to radiation. Merely one-half hour of exposure per day was enough to cause observable pain, swelling, stiffness, and blistering of the skin.

In addition to his social awareness of the dangers of X rays and their responsible use, Thomas demonstrated through his inventions his care for the health of the average worker (perhaps inspired by his working-class ancestors) and was particularly interesting in improving working conditions. He espoused the use of helium rather than nitrogen in the breathing mixture used by divers and tunnel workers to prevent "the bends," also known as caisson disease. Further, the inert nature of helium, he theorized, could extend the depth to which divers could proceed underwater.

Besides X-ray technology and the creation of electric coils, Thomson was also interested in improving technology once used by his father. Before 1887, a mechanic could only weld two pieces of metal together by heating one or both in a fire—a technique that had evolved out of ancient metalworking practices and had not seen much refinement since. High

The Recording Watt Meter

For much of Elihu Thomson's career and in many of his most famous patents, Thomson refined the existing technology created by other inventors as often as, if not more often than, he would create technology based on new principles. For example, during the 1880's, Thomson took competitor Thomas Alva Edison's design for a motor meter, improved on it, and created an early version of his "recording wattmeter"—an invention that proved very popular because of its ease of use and rugged design.

Between 1878 and 1888, Edison had invented an electricity meter that used the principle of electroplating to measure an amount of electricity instead of merely recording an electrical current's duration. In Edison's "chemical meter," copper plates were suspended in jars containing copper sulphate, and the whole jar was exposed to an electrical current. The electricity would cause a chemical reaction to occur in the jars, dissolving the zinc. Once the current ceased, a person "read" the amount of electricity used by removing the copper plates from the jars and weighing them. Even though the system was clumsy and difficult to use (on more than one occasion, an assistant's mishandling of the plates caused errors in measurement and, consequently, overbilled customers), Edison preferred it to later experiments he tried involving a meter run by an electric motor because he found chemistry experiments more personally satisfying. Consequently, Thomson observed an opportunity to design what he thought might be a more effective system for measuring electric output.

Thomson's meter operated using both alternating and direct current and was less often affected by user error and inaccuracy than Edison's chemical meter. A heating element was connected into Thomson's meter's circuit and warmed the lower of two alcohol-filled bottles. The alcohol in the bottle would slowly evaporate as it heated and floated into the other bottle above it. With the shifting of weight, the top bottle would drop down like a pendulum closer to the thermal unit and move the now-lighter bottle into cooler air. This rocking motion would cause the register to tabulate the energy used, moving slowly and smoothly enough that friction between the gears would not cause the meter to mistake gear friction for energy usage.

melting points and two metals with radically different melting points made forging in the traditional way impossible. Thomson's solution, to insert two materials to be welded in a parallel circuit and run an electric current through them, was an elegant way to overcome this problem. The creation of this process allowed Thomson Electric Welding, a second Thomson-founded company, to advance the construction of new appliances and vehicles in society. The electric air drill, still used in industry today, is but one of the many practical and useful discoveries for which Thomson became not only wealthy but also renowned.

Having achieved a certain financial stability for his family, Thomson finally turned his attention back to education and attended first Yale University and then Tufts College (where he received his Ph.D.). Thomson's Ph.D., however, was one of several degrees he received from many other prestigious universities around the world. He was, for many years, a professor of electrical engineering at the Massachusetts Institute of Technology (MIT) and even an interim president (twice, between 1920 and 1923) for the university.

Thomson's personal life, however, was more difficult than his professional one: his first wife, Mary Louise Peck, whom he had married in 1884 and with whom he had four children (Stuart, Roland Davis, Malcolm, and Donald Thurston), died in 1916. It was only in 1923 that he married again, to Clarissa Hovey, whom he described as the ideal assistant and supporter in his research. Thomson died in his bed at his estate in Swampscott, Massachusetts, on March 13, 1937, at the age of eighty-four. He was buried in the Pine Grove Cemetery in Lynn, Massachusetts.

Impact

Thomson's studiousness and determination led to a prolific career as an inventor. His nearly seven hundred patents (a wide variety of inventions and refinements involving dynamos, three-phase generators, repulsion-induction motors, electric welding, transformers, meters, lamps, railways, and steam engines) made him the third most prolific inventor in history. Thomson was educated in engineering, mechanics, and chemistry, and he used a combination of these disciplines (some learned at his father's knee) to power the creative imagination that spawned so many new inventions. His work demonstrates clearly how a thorough understanding of a mechanical skill can lead to the creation of new processes and new products. Further, his financial success and the continued existence of many of the companies founded by him demonstrate the value of practical thinking and skillful marketing techniques. At General Electric, it was Thomson's skill as a marketer as well as his creativity as an inventor that allowed profitable products to become a realistic outcome of creative thought. Unlike his contemporary Nikola Tesla, who was perhaps more creative as an inventor but died in poverty, Thomson was also a shrewd businessman who left a legacy behind after his death.

Max Tishler

American chemist

Tishler led research teams that synthesized ascorbic acid (vitamin C), cortisone, riboflavin, pyridoxin, pantothenic acid, nicotinamide, methionine, threonine, and tryptophan. He led a microbiological group that developed fermentation processes for actinomycin D, vitamin B_{12}, penicillin, and streptomycin. He also invented sulfaquinoxaline to treat coccidiosis.

Born: October 30, 1906; Boston, Massachusetts
Died: March 18, 1989; Middletown, Connecticut
Primary field: Chemistry
Primary inventions: Synthetic vitamins; sulfaquinoxaline

Early Life

Max Tishler was born in Boston, Massachusetts, the fifth of six children of Samuel and Anna Tishler, Jewish immigrants from Romania and Germany, respectively. Samuel abandoned the family when Max was four or five years old, and from an early age everyone had to work. Max and his younger sister were the only ones to graduate from high school, and he was the only one to attend college. Max worked in a drugstore until he completed graduate school (Boston English High School) and earned enough to support himself, pay his tuition, and help his mother and younger sister.

Tishler attended Tufts College (now Tufts University) with a $400 annual fellowship and, during his senior year, with a teaching assistantship. First an English major, he later became a chemistry major. Although one professor advised him not to do so because of prejudice against Jewish chemists, another encouraged him to enter the field to help break down the current barriers. In 1928, he received his B.S. degree in chemistry and became a licensed pharmacist.

Beginning in 1930, Tishler attended Harvard University with a $1,000 annual teaching assistantship. He received his M.A. and Ph.D. degrees in 1933 and 1934, respectively. On June 17, 1934, he married Elizabeth M. Verveer, who had been a student in his freshman chemistry laboratory at Tufts. The couple had two sons, Peter Verveer Tishler (b. 1937), a physician and genetics researcher, and Carl Lewis Tishler (b. 1947), a clinical psychologist.

Tishler stayed at Harvard as research associate (1934-1937) and instructor (1936-1937). Since no academic position was available, in 1937 he became a research chemist at Merck and Company in Rahway, New Jersey, then known only as a producer of reagent chemicals, where he was put in charge of developmental research.

Life's Work

In the late 1930's, George Merck, Jr., the president of Merck and Company, decided that, because no other American firm was working on vitamin research, his company should enter the field. Tishler's first assignment, the first of his numerous successes, was to develop a synthesis of riboflavin (vitamin B_2) different from that already patented in 1934. He simplified the procedure and increased the yield. His large-scale, economical method permitted riboflavin to be used to enrich white bread.

Tishler's next task, a new synthesis for the sulfa drug sulfapyrazine, which the cheaper penicillin had rendered uneconomical, resulted in an important spin-off. Sulfaquinoxaline, which Tishler discovered with John Weijlard in 1942, was added to chicken feed and dramatically reduced the incidence of coccidiosis (a parasitic disease of the intestinal tract caused by microscopic organisms called coccidia), which had previously killed as much as half of the flocks. Its application not only made available disease-free, nutritious, cheap food but also encouraged the search for new drugs for the poultry industry.

Although Lewis H. Sarrett had synthesized the anti-inflammatory, steroidal hormone cortisone in 1948, the yield was very low. Tishler and his team reduced the number of steps required from forty to twenty-six and greatly increased the yield. According to Sarrett, Tishler "transformed complicated organic synthesis from an esoteric intellectual exercise in the laboratory to useful products of great public value. . . . He created the paradigm of pharmaceutical research and development which has been followed by his successors throughout the industry ever since."

Tishler's research on cortisone, hydrocortisone, and dihydrostreptomycin brought him Merck's Board of Directors' Scientific Award in 1951. In what Tishler himself called "a golden age as far as medicinal chemistry is concerned," his teams developed commercial syntheses for pantothenic acid (vitamin B_3), biocytin vitamins, alpha-tocopherol (vitamin E), indomethacin (a nonsteroidal, anti-inflammatory drug), nicotinic acid (niacin), chlorothiazide, amitriptylene, aminopyrazine, aminoquinoxaline, alpha-methyldopa, and the amino acids threonine and tryptophan. His team with Robert Denkewalter and Ralph Hirschmann developed the first total synthesis of the enzyme ribonuclease. His work with Selman A. Waksman on the antibiotic streptomycin helped empty sanatoriums of patients suffering from tuberculosis, and he collaborated with Louis F. Fieser of Harvard University on a large-scale synthesis of phylloquinone (vitamin K) and a study of its relationship between its structure and biological activity.

Tishler met once a week with each of his research teams to discuss their progress. He was the author of more than 130 articles and the holder of more than one hundred patents on chemicals, vitamins, drugs, and hormones. To quote Sarrett again, "He taught me how to be human, to get a lot out of people by being warm with them. . . . I learned more from Max Tishler about research in the pharmaceutical industry than from any other man." According to Tishler's wife, "Max's vocation and avocation was chemistry."

Tishler advanced through the Merck hierarchy rapidly. From research chemist (1937-1941) he became section head in charge of process development (1941-1944), director of development research (1944-1953), vice president and executive director of scientific activities (1954-1956), president of Merck, Sharpe, and Dohme Research Laboratories (1956-1969), member of the board of directors (1962-1970), and senior vice president of research and development (1969-1970).

As he approached his mandatory retirement age of sixty-five, Tishler was asked to become head of the Weizmann Institute in Rehovot, Israel, but he declined the offer. He soon received offers from no less than nine universities. In 1970, he began his second career by joining the faculty of Middletown, Connecticut, which had recently begun its graduate program in chemistry. He continued his research on biologically active compounds with his students until a few weeks before his death. He served as professor of chemistry (1970-1974), university professor of the sciences (1972-1974), chairman of the Department of Chemistry (1973-1974), and from 1975 until 1989 as professor of chemistry emeritus and university professor of the sciences emeritus.

A lifelong smoker, Tishler ceased smoking in the hope that this would relieve his emphysema. This unpretentious and friendly scientist who had spent his whole life using chemistry to fight various diseases and who had served as mentor and role model to generations of both industrial and academic chemists succumbed to this disease at the age of eighty-two.

Synthesizing Vitamins

Max Tishler's first assignment at Merck was one of the two inventions cited for his induction into the National Inventors Hall of Fame (1982). He was asked to develop a practical synthesis for riboflavin (vitamin B_2) that was different from the methods that had been patented in 1934 by Nobel laureate in chemistry (1937) Paul Karrer—for Hoffmann-La Roche—and by Nobel laureate in chemistry (1938) Richard Kuhn—for I. G. Farben. With a catalyst, Tishler reduced an *o*-aminoazo compound that contained a ribose nucleus and reacted it with barbituric acid (a white, odorless, crystalline acid, CHON, used in the manufacture of sedatives and hypnotics, in making dyes, and as a polymerization catalyst) instead of the more expensive alloxan that Karrer and Kuhn used. His simplified procedure with increased yield ("Alloxazines and Isoalloxazines and Processes for their Production," U.S. Patent number 2,261,608, November 4, 1941) reduced the price of riboflavin from $17,479 per kilogram to less than $100 per kilogram in 1947. His large-scale, economical method allowed riboflavin, which is easily destroyed in the production of bread and milk, to be used for the first time to enrich white bread.

Tishler's next task resulted in the second invention cited for his induction into the National Inventors Hall of Fame. He was asked to develop a new, cheaper synthesis for sulfapyrazine, a sulfa drug that demonstrated possible medical applications but which was more expensive than the cheaper and better-known antibiotic penicillin. In 1942, together with John Weijlard, Tishler prepared a new sulfa drug, sulfaquinoxaline ("2-Sulphanilamido-quinoxaline Vitamins," U.S. Patent number 2,404,199, July 16, 1946), which was found to be effective against malaria in monkeys but which caused kidney stones in animal tests. Because the kidney system of fowl is different from those of monkeys and humans and because fowl are subject to coccidiosis (a disease which, like malaria, is caused by protozoa), David Green, the director of Merck's Veterinary Services, suggested that the drug be tested on them. Use of Tishler's new drug in chicken feed reduced the incidence of coccidiosis, which had hitherto killed 10 to 50 percent of the fowl, by 80 percent. His drug caused the explosive growth of broiler flocks from hundreds of thousands to billions of chickens; made available disease-free, nutritious, inexpensive food; and stimulated research on a new generation of pharmaceutical agents for poultry.

Impact

A great believer in team research, Tishler transformed complex organic synthesis from an intellectual laboratory exercise to the production of useful products of significant value to the public. On Tishler's death, F. Roy Vagelos, Merck's chairman and chief executive officer, described him as "an example of scientific integrity, and an inspiration of research achievement, for whole generations of scientists both in industry and academia. . . . The lives of countless patients around the world were benefited by drugs resulting from his pioneering in developmental research, and the science of chemistry was enriched." In introducing Tishler at his election to the National Inventors Hall of Fame for his large-scale syntheses of riboflavin and sulfaquinoxaline, on February 6, 1982, Lewis H. Sarrett stated, "You might say Dr. Tishler invented the term 'developmental research.'"

Tishler received many awards and honors: election to the U.S. National Academy of Sciences (1953), the Chemical Industry Award (1963), the American Institute of Chemists' Chemical Pioneer Award (1968) and Gold Medal (1977), the Eli Whitney Award for Inventions (1973), and the Sloan-Kettering Institute for Cancer Research's Chester Stock Award. In the American Chemical Society, he was chairman of the Division of Organic Chemistry (1951), society president (1972), and recipient of the Priestley Medal, the society's highest award. President Ronald Reagan awarded him the National Medal of Science in 1987 as "a giant on the chemical scene these past fifty years."

Evangelista Torricelli

Italian physicist and mathematician

In an attempt to solve the problem of raising water over ten meters, Torricelli decided to employ mercury, which is fourteen times as heavy as water. He succeeded, thus inventing the barometer.

Born: October 15, 1608; Faenza, Romagna, Papal States (now in Italy)
Died: October 25, 1647; Florence, Tuscany (now in Italy)
Primary fields: Mathematics; physics
Primary invention: Barometer

Early Life

The eldest of three children, Evangelista Torricelli (eh-vahn-jeh-LEE-stah tohr-ih-CHEH-lee) was born to Gaspare Torricelli and Caterina Angetti in 1608 in Faenza, at the time part of the Papal States. Having been left fatherless at an early age, Torricelli was educated first by his paternal uncle Jacopo, a religious of the Order of the Camaldolesi, and in 1624 he entered the Jesuit College at Faenza, where he studied mathematics and philosophy until 1626. The following year, Torricelli transferred to the University of Rome to study under the

Benedictine Benedetto Castelli, an illustrious water engineer and professor of mathematics, who had also been a student of Galileo at Pisa. Among Torricelli's peers at Rome were other future well-known physicists and mathematicians such as Alfonso Borelli, Bonaventura Cavalieri, and Michelangelo Ricci. After completing his studies, Torricelli became Castelli's secretary and held this post between 1626 and 1632.

Little is known of Torricelli's activities in the period 1632 to 1641. During these years, he appears to have been secretary to Monsignor Giovanni Ciampolli, a friend of Galileo, who served as governor of a number of cities in Umbria and the Marches. Torricelli also stood in for Castelli at Rome and lectured at the university during the academic year 1640-1641. Part of the correspondence dating to Torricelli's early life has been preserved, most notably a letter of September 11, 1632, to Galileo in which he described having read the latter's *Dialogo sopra i due massimi sistemi del mondo* (1632; *Dialogue Concerning the Two Chief Systems of the World*, 1661) with delight. In his letter, Torricelli acknowledged being a follower of Galileo "in profession and sect." Yet, after Galileo's trial in 1633, Torricelli decided to shift his attention from astronomy to mathematics, an area that seemed less controversial than the Copernican theory defended by Galileo.

Evangelista Torricelli with his barometer. (The Granger Collection, New York)

Life's Work

In April, 1641, Torricelli's treatise on the path of projectiles (*De motu gravium naturaliter descendentium et proiectorum*) was presented to Galileo by Castelli. Galileo, then a man of seventy-eight, was so impressed with Torricelli's work that he invited him to his house at Arcetri, near Florence. Wishing to care for his ailing mother, Torricelli accepted the invitation but was forced to delay his departure. He finally arrived at Galileo's villa on October 10, but, after Galileo's death only three months later (January 8, 1642), he was asked to succeed the great scientist as Grand Duke Ferdinando II de' Medici's mathematician and philosopher. Torricelli remained in Florence for the rest of his life, living in the ducal palace and lecturing as professor of mathematics at the local university. He was elected to the Accademia della Crusca in Florence in 1642.

Under the auspices of the grand duke, Torricelli's *Opera geometrica* (works on geometry) was published in three parts in October, 1644. As with many scientific works published at the time, it was written in Latin because this language still expressed ideas and reported events with a precision that the vernacular lacked. Torricelli's volume included his monograph on the parabolic motion of projectiles of 1631, a commentary on Archimedes, and a series of treatises on the parabola, the cycloid, and other dimensional figures. The texts received much acclaim throughout Europe and were praised for the clarity and precision with which the author discussed rather difficult concepts. Moreover, in his work, Torricelli rendered Bonaventura Cavalieri's theory of indivisibles accessible and expanded the latter's method of indivisibles to cover curved indivisibles. With these tools, he was able to show that rotating the unlimited area of a rectangular hyperbola between the y-axis and a fixed point on the curve resulted in a finite volume when rotated around the *y*-axis.

In his *Opera geometrica*, Torricelli also paid attention to hydraulics, showing that, aside from his theoretical work, he had practical skills too. As an example, Torricelli advised the grand duke on marsh drainage on the Chiana Valley in Tuscany. In fact, attempting to solve a practical problem with which Ferdinand's pumpmakers had been posed, he realized that, if water could be pumped upward, this was because it was exerted by the surrounding air. Instead of water, he decided to use mercury, and he created a tube filled with quicksilver and inverted over the same liquid. This led to the development of a device that he described to his friend Michelangelo Ricci in a letter of June 11, 1644. Known first as "Torricelli's tube," it was named "barometer" by the Frenchman Edme Mariotte in his *Discours de la nature de l'air* (discourse on the nature of air) of 1676. Torricelli's practical skills were also applied to ballistics and optics. He studied projectile motion, built several large lenses, and devised telescopes and simple microscopes, making substantial financial gains from his skill in lens grinding in the last period of his life. In 1644, the grand duke gave him a golden chain bearing the words *virtutis praemia* (rewards for your talent) in return for some of the scientific instruments Torricelli had designed.

In October, 1647, Torricelli contracted typhoid fever and died a few days later at the age of thirty-nine. He was buried in the church of San Lorenzo in Florence. In his will, he entrusted his unpublished manuscripts and letters to his friends Cavalieri and Ricci, who were to prepare the material for publication. However, Cavalieri died weeks after Torricelli, and Ricci failed to accomplish the task, resulting in the bulk of Torricelli's texts being published as late as 1919. Some of the lectures given at the Accademia della Crusca had, however, already been published by Tommaso Bonaventura in 1715.

The Barometer

As Evangelista Torricelli informed his friend Michelangelo Ricci in June, 1644, he had long been working on certain experiments relating to vacuum. Opposing those who claimed that a vacuum did not exist, Torricelli set out to make the barometer, "an instrument which will show the changes in the atmosphere, as it is now heavier and grosser and now lighter and more subtle."

The Torricelli barometer is made by first filling a dish with mercury. Mercury is then poured into a long tube. The tube is filled almost to the top and inverted several times, taking care that no air bubbles should get into it. After the tube has been completely filled with mercury, a finger is placed over the top of the tube, and the tube is inverted and placed into the dish below the level of the mercury. When the finger is removed, the level of the mercury inside the tube drops until the pressure at the bottom of the column of mercury is equal to the pressure exerted by the surrounding air. Since no air was allowed to enter the tube, the empty space above the mercury column is a vacuum. The pressure exerted by the atmosphere can be quantified by measuring how high the mercury column rises above the level of the mercury in the dish. The pressure in this case is 731 millimeters of mercury.

Barometers are mainly used by meteorologists to measure atmospheric pressure (also known as air pressure, or barometric pressure) and to forecast weather. As an example, whereas a quick drop in pressure over a short period of time indicates that a storm is likely in five to six hours, a slow and sustained rise in pressure indicates that a long period of fine weather is approaching. The common units of measurement that barometers use are millibars (mb) or inches of mercury. Although the classic mercury barometer is still very much used, weather stations employ a digital barometer that uses electrical charges to measure air pressure. This enables them to take multiple accurate recordings of the pressure and to produce more accurate weather forecasts.

Impact

Torricelli's contribution to physical and mathematical sciences is outstanding. Attempting to prove wrong the old saying that "nature abhors a vacuum," to which Galileo himself had also adhered, Torricelli was the first person to create a sustained vacuum (the so-called Torricellian vacuum). He demonstrated that atmospheric pressure determines the height to which a fluid will rise in a tube inverted over the same liquid. With his experiment, he was able to discover the principle of a barometer. As proof of Torricelli's lasting impact, his method of getting a very high vacuum is still often employed.

In the field of mathematics, Torricelli devised a problem due to the French mathematician Pierre de Fermat when he determined the point in the plane of a triangle so that the sum of its distances from the vertices is as small as possible. Torricelli's correspondence to Roberval on the area and the center of gravity of the cycloid reveals his honesty and modesty. Torricelli's achievements were extolled by many of his contemporaries, in particular by René Descartes and Constantijn Huygens. Blaise Pascal described Torricelli's work on geometry as "surpassing the discoveries made by all ancient mathematicians." The asteroid 7437 Torricelli and the torr, a unit of pressure, were named in Torricelli's honor.

Charles Hard Townes

American physicist

Townes invented the maser, a device that amplifies microwaves for practical applications. His work led to the development of the laser, one of the most significant inventions of the twentieth century.

Born: July 28, 1915; Greenville, South Carolina
Primary field: Physics
Primary invention: Maser

Early Life

Charles Hard Townes was the fourth of six children born to Henry Keith Townes, an attorney in Greenville, South Carolina, and Ellen Hard Townes. At an early age, Townes was interested in finding out how mechanical objects worked. He was also interested in nature, catching insects and frogs and watching the stars with his older brother.

Townes graduated from high school at the age of fifteen and attended Furman University in Greenville. Furthering his interest in natural history, he served as curator of the university's museum. He became fascinated by the logical structure of physics during his first physics course, which he took as a sophomore. He participated in a variety of college activities, including the swimming team, the newspaper, and band. In 1935, Townes graduated summa cum laude with bachelor's degrees in science and modern languages. He enrolled at Duke University, where he was awarded a master of science degree in physics in 1936. He then enrolled at the California Institute of Technology, where he received his Ph.D. in 1939. His doctoral research focused on isotope separation and nuclear spins.

Life's Work

Townes served on the technical staff at Bell Telephone Laboratories from 1939 to 1947. During World War II, he worked on the development of radar-assisted bomb sights at Bell and received several patents in radar technology. In 1948, Townes joined the physics faculty at Columbia University in New York, where he was appointed associate professor that year and full professor in 1950. His research focused on the application of microwave radiation in microwave spectroscopy, the study of interactions between microwaves and molecules. Townes

The Maser

An atom consists of negatively charged electrons bound to a positively charged nucleus. These electrons can occupy only certain specific energy levels, called orbitals. A photon, or light wave, that interacts with an electron in an atom has a high probability of being absorbed if its energy is exactly matched to the difference in energy between the initial orbital the electron is in and another orbital that the electron can move to. This interaction moves the electron to the higher energy level. However, once an electron has moved to a higher energy orbital, called an "excited" state, the electron will move back to a lower energy state, emitting a photon that carries away the excess energy. This process is called "spontaneous emission." Normally, spontaneous emission occurs quite rapidly, on time scales shorter than a few nanoseconds. However, some excited states are "metastable," allowing the electron to remain in these excited states for a much longer time.

If a photon having an energy corresponding to the difference in energy between the metastable state and the lower energy state interacts with an electron in a metastable state, this interaction can induce the electron to return to the stable state. This process, called "stimulated emission," results in the emission of two photons, each having an energy corresponding to the difference between the higher and lower energy states. The maser operates on the principle of stimulated emission, which was introduced by Albert Einstein in 1917.

In a collection of molecules, most of them will normally be in the lowest energy state. Charles Hard Townes had to find a way to concentrate the molecules in the excited state, something physicists call a "population inversion." He devised a technique using a nonuniform electric field, so that ammonia molecules in the excited state were repelled by the field and focused into the active chamber of his device, while molecules in the ground state were attracted by the field. Thus, many of the molecules in the chamber of his device were in the metastable excited state.

Initially, Townes added energy into a chamber filled with ammonia gas, a process called "pumping," because it causes some of the ammonia molecules to be pumped up to the excited state. The gas then went through the separator that Townes devised, concentrating the molecules that are in the excited state in the chamber. Introducing a photon of the correct energy into this chamber resulted in the de-excitation of an ammonia molecule, producing two photons having the same energy as the initial photon. These two photons could then interact with two more ammonia molecules in excited states, causing them to de-excite and producing four photons. As this process continued, more and more photons, all of the same energy, were produced, thus amplifying the initial photon. By 1953, Townes had produced a working model of the maser.

worked at the Columbia Radiation Laboratory, where he was interested in producing short-wavelength microwave radiation and amplifying microwaves for use in practical applications. He served as the executive director of the laboratory from 1950 to 1952.

In 1917, Albert Einstein had developed the idea of "stimulated emission," a process in which a photon that interacts with an atom that is in an "excited," or high-energy, state can induce the emission of a second photon. By 1951, Townes had recognized that Einstein's idea could result in a device to amplify microwaves, starting with one microwave photon and producing a second photon, then allowing each of the photons to produce another, in a cascade effect eventually producing a huge number of microwave photons. Within a few months, Townes and his assistants began building a device that used ammonia molecules in a gas as the emission medium. It took the team until 1953 to produce the first amplification of microwaves using this technique. In their first scientific paper describing their device, Townes and his coauthors called the process "microwave amplification by stimulated emission of radiation," and introduced the acronym "maser" to describe their device.

With the development of the maser, the next logical step was to employ the same physical principles to the amplification of visible light. One challenge was finding the correct atom or molecule, one that had a long-lived excited state at the right energy for the amplification of visible light. In 1957, Townes spoke to Gordon Gould, a graduate student at Columbia University, about Gould's work using visible light to excite thallium atoms. Both men quickly realized that thallium might provide the key to a visible-light, or optical, maser. Townes worked with his brother-in-law, Arthur L. Schawlow, and researchers at Bell Labs. In 1958, Townes and Schawlow, a professor at Stanford University, described how masers could be designed to operate in the visible and infrared regions of the spectrum, but they did not produce a working device.

Gould left Columbia before finishing his degree. He joined the Technical Research Group (TRG), a company that received a grant from the Advanced Research Projects Agency to develop an optical maser. Meanwhile, Theodore Harold Maiman of Hughes Research Laboratories in California thought that he could make an optical maser by exciting the chromium atoms in a ruby crystal. It was Maiman who first succeeded in building a small optical maser, which he demonstrated on May 16, 1960. The device was named the "laser" (light amplification by stimulated emission of radiation).

Townes and Schawlow were awarded a patent for the laser in 1960 based on the designs in their 1958 paper, but a thirty-year patent battle erupted. Gould and TRG challenged the patent. They argued that Gould's notarized notebook entries from 1957 described the operating principles of the laser. Others, including Hughes Research Laboratories, joined in the legal battle, which was not resolved until 1985, when a federal court in Washington, D.C., ordered the Patent Office to issue some of the patents Gould had submitted for the laser. Eventually, Gould was issued forty-eight patents, including one for "optical pumping," the technique used in Maiman's ruby laser.

Townes took a leave of absence from Columbia University from 1959 to 1961 to serve as vice president and director of research of the Institute for Defense Analyses, a nonprofit organization operated by eleven universities that advises the Department of Defense on national security issues, particularly those involving scientific and technical issues. In 1961, Townes was appointed provost at the Massachusetts Institute of Technology (MIT). In 1966, he was named institute professor, the highest honor awarded to MIT faculty. Later that year, he resigned as provost to return to his research. Between 1966 and 1970, Townes chaired the National Aeronautics and Space Administration's Science Advisory Committee for the Apollo program, which led to the first lunar landing.

Townes shared the 1964 Nobel Prize in Physics with two Russian physicists, Nikolay Gennadiyevich Basov and Aleksandr Prokhorov. The prize was awarded for their contributions to quantum electronics that led to the development of the maser and the laser.

Townes left MIT in 1967 to join the faculty at the University of California, Berkeley, where he continued his research in astronomy and defense issues until his retirement in 1986. He developed a technique to use laser light to see through the veil of dust and gas that shields large stars, called red giants, from direct observation. His group used two 65-inch-diameter telescopes on Mount Wilson in California to collect the infrared emission from the red giants. Most of this infrared emission is from the gas and dust surrounding the star. By combining the starlight collected by the telescopes with light from a laser in their laboratory, they could separate out only the starlight at the specific wavelength of the laser light. Looking at only this narrow wavelength range allowed them to see the star through the more intense emission from the gas and dust. One of the red giants they observed, Mira, appeared to be thirty percent larger than astronomers had believed.

Impact

Initially, many people were skeptical that the maser and laser would have practical applications. Although it took a decade or more for lasers to become small and inexpensive, the laser has had an enormous impact on modern society. It is employed in many consumer products, including supermarket checkout scanners, compact disc (CD) and digital video disc (DVD) players and writers, and laser pointers. As a commercial product, the laser is used for fiber-optic communications. Laser surgery, particularly laser eye surgery, has become an important medical procedure. The military has developed weapons systems using lasers and has explored the use of X-ray masers in antimissile defense systems.

The status that Townes gained from his invention allowed him to influence public policy. Townes was a founding member of the Jasons, a group of scientists that provides advice to the Department of Defense, the Department of Energy, and the U.S. intelligence community on scientific and technical issues.

Sakichi Toyoda

Japanese mechanical engineer

From 1890 to 1925, Toyoda's inventions revolutionized the Japanese loom to become a globally competitive automatic power machine. He helped Japan to catch up with the Western industrial revolution. His success and vision enabled his son to do the same for Japanese cars by founding Toyota.

Born: February 14, 1867; Yamaguchi (now Kosai), Shizuoka Prefecture, Japan
Died: October 30, 1930; Nagoya, Aichi prefecture, Japan
Primary field: Manufacturing
Primary inventions: Automatic power loom; automatic shuttle-changing device

Early Life

Sakichi Toyoda (sah-kee-chee toh-yoh-dah) was born in rural Japan in 1867, the oldest son of the carpenter Ikichi Toyoda. His native village of Yamaguchi (now Kosai), in Shizuoka Prefecture southeast of Tokyo, was part of Japan's textile region. Here, primarily women weavers manufactured cotton cloth on labor-intensive hand looms to support the family income from rice farming.

Toyoda's boyhood was affected by fundamental changes in Japan. After the United States forced Japan to open itself to Western commerce in 1853 and the shogun abdicated and relinquished power to the Meiji emperor in 1868, Japan embarked on a quest to catch up with the West's industrial revolution. Even in villages, basic schooling became mandatory. Toyoda finished elementary school in 1877. He was then apprenticed to his father.

Unhappy with the traditional life laid out for him, in 1885, at the age of eighteen, Toyoda was electrified when a traveling teacher told of the new Japanese patent law and urged the boys of Yamaguchi to contribute to Japan's technological development. On that day, Toyoda decided to become an inventor.

Reading the translation of British author Samuel Smiles's inspirational *Self-Help* (1859) confirmed Toyoda's choice. He decided to invent an improved loom to benefit life and work of the women weavers of his community. As a carpenter, Toyoda knew about the physical construction of the hand looms in operation, basically unchanged since medieval days. As he lacked a theoretical scientific background, he observed the looms, then made his modifications to models and conducted experiments. He made his inventions by learning through trial and error, a method he used throughout his life.

Toyoda's big break occurred when he attended the Third National Industrial Exhibition in Tokyo in 1890 at age twenty-three. For two weeks, Toyoda observed the foreign power looms on display. He then invented his first new wooden manual loom in the fall of 1890 and patented it in early 1891. Toyoda's invention increased weaver productivity by 50 percent by linking the flying shuttle to the mechanism holding down the yarn just woven.

Life's Work

Toyoda built four or five of his own looms and set up a small weaving factory in Tokyo in 1891. Pressured by his family, he married his first wife, Tami, and tried to earn enough money from his new looms to finance further inventions. However, he found that foreign competition was too fierce. Efficient French hand looms were cheaper, and Western power looms more productive. By the fall of 1893, Toyoda's first business built upon his invention failed, and he moved back to Yamaguchi. Soon, he left to work for an uncle in the commercial city of Nagoya. His son, Kiichiro, was born on June 11, but his marriage to Tami failed. Sakichi kept his son after the divorce.

In late 1894, Toyoda invented a yarn-reeling machine, the foot pedal of which freed one arm of its operator, doubling productivity. In 1895, he opened the Ito Retail Store in Nagoya with his uncle and a third partner. He married again, to Asako Hayashi, who proved an astute businesswoman who managed the store together with Toyoda's younger brother Heikichi.

In 1896, Toyoda's store nearly crashed as a result of the fraud of the third partner. Marshalling all his strength, Toyoda managed to save the store and invent his narrow wooden power loom, which became operational in 1897, the year his daughter, Aiko, was born. For the first time, a Japanese inventor held a patent to a power loom, a milestone in Japan's industrialization.

In 1899, Toyoda sought to set up a business that earned enough revenue to allow him to conduct his expensive research. Together with the Japanese trading conglomerate Mitsui, Toyoda founded the Igeta Shokai (trading) company, with himself as chief engineer. Igeta's business was to produce and sell Toyoda's power looms under a ten-year license agreement.

At Igeta, Toyoda articulated his later famous principle of *kaizen*, or continuous improvement, as he strove to better his inventions. Yet his demand for research funds clashed with the company's goals to save money during an economic downturn. Angrily, in 1902, Toyoda resigned from Igeta, and he returned to his old Ito trading firm he renamed Toyoda Shokai. His wife, Asako, and his second younger brother, Sasuke, managed operation of the company's 138 power looms.

In 1903, Toyoda invented a new automatic shuttle-changing device for his power looms. However, to his big disappointment, his new steel looms failed in an endurance test against the British competition of Platt Brothers and Company in 1905. Part of his problem was that Japanese metallurgy could not yet yield steel of sufficient quality for Toyoda's innovative power looms.

To gain more capital, Toyoda teamed up with Mitsui again. He dissolved his own company and founded Toyoda Loom Works in 1906 with himself as operating manager. Soon, Toyoda clashed again with Mitsui over his research budget. Thoroughly disillusioned, Toyoda resigned again and left for the United States on May 8, 1910, intending to immigrate. However, Japanese American chemist Jokichi Takamine persuaded Toyoda to return to Japan.

In 1911, Toyoda founded the Toyoda Automatic Weaving Factory. In October, 1912, he sold his rights to future earnings from his inventions for a lump sum to finance his ongoing inventions. In 1914, he founded a spinning business and cooperated with Mitsui again.

In his ultimate quest to invent an internationally competitive Japanese power loom, Toyoda relied on friends and family. In October, 1915, his daughter, Aiko, married Risaburo Kodama, younger brother of Mitsui's Ichizo Kodama and a managing talent. Toyoda adopted Risaburo as his son, and in 1918 Risaburo Toyoda became managing director of the newly founded Toyoda Boshoku, a spinning and weaving company.

At the same time, Asako Toyoda made sure that

Automatic Power Loom

Sakichi Toyoda's crowning achievement was the first Japanese automatic power loom, which he patented in 1925. With it, he reached his goal, set when he decided to become an inventor at the age of eighteen, to make Japanese looms competitive with Western imports.

The basis for the 1925 loom was Toyoda's invention of the first Japanese manual power loom in 1896. Instead of human labor, a steam engine attached to a drive shaft provided power to weave the delicate weft yarn from left to right into the strong lengthwise warp yarn and to advance the finished cloth on the loom. The shuttle still had to be changed manually, but this invention represented a quantum leap for Japanese technology.

One of Toyoda's next inventions ensured that the warp yarn was held at constant tension. Finally, working together at a fever pitch with his son, Kiichiro, from November to December, 1924, Toyoda acquired ten new patents that formed the innovative basis of the 1925 automatic power loom. His most crucial invention was the design of an automatic shuttle-exchange system, which Kiichiro developed into a functional device. The Toyoda mechanism joined the front and rear panels of the flying-shuttle box so that both panels were lifted simultaneously when a new shuttle with a fresh bobbin containing new yarn was automatically pushed into the shuttle box and the old shuttle with the empty bobbin was ejected. Because of this invention, the Toyoda loom could replace shuttles very quickly and smoothly and did not stop during the exchange. Other key inventions were a warp let-off device and a mechanism to automatically stop the loom if the weft yarn broke.

The invention of Sakichi and Kiichiro Toyoda provided the Japanese textile industry with great momentum. On automatic Toyoda looms, Japanese weaving companies produced quality textiles for domestic consumption and export, particularly to Asian markets. Manufacture of ever-improved power looms continued to be an important business of the Toyota group. Since 2001, loom manufacture is done by the Toyota Industries Corporation.

Kiichiro Toyoda went to Tokyo University. Kiichiro graduated in mechanical engineering in 1920, part of the new elite of Japanese engineers. After some initial clashes, father and son soon worked as a successful team of inventors. The older Sakichi provided his practical experience, and Kiichiro used his university training to improve on the ideas of his father.

Beginning in 1921, Kiichiro was responsible for giving his father's inventions their final practical shape. Their teamwork was crowned with the success of the first Japanese fully automated loom, patented in 1925. Kiichiro invented a shuttle-change box based on Sakichi's original design. This invention led to the 1926 founding of the Toyoda Automatic Loom Works. There, textile production on the new power looms ran simultaneously with industrial field testing of new inventions.

Recognizing Sakichi Toyoda's achievements as one of Japan's ten most influential inventors of his time, Japanese emperor Hirohito bestowed the Imperial Order of Merit on Toyoda in 1927. Toyoda suffered a mild cerebral hemorrhage later that year.

Turning to what he saw as the next big field for Japanese inventions, Sakichi exhorted Kiichiro to turn to automobile manufacture. To provide his son with the necessary start-up funds, Toyoda sold the worldwide patents of his automatic power loom to the Platt Brothers of Great Britain for ¥1 million, or $150,000. Kiichiro closed the deal on December 24, 1929. This proved sufficient seed money for what would become the Toyota Motor Company in 1937, even though Platt only paid $58,000 at closing and later tried to get out of its commitment. Sakichi Toyoda contracted pneumonia in October, 1930, and died in Nagoya later that month at age sixty-three.

Impact

Toyoda was one of the great Japanese inventors who ensured that their country caught up with the Western industrial revolution. Inspired by the spirit of the Meiji Restoration that provided unheard-of opportunities to an inquisitive, intelligent, and restless young man like himself, Toyoda magnificently rose to the occasion. Once he decided to become an inventor, he turned to the field he knew best. He ceaselessly worked to invent ever more efficient Japanese looms, making his country independent of foreign looms. His inventions provided Japan with the means of manufacturing domestic textiles to replace imports and allowed the country to become an exporter of well-spun cotton products.

As an inventor, Toyoda continuously struggled to make his ideas economically viable and successful in a mass industrial setting. Teaming up with financial partners, he always ran into difficulties when resources became scarce. His reliance on his family network laid the foundation for the survival of his companies into future generations. His first wife gave him his son, Kiichiro, who, aided by Sakichi's second wife's insistence on his academic training, would found Toyota Motor Company, slightly changing the family name for a more auspicious Japanese spelling. Through his daughter, Aiko, Toyoda gained an adopted son invaluable for his management capabilities.

Just as Sakichi Toyoda invented Japanese looms that eventually surpassed their Western models in quality and price, so his son's Toyota cars would do the same. Toyoda embodied the ideal of the Meiji era Japanese inventor: Through total commitment to his task, seen as a duty to both nation and community, he lifted Japan into the industrial age. With his visionary decision to shift the focus of his son's inventions from looms to cars, Toyoda ensured that after the dark days of World War II, Toyota cars would gain a world market. His *kaizen* philosophy of continuous invention and process improvement became the business philosophy of Toyota. The company's outstanding success would be widely studied and praised by U.S. corporations and economists.

Richard Trevithick

English mechanical engineer

Trevithick was the first person to develop a working steam locomotive. The particular application of high-pressure steam that made that application possible also resulted in the stationary steam engine known as the Cornish engine, which obtained far more widespread practical success.

Born: April 13, 1771; Illogan, Cornwall, England
Died: April 22, 1833; Dartford, Kent, England
Primary fields: Mechanical engineering; railway engineering
Primary inventions: Steam locomotive; Cornish engine (steam engine)

Early Life

Richard Trevithick was the only son and youngest of six children of an identically named father, who was a miner, and his wife, Anna, née Teague. The elder Richard Trevithick worked in numerous copper mines, eventually rising to managerial positions at four mines, including Wheel Treasury and Dolcoath—positions that allowed him to provide initial arenas for his son's technical ingenuity.

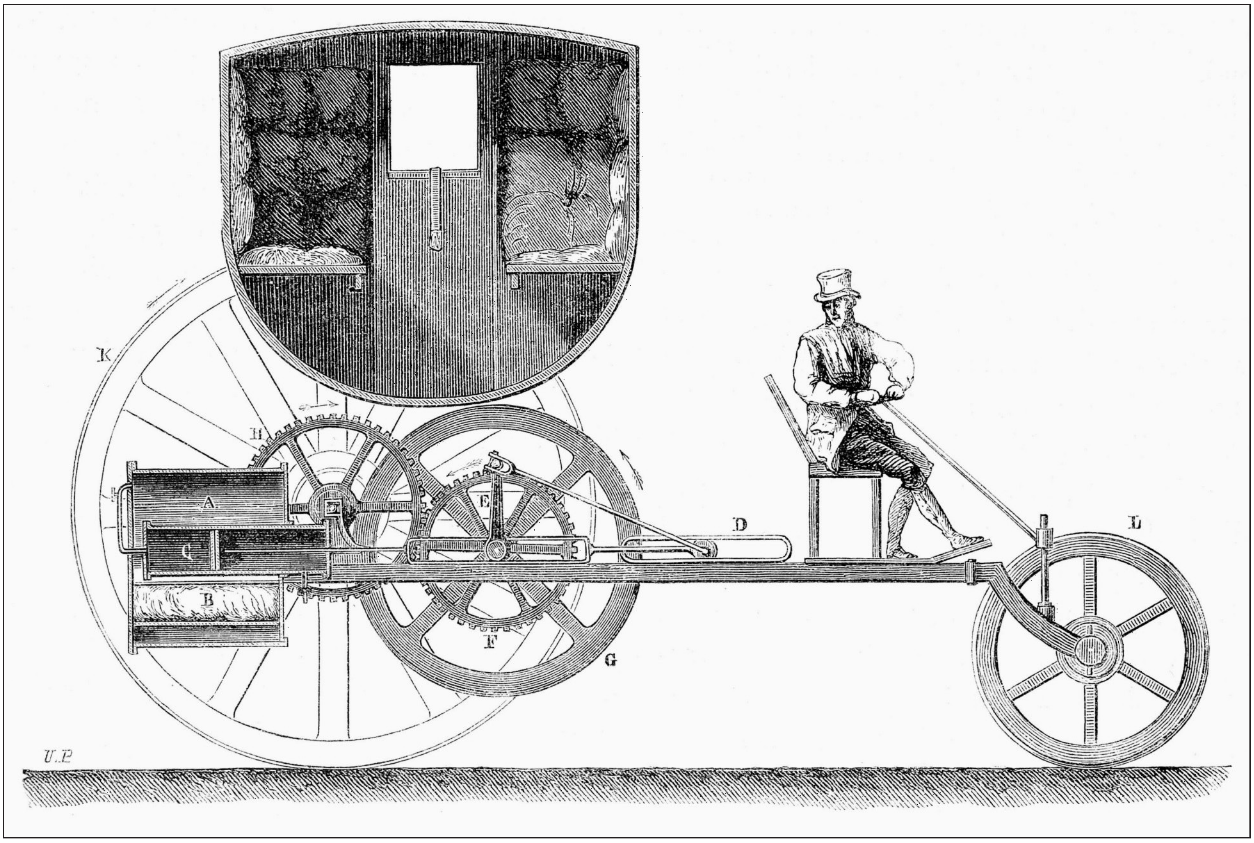
Unsurprisingly, given his situation in the family, the younger Richard was spoiled by his mother and became something of an enfant terrible at elementary school in Camborne. He was tall—six foot, two inches—and strong; in his teens, he became a renowned wrestler and was nicknamed the "Cornish Giant," presumably encouraging his overweening self-confidence even further. On leaving school, he went to work for his father, not as a common miner but as a sort of technical consultant, overseeing the deployment and advising on the potential application of steam engines invented by James Watt, exemplars of which were then being installed in many Cornish mines.

On November 7, 1797, Trevithick married Jane Harvey (1772-1868), the daughter of John Harvey of Hayle Foundry, which produced mining equipment for local use and export. The couple had four sons and two daughters. Trevithick had begun introducing fuel-saving innovations to Watt engines for some years before his marriage, while he was employed at Wheel Treasury, but by the end of 1797—in which year his father died—he was employed as an engineer at the Ding Dong Mine near Penzance, where he began working on an engine designed by William Bull.

Life's Work

With James Watt's patent—which Watt had defended fiercely—about to expire in 1800, there was much anticipation of the free-for-all that would follow. When Watt named Trevithick as the chief offender against his patents, as his legal defense of them drew to a close the accusation made Trevithick a local hero in Cornwall and gained him the nickname "Cap'n Dick." Trevithick immediately began work on a new kind of steam engine, using much higher pressures than the Watt engine; it was more expensive to construct, but it promised to be much more fuel-efficient—a vital consideration in Cornwall, whose mine owners had to import coal from Wales. Trevithick's engines became known as "puffers" by virtue of the noise they made in operation.

The first operative puffer was probably installed at Dolcoath not long after the elder Richard Trevithick's death, but it was not widely advertised because Watt's patent was still in force. There was certainly one in operation at Cook's Kitchen in 1800, which was still in service in 1870. Trevithick built an advanced model for use at Coalbrookdale in Shropshire in 1802, which operated at the then-unheard-of pressure of 145 pounds per square inch. It was, however, only a matter of time before one of these high-pressure engines exploded, and one did so at Greenwich in 1803, killing four men. Watt and his partner, Matthew Boulton, did their best to capitalize on the public relations disaster, condemning Trevithick machines as inherently unsafe. Trevithick responded by devising new safety mechanisms, including the "fusible



Richard Trevithick's steam carriage of 1801. (The Granger Collection, NewYork)

plug," which remained a standard feature of steam engines thereafter.

Trevithick had long been interested in the problem of building an operable steam locomotive—various models of such machines had been constructed since 1770, but none had proved viable—and he had constructed his own working model in 1797. By that time, he had become acquainted with Davies Giddy (who subsequently changed his surname to Gilbert), a local member of Parliament who took a great interest in local technological initiatives. Giddy funded the construction of a full-scale version at Stephen Williams's foundry near Camborne, whose first public demonstration, on Christmas Eve of 1801, generated sufficient interest to be commemorated in a popular song. Trevithick's first steam locomotive broke down four days after that first demonstration, however, while being moved to a new location, and the team supervising its removal repaired to the local pub, with the result that the boiler overheated and was irreparably damaged.

In spite of this calamity, Trevithick succeeded—with the help of one of his backers, Andrew Vivian, and another protégé of Giddy, Humphry Davy—in securing a patent for the locomotive on March 24, 1802. A second locomotive built at Camborne in 1803 was successfully transported to London, but it too broke down. Vivian then withdrew his support, but Tevithick persisted, building the first railway locomotive at Pennydarren Ironworks near Merthyr Tydvil, where he was then employed as an engineer. It had its first successful trial on February 13, 1804, but the poor condition of the track resulted in continual derailments, and it was relegated to work as a stationary engine.

Because of his difficulties in constructing a viable locomotive, Trevithick's work with high-pressure engines began to concentrate increasingly on the improvement of the boilers; it was this that led to the development after 1806 of the so-called Cornish engine, which was first put to work at Dolcoath in 1812 and whose clones subsequently spread far and wide throughout the world. Had Trevithick stuck to stationary engines thereafter, he might have become much more prosperous, but locomotives had become his primary passion. His second railway locomotive, nicknamed *Catch-Me-Who-Can*, was established on a circular track near Gower Street in London for the purposes of advertisement. It obtained some popular renown as a "steam circus" charging for rides but did not attract further financial backing. Trevithick apparently lost heart, abruptly abandoning the project. That too proved to be a disastrous mistake; his assistant, John Steele, carried the project forward alone, building new engines to Trevithick's design, and the establishment of one of these at Wylam in northeast England prompted George and Robert Stephenson to build their own rival, the *Rocket*. In the meantime, Trevithick's career began a downward trajectory from which it never recovered.

Between 1803 and 1807, Trevithick also worked on a steam dredger for use in the Thames, and he involved himself in a project to build a tunnel under the river from Rotherhithe. When the tunnel collapsed and was flooded in August, 1807, Trevithick might have gone home, or traveled to the northeast to work with the Stephensons, but instead he went into business with a merchant involved in trade with the West Indies, Robert Dickinson. The workshop they established in Limehouse generated several patent applications, including one for a "nautical laborer"—a steam tug equipped with a crane—but nothing came of any of them. Trevithick contracted typhus in 1810, and the business was declared bankrupt in February, 1811. Although Trevithick did return to Cornwall briefly to resume work on the development of the Cornish engine, he could not settle. He became interested in South American silver mining, and in 1814 he was hired by Francisco Uvillé to build an engine for use in a mine in Peru.

There was no need for Trevithick to follow his engine to Peru, but he set sail in September, arriving in February, 1817, arriving to an extravagant reception. He soon fell out with Uvillé, though, and began roaming the war-torn continent. He was briefly attached to Simón Bolívar's army as a military engineer but was forced to flee after a disastrous defeat. He took over Uvillé's mine when the latter died in 1818, but the war followed him and the site became a battlefield. He traveled to Costa Rica thereafter, entering into partnership with a man named James Gerard and staking claims on several potential mining sites, but he could not find backing for their exploitation. He wound up in Cartagena, Colombia, destitute, but there had the remarkable good fortune to run into Robert Stephenson, who paid for his passage home.

Trevithick received a warm welcome in Cornwall—where his wife was still waiting for him, in conditions of abject poverty—when he arrived there in October, 1827, but his attempts to find backers for further projects failed dismally. He was reportedly offered several thousand pounds for his claims but refused to sell. He made plans with Gerard to set out for Costa Rica once again, but Gerard died and the plans came to naught. Instead, Trevithick went to the Netherlands to advise on the application of steam engines to land drainage—apparently with some success, although new plans he drew up for a ship powered by a water jet were stillborn. He continued to apply for patents, filing one for an engine using superheated steam (1832), but he had to return to England to work on a machine designed by John Hall in Dartford in Kent. There he fell ill, dying in his lodgings in April,

The Steam Locomotive

Steam locomotives were impracticable using Watt engines, because the relatively low pressures used by those engines were inadequate for the purpose of propulsion. The use of higher pressures overcame that problem but brought with it corollary problems of strengthening and securing the boilers. The "Cornish boiler" that Richard Trevithick developed for eventual use in the so-called Cornish engine was a horizontal cylinder with a fire tube running through the middle; these design modifications not only proved extremely useful in stationary machines but also permitted Trevithick's first full-scale steam carriage to attain a velocity of between five and nine miles per hour. The subsequent history of Trevithick's locomotives was, however, a tale of tragic ifs and buts.

If Trevithick's first and second steam carriages had not broke down on inadequate roads, and if the first designed to run on a railway had not found the track just as inadequate as the road, his enthusiasm might not have become so fragile as to shatter when the Gower Street "steam circus" failed to win immediate backing. John Steele demonstrated that if Trevithick had only persisted—even if that meant going into partnership with George and Robert Stephenson—he could have not only retained his credit for the invention but also made his fortune from it. Unfortunately, he lost heart at exactly the wrong moment and set out instead on the road to ruin. Meanwhile, the improved version of his machine that the Stephensons built became the prototype of a vast number of future machines as well as the foundation stone of the railways that transformed the communications of Victorian Britain, Europe, and the rapidly expanding United States.

1833; his workmates had to club together to pay for his burial in an unmarked grave. His wife, meanwhile, continued to support her children as best she could.

Impact

Trevithick represents the downside of the early nineteenth century enterprise culture; his eventual failure to exploit his technological innovations resulted in his being relegated to the sidelines of the history of the Industrial Revolution. He was undoubtedly a brilliant engineer who fully deserved his brief celebrity, but his crucial decision to abandon the steam locomotive and concentrate on other projects proved fatal to his fortune and fame alike. He retains the credit for devising the Cornish engine, but that was never going to eclipse the honor given to James Watt as the inventor of its inferior predecessor.

One can only speculate as to Trevithick's reason for his stubborn determination to stay as far away from his wife and his home as possible after 1802, but whatever the reason was, it did not prevent his sons from attempting to follow in his footsteps. One of them, Francis, became the chief engineer of the London and North-Western Railway Company, while another, Frederick Henry, constructed the floating steam bridge between Portsmouth and Gosport in 1864. Francis also wrote a biography of his father, hailing him as the inventor of the steam locomotive, but it came too late to rescue his reputation; George and Robert Stephenson had already grabbed all the glory.

Konstantin Tsiolkovsky

Russian rocket scientist

Tsiolkovsky was the first man to design rocket-powered vehicles and life-support systems for space travel, and to promote the idea of the colonization of space by means of the construction of artificial Earth satellites.

Born: September 17, 1857; Izhevskoye, Russia
Died: September 19, 1935; Kaluga, Soviet Union (now in Russia)
Also known as: Konstantin Eduardovich Tsiolkovsky (full name)
Primary field: Aeronautics and aerospace technology
Primary inventions: Space-traveling projectiles; rocket propulsion design

Early Life

Konstantin Eduardovich Tsiolkovsky (KON-stuhn-teen ehd-WAHR-duh-vihch tsyawl-KAWF-skee) was the son of Eduard Tsiolkovsky, a Polish forester who had migrated to Russia, and his wife, Maria, née Yumasheva; their family was poor but large, Konstantin being one of eighteen children. At the age of ten, he suffered a bad bout of scarlet fever and was left with hearing difficulties, with the result that he did not go to school and was forced to educate himself. In 1873, he went to Moscow to complete this course of self-education, and he was taken under the wing of the futurist philosopher Nikolai Fyodorovich Fyodorov, who was then working in a Moscow library. Fyodorov was enthusiastic about the possibilities of radical life extension, technological resurrection, and the colonization of space, which he believed to be essential steps in the progressive improvement of humankind.

Fyodorov's ideas left a deep impression on Tsiolkovsky, who remained the older man's fervent disciple

Space-Traveling Projectiles

Konstantin Tsiolkovsky's first design for a spaceship, contained in his 1883 monograph *Svobodnoe prostranstvo* (free space), depicts a spherical vessel propelled by the recoil of shots fired from a cannon mounted in the rear. The most interesting aspect of that design is not the propulsion system but the gyroscopes employed to modify the orientation of the vessel. Tsiolkovsky modified this design progressively in his later works, substituting more sophisticated devices for the crude cannon and modifying the shape of the shell into an elongated ellipse.

The first experimental design described in *Vne zemli* (1920; *Outside the Earth*, 1963) is of a vehicle variously described as "egg-shaped" and "cigar-shaped" whose liquid propellants burn in a carefully measured fashion to produce a uniform gaseous jet, which is directed through an "exhaust nozzle," thus resembling the rockets then in use as fireworks and weapons of war. The text is deliberately vague regarding the formula of the propellant fuel, admitting that then familiar fuels, whether solid, liquid, or gaseous, were inadequate to the task of accelerating a projectile to the velocity required to escape Earth's gravitational attraction, but insisting that a new, highly flammable combination of two liquids has been recently discovered that could serve as a propellant.

The rocket in which the actual ascent described in the novel is made is a more advanced "compound" form made up twenty separate sections—what would now be called "stages." The whole structure forms an elongated and "streamlined" body about one hundred meters long and four meters in diameter, the exhaust nozzles being mounted in pipes coiled around the hull, whose rotational effect gives the rocked greater stability in forward movement. The rocket ship's shell has three layers, the outer one functioning as a kind of heat shield, radiating frictional heat into space, while the second layer is resistant to conduction and the third embodies a cooling system. In addition to a supply of oxygen, its cargo includes water suspension chambers to protect the crew members from the effects of the initial acceleration and space suits for subsequent use outside the vessel.

Tsiolkovsky's subsequent essays and scientific papers made little further modification to the hulls of his rocket ships, although the compound structure and abundant equipment were greatly simplified. Among the innovative details he introduced was a "gas rudder" fitted over the exhaust nozzles from which the reaction gases were blasted, which was supposed to allow the spaceship to be steered; this device appears in various sketches made in the 1930's.

Although all these designs were hypothetical, they anticipated all the major problems associated with manned spaceflight, and they made some attempt to solve them. Friedrich Zander and his colleagues, who carried out the actual experimental test of early Soviet rockets, made only slight modifications to his designs. Although Tsiolkovsky's own representation of a multistage rocket left something to be desired, his anticipation of the principle was highly significant, and his conviction that new combinations of liquids might ultimately produce a viable fuel proved to be correct.

when Tsiolkovsky left Moscow in 1876. He lived briefly in Vyatka and Ryasan before applying to work as an elementary school teacher. While waiting for his appointment to be confirmed, he filled a notebook with designs for propulsion systems and life-support systems that might facilitate space travel. He taught at a school in Borovsk from 1879 until 1892 and married the daughter of a local priest, Barbara E. Sokolova, while he was there; they had four sons and three daughters.

Life's Work

Tsiolkovsky's speculations regarding the practicalities of space travel led him to conclude that the principle of jet propulsion was the most likely means of its achievement. He adopted this opinion from the outset, in the notebook he began to write in 1878. While he was working in Borovsk, he further developed those ideas into an 1883 monograph titled *Svobodnoe prostranstvo* (free space). He followed this up with many other papers, including one on "How to Protect Fragile and Delicate Objects from Jolts and Shocks" (1891). In 1892, he was transferred to a larger elementary school in the provincial town of Kaluga, where he met other people with scientific interests, and his ideas began to gain wider circulation.

In 1895, Tsiolkovsky compiled a collection of didactic science-fiction stories and speculative essays translated as *Dreams of the Earth and Sky and the Effects of Universal Gravitation*, in which he extended his speculations to the possibility of building an artificial satellite for scientific purposes. He suggested that it might be provided with power by means of "solar motors," and he devoted a good deal of attention to the life-support systems that it would require. Tsiolkovsky produced a technical analysis of "The Exploration of Cosmic Space by Means of Reaction-Propelled Apparatus" shortly after the turn of the century, whose first chapters were published in *Nauchnoye Obozrenie* (science review) in 1903. It contained his first detailed design for a rocket, but the article was slightly garbled by the printers and the magazine was suppressed by the authorities before publication was completed. It was not until 1911 that the next part appeared in *Vestnik Vozdukhoplavania* (herald of aeronautics), where it attracted much more attention in a burgeoning community of aeronautical engineers. The article included the "Tsiolkovsky rocket equation" for calculating escape velocity.

Tsiolkovsky attempted to popularize his ideas further by completing a didactic science-fiction novel that he had begun in 1896, *Vne zemli* (initially translated into English as *Beyond the Planet Earth* in 1960, then as *Outside the Earth* in 1963), describing an epoch-making space journey and its Fyodorovian aftermath. Its publication in 1916 was interrupted, however, when the magazine serializing it ceased publication; the problems and shortages associated with the Russian Revolution of 1917 prevented its appearance as a book until 1920. Its account of the first stages in the colonization of the solar system fully entitles Tsiolkovsky to be retrospectively recognized as the originator of the myth of the space age, although the original prospectus had been Fyodorov's. The story also imagines the inauguration of an international scientific fellowship, whose crew members on the expedition all bear the surnames of famous scientists of their homelands' past; thus, Galileo, Newton, Helmholtz, Laplace, and Franklin take their places in the epoch-making rocket alongside the Russian engineer Ivanov.

Tsiolovosky became a member of the Soviet Academy of Sciences in 1919 and was awarded a pension by the Soviet government in 1920, which allowed him to give up teaching, although he continued to live in Kaluga. When his ideas regarding the practicalities of space travel were echoed elsewhere—notably in a book by Hermann Oberth, the founder of the German Rocket Society, in 1923—Tsiolkovsky was contacted by Friedrich Zander, who had also published works on the theory of rocket travel and life-support systems in 1908-1911. The Soviet authorities, who were then taking a strong interest in the development of aeronautics, appointed Tsiolkovsky as a professor at a newly formed Military Air Academy on August 23, 1924; he, Zander, and Yuri Kondratyuk immediately established a Soviet Society for the Study of Interplanetary Travel in imitation of the German Rocket Society.

In 1926, Tsiolkovsky published a definitive book updating his earlier essay, whose title translates as *The Exploration of Space by Reaction-Propelled Devices*. The Soviet government began sponsoring rocket tests in 1930; although Tsiolkovsky—who was then nearing seventy—was not directly involved, Zander was in charge of one of the programs, and the designs employed were based on those Tsiolkovsky had first committed to paper thirty years before. Tsiolkovsky continued writing until his death in 1935, attempting to summarize his own version of Fyodorov's visionary philosophy in *The Cosmic Philosophy* (1932), which proposed that the end of progress would be the happiness of all the thinking beings in the galaxy, which would involve the formation of a galactic community and the colonization of all its potential habitats. Tsiolkovsky's *Collected Works* were issued by the U.S.S.R. Academy of Science Publishing House in 1954. His science-fiction stories and some of his speculative essays were reprinted in the showcase omnibus *Put'k zbezdam* (1960), which was translated into English as *The Call of the Cosmos* in 1963.

Impact

Tsiolkovsky's crucial contribution to space research was recognized by the placing of an obelisk over his grave in Kaluga, inscribed with a quotation that translates, "Man will not always stay on Earth; the pursuit of light and space will lead him to penetrate the bounds of the atmosphere, timidly at first but in the end to conquer the whole of solar space." Another monument to him was established in Leningradsky Prospekt in Moscow to mark the centenary of his birth; a few weeks later, on October 4, 1957, *Sputnik*—the first artificial Earth satellite—was launched, apparently initiating the space age of which he had dreamed.

The Fyodorovian notion that the future of humankind would consist of a biotechnologically assisted expansion into space and the gradual colonization of the galaxy was echoed elsewhere in Europe and—much more fervently—in the United States, where it became the standard mythical future of generic science fiction. Tsiolkovsky was not responsible for that diffusion of ideas, but he was responsible for the fact that the Soviet Union became involved in rocket research at an early stage and pushed that research forward so determinedly. His ideas helped to give the Soviet Union a lead in the space race that developed after World War II, and the United States would not have made such rapid progress in space technology had it not been spurred on by that political competition. However indirectly, Tsiolkovsky played a major role in the chain of causation that led the United States to land a man on the Moon in 1969.

Jethro Tull

English agriculturist

Tull, often hailed as the "father of British agriculture," paved the way for the late eighteenth century agricultural revolution in England by inventing the seed drill, which resulted in increased crop yields (up to eightfold) and greater weed control over earlier hand-broadcasting methods.

Born: March 30, 1674 (baptized); Bradfield, near Basildon, Berkshire, England
Died: February 21, 1741; Prosperous Farm, near Hungerford, Berkshire, England
Primary field: Agriculture
Primary invention: Tull seed drill

Early Life

Jethro Tull was born in rural Berkshire, England, but his father, also named Jethro, and his mother, Diana Buckridge Tull, hoped he would train for public service rather than farming. He matriculated at St. John's College, Oxford, but finished without taking a degree, instead pursuing legal studies at Gray's Inn in London. When ill health interrupted his studies, he settled down to farm with his father on the family estate at Howberry. He also married Susannah Smith of Warwickshire, with whom he had a son, John, and a daughter, Susannah.

In the eighteenth century, the title "farmer" implied a gentleman who directed other men and women, not a laborer. As bailiff, or field supervisor, Tull was frustrated

Jethro Tull. (Library of Congress)

by the field hands' inability to plant seeds in a consistent, measured depth. In 1701, he invented a machine to do what his workers could not (or would not). Tull did not promote his invention, and it remained known only to his circle until circumstances forced him to move his family. In 1711, Tull's increasing illness (a weak heart) drove him to take a convalescence tour of the Continent, where he studied current European farming methods. Returning in 1714, he found the farm's revenue insufficient to cover the expenses of his three years in Europe. He sold the acreage and moved his family to a more modest farm near Hungerford, where he improved his machine and his methods, based on what he had seen in Europe.

Life's Work

Tull's seed drill might have remained a local innovation were it not for the enthusiasm of his Hungerford neighbors when he moved there in 1714. They encouraged him to publicize the success of his planting technique. Not conversant with the scientific community, however, Tull could think of no method of disseminating his ideas beyond publishing a book, which he could not afford to do. With his farm barely supporting his family, Tull decided to continue his legal studies, and he was admitted to the bar in 1724. About that time, he began writing a full account of his invention and his agricultural system. By 1731, he had finished his manuscript but could still not afford to publish a full-length book, so he had an eighty-one-page "specimen" published cheaply in Dublin under the title *The New Horse-Houghing Husbandry: Or, An Essay on the Principles of Tillage and Vegetation Wherein Is Shewn, a Method of Introducing a Sort of Vinyard-Culture into the Corn-Fields, in Order to Increase Their Product, and Diminish the Common Expence, by the Use of Instruments Lately Invented*. In two years, the sales of this pamphlet justified the publication of an expanded two-hundred-page volume under virtually the same title, and Tull's place in the history of agriculture was assured.

In the interim, influential noblemen had become interested in what became playfully known as "Tullian" agriculture. Tull had criticized the fact that English farmers were still using the "Virgilian" methods described by the Roman poet Virgil (70-19 B.C.E.) in his *Georgics* (37-29 B.C.E.), popularized in his day by John Dryden's translation. Eighteenth century wits noted the irony that the adjective applied to Virgil's near-contemporary Cicero (106-43 B.C.E.) in earlier times had been "Tullian" (for Marcus Tullius Cicero). In 1729, the Scottish Lord Ducie (Matthew Ducie Moreton, 1663-1735) introduced what he called Tullian or "Anti-Virgilian" methods to Charles, Eighth Lord Cathcart (1686-1740), the Parliamentarian in the House of Lords most active in agricultural concerns. On May 9, 1730, Lord Cathcart took a party of noble

The Tull Seed Drill

Jethro Tull's first seed drill was constructed on the frame of a wheelbarrow. He removed the gudgeon—the metal cylinder mounted on the wheel's axle that allowed it to turn independently of the wheel—and replaced it with a larger cylinder with holes drilled at intervals. This perforated cylinder was fitted into the trough of the wheelbarrow, into which a slot was cut opposite the gudgeon. As the cylinder turned, its holes would pick up one seed at a time from the trough and drop them into a tube. This was the basic design, but Tull did not stop there.

The rotating cylinder reminded Tull of the groove, tongue, and spring of the sounding board of a church organ he had worked on, so he replaced his crude perforated cylinder with a much more closely fitted one made from the foot pedal of an old organ. Having mechanized the placement of the seed, Tull realized that mechanization allows duplication. A wheelbarrow could only accommodate one row at a time; enlarging the frame could allow simultaneous deposit of multiple rows of seed. Doing so, however, would create a machine too heavy for one farmer to push. English farmers of the time generally used oxen to plow their fields. Tull designed his second-generation, three-row (and later four-row) seed drill to be pulled by the lighter and smaller horse. However, the seed was only the middle part of the process. Ahead of his enlarged drill, Tull mounted three plowshares, which opened furrows immediately ahead of each seed depositor. Then, after the seed was dropped, a metal disk known as a coulter turned behind each row to place the soil back over the newly planted seed, spacing the rows widely enough to allow horse-drawn hoes to weed the fields once the crop germinated.

For the next two centuries, the only improvements on Tull's drill was simply increasing the number of rows: Tull's horse-drawn model remained basically unchanged until the 1930's, when they were attached to tractors. Twenty-first century seed drills move the seed by pneumatic tubes and inject them into the soil by air pressure. Nevertheless, other than the switch from Tull's gravity-feed (which remained in use to the end of the twentieth century), modern seed drills still employ the principles Tull had perfected by the early 1700's.

lords to meet with Tull and discuss his theories and results. Thus, when Tull's pamphlet appeared a year later, a great number of influential policy makers were prepared to read it with interest.

Although the Tull seed drill soon became the standard implement for planting in Europe and its colonies, the complete adoption of Jethro Tull's agricultural method was delayed by controversy. The controversy was well founded, for one of Tull's theoretical assumptions was wrong. He opposed the use of animal waste as fertilizer, convinced, first, that the soil contained all of the nutrients grains needed and that it needed only to be pulverized to release the nutrients to the germinating seed; and second, that animal waste contained unwanted seeds that would compete with the grain seed. His first assumption was not completely accurate: Preparing the soil did release more of the nutrients, which explained the success of Tull's experiments, but he was not aware that the grains would eventually exhaust the nitrogen from the soil, which animal manure replaced. His second assumption, however, was correct, and the resultant weed control of Tull's method—weed seeds were no longer spread through animal dung—was an important factor in its success.

Weed control was not just a function of the elimination of fertilizer, however. The regular spacing that resulted from the use of the seed drill meant that weeds could be removed from the spaces between rows without harming the planted grain. In modern times, it is taken for granted that fields are planted in rows, but before Tull's seed drill planting was done by broadcast in a random fashion. The waste involved in this method—some landing on rocks or dry soil, some being eaten by birds—was considered unavoidable, which is the point of the familiar New Testament parable of the sower (Matthew 13:1-23, Mark 4:1-20, Luke 8:1-15). Tull's machine, however, placed each seed at an ideal, uniform depth and immediately covered it over with soil.

The seed drill was not the only Tull invention that would become standard throughout Europe by the end of the eighteenth century. Tull also invented a plow that was essentially a horse-drawn hoe, with the blade elevated so that it uprooted grass and weeds, leaving them on the surface of cultivated land so that they could be gathered and destroyed (rather than reseeding). It is significant that the title of Tull's work emphasized the plowing and hoeing rather than the planting aspect of his method.

Tull never lived to see his agricultural methods become standard, as they were by the end of the century. His financial struggles continued to the end of his life, exacerbated by a profligate son John, who ended up in Fleet Prison, London, for debt, shortly after Tull died penniless in 1741.

Impact

Though the process of dropping grain individually through a tube pressed into the ground was known in ancient Babylon (as early as 1500 B.C.E.), European farming had reverted to the broadcast method used by the ancient Romans and continued until Tull's day. Tull's innovation, therefore, lay not in the subsoil drilling but in the mechanical regularizing of the depth and distribution of seeds, as well as the simultaneous removal of weeds that would compete with the seed for nutrients, and covering over the seeds immediately after placement, to keep birds from eating them before they could germinate. By the end of the eighteenth century, agricultural authorities were still divided on whether the Tullian method worked, but influential authors such as John Randall in *The Semi-Virgilian Husbandry* (1764) and Francis Forbes in *The Modern Improvements in Agriculture* (1784) promoted it.

With the rise of industrial manufacturing in England, mass-production of the Tull seed drill became a key to its standardization, and James Smyth and Sons began producing modified Tull drills in 1800, continuing into the middle of the twentieth century. The invention of the subsoil plow in the 1830's improved Tull's drill and was seen to be an extension of his theory that tillage was more important than manuring; as late as 1859, Alexander Burnett's *Tillage a Substitute for Manure* presented the new soil aeration as an extension of *The Precepts and Practice of Jethro Tull*. Twentieth century planters continued Tull's basic design, though the emphasis in weed control shifted from hoeing to fertilizing. The increasing popularity of organic farming methods began to reverse that trend in the early twenty-first century, making plant culture in the United Kingdom, particularly in wheat, closer to the process Tull knew than it had been only fifty years earlier.

Andrei Nikolayevich Tupolev

Russian aircraft designer

Tupolev was among the world's leading designers of military and civilian aircraft. He designed more than one hundred airplanes, which set nearly eighty world records.

Born: November 10, 1888; Pustomazovo, Russia
Died: December 23, 1972; Moscow, Soviet Union (now in Russia)
Primary fields: Aeronautics and aerospace technology; manufacturing
Primary invention: Military and commercial aircraft

Early Life

Andrei Nikolayevich Tupolev (ahn-DRAY-ee neek-eh-LAY-yehv-yihch TEW-pohl-yihf) was born in the small village of Pustomazovo, near Kimry, Tver region, Russia. He was the sixth of seven children. His early education was entirely at home, but he later attended the Tver Gymnasium, where he excelled, graduating in 1908. He then applied to two major Russian universities: the Imperial Moscow Technical School (IMTU) and the Institute of Railway Engineers. He enrolled at IMTU, where he studied aviation with Nikolai Yegorovich Zhukovsky, the Russian aerodynamic pioneer. While at IMTU, Tupolev built one of the world's first wind tunnels, which formed the heart of the IMTU aviation laboratory.

Andrei Nikolayevich Tupolev. (Library of Congress)

The Russian universities were hotbeds of revolutionary activities, and Tupolev was accused of antigovernment activity and arrested in 1911. He avoided prison on the condition that he remain with his family in Pustomazovo. He studied privately at home and was allowed to return to IMTU in 1914. He wrote his thesis on the development of seaplanes and was granted his degree in 1918.

Life's Work

Tupolev's life work was done at the Central Aero-Hydrodynamics Institute (TsAGI) in Moscow from 1929 to 1972, the year he died. The Central Design Office (TsKB) within this institute produced large aircraft—bombers and airliners. In the 1930's, Tupolev based much of his work on the all-metal designs of German engineer Hugo Junkers, and these prevailed until World War II. Throughout the 1930's, the number of fully trained airplane designers increased, and Tupolev began producing his designs (designated with the prefix "ANT," based on his initials) out of his own office.

During the Stalinist military purges of the late 1930's, Tupolev and his associate, Vladimir Petlyakov, were arrested on false charges that they had participated in an anti-Soviet "Russian Fascist Party." As World War II began in 1939, Tupolev's talents were so badly needed that he was transferred to a secret research laboratory within the Soviet Union's labor camp system operated by the secret police (NKVD). The laboratory was located near the Moscow suburb of Bol'shevo, and many people from TsAGI were already working there. After this laboratory was moved to Moscow, Tupolev was finally tried, convicted, and sentenced to ten years in prison, but he was released in 1944 to conduct vital defense work.

During this period, Tupolev's greatest success came in dismantling, rebuilding, and redesigning the Boeing B-29, the most advanced bomber at that time. This process, known as reverse engineering, was a daunting task. Three such planes were forced to land in Siberia during the Japanese air raids of 1944. Using these three models, Tupolev was able to mass-produce the Russian version, named the Tu-4, in time for the May Day festivities in 1947—much to the chagrin of the Americans. Tupolev continued to design a number of large aircraft. He shifted from piston-driven propeller aircraft to turboprop planes in the early 1950's. By the time Nikita S. Khrushchev came to power in 1953, Tupolev had produced his unique strategic bomber, the Tu-95. Khrushchev denounced Stalin's terror and, holding Tupolev in high esteem, removed his arrest record. During this time, Tupolev was able to use Khrushchev's support to fend off rival designs from Vladimir Myasischev, who was working on his M-4 series of jet-powered strategic bombers.

In 1955, Tupolev introduced the Tu-104, one of the world's first jet airliners to provide regular passenger service. It was the only jet airliner in service in the world from 1956 to late 1958. Tupolev produced a series of other "Tu" jet passenger planes, and his son Alexei, codesigned the supersonic Tu-144, which made its first flight in 1968.

Khrushchev lost power in 1964, and Tupolev gradually lost his most significant positions to his rival designers. The Tu-144 continued to have prominent support until 1973, and the Tu-154 was also appreciated as a significant design. However, it was clear that the aging Tupolev had lost—and would never regain—his position as the premier large aircraft designer. The Russian design bureau Ilyushin had taken his place. Tupolev died on December 23, 1972, and was interred in Novodevichy Cemetery in Moscow.

The Tupolev Tu-144

In 1909, as a twenty-one-year-old college student, Andrei Nikolayevich Tupolev began his lifelong career as a pioneer airplane designer by building Russia's first, and one of the world's first, wind tunnels—just six years after Wilbur and Orville Wright used their wind tunnel to test the world's first heavier-than-air, gasoline-powered airplane. Tupolev would go on to produce some of the world's most impressive aircraft, including the Tu-4, reverse-engineered from Boeing B-29 Superfortresses; the Tu-104, one of the world's first jet transports to provide regular passenger service; and the Tu-144, the world's first supersonic transport aircraft.

The Tu-144 was designed by Tupolev and his son Alexei and made its first flight on December 31, 1968. Tupolev was eighty. The aircraft had swept wings and a nose section that could be "drooped" to improve visibility. It was capable of speeds up to 1,500 miles per hour, more than twice the speed of sound, which it first exceeded in June, 1969. By 1971, it was in production. At the Paris Air Show in June, 1973, the aircraft crashed, killing the flight crew. Apparently, the crash was not caused by aircraft failure, but the negative publicity generated by the disaster hurt production. Following another crash in 1978, the Tu-144 was retired.

Impact

Tupolev was one of the world's greatest aircraft designers of the twentieth century. Although some of his work was based on earlier German designs and the Tu-4 was reverse-engineered from the U.S. B-29, during his career Tupolev came up with many unique designs. Despite his prison sentence under Stalin, he was one of the most decorated Soviet aircraft designers. He was made a member of the Soviet Academy of Sciences in 1953 and three times named a Hero of Socialist Labor, in 1945, 1957, and 1972. Tupolev's impact on Russian aviation is unparalleled. Almost every twentieth century Russian aviation giant, from Pavel Sukhoi, famous for his jet fighters, to Sergey Korolev, the space rocket designer, studied under Tupolev. Though a communist hero, Tupolev was so widely accepted as an international aviation pioneer that he was made an honorary member of the top British and American aeronautical organizations. At intervals during his career, Tupolev's designs were often the world's best, and they earned a total of seventy-eight world records.

Earl S. Tupper

American entrepreneur and landscaper

Employing new plastics technology and innovative marketing techniques, Tupper revolutionized food storage and preparation with his Tupperware containers, creating a cultural and economic phenomenon that endured into the twenty-first century.

Born: July 28, 1907; Berlin, New Hampshire
Died: October 5, 1983; San José, Costa Rica
Also known as: Earl Silas Tupper (full name)
Primary field: Household products
Primary invention: Tupperware

Early Life

Earl Silas Tupper was born to Earnest Leslie Tupper and Lulu Clark Tupper on a farm in rural New Hampshire in 1907. His family struggled financially and moved frequently during his childhood, settling in rural Massachusetts in the early 1920's and establishing a greenhouse business. A mediocre student who barely finished high school, Tupper nevertheless was an ambitious teenager with a strong work ethic and a dream of achieving fame and wealth as an inventor and entrepreneur. His father was an aspiring inventor who was granted a patent for a device to facilitate the cleaning of chickens, and Tupper, though reportedly harboring resentment of his father for his lack of ambition, shared his love for invention, filling numerous notebooks with ideas and sketches. Some, such as his idea for a fish-powered boat, appeared impractical; others, such as his suggestion that his parents open a free playground for the children of their greenhouse customers, would prove to be ahead of their time.

Tupper married in 1931, and he continued his efforts to create and market new inventions while operating a landscaping and tree surgery business to support himself and his family. His business folded during the Great Depression. After declaring bankruptcy, Tupper was forced to take a job in a plastics factory owned by the DuPont Corporation. Despite falling on hard times, he retained his ambition of becoming an entrepreneur, purchasing some used plastic-molding machines from his employer and establishing his own plastic container business in 1938. His company, Tupper Plastics, achieved modest success as a subcontractor for DuPont, making parts for gas masks and other devices for military use.

Tupperware-style storage containers and a basin from 1953. (Getty Images)

Life's Work

After World War II, Tupper experimented with manufacturing various products for the bourgeoning postwar consumer market, including plastic cups, cigarette cases, and soap dishes. Yet he would realize his life's ambition by applying his knowledge of plastics to the development of new means of food storage. His experimentation in plastics refinement led to the development of the Wonderbowl, the first practical plastic food-storage container, in 1946. Realizing the potential of the Wonderbowl, Tupper marketed it vigorously to retailers, but he realized little initial success and continued to struggle financially.

During the late 1940's, Tupper would establish a business relationship with Brownie Wise, a Florida woman who had begun selling Tupperware as a sideline to her work as a distributor for Stanley Home Products. Along with Ann and Thomas Damigella, a Massachusetts couple who also sold Stanley Home Products, Wise attracted the attention of Tupper by selling large amounts of Tupperware products through home parties, a direct marketing technique employed by Stanley in which sellers would invite friends and neighbors into their homes for informal gatherings that included product demonstrations and sales presentations. Wise modified and expanded upon the home party model to create a network of Tupperware distributors and salespeople composed almost entirely of women, a large percentage of whom did not work outside the home. Through this network, Wise realized sales of Tupperware products that outstripped those of other distributors and retailers. Because of the success of Wise and the Damigellas, Tupper decided to market Tupperware products exclusively through home parties.

Tupper met with Wise, the Damigellas, and others in 1948 to create Tupperware Home Parties, Inc., making Wise the head of sales. Wise would continue to refine the home party model and build a nationwide network of salespeople and distributors during the 1950's, making Tupperware a household word and a symbol of both the emerging postwar consumer culture and the changing role of women in American culture. The Tupperware party performed several functions: disseminating information about an innovative product whose uses and benefits were not readily apparent to retail shoppers, empowering women to supplement their household incomes and achieve a measure of independence as businesspeople, and providing a social outlet that proved particularly useful in an increasingly mobile postwar society, as women often attended Tupperware parties to establish or solidify relationships with neighbors.

With his sales division thriving and its operation delegated to a trusted leader, Tupper again focused his creative energy on product development during the early and mid-1950's. Consistent with his reputation for strict, detail-oriented management, Tupper closely supervised every detail of the operation of his factory and personally designed each new product, which was then tested in demonstration kitchens in the factory and introduced to the public at home parties. Wise remained the most visible figure in the Tupperware company, attracting media attention as a master marketer and attaining status as one of the most successful American businesswomen of the 1950's. Wise built a network of salespeople and distributors through an elaborate system of rewards, many of which were presented during lavish "jubilees" that showered top sellers with praise and material rewards. As the phenomenon of the Tupperware party spread across the United States, sales of Tupperware products proliferated, making Tupperware one of the most widely recognized brand names in the United States by the end of the decade.

Despite the success of his company, Tupper reportedly grew restless as the Tupperware empire grew larger and more difficult to control. Frustrated by the media attention focused upon Wise and the expenses incurred by the elaborate system of seller incentives that she created, Tupper abruptly fired her in 1958, subsequently erasing all references to her from advertisements and company literature. Under increasing pressure to incorporate his company and offer public stock to avoid tax liability, Tupper sold the Tupperware company to the owner of the Rexall drugstore chain for $16 million later that year. Rexall retained the business model that had proven successful during the 1950's, and Tupperware parties remained the primary method of marketing Tupperware products through the remainder of the twentieth century. In 1960, Rexall introduced Tupperware products to international audiences, sanctioning the first Tupperware party in the United Kingdom.

Firing Wise and selling his company were but the first of a series of drastic decisions that Tupper made in the late 1950's. Soon afterward, he divorced his wife, relinquished his U.S. citizenship, and purchased a private island in Central America. Tupper soon grew restless in retirement and resumed efforts to invent new products; however, despite his reputation as the inventor of Tupperware, his inventions attracted little interest. He later moved to Costa Rica, where he died in 1983.

Impact

The life and work of Tupper exemplified the transition of American society during the mid-twentieth century. A self-taught tinkerer, he realized success as an independent inventor at a time when invention was rapidly becoming the domain of corporate laboratories and major research universities. Tupper was a product of the prewar rural Midwest whose most successful creation exerted a significant impact on life in the growing suburbs of postwar America.

The invention of Tupperware solidified the reputation of Earl Tupper as one of the most influential inventors of the twentieth century. Tupperware joined television, fast food, motels, and interstate highways as

Tupperware

Humans have employed various devices and methods throughout history to protect food from decay and consumption by animals, insects, and bacteria. Technological innovations of the early twentieth century, most notably the development of refrigeration technology, had dramatically improved food preservation, yet the metal, glass, and ceramic containers available to households were limited in their ability to preserve food for long periods.

A by-product of petroleum distillation, plastic came into use as a manufacturing material during the early twentieth century as the use of automobiles proliferated in the Western world. The first commercial plastic, Bakelite, was introduced in 1909. However, early plastics were brittle, greasy in texture, and emitted noxious odors, making them unsuitable for use as food containers. Nevertheless, as World War II drew to a close, Earl S. Tupper, eager to develop marketable consumer products from plastic, began work toward refining a plastic product that was durable, pliable, odor-free, and suitable for use in household food containers.

Working with polyethylene waste acquired from the DuPont factory where he worked, Tupper experimented with various chemical formulas and refinement techniques before developing a suitable product in 1946. The end result was the Wonderbowl, which featured a translucent lid with an airtight seal that allowed the user to expel excess air from the inside of the container by pressing down on the lid prior to sealing it (a technique that he dubbed "burping") in order to slow decay by minimizing the exposure of food to air. Tupper produced these bowls, which he eventually renamed Tupperware, in a variety of shapes and sizes and marketed them to wholesale distributors, department stores, and other establishments. However, the bowls sold slowly at first, as many consumers still distrusted plastic and were unconvinced of the benefits of the burping seal. Popularizing the new technology would require the personal touch of the Tupperware party, which allowed consumers to witness firsthand demonstrations of the product.

Other manufacturers soon introduced their own lines of plastic food containers to the consumer market; but the patented burping seal that Tupper had developed distinguished his products from those of his competitors. After the patent for Tupperware expired in 1984, numerous imitation products, many of which featured some variation of the burping seal, flooded the market; yet the Tupperware brand remained the archetypical plastic food container in the minds of Americans, many of whom continued to use "Tupperware" as a generic term to describe all sealable food containers.

symbols of postwar American consumer society and the rapid changes in technology and culture that accompanied it. A simple household product, Tupperware provided a solution to a common and long-standing problem that had assumed a new urgency in the 1950's as young working couples with growing families and increasing demands on their time benefited from ways to preserve leftover food and prepared ingredients more effectively. By developing a new method of refining plastic for practical use, Tupper revolutionized the plastics industry, facilitating the widespread use of plastic products in various household applications. In addition, the business model that he helped create transformed the marketing of consumer products, creating the concept of the home party and influencing other marketing techniques such as infomercials and home shopping channels that emphasized product demonstration and targeted sales pitches.

Alan Mathison Turing

English mathematician, cryptographer, and logician

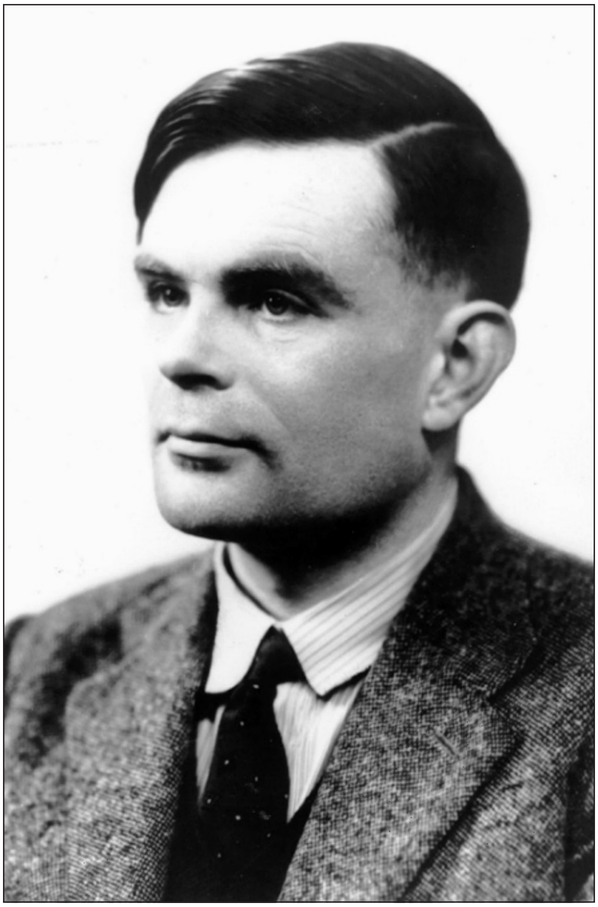
In addition to theoretical work on the possibility of computation, Turing was responsible for laying out some of the basic ideas that enabled early computers to be designed efficiently. In addition, he laid down some of the principles for judging what a computer could do.

Born: June 23, 1912; London, England
Died: June 7, 1954; Wilmslow, Cheshire, England
Primary fields: Computer science; mathematics
Primary inventions: Automatic Computing Engine; Turing test

Early Life

Alan Mathison Turing, the individual most responsible for the modern computer, was the son of Julius M. Turing and his wife, Ethel Sara. Turing's father was a British civil servant who spent much of his time working in India when Turing was a child. This required either arrangements for keeping Turing and his older brother John in the home of a family willing to look after them or for Turing's mother to spend time away from her husband. While Turing's mother was around, he seemed to be a bright and sociable child, but he lost some of those aspects of personality in her periods of absence. After having gone to a day school until 1921, he was sent to a boarding school where his brother was a student. From there, he proceeded to Sherborne School in 1926, one of the great English private schools designed to prepare its students for Oxford or Cambridge.

At Sherborne, Turing made significant progress in mathematics and science, but he continued to display lit-



Alan Mathison Turing. (Smithsonian Institution)

tle interest in his fellow students, many of whom were more interested in athletics than in academic matters. He developed a close friendship with Christopher Morcom, a student whose academic record was unblemished and who served as a model for Turing. There may also have been a touch of romance in the friendship, and it can be argued that many of Turing's subsequent relationships with men were attempts to recover the friendship with Morcom, who died in 1930. It was typical of Turing's interests that one of the prizes he won as a student at Sherborne was a book on the foundations of quantum mechanics by the Hungarian mathematician John von Neumann.

In 1931, Turing matriculated at King's College, Cambridge, one of the grandest colleges in the university and one with a tradition of mathematical accomplishment. He was already indulging in mathematical research, although some of it was rediscovery of what had already been known. Many students tended to concentrate on the material that would appear on the final examination that they would face at the end of their undergraduate careers, but Turing had a broader range of interests, from statistics to applied mathematics. In particular, he was able to come up with an improvement on one of the results of von Neumann. When he took the Tripos (the final examination in mathematics) in 1934, Turing emerged with a first-class degree and with the offer of a studentship at King's College. From there, he proceeded to a fellowship the next year. At this point, Turing had a more positive view of the future than he had had since starting at Sherborne.

Life's Work

Turing attended a sequence of lectures on the foundations of mathematics by Cambridge colleague M. H. A. Newman. Newman introduced Turing to the work of the Austrian mathematician Kurt Gödel, who had proved a few years before that there were undecidable statements in arithmetic. Undecidable statements are those that cannot be proven or disproved within the rules of arithmetic, and their existence came as something of a surprise. Some viewed Gödel's result as the refutation of some of the schools of mathematical philosophy that had been most popular earlier in the century.

One of those schools of mathematical philosophy was associated with the name of David Hilbert, long associated with the German university of Göttingen. Hilbert had claimed that mathematics needed to find a procedure that would enable every question to be decided in a finite amount of time (called a "decision procedure"). One of the difficulties in tackling Hilbert's problem was trying to find a way to represent what form a solution would take. Turing came up with a method for tackling Hilbert's problem that enabled him to answer the question of whether every problem is decidable in the negative. He could use some of the ideas in Gödel's work associated with self-reference, but he also came up with the model for computation that underlay the developments in computer science for the rest of the century.

Turing's idea was a simple one. He imagined an infinite tape divided into squares and a machine that would scan one of those squares at a time. The machine would either mark something on the square, erase what was on the square, or just leave the square alone and then move to an adjacent square. The machine's behavior was based on the state in which it was while scanning the square, and it could move from that state into another one as it scanned the next square. This simple and easily imaginable machine became known as a "Turing machine." A Turing machine could be designed to handle any particular problem, provided that it was theoretically possible. Turing's article describing this approach to mathematics (and founding, in the process, the discipline of computer science) was ready for publication in 1936.

That same year, the American logician Alonzo Church at Princeton University produced a different way to show that Hilbert's problem was unsolvable. While it took some time to sort out the connections between Church's and Turing's approach, Turing felt that it would be worthwhile to go to Princeton for a couple of years in order to learn about what was being done there. He received financial support and was able to benefit from the company of many of the world's leading logicians, either as visitors or colleagues there. Among them was von Neumann, with whom Turing also spoke about some of his ideas for the future of computation. Turing had an interest in physically constructing the kind of machine that he had envisaged.

A more immediate concern arose in the form of dealing with the war with Nazi Germany. After Turing returned to Cambridge in 1938, he was recruited for service to the war effort (in advance of the outbreak of war) and became part of the group of code-breakers at an establishment at Bletchley Park determined to unravel German naval codes as created by what was called an Enigma machine. There was a great deal of mathematical talent in that group, but there was also the need for some computing assistance. While the group's ultimate success contributed to the defeat of the Germans, one of the important tools was a machine called the Colossus. It did not have the theoretical features of a computer such as Turing envisaged, but it demonstrated the potential of what technology could offer.

At war's end, Turing became employed by the National Physical Laboratory. Within a couple of months, he had written a proposal for an "Automatic Computing Engine" (ACE), based on his theoretical and practical understanding of what could be accomplished. If the machine had been built at the time, it would have been the first stored-program computer in the world, but all sorts of practical difficulties intervened. Turing had never been the most diplomatic of researchers, and it required the help of others to elicit the funds to make ACE, even in pilot form. By the time it was finished in 1950, Turing had gone on to work at the University of Manchester, also a center for the design and construction of computers. He also took up the application of mathematics to understanding biological development.

Turing had not let his eminence interfere with his social life, and this had dire consequences. Homosexuality, even between consenting adults, was a criminal offense in the England of the 1950's, and Turing found himself arrested in 1951 and convicted in March, 1952. The sentence involved his taking a course of hormone therapy, whose emotional effects were not fully explored. Two years later, Turing died of eating an apple that had been

The Automatic Computing Engine

Calculators capable of carrying out arithmetic operations had been designed long before Alan Mathison Turing. One of the innovations of the work of Charles Babbage in the nineteenth century had been the attempt to construct a machine that could go beyond simple calculation, but there had still been limits as to what scientists believed a machine could do. Turing, by virtue of the formalism he had discovered in the 1930's, conceived of a machine that could do anything if it was given the appropriate program. The problem that he faced in his proposal for the "Automatic Computing Engine" (ACE) was realizing this theoretical model in practical form.

By the end of the World War II, Turing had learned enough about engineering to provide the specifications for his machine rather than leaving this work to others. Turing favored ingenuity in programming over the construction of more complicated machinery. Rather than building a component for doing addition, Turing would write a series of instructions that would carry out the addition on the standard circuitry. Turing used a delay line (a contribution from others that he acknowledged) for storage of information. The delay line consisted of a tube of mercury in which there would be an acoustic delay in transmitting pulses. This provided for indefinite storage of information, an essential step for writing programs.

The crucial notion of optimum coding involved having each instruction give the address for the next instruction. This avoided the issue of latency, which had limited the number of executions that could be instructed in a cycle. As simulations conducted long after Turing's death indicate, the Pilot ACE (the first version of the proposed machine to be constructed) was faster than the other British computers of the time. It had among its descendants the DEUCE machines, constructed between 1955 and 1962. By the end of that period, the physical machine that Turing built had lost its applicability, but Turing machines have not.

coated with cyanide. The usual explanation is that he committed suicide as a result of depression.

Impact

The Automatic Computing Engine designed by Turing was an improvement on any of the other machinery available at that time. It remained an important feature of the computing landscape for the rest of the decade. After the difficulties involved in getting a pilot version built, the results were enough to convince industry that the features of the machine deserved to be more generally adopted.

Beyond the specific machine that Turing designed, his vision of computing was the inspiration for many in both machine design and theoretical computer science. Turing foresaw that, as computers became more powerful and widely used, issues would arise about whether a computer could "think." For example, it was tempting to argue that a chess-playing computer would be a "thinking machine"; however, it could be argued that such a machine showed instead that chess playing did not require thinking. Turing proposed a simple test to determine whether a computer could "think": If someone interacting with the computer was unable to tell whether it was a machine or not, then it could be considered intelligent. As computers have increased in the number of tasks they can perform, the Turing test remains a way of addressing the issue of machine intelligence.

The Turing machine served as a theoretical basis for generations of computers. By the end of the twentieth century, there were a couple of theoretical alternatives to consider. Nondeterministic Turing machines, for example, allowed for a randomizing device capable of producing a solution faster than a traditional Turing machine, which was used as the means for measuring the complexity of a problem. Theoretical "quantum computers" were also introduced, again with the possibility of solving problems faster than a standard machine. These faster machines have not been built, but the fact that the Turing model is still being compared with them is testament to the lasting influence of Turing's work.

Mark Twain
American author

Although he earned a great deal of money from writing the books that made him famous, such as Tom Sawyer *and* Adventures of Huckleberry Finn, *Twain always aspired to greater wealth through business ventures and investments in new technologies. He greatly admired inventors, who figure prominently in his writings, and patented inventions of his own.*

Born: November 30, 1835; Florida, Missouri
Died: April 21, 1910; Redding, Connecticut
Also known as: Samuel Langhorne Clemens (birth name)
Primary field: Printing
Primary invention: Self-pasting scrapbook

Early Life

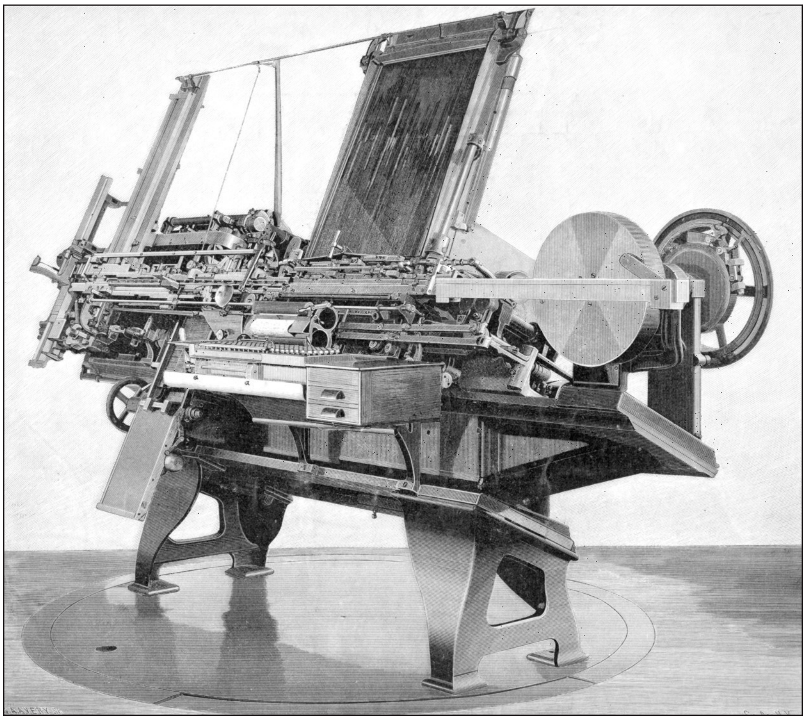
Born Samuel Langhorne Clemens in the northeastern Missouri village of Florida, Mark Twain grew up in nearby Hannibal, a port town on the Mississippi River. His formal education ended there when he was eleven, but around that same time he was apprenticed to a local newspaper publisher. Thus, like many other nineteenth century American writers, he began his career as a printer. Working on newspapers fostered a lifelong habit of reading that eventually made him one of the great autodidacts of his time. Science, technology, and history were his favorite subjects, and he grew up acutely aware of the changes brought by the Industrial Revolution.

In 1853, before turning eighteen, Twain left Hannibal permanently. Working as an itinerant printer, he made his way to New York City, where he thrilled to the marvels of a great world's fair. He also spent time working in Philadelphia, the home of America's first great inventor, Benjamin Franklin, whose career would always fascinate him. After returning to the Midwest, he continued working as a printer, mainly for his older brother, Orion Clemens, who had relocated to southern Iowa.

Twain's life turned in a radically new direction in 1857. Early that year, he went to New Orleans, where he persuaded a veteran steamboat pilot to take him on as an apprentice. Over the next four years—first as an apprentice and then as a licensed pilot—he steered steamboats between St. Louis and New Orleans. He loved the freedom and prestige of his work and might have remained on the river indefinitely. However, the outbreak of the Civil War in early 1861 ended commercial traffic on the Lower Mississippi. While other steamboatmen joined the Union and Confederate navies, Twain went west with his brother Orion, whom President Abraham Lincoln had appointed secretary of the new Nevada Territory.

Life's Work

After crossing the plains with his brother, Twain took up prospecting in western Nevada. A year of unremunerative mining work spoiled his dreams of easy riches, so he became a beat reporter for the *Virginia City Territorial Enterprise*. In early 1863, he adopted the pen name "Mark Twain" as he built a reputation as a humorous



With its 18,000 separate parts, the Paige compositor was far too complicated to provide reliable service in newspaper printing offices. (*Scientific American*, March 9, 1901)

The Paige Compositor

Almost certainly the most complex typesetting machine ever made, James W. Paige's two-and-one-half-ton compositor had more than 18,000 parts. Not surprisingly, it also generated some of the most complicated paperwork in U.S. patent history. Paige's 1887 patent application alone contained 275 sheets of drawings and 123 pages of technical specifications.

Paige's machine could handle only one size of metal type (a significant limitation), which was stored in nearly vertical channels holding two hundred pieces each. A human operator used the machine's keyboard to arrange the type in text: Each keystroke made a plunger push a piece of type from its gravity-fed channel into a horizontal raceway. As each word was completed, the operator pressed another key to move it to a raceway in which full lines were assembled. Each time the machine signaled that a row was filled, the operator pressed another key launching the machine's delicate justification operation, which measured the row and inserted spaces to fill out the line before moving it to a galley tray. While all these operations were proceeding, dead matter deposited beneath the machine was automatically sorted and moved up channels on the machine's backside to be distributed for reuse.

The machine's sheer complexity and particularly its large number of moving parts, which turned on eight hundred separate shaft bearings, combined with the delicacy of its individual operations to make it jam frequently. Paige never got it to operate for sustained periods without breaking down. When his machine was running smoothly, it set type faster than Ottmar Mergenthaler's Linotype machine, but the latter proved more reliable because it used significantly fewer moving parts. Instead of emulating human typesetting steps that required handling individual metal pieces for each character and space, the Linotype machine used molds of individual characters to make matrices of entire lines into which hot lead was poured. As the lead cooled into firm metal bars, the molds returned to their original places without leaving the machine. Later, after the lead bars were used for printing, they were simply melted down and poured back into the machine, so there was no need to distribute dead matter.

writer. The following year, he relocated to San Francisco, where he worked for a local newspaper and continued writing humorous sketches. Reports he wrote from Hawaii in 1866 enhanced his West Coast reputation, but national fame arrived a year later, when he went to Europe and the Middle East on the cruise ship *Quaker City* and wrote dozens of humorous letters that were printed in newspapers throughout the United States. Afterward, he capitalized on his new celebrity by publishing *The Innocents Abroad* (1869), an account of his trip that became the best-selling American travel book of the nineteenth century. He soon followed it with *Roughing It* (1872), an almost equally popular book about his years in the West.

The large sums that Twain made from his early travel books set the standards by which he measured the success of all his future books. Meanwhile, he got married in 1870 and settled in Buffalo, New York. After a brief stint as the part owner and coeditor of the *Buffalo Express*, he realized that his true calling was that of a writer. In 1871, he moved to Hartford, Connecticut, which remained his primary home for two decades. Those years were his most productive period as a writer, and he earned worldwide fame with such books as *The Adventures of Tom Sawyer* (1876), *A Tramp Abroad* (1880), *Life on the Mississippi* (1883), *Adventures of Huckleberry Finn* (1884), and *A Connecticut Yankee in King Arthur's Court* (1889). Twain probably netted more from his books and lecture tours than any other writer of his time, and his wife inherited a substantial fortune. Nevertheless, fear of returning to his childhood poverty continually drove him to look for more ways to increase his income.

Twain's experience as a printer, steamboatman, and miner helped increase his interest in new technologies. During the mid-1870's, he became one of the first writers to use a typewriter. In 1877, his Hartford home became one of the first private residences in the world to have a telephone installed. He enjoyed associating with scientists and inventors and had memorable meetings with Nikola Tesla and Thomas Alva Edison. The latter recorded Twain's voice on wax cylinders (later lost in a fire) in 1888. Twain's writings make it clear that he regarded the nineteenth century as the period of the greatest technological advancement in human history and esteemed the inventors who made the advances possible. Inventors figure prominently in his novels *A Connecticut Yankee in King Arthur's Court*, *The American Claimant* (1892), and *Tom Sawyer Abroad* (1894), and he wrote numerous essays on inventors and technology.

Twain's interest in technology made it natural for him to invest in new inventions and even to dabble in inventing gadgets himself. In 1872, for example, he hit on the idea of making scrapbooks with preprinted glue strips on pages that needed only to be dampened with water. After patenting the idea the following year, he arranged with Dan Slote, a friend he had made during his 1867 trip to Europe, to manufacture the books. Slote's company eventually produced more than thirty different sizes and specialized models of "Mark Twain's Patent Self-Pasting Scrap Book." The books sold well through the 1870's.

Other inventions that Twain patented during this period included a bed clamp and a self-adjusting garter, neither of which he ever marketed. In 1885, he patented a history board game that he called "Mark Twain's Memory Builder," based on a game he played with his daughters. He had several models of the game manufactured for test-marketing in 1891, but it was too complicated to catch on with the pubic, and he gave up on it.

Twain's self-pasting scrapbook was his only profitable invention, but he invested a great deal of money backing other people's inventions. However, his fascination with impressive novelties often blinded him to practical difficulties, causing him to make poor investment choices. For example, he lost about $50,000 backing a process for making engraved printing plates called Kaolatype, whose patent he bought in 1880. With the misguided optimism that typically characterized his investments, he predicted that Kaolatype would revolutionize engraving in the printing industry and formed a company with himself as president and principal stockholder. Soon, however, Kaolatype was made obsolete by cheaper photographic engraving processes that produced better results.

As Twain was giving up on Kaolatype, he found an even more promising investment opportunity—an automatic typesetting machine that James W. Paige (1842-1917), a mechanic working in Hartford's Colt Arms Factory, had begun developing around 1873. Paige was addressing a need dear to Twain's heart. After Johann Gutenberg had invented movable type during the fifteenth century, typesetting had seen few improvements up to the time Twain himself worked as a printer. Rotary presses and other nineteenth century innovations greatly improved the speed of printing, but typesetting remained a bottleneck crying out for automation. Paige's machine promised to meet that need, and Twain was awed by its mechanical brilliance.

For four centuries, compositors had used only their hands to set type, by painstakingly selecting individual metal characters from boxes and arranging them, row by row, on galley trays. After type was used for printing, it was sorted and "distributed" to the original boxes. A keyboard-operated machine that used individual pieces of metal type, Paige's machine automated each human typesetting step, making it possible for a single operator to set type as much as six to ten times faster than could be done by hand.

Twain estimated that thousands of newspapers would buy Paige's machine, and he may have invested as much as $200,000 in the machine between 1880 and 1894, by which time he owned a half-interest. The unpleasant reality was that not a single machine was ever sold. The machine was a true marvel of engineering but was doomed by a fatal flaw: It had too many moving parts to stand up to heavy use over time. Its inventor was a perfectionist who toiled ceaselessly to improve its performance but never quite succeeded. He repeatedly failed to live up to his promises to complete the machine on schedule but used his extraordinary powers of verbal persuasion to string Twain along for years.

The end came in 1894, when Paige finally had a working model ready for testing in a Chicago newspaper office. By then, however, his machine had already been made obsolete by Ottmar Mergenthaler's slower but more reliable Linotype machines. On the basis of the machine's Chicago trial, Twain's friend and financial adviser, Henry Huttleston Rogers, a Standard Oil executive, declared that the machine had no commercial potential. Twain's investments were a complete loss that helped drive his publishing company to brankruptcy. Paige himself later died in a poorhouse in Chicago.

Twain's mistake was allowing himself to become so beguiled by the brilliance of Paige's engineering feat that he failed to see the machine's fundamental flaw. It was not the last time he made that mistake. While living in Vienna in 1898, he befriended a brilliant inventor named Jan Szczepanik, whom he called the "Austrian Edison," who had invented a photographic process for transferring patterns to woven textiles. Despite having only recently recovered from the huge financial losses of his investments in the Paige compositor, Twain was eager to invest in Szczepanik's new invention. Wiser counsel eventually prevailed, however, when his friend Rogers investigated the economics of the weaving industry and concluded that Szczepanik's marvelous invention had no valuable commercial applications.

Impact

As a writer, Twain was one of the most influential innovators in American literary history, particularly in narrative technique. He probably had a higher regard for technology than for literature, but his contributions to technology were those of a gadgeteer, not a true inventor. His material inventions were mostly novelties that are remembered now only because he invented them. His closest brush with greatness in technological innovations was his connection with the Paige compositor, which he sincerely believed would revolutionize the publishing industry. Had Paige managed to get the machine working reliably by the mid-1880's, Twain's grandiose dreams for it might have come true. However, by the time it was tested in a newspaper office in 1894, Mergenthaler's more reliable Linotype machines were too well established for it to compete, and they dominated typesetting over the next century. It is perhaps ironic that Mark Twain, whose own inventions were simple gadgets, should blow his fortune on a machine whose greatest failing was its complexity.

JOHN TYNDALL

Irish physicist

A promoter of science in Victorian-era England, Tyndall laid the groundwork for later scientific developments in atmospheric sciences. He developed the idea of an "atmospheric envelope," which suggested that water vapor and carbon dioxide in Earth's atmosphere retain heat radiated by the Sun (the "greenhouse effect").

Born: August 2, 1820; Leighlinbridge, County Carlow, Ireland
Died: December 4, 1893; Hindhead, Surrey, England
Primary field: Physics
Primary invention: Fireman's respirator

EARLY LIFE

Born in Leighlinbridge, County Carlow, Ireland, the son of a local police officer and small landowner, John Tyndall attended a common school in County Carlow. He joined the mapmaking Irish Ordnance Survey as a draftsman at age nineteen. His surveying experience later took him to England as an employee of the English Ordnance Survey beginning in 1842, after he was selected as one of the best draftsmen in his department. While there, Tyndall attended lectures at the Preston Mechanics' Institute. His surveying work extended the British national network of railways during the 1840's. By 1844, Tyndall was working as a railway engineer.

Tyndall played many roles during his career, including surveyor, draftsman, surveyor, professor of physics, mathematician, mountaineer, geologist, atmospheric scientist, author, and popular public lecturer. He left surveying in 1847 to teach mathematics at Queenwood College, in Hampshire, but soon enrolled at Germany's Marburg University, where he studied science between 1848 and 1851 with a colleague, Edward Frankland, and the mathematician Thomas Hirst. Tyndall studied under Professor Robert Wilhelm Bunsen, and his dissertation was on screw surfaces. He completed three years' worth of graduate work in two.

Tyndall married Louisa Hamilton, a daughter of Lord Claud Hamilton, in 1876. The next year, the new couple built a small cottage at Belalp in the Swiss Alps above the Rhone Valley. Eight years later, they also built a home at Hindhead, near Haslemere in Surrey, England.

Life's Work

A prolific lecturer and writer about many scientific subjects, Tyndall was the first person to calculate quantitative, spectroscopic measurements describing ways in which water vapor and carbon dioxide trap thermal radiation. Tyndall also theorized that Earth's climate could warm or cool in proportion to the amount of carbon dioxide and other trace gases in the atmosphere. As a student of glacial movement, he also speculated in 1861 that a decline in the atmosphere's carbon dioxide levels might have played an important role in the onset of ice ages. Tyndall also invented several precision instruments to measure phenomena about which he theorized. During his working life, he published at least sixteen books and 145 scientific papers.

Tyndall's first scientific work, between 1850 and 1855, involved experiments on magnetism and diamagnetic polarity, undertaken while he was teaching at Queenwood College. This work brought him to the attention of well-known scientists, and he was elected as a fellow of the Royal Society in June, 1852.

While he studied glaciers, Tyndall also trained himself as a world-class mountain climber. In 1861, he became the first person to reach the summit of the Weisshorn in the Swiss Alps. Tyndall nearly reached the top of the Matterhorn in 1864, failing by only a few hundred feet because of a storm. A year later, Edward Whymper reached that goal. The penultimate peak of the Matterhorn was named "Pic Tyndall" for him.

In 1862, Tyndall succeeded the popular teacher Michael Faraday, giving popular physics lectures at London's Royal Institution (which he later directed), as he became one of the best-known scientists of the Victorian era. He had first met Faraday in 1850, and he later celebrated the physicist in a book, *Faraday as a Discoverer*, published in 1868. Tyndall also was a member of the X Club, composed of renowned scientists, along with other

The Fireman's Respirator

Masks to protect firefighters and others against smoke and toxic fumes were invented in the middle of the nineteenth century. Before that time, most firefighters had used primitive bags over their heads. As early as the sixteenth century, Leonardo da Vinci wrote that a woven cloth dipped in water could protect sailors from a toxic fumes. One of John Tyndall's most notable inventions was the fireman's respirator, one of the best-known early gas masks, introduced in 1871. The technology and design of Tyndall's respirator improved at least two earlier designs by other inventors. In 1847, Lewis Haslett of Louisville, Kentucky, designed an air-purifying mask that filtered contaminated air with moist wool or other porous substances. He gave it the name "Inhaler or Lung Protector." In 1854, chemist John Stenhouse of Scotland developed the "Stenhouse Gas Mask," using powdered charcoal to remove toxic gases.

Some chemical factories in the United Kingdom used Tyndall's gas mask. Tyndall's respirator took advantage of Stenhouse's technology and combined it with cotton saturated with glycerin and lime. The lime absorbed carbonic acid (common in the combustion of fires), and the glycerin helped to catch particles in smoke. The July, 1875, issue of *Manufacturer and Builder* described Tyndall's device as a "fireman's hood" containing a valve chamber and filtering tube roughly four inches long that attached from the outside with a screw. The respirator used a wooden mouthpiece.

Tyndall promoted his respirator by declaring that a firefighter using it could survive a half hour in the most noxious fumes. Without the protection offered by his mask, the same person would have been incapacitated in less than a minute, Tyndall said. Tyndall exhibited his respirator at a meeting of the Royal Society in London in 1874; he also described its origins and workings in *Proceedings of the Royal Society*.

Tyndall faced considerable competition. Three years after he exhibited his invention, Samuel Barton of London invented a device that used a face covering of rubber and metal, a head harness, and glass eyepieces. Barton's filtering technology was substantially the same as Tyndall's, however. Later designs by other inventors refined both the design and filtering technology of the masks.

notables, including Thomas Henry Huxley and Herbert Spencer. By this time, the nature of atmospheric gases had become Tyndall's major scientific inquiry.

Tyndall also was a tireless public intellectual, a public advocate of science who wrote for a number of popular magazines in addition to his popular lectures. He toured the United States during 1872 and 1873, drawing large audiences. Tyndall earned several thousand dollars from his American tour that was donated to scientific work in the United States. He also donated money for a new technical school in County Carlow.

During 1874, Tyndall gave a speech, now known as the "Belfast Address," at the British Association for the Advancement of Science's annual meeting. This speech became a cardinal citation in arguments that the rational, materialist methods of scientific inquiry (usually called "natural law," as opposed to church law) were superior to religious or other explanations for phenomena. He addressed the brewing controversy over Charles Darwin's theories of evolution that continue to incite political controversy today.

In his later years, Tyndall suffered from insomnia to a point that imperiled his health. On December 4, 1893, at Hindhead, Tyndall died after Louisa accidentally gave him an overdose of chloral hydrate (which he had been being used to induce sleep). As he died, Tyndall moaned that the drug was killing him. Louisa searched frantically (and fruitlessly) for an antidote. She summoned a doctor who gave Tyndall an ineffective emetic as he died.

Louisa spent the rest of her life looking after Tyndall's reputation, including clashes with several commissioned biographers whose work did not meet her expectations. Having chosen Leonard Huxley (and later A. S. Eve and C. H. Creasey) to write John's biography, Louisa refused them access, for unstated reasons, to some of his private papers. She also purged her own diaries of material on her relationship with him and otherwise made the compilation of an accurate life story difficult. The parts of these diaries that survived her editing have been archived in the Royal Institution of London.

Impact

Tyndall became very well known in his time, in part because of his writings, which ranged from scientific papers describing his discoveries to popular essays on scientific subjects, as well as religion, literature, and travel, including his passion for mountaineering in the Alps. Tyndall went out of his way to present science to children. He received five honorary doctorates and was a member of thirty-five scientific societies.

Tyndall's own work is important as well, because he laid the groundwork for later scientific developments in atmospheric sciences that provide the basic intellectual infrastructure for studies of Earth's climatic heating and cooling cycles. His work on purification led to methods of sterilization for liquid water and other liquids that involve heating to the boiling point. His work on sterilization also became central to the practice of medicine.

Tyndall also found ways to filter air so that it was "optically pure," containing very few microorganisms, for experimental purposes. His "pure air" prevented most putrefaction, or decay. Studies of this type of air were used by other scientists to refine Louis Pasteur's germ theory of disease. Tyndall refined his pure air many times, further reducing its impurities. He is also believed to have been the first scientist to measure urban pollution, using samples of his own urine to measure accumulation of various toxins (which caused the urine to putrefy).

Tyndall also pioneered methods to monitor London's air quality at a time when the city was prone to noxious, sometimes deadly, smogs that combined natural, stagnant fog with coal smoke. He was also the first to show that ozone is a cluster of three oxygen atoms. Before his discovery, many scientists believed that ozone was a hydrogen compound.

Tyndall invented a fireman's respirator, a hood that filtered smoke and gas. He was the first person to characterize scientifically the scattering of light by dust and large molecules in the air, a process that became known as the "Tyndall effect." His experiments also helped explain why the sky is blue (from Rayleigh scattering of sunlight).

Lewis Urry

Canadian chemical engineer

Urry's development of the alkaline battery made it possible to significantly extend the effective lifetime of batteries used in personal and household items ranging from commonplace flashlights and smoke detectors to complicated electronic devices. By the end of Urry's active career, his original contribution had been carried forward by researchers who developed the extremely sophisticated batteries that power not only modern portable electronic devices but also critical medical devices such as pacemakers.

Born: January 29, 1927; Pontypool, Ontario, Canada
Died: October 19, 2004; North Olmsted, Ohio
Also known as: Lewis Frederick Urry (full name)
Primary fields: Chemistry; electronics and electrical engineering
Primary invention: Alkaline battery

Early Life

Lewis Frederick Urry was born in 1927 in Pontypool, Ontario, Canada. After serving in the Canadian army between 1946 and 1949, he studied at the University of Toronto, receiving a degree in chemical engineering in 1950. His first employment was with the Eveready Battery Company, the firm that had a very long history going back to the development of battery cells for use mainly in household flashlights. While still a young man of twenty-eight, Urry moved in 1955 to the Eveready main research laboratory in Parma, Ohio. His assigned task, which yielded results by the end of the decade, was to find a way to lengthen the life span of what was then the commercially dominant zinc-carbon battery.

Life's Work

When Urry moved to Eveready's laboratory in Ohio, a number of researchers working for battery manufacturing companies had already begun investigating the possibility of extending the effective life of common household batteries using zinc-carbon electrodes and acidic components as electrolytes. Batteries in this category were called galvanic cell batteries. Although an entirely different category of battery—dominated by the technology used to produce automobile batteries—involved combinations of chemical components that lent themselves to recharging, the market sector that interested Eveready covered mainly portable electrical devices. The limitations of size and weight precluded any possibility that the technology of automobile batteries would attract Urry's attention.

In retrospect, the essentials of the challenge Urry faced would appear rather simple to a modern student of chemistry familiar with the process of ionization. Ionization occurs when electrons contained in an atom (or a molecule composed of diverse atoms) absorb at the time of a chemical reaction a sufficient amount of energy (called the ionization potential) to break away from the normal electric potential system that binds them in atomic orbit. When electrons break loose, what remain are referred to by chemists as (variously charged) ions. Electrons are the bearers of energy known as electricity. Battery technology involves containing and directing the movement of electrons released through chemically induced ionization. It was Urry who introduced the idea that, by using an alkaline-based electrolyte together with manganese dioxide and solid (later powdered) zinc in what was essentially the same structural makeup as batteries already being produced, one could obtain a higher level of electron emission in the ionization process than was produced by acid-based components.

In 1980, Eveready decided to adopt the name Energizer as the new label, for marketing the (by then improved) alkaline battery originally developed by Urry. The Eveready label was retained for marketing standard carbon-zinc batteries that, because of their lower price, continued to supply a significant portion of the consumer demand market.

Over time, and indeed right up to Urry's departure from the active scene that he had originally pioneered with Eveready, developing technology made it possible to market an entire line of Energizer batteries offering significantly different performance specifications. Two models beyond the widely used Energizer Max alkaline battery (essentially designed for common household and portable electronics), the very lightweight Advanced Lithium and Ultimate Lithium Energizer batteries would carve out somewhat specialized segments of the consumer market. Both lithium-based batteries not only proved to be more efficient for use in technologically more complex systems demanding higher levels of electrical current but also could promise consumers longer storage life, ranging between ten and fifteen years.

Although such qualitative differences came to characterize the market for alkaline-based batteries, impressive quantitative developments were recorded in another

ALKALINE BATTERIES

Understanding the basic principles of electrical current helps one to understand the workings of even the most commonplace flashlight battery. All batteries have a positive and a negative terminal. In large batteries such as those used in automobiles, the terminals are easily visible as lead posts, or poles; in most common batteries, the terminals are at opposite ends. In simple terms, electrical current within a battery occurs when electrons (which are by definition negatively charged) concentrated around the negative terminal flow via a conducting link (something as simple as a wire) toward the attractive force in the positive terminal. The energy of this electron flow, or electricity, can be tapped by connecting a "load," be it a light bulb or a motor, to the path of flowing electrons.

The supply of electrons in the battery comes from the chemical process of ionization described in basic chemistry texts. Once this process is set in motion—and if a wire connects the two terminals—the flow of electrons starts. Without a connection, no flow occurs because no chemical reaction has been set off. This helps explain why batteries have a surprisingly long shelf life.

On the other hand, very concentrated or rapid flow of electrons between terminals (measured in terms of internal resistance) can have the effect of wearing out the battery. Inventors of the earliest batteries devised the "voltaic pile" as a means of controlling internal resistance. In 1800, Alessandro Volta's first battery incorporated alternating "sandwiches" of zinc and silver (one metal on one end acting as the negative pole, the other as the positive pole) separated by paper layers. In modern terms, this voltaic pile served as an electrolyte in the overall process of creating and controlling electrical current inside a battery.

Experiments over time with various metals and electrolyte components (creating conditions for different types of chemical reactions and different levels of voltage) led to the development of a variety of different batteries by the late twentieth century. Notable among these were Energizer's Advanced Lithium battery and titanium batteries offered by a number of commercial producers.

Lewis Urry's own improvements over previously common zinc-carbon batteries using an acidic electrolyte involved the use of zinc and manganese dioxide with an alkaline electrolyte (typically potassium hydroxide). The quantity of electrical current produced by this combination (depending on size, usually indicated by A, AA, or AAA categories for smaller batteries, or C and D for larger models) is only one factor for evaluating the alkaline battery's performance. Longevity—which can be three to five times that of "common" batteries—catapulted the alkaline battery into the top commercially competitive position soon after its introduction in the 1960's.

sphere: battery longevity. Even though consumers were impressed in the 1960's by battery longevity, by the end of the twentieth century "ordinary" but technologically improved alkaline batteries lasted up to forty times as long as the earliest Energizer batteries.

Despite the modesty that surrounded his person and his work by the time of his death in 2004, Urry was able to consider himself a first-generation contributor to the continuously expanding technology of battery cell technology. Several products of the next generation—rechargeable batteries based first on nickel-cadmium and later more efficient nickel-metal-hydride, zinc-air, and lithium-ion components (the latter essential to the laptop computer and cell phone industries)—were being patented and commercialized by inventors whose work owed much to Urry's pioneer discoveries. Patients requiring pacemaker technology to monitor the proper functioning of their hearts owed the very security of their lives to the lithium-iodide battery—another generational product stemming from Urry's pioneer invention.

IMPACT

Although Urry's development of the alkaline battery did not represent what one might call a striking technological breakthrough (since a wide variety of different types of batteries had been in use for several generations, and many would remain on the market alongside the alkaline battery), it certainly had a major impact on the commercial marketing of batteries used for everyday purposes. Because of their longer service life, and despite their visibly higher initial purchase price, alkaline batteries attracted buyers who wanted to avoid recurring unpredictability (and therefore a certain degree of risk, depending on the nature of the battery-powered device being used) associated with "conventional" zinc-carbon batteries.

Success in market competition depends not only on the proven technical qualities of a given product but also on the attractive power of advertisements. Potential Energizer consumers came to recognize the company's slogans during the mid- to late 1980's: "It's supercharged!"

in 1986 and, beginning in 1989, "It keeps going and going and going"—the company's classic slogan that accompanied the now familiar figure of the Energizer Bunny, who "beat the drum" in energetic support of the superior Energizer battery. As the popular demand for long-life batteries expanded, Energizer, alongside the competitor product developed by Duracell, essentially dominated the consumer market. Energizer's use of a battery-driven bunny was inspired from a similar rabbit figure adopted earlier by Duracell for advertisements in Great Britain. In stages, alkaline batteries became commonplace items on display in drugstores, supermarkets, and convenience stores all over the world. Although the alkaline battery stands out as the most widely known of Urry's inventions, his name appears on the original certificates of more than fifty patents.

Jacques de Vaucanson

French mechanical engineer

Vaucanson made significant contributions in the automation of manufacturing. He was responsible for the invention of a number of machine tools as well as tool-making machinery. His creation of the punch card has played an important role in computer technology, and his work with automata has been influential in the field of medicine.

Born: February 24, 1709; Grenoble, France
Died: November 21, 1782; Paris, France
Primary fields: Manufacturing; mechanical engineering
Primary inventions: The Flute Player (automaton); Digesting Duck (automaton); automated loom

Early Life

Jacques de Vaucanson (voh-kahn-sohn) was born in Grenoble, France, on February 24, 1709. He was the tenth child born into his family; his father was a glove maker. From 1717 to 1721, Vaucanson attended the Jesuit College of Juilly in Grenoble and then that of the Oratorians. He was fascinated by science, particularly mechanisms, and began repairing clocks and watches. He was greatly influenced by the works of René Descartes.

Vaucanson was also drawn to a career in the Roman Catholic Church, joining the Order of the Minims at Lyon as a novice. Unfortunately, his ecclesiastical vocation and his penchant for science and mechanisms were scarcely compatible. During this time, he became interested in automata—self-operating, lifelike machines. When he showed some automata that he had made to a visiting dignitary of the order, he was ordered to destroy them and expelled from the Minims. He went to Paris, where he obtained the protection of the banker Samuel Bernard. From 1728 to 1731, he studied anatomy, physics, mechanics, and music. Vaucanson was fascinated by human anatomy and tried to create a mechanical model that replicated the primary functions of the human body. François Quesnay and Claude-Nicolas Le Cat, surgeons who were exploring the possibility of creating artificial devices to aid in the treatment of illness, encouraged him in his work, but, at that time, Vaucanson had little success with his models.

Life's Work

In spite of the problems he encountered in his early attempt to make an automaton that performed the various functions of the human body, Vaucanson continued to investigate and work on the creation of mechanical models. Inspired by his interest in music, he worked on The Flute Player automaton beginning in the early 1730's, and this became his first successful robot. In 1738, he presented his creation to the Académie des Sciences, where it was well received and recognized as being more than a mere toy because of its lifelike qualities. The life-size Flute Player, dressed as a shepherd and seated on a rock, fascinated the public with its ability to play songs. Vaucanson exhibited his automaton at the fair of Saint Germain and then at the Hôtel de Longueville.

In 1738, Vaucanson constructed two more automata. One was another flute player that also played the tambourine (The Tambourine Player). This second flute player resembled the first; it was life-sized and dressed as a shepherd, but its ability to play instruments was more sophisticated. The first automaton's ability to play the instrument depended entirely on the movement of its fin-

Jacques de Vaucanson. (The Granger Collection, New York)

Vaucanson's Digesting Duck

After successfully creating his musical automata, The Flute Player and The Tambourine Player, Jacques de Vaucanson invented his most famous automaton, a lifelike duck that was capable of standing, sitting, swimming, flapping its wings, eating, digesting, and defecating. The Digesting Duck was exhibited with the two musicians in many cities in France, including Paris, Rennes, Angers, and Tours. The duck was an exact reproduction of a real duck; Vaucanson even carefully recreated the entire bone structure of the wings. The wings contained more than four hundred moving parts and were operated by a complex set of levers.

The duck automaton was first exhibited in 1738. Mounted on a pedestal in which the complex mechanism of the duck was visible to the observer, the duck stretched its neck out to receive a grain of corn, which it appeared to swallow, digest, and defecate. It was later discovered that the duck did not actually digest the corn; the material excreted was a mashed grain of corn placed in a small compartment in the duck's anus.

Nevertheless, the duck was a very important advance in the creation of automata. Vaucanson used an extremely complex combination of weights and cams and a system of levers to make his duck function. For the duck's intestines, he used rubber tubing, and he invented a machine to produce the tubing. The duck was extremely popular throughout Europe. Unfortunately, all of Vaucanson's automata have since disappeared. It is believed that the musicians were destroyed during the French Revolution; the fate of the duck is unknown. A replica of the duck made by Frédéric Vidoni is on display at Le Musée des Automates de Grenoble.

The technology that Vaucanson developed and used in his duck and other automata changed attitudes toward automata, which up to that time had been appreciated for their novelty but considered primarily as toys. Vaucanson's creations earned automata a place in the field of serious scientific research, especially in surgical medicine, as well as advancing the technology of automation in manufacturing.

gers and lips and mechanical control of the air supply. Another instrument could be substituted for the flute. The second robot actually interacted with the musical instrument. For the proper notes to play, the movements of the tongue had to be precise and the fingers of the automaton had to cover the holes in the flute, requiring more complex finger movements. Vaucanson was very proud of his creation and credited it with playing better than a human flutist. His most famous and most complex automaton, the Digesting Duck, was exhibited that same year. The automaton could flap its wings, eat grain, and even defecate feces. The mechanism that made the duck function was left visible so that spectators could appreciate the complexity of the mechanical construction.

Returning to his interest in the functioning of the human body, Vaucanson attempted to build an automaton that possessed an interior mechanism recreating the human system of blood circulation. He did not finish this invention, but he did utilize India rubber to form the veins and arteries of the automaton. Therefore, he is often credited with inventing the flexible rubber tube. This was Vaucanson's last work with automata. He apparently lost interest in his creations and sold them in 1743, possibly as a result of his entering government service.

In 1741, Vaucanson was appointed inspector general of silk manufacturing by Cardinal de Fleury (André-Hercule de Fleury), prime minister of Louis XV, who wanted to reorganize and improve France's silk-manufacturing industry, which was suffering severely because of competition from silk manufacturers in England and Scotland. Vaucanson visited silk factories in both France and Italy and quickly envisioned ways to make the industry profitable for France by improving the weaving process with new technology.

In 1745, Vaucanson introduced the world's first fully automated loom, refining the work of Basile Bouchon and Jean Falcon. In order to mechanize the weaving industry and automate the weaving process, Vaucanson developed a series of perforated cards (ancestors of today's punch cards) that guided hooks connected to the warp yarns. These techniques were not readily accepted by the workers, who resented the innovation, and many of Vaucanson's ideas were virtually ignored. At Lyon, workers even chased him and threw stones at him. However, his innovations in weaving were significant and long-lasting, as they were implemented later.

In 1746, Vaucanson was made a member of the Académie des Sciences. Denis Diderot and Jean le Rond d'Alembert called upon him to contribute to the mechanical and tool sections of their *Encyclopédie: Ou, Dictionnaire raisonné des sciences, des arts, et des métiers* (1751-1772). Vaucanson was responsible for the invention of a number of machine tools. This same year, he invented the first calender, a machine using rollers to smooth and create a special finish on the silk. In 1750, he invented a special machine to weave silk with a double twist. While mechanizing the tools of the silk-manufacturing industry, he also invented machines to make the tools. In 1751, he created the all-metal slide rest lathe and was the first to use a drill. For one of his machines, he created a special endless chain, which came to be known as the *chaîne Vaucanson* (Vaucanson chain). In 1757, Vaucanson introduced an improved calender.

In addition to improving the methods used in weaving and developing new machines, Vaucanson reorganized the industry by setting up new weaving shops and building establishments to make the looms and other machinery necessary to silk manufacturing. In 1764, he set up a shop at Montpellier, and in 1768 a lathe manufacture at Amboise. From 1773 to 1778, he was involved in establishing additional manufacturing units. In 1778, he fell and his health deteriorated rapidly, resulting in his death in Paris on November 21, 1782.

Impact

Toward the end of his life, Vaucanson collected together his own works and those of others that he found significant and left them to King Louis XVI, who was also fascinated by mechanical technology. This collection provided the foundation pieces for the Conservatoire National des Arts et Métiers in Paris.

Although Vaucanson's efforts in 1745 to automate the French silk-weaving trade met with intense resistance from the weavers, and though many of his inventions were not put into general use, his work was eventually of great importance to the weaving industry. Using his system of punch cards, Joseph Marie Jacquard, a weaver and inventor, perfected the Jacquard loom from 1804 to 1805. This loom made possible the rapid weaving of intricate patterns and virtually revolutionized the weaving business. The lathe, drill, and other tools that Vaucanson invented made possible the automation of manufacturing and rapid production of standardized products.

With his automata, Vaucanson made a significant contribution to the development of the field of human physiology and to the creation of mechanical devices to replicate the body's functions, thus enabling advances in medicine. The automata also laid the basis for the field of robotics. In addition, the punch-card technology created by Vaucanson provided the groundwork for the development of computer technology in the twentieth century. Punch cards were used to input data and to store information in binary form.

Alessandro Volta

Italian physicist

Most famous as the inventor of the electric battery, Volta also invented other electrical devices, including the electrophorus and microelectroscope, as well as an eudiometer for measuring air's purity.

Born: February 18, 1745; Como, Duchy of Milan (now in Italy)
Died: March 5, 1827; Como, Kingdom of Lombardy-Venetia (now in Italy)
Also known as: Alessandro Giuseppe Antonio Anastasio Volta (full name); Count Volta
Primary fields: Chemistry; physics
Primary inventions: Voltaic pile (electric battery); electrophorus

Early Life

Born into a struggling noble family in 1745, Alessandro Volta (ah-lay-SAHN-droh VOHL-tuh) had, in his early years, to adapt himself to his father's straitened circumstances and to being the youngest of seven (of nine) children who survived to adolescence. His father, Filippo, had been a Jesuit for eleven years, a training that did not equip him to be a good provider. His mother, Maddalena dei Conti Inzaghi, was twenty-two years younger than her husband. Since Alessandro did not speak until he was four, his father and mother assumed that he was mentally impaired, but within a few years he exhibited signs of being more quick-witted than his brothers and sisters. After his father died, Alessandro, who was still a child, went with his mother and two sisters to live with an uncle, an archdeacon in the Como cathedral. Roman Catholicism would have a profound influence on the Volta family (two of his sisters became nuns; three of his brothers, priests). Throughout his life, Volta grappled with reconciling his Catholicism and the secular Enlightenment philosophy that undergirded the new science to which he was strongly attracted.

Alessandro Volta. (AIP Niels Bohr Library)

Records concerning Alessandro's early education no longer exist, but from later correspondence it is known that, as a teenager, he attended, as a boarder, the Jesuit college at Como, where he received a disciplined training in languages, including Latin and French, Italian literature, and philosophy. However, an uncle, a member of the Dominican order, feared that Alessandro would be recruited by the Jesuits, and he withdrew him, sending him to one of the town's seminaries. Although the diocesan priests were not as learned as the Jesuits, Volta was able, through friendships, to develop his growing interest in natural philosophy, particularly electricity. He even wrote a long Latin poem in which he praised the chemical and electrical discoveries of such natural philosophers as Joseph Priestley. Despite family pressure to pursue advanced learning in law or some other practical profession, Volta decided to follow his heart. Even before leaving school in 1765, he had begun corresponding with an eminent French physicist, Jean-Antoine (Abbé) Nollet, to whom he explained his idea that electrical phenomena could be understood through analogies with magnetic and gravitational forces. He also corresponded with Giovanni Battista Beccaria, a physics professor at the University of Turin, and it is to this physicist that Volta addressed his first publication in electrical studies.

Life's Work

By 1769, the time of his first scientific publication, Volta had completed his formal education and become a teacher of physics at the Royal School in Como. His seventy-two-page treatise, *De vi attractiva ignis electrici* (on the attractive force of the electric fire), was derived from electrical experiments of Benjamin Franklin and Beccaria, and from physical ideas of Sir Isaac Newton and Roger Boscovich. Although most contemporary physicists accepted a dualistic theory, Volta shared with Franklin a belief in a single electric fluid, and he thought that two objects possessing unequal amounts of this electric "fire" would attract each other with a force proportional to their imbalance.

After the Jesuit order was suppressed in 1773, its college in Como became state property, and in 1774 Volta was hired as its superintendent and director, with the task of modernizing its curriculum. He had sufficient time to continue his electrical studies, and he announced, in 1775, his first invention, an electrophorus. This device—consisting of a metal plate covered with resin, wax, or ebonite, and a second metal plate with an insulated handle—was able to produce static electricity by means of electrostatic induction. Volta's charge-accumulating machine was called "the most intriguing electrical device since the Leiden jar." This invention made Volta famous, and he even suggested that it might be used in an electrical message system from Como to Milan.

Volta's enhanced reputation led, in 1778, to an offer of a professorial appointment at the University of Pavia. He accepted this position, which allowed him to continue his work as an experimental physicist. He constructed one of the best laboratories in Europe, which enabled him over the next four decades to make important discoveries in electricity, chemistry, and meteorology. A few years before this move, Volta had become interested in the study of gases, then called chemical pneumatics. He had collected a gas from lakeshores and marshes, then investigated its properties, most notably its extreme flammability. His discovery of "marsh gas" (today's methane) led to marsh-gas lanterns and his invention of the "electric pistol," in which a spark exploded this gas.

European trips in the late 1770's and early 1780's consolidated Volta's reputation as an accomplished experimenter. For example, in 1781 he met in Paris the nat-

The Voltaic Pile

Because of the absence of many primary documents, scholars have found it difficult to determine precisely how Alessandro Volta discovered the first electric battery. Nevertheless, the story that has been pieced together from a variety of sources is a fascinating one in which the frog and electric fish played influential roles. Evidence certainly exists that Volta was intrigued by Luigi Galvani's discovery of "animal electricity" through his experiments with frog's legs, although, in 1794, Volta formulated an explanation that dissimilar metals were primarily responsible for the phenomenon. In his contact (or metallic) theory, Volta was even able to show that the "electromotive force" developed depended on how far apart the metals were in the following series: zinc, tin, lead, iron, copper, platinum, gold, and silver. Consequently, the most effective pair in producing electricity was zinc and silver.

According to some scholars, the event that precipitated Volta's discovery of the battery was his reading of a 1799 paper by William Nicholson on the detection of weak electricity, in which he discussed a model for an electrical device based on the anatomy of the electric (or torpedo) fish. Nicholson's idealized model had different disks in opposing electrical states. Although Volta disagreed with this model, it stimulated him to pile zinc and silver disks with other disks of felt or cardboard that had been saturated with brine. Through experimentation, he discovered the following series for his column of disks: silver, zinc, cardboard, silver, zinc, cardboard, and so on. When Volta touched the highest and lowest disks simultaneously, he received an electric shock, and when he connected these with a wire, he got a continuous flow of electricity.

Other scholars think that Volta first discovered the battery by experimenting with a series of goblets filled with salt or acid solutions. These goblets were bridged by different metals that had been soldered together. Volta illustrated the second part of his paper announcing the battery with diagrams of both the pile and the series of goblets (called the "crown of cups"). He sent this two-part paper to Joseph Banks, president of the British Royal Society, who published it in the society's *Transactions* in 1800. Volta suggested two possible names for his device: "artificial electric organ" (in analogy with the natural electric organ of the torpedo fish) or "electromotive apparatus" (for its capacity to set the electric fluid in motion). Others called it "Volta's pile" or the "voltaic pile," but its resemblance to the batteries (or yoked units) of Leiden jars, used since the 1740's, led to the name "battery." Unlike these earlier batteries, which needed to be charged after each discharge, Volta's pile provided a continuous source of electric current. In 1881, Volta's own name became an important electrical unit, the volt, a measure of the force that drives an electric current.

uralist Georges-Louis Leclerc, the astronomer Pierre-Simon Laplace, and the chemist Antoine Lavoisier. In 1782, he spoke with his boyhood hero Joseph Priestley in England. On his return to Pavia, he continued his experiments in electricity and chemistry. He improved the eudiometer, the instrument chemists used to determine the amount of "dephlogisticated air" (today's oxygen) in common air, and he found that air is about one-fifth oxygen.

An electroscope is an instrument for measuring the quantity of electric charge, but with Volta's invention of the microelectroscope, scientists, especially meteorologists interested in atmospheric electricity, had a way to detect and quantify extremely weak electricity. In this way, Volta helped to found the new field of electrometry, and his discovery of exactly how air expands with increasing heat helped to establish a basic law useful to both physicists and chemists.

In the 1790's, Volta became involved in a controversy with Luigi Galvani over the interpretation of Galvani's discovery that dissected frog legs twitched in the presence of an electrostatic machine. Galvani saw this as evidence for "animal electricity," whereas Volta explained the phenomenon mechanistically, as solely due to the contact of different metals with wet substances in the dead frog. The debate spread beyond Italy, and Galvani's position was supported by such distinguished natural philosophers as Alexander von Humboldt and Volta's position by Charles-Augustin Coulomb, who had discovered the quantitative law of attraction between electrostatic charges.

In the midst of this controversy, and while important changes were occurring in his personal life, Volta created his most famous invention. He had fallen in love with an opera singer, but family opposition prevented this union. In 1794, he married Teresa Peregrini, the youngest of seven daughters of a count, and their three sons were born in 1795, 1796, and 1798. Toward the end of 1799, Volta constructed his first device that produced a constant flow of electricity. In one version, he stacked copper and zinc disks, interspersed with brine-soaked felt, into a "voltaic pile," which constituted a battery. This invention was Volta's crowning achievement, and after it was published in 1800 he was showered with honors. For example, Napoleon I invited him to Paris, where he received a gold medal, the Cross of the Legion of Honor, and six thousand francs. He was later made a count and a senator of the Kingdom of Lombardy.

In the remaining decades of his life, Volta invented little of significance and cut back on his teaching and administrative duties. In 1816, his collected works were published in five volumes in Florence, and in 1819 he retired to his family's country estate in Como. Here he was visited by such scientists as Humboldt and such dignitaries as Prince Christian of Denmark. After a long illness, Volta died in 1827 and was buried in the family plot not far from Como.

Impact

Volta, "the Newton of electricity," had great influence even during his lifetime, especially through his invention of the electric battery. For example, soon after the battery became public, the chemist William Nicholson built England's first voltaic pile, and, with the help of a friend, he used it to "electrolyze" water, thus breaking it into its component elements, hydrogen and oxygen. Several years later, another English chemist, Humphry Davy, used a powerful voltaic pile to electrolyze a series of molten salts, thereby discovering such new elements as potassium, sodium, barium, strontium, calcium, and magnesium. Davy's interpretation of the battery as a device that converted chemical changes into electricity actually prevailed over Volta's contact theory. The voltaic pile became an essential instrument not only for chemists but also for such physicists as Hans Christian Ørsted and Michael Faraday, who employed it in making such significant discoveries as electromagnetism and electromagnetic induction.

During his lifetime, Volta was seen as an ingenious inventor of electrical instruments, someone who had "his brain in his fingertips," rather than as an astute theoretician. His contact theory proved wrong, and his adherence to the outdated phlogiston theory (which held that combustible substances contained a weightless fluid called phlogiston) in chemistry was misguided. His lack of expertise in advanced mathematics meant that he was unable to transform his ideas of electrical attraction, tension, and capacity into full-fledged theories. Nevertheless, his instruments did foster the discoveries that helped to create the great theories of electricity and magnetism developed in the nineteenth century. After Volta's death, his battery had a growing number of practical applications, such as the development of electric telegraphy in the 1840's. From the perspective of the twenty-first century, scholars now describe Volta's invention of the battery as "epochal," comparable in significance to the telescope in advancing science. Others have compared its importance to the steam engine, since it played an important role in transforming society. Electrical current became an integral part of advanced industrial societies, and current electricity had its origin in Volta's felicitous invention.

Faust Vrančić

Croatian mathematician, physicist, and philosopher

Vrančić was regarded as something of a Renaissance man for the range and diversity of his interests and achievements. Most notable was his illustrated book of inventions, Machinae novae, *which included the first printed design of a parachute.*

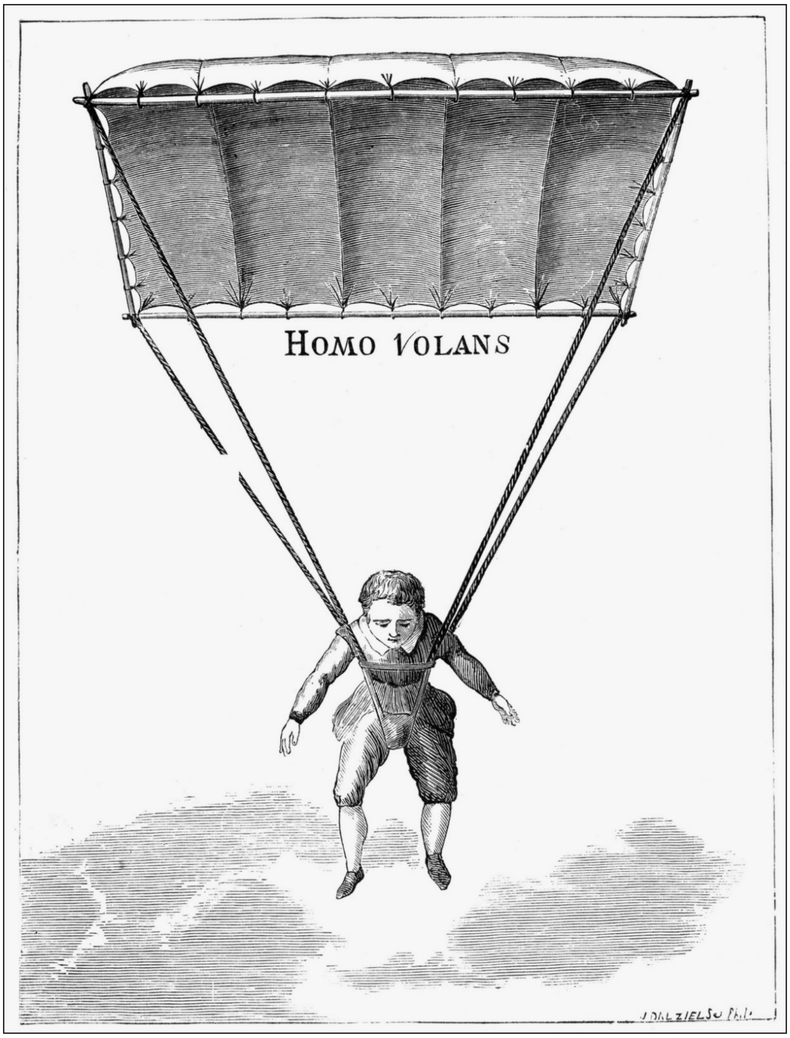
Born: 1551; Šibenik, Dalmatia (now in Croatia)
Died: January 17, 1617; Venice (now in Italy)
Also known as: Fausto Veranzio; Faustus Verantius
Primary field: Physics
Primary invention: Parachute design

Early Life

Faust Vrančić (fowst VRAWN-chihk) was born into an aristocratic family near the Dalmatian town of Šibenik, just across the Adriatic Sea from Italy. His early education was in the household of his uncle, who was successively archbishop and cardinal primate of Hungary. Vrančić completed his education in Italy, which retained its Renaissance reputation for first-rate schools. There he studied philosophy, law, and mathematics. He had no known training in engineering.

In 1581, the Emperor Rudolf II named Vrančić counselor and secretary of the imperial chancery for Hungary, a key administrative position in an important region of the empire. The influence of Vrančić's uncle was likely a factor in this selection. For the next thirteen years, Vrančić served the emperor as administrator and diplomat. He often resided at the imperial court in Prague, Bohemia, where the emperor, a dedicated patron of science as well as the arts, had assembled many of the most distinguished scientists and engineers of the day. Vrančić flourished in this lively intellectual environment.

However, the death of his wife prompted Vrančić's resignation from the emperor's service in 1594. Vrančić became a priest and then a titular bishop before entering a monastery in Rome where he resumed several long-delayed scholarly projects. He completed two histories and published treatises on logic, theology, and Christian ethics. Vrančić had earlier published a dictionary of five European languages that contained many entries of scientific and engineering terms not found in other dictionaries. Overall, the scope and quality of his literary



The "Homo Volans" (flying man) parachute invented by Faust Vrančić. (The Granger Collection, New York)

achievements were impressive, but it was in the realm of science and technology that Vrančić would leave his mark.

LIFE'S WORK

Vrančić's interest in machines had been intense since his student days in Italy, where the exciting potential of technology was well understood. Evidence of this was all around, as in the elaborate sprinkler systems installed by many wealthier Italians to maintain their private gardens.

In 1595, Vrančić published a book that had been in preparation for many years. He titled it *Machinae novae* (new machines). This folio volume contained forty-nine copperplate engravings of various machines, accompanied by concise explanations in Latin and Italian. He described eleven other devices, not pictured, which raised the total number to sixty. Vrančić had seen many of the machines over the years, but most were of his own invention or were revised versions of existing machines. A new edition of the book in 1615 translated the text into three other languages.

The devices described in *Machinae novae* ranged across a broad spectrum. Prime among them were mills, dredging machines, aerial trams, bridges, and, above all, the design of a parachute. Mills were clearly of special interest to Vrančić. He displayed some eighteen varieties, all of which were powered by readily available natural resources of water or wind. For example, he conceived of a mill situated along coastal waters capable of trapping tidewaters in "accumulation pools" during high tide. At ebb tide, gravity would guide the flow of receding water to drive a millstone for grinding grain. Vrančić also designed windmills that, similar to modern airplane wings, had flaps on their blades for catching more wind.

Another of Vrančić's innovations was a water-powered dredging machine mounted on a barge. Its purpose was to clear rivers and other waterways of sediment that could hinder boat traffic. Vrančić's dredger had a paddle wheel with a horizontal shaft to which wooden arms were attached. The current of the river would rotate the shaft and its arms to scrape the riverbed.

Elsewhere, Vrančić cleverly addressed the problem of how to move people and freight up a steep incline. He contrived a kind of aerial tramway that could, in theory, transport cargo by suspending carriages from rope cables strung along a series of towers. As one cargo carrier was manually raised up the incline, the second would automatically descend. Each carrier served to counterbalance the other and give it impetus.

Vrančić also made a major contribution to bridge technology. He had studied dozens of bridges in his trips around Europe as a diplomat. In *Machinae novae*, he described two basic kinds of bridges that he modified considerably from the conventional arch and beam bridges he had observed. The suspension bridge had originated in ancient China but remained unknown in Europe until Vrančić published a drawing of it in his book. It is not known where he found the idea. His sketch of the "cable-stayed," or cable-supported, bridge was the first printed version.

Both types of bridge, suspension and cable-stayed, required pillars or towers built at each end of the floor or deck over the chasm to be spanned. The two types differed in how the cables were attached. Suspension bridge cables were composed of heavy rope connected over each tower to anchors at the end of the bridge deck. This transmitted the full weight of the deck to the tower. In Vrančić's cable-stayed bridges, cables made of rope connected at regular points to the nearest tower before descending to connect at regular points along the edge of the deck. This placed the main pressure on the deck. Vrančić also designed a hybrid bridge with features of both the suspension and the cable-stayed types. He replaced the rope cables with iron chains linked to each other by eyebars made of brass. These various bridge models were not actually built until the nineteenth and twentieth centuries, but they remain popular today.

Of all Vrančić's devices, one in particular captured the popular imagination, namely his design for a parachute. Toward the end of his book, wedged between depictions of dredging machines and different kinds of boats, was a striking illustration of a man dangling from a square parachute, having just jumped from a church bell tower. While this drawing resembled a sketch by Leonardo da Vinci done more than a century before, Vrančić's version was simpler and more practical in design. It was also the first printed illustration of a parachute. The conceptions of Leonardo and Vrančić were themselves part of a history of experiments with parachute-like devices that reflect the recurrent human fascination with flight.

The Parachute

The ancient Chinese had the idea of a parachute as a kind of umbrella, but it did not always take that shape outside China. For example, the venturesome ninth century Arab ʿAbbas ibn Firnas jumped from a high place wearing a billowing cape complete with wooden struts to keep his cape more open to the air. However crude the device, the clear intent was to break the force of the fall through the friction of air against an unfurled cape.

In Renaissance Italy, the parachute idea was among many others that received fresh attention. An unpublished manuscript dated about 1470 contained a sketch by an unknown artist of a cone-shaped parachute made from cloth. The jumper was equipped with two long cloth streamers attached to two wooden bars that he held in his hands. The bars were fastened to his belt by cords. He had a sponge in his mouth to protect against the shock of landing. The streamers were clearly intended to break his fall, but this does not seem much of an improvement over the billowing cape of the medieval Arab. Nonetheless, this unknown Italian engineer managed around 1470 to conceive of what might be the first true parachute device in history.

A few years later, just after 1480, the great Italian engineer, inventor, and artist Leonardo da Vinci sketched in the margin of his notebook his own conception of a parachute. It is doubtful whether he had seen the version by the anonymous engineer, but similar ideas were circulating at the time. In any case, Leonardo had closely observed the wing motion of birds in flight, especially the resistance of air under the wings. Leonardo's parachute differed significantly from that of his predecessor. First, it was shaped like a pyramid rather than a cone. He conceived of the canopy as the central element of a rigid-framed, four-cornered structure attached by metal rods to each corner of the canopy. Cords of rope connected to the rods converged in the outstretched hands of the jumper, who is shown hanging on with obvious determination since he would be in immediate free fall should he let go. Leonardo's device was a clear improvement over the parachute with the streamers.

Finally, just over a century later, Faust Vrančić depicted in his *Machinae novae* (1595; new machines) a parachute launched from a tower. Its canopy, like Leonardo's, was square-shaped and rigid-framed, and it also featured long rope cords secured by rods to each corner of the parachute. Unlike Leonardo's device, the cords descended to a harness at the man's waist. Finally, secured by the rope cords, the chutist's body hung loosely and his arms extended out from his body, almost like wings. Vrančić titled the sketch "Homo Volans" (flying man). No firm evidence supports the rumor that Vrančić built and personally tested his device.

The first parachute known to have performed successfully was constructed and manned in 1783 by a Frenchman, Louis-Sébastien Lenormand. The device became widely popular with the advent of the airplane in the early twentieth century. As the first to put the concept and the model of a parachute into print, Vrančić has merited a prominent place in the history of this valuable, multipurpose apparatus.

Impact

Vrančić was a true man of the Renaissance. In addition to a distinguished public career as royal administrator, diplomat, and churchman, he displayed impressive scholarly expertise as philosopher, historian, lexicographer, and Christian humanist. Despite these achievements, he would be known above all for his history of technology, *Machinae novae*. In this work, Vrančić depicted and described a wide variety of technical designs, many for the first time. He offered practical solutions to common problems by presenting labor-saving machines to improve everyday living. Still, for Vrančić and many of his fellow engineers, there was also, beyond any solely utilitarian motivation, the pure joy of discovery. He most likely never built or tested any of the models he sketched. In any event, Vrančić demonstrated how water and air could be readily adapted to worthy agricultural, commercial, or personal uses. Among his water-dependent devices were dredging machines, suction pumps, and watermills of several kinds. Windmills and the parachute relied necessarily on the air.

As to Vrančić's originality, he did invent devices like a water suction pump, a wooden vertical waterwheel, and a flywheel similar to that used in modern engines. He also drew the first printed sketch of a parachute and of a cable-stayed bridge. His drawing of a suspension bridge reinforced by chain links of iron connected by eyebars was probably original as well.

Nevertheless, Vrančić was less a major inventor than a significant transmitter of technological ideas to future generations. Many of the concepts and mechanisms in *Machinae novae* would come to fruition in the great age of machine technology in the eighteenth and nineteenth centuries, which culminated in the Industrial Revolution. This movement would in turn transform civilization.

Selman Abraham Waksman

Russian American biochemist and microbiologist

Waksman's research into soil microorganisms and their processes and interactions led to the discovery of streptomycin, actinomycin, and numerous other antibiotics. His work was critical to enhancing public health worldwide.

Born: July 22, 1888; Priluka, Russia (now in Ukraine)
Died: August 16, 1973; Hyannis, Massachusetts
Primary fields: Agriculture; biology; medicine and medical technology
Primary invention: Antibiotics

Early Life

Selman Abraham Waksman (WAHKS-mehn) was born the son of Jewish parents, Jacob Waksman and Fradia London Waksman, in the rural Ukrainian town of Priluka in what was then Russia. He received his early education primarily from private tutors and completed his school training in Odessa in an evening school. He studied the Torah and Talmud for many years as well. As a result of childhood experiences with anti-Semitism and with the unsuccessful revolution of 1905, Waksman concluded that he could not achieve his personal and professional goals in czarist Russia.

In 1910, after obtaining his matriculation diploma from the Fifth Gymnasium in Odessa as an extern, Waksman emigrated to the United States, settling with his cousin, a chicken farmer, in Metuchen, New Jersey. He worked there for a few years on a family farm and by fall, 1911, enrolled in Rutgers College (now Rutgers University) in New Brunswick, having won a state scholarship. He received his bachelor of science degree in agriculture in 1915, graduating Phi Beta Kappa.

By 1916, Waksman had become a naturalized U.S. citizen. He was appointed research assistant in soil bacteriology under Dr. Jacob Lipman at the New Jersey Agricultural Experiment Station and was permitted to continue graduate work at Rutgers, earning his master of science degree in 1916. In the same year, he was appointed a research fellow at the University of California, Berkeley. Waksman received his Ph.D. in biochemistry after only two years.

Waksman's decision to enter an agricultural rather than a medical career was inspired by Dr. Lipman, a bacteriologist, the dean of the College of Agriculture, and also an immigrant from Russia. Courses in bacteriology with Lipman and summer projects with Dr. Byron Halstead, a plant nutritionist and geneticist, strongly influenced Waksman's future career. After receiving his doctorate from the University of California, Berkeley, in 1918, Waksman secured a position at the Rutgers Bacteriology Department, where he continued his research on soil actinomycetes and fungi.

Life's Work

Upon Waksman's return to Rutgers, his initial task was to complete earlier investigations in the nature and abundance of the actinomycetes in soil, including the delineation of their physiological and biochemical processes. Much of his energy was consumed during the next two years by a position with a local industrial laboratory and in developing a course in soil microbiology; however, all time available for research was devoted to the actinomycetes.

Selman Abraham Waksman. (©The Nobel Foundation)

Following studies of microbial interactions in the decomposition of plant residues, Waksman conducted a comprehensive investigation of the ecological relationships of soil microorganisms. He also described new thiobacilli involved in the oxidation of elemental sulfur. His results demonstrated that actinomycetes exert a substantial influence on the activities of soil bacteria and fungi.

During the 1920's and 1930's, Waksman traveled throughout the United States, Europe, and the Middle East, conducting systematic studies of the biology of peat soils and compost piles. He met several noteworthy soil microbiologists, including Sergei Winogradsky. Waksman developed professional relationships with industries that produced enzymes and other microbially generated products, thus establishing the vanguard of entrepreneurs in the modern biotechnology industry.

During the 1930's, Waksman and his colleagues engaged in methodical efforts to identify soil organisms producing substances with potential for control of infectious diseases. Two events provided the stimulus for this focus. One was the work of a former student, R. Dubois, on the identification of two polypeptides (gramicidin, tyrocidine) by soil bacilli that have a lethal effect on disease-causing bacteria. Waksman believed that fungi and actinomycetes would provide far more effective antibacterial agents than the bacteria. The looming threat of World War II provided the second stimulus, which underscored the need for new agents for the control of infections and epidemics that would presumably arise.

The first antibacterial substance Waksman identified was from *Actinomyces antibioticus*, a member of the actinomycetes family. The microbe produced a substance that he termed actinomycin, which possessed both bacteriostatic and bactericidal properties. This discovery was soon followed by the isolation of other antibacterials. An antibiotic labeled streptothricin was identified within a culture of an actinomyces. This substance was soluble in water, stable to heat, and active against both gram-positive and gram-negative bacteria. Streptothricin was considered a new type of antibiotic that could supplement penicillin. It soon became apparent, however, that this substance was not an ideal chemotherapeutic agent since it exerted undesirable effects in mammalian systems. The discovery of streptothricin was, however, a major step forward in Waksman's investigations of antibiotics.

Waksman formulated simple microbial screening techniques and applied these to soil and other natural materials. By 1940, Waksman and his colleague H. B. Woodruff had devised a technique for identifying natural substances with antibacterial properties. The screening was conducted by looking for

Antibiotics

Antibiotics are derived wholly or partially from selected microorganisms. The term "antibiotic" (from the Greek for "fit for life") was coined by Professor Selman Abraham Waksman in 1942 to describe any substances produced by microorganisms that were antagonistic to the growth of other microbes. Many antibiotics are relatively small molecules having a molecular weight less than 2,000 daltons. Antibiotics can be categorized based on their target specificity: Narrow-spectrum antibiotics are used against specific bacterial types, such as gram-negative or gram-positive bacteria, while broad-spectrum antibiotics can be used effectively against a wide range of bacteria.

Prior to Waksman's discoveries, treatments for infections often consisted of administering broad-spectrum (and potentially host-toxic) compounds such as strychnine. In contrast, antibiotics derived from microbes impart few side effects and enjoy precise and effective activity at its target. Most antibacterial antibiotics have no activity against viruses, fungi, or other microbes. Antibiotics are among the most frequently prescribed medications in modern medicine. Some antibacterials are known to kill bacteria (that is, they impart bactericidal effects), whereas others prevent bacteria from multiplying (bacteriostatic effects).

The first antibiotic was penicillin, discovered accidentally in 1928 by Alexander Fleming while he was experimenting with a culture of *Staphylococcus*. Today, more than one hundred different antibiotics are available to treat both minor ailments and life-threatening infections. The majority of antibacterials originate from a small group of compounds. The main classes of antibiotics include penicillins, cephalosporins, macrolides, fluoroquinolones, sulfonamides, tetracyclines, and aminoglycosides.

With advances in medicinal chemistry, most antibiotics are now modified chemically from compounds discovered within natural environments. Some antibiotics are still produced and isolated from living organisms; many others have been formulated through purely synthetic processes. In recent years, three new classes of antibiotics have been brought into clinical use. These new antibiotics show promise as a means to counteract the growing bacterial resistance to conventional antibiotics.

growth inhibition zones around single colonies of isolated soil microbes grown under a variety of culture conditions, then testing the inhibition on specific pathogenic bacteria.

In September, 1943, Waksman succeeded in isolating an organism that produced an antibiotic that possessed properties similar to those of streptothricin but that was less toxic to the host. The new antibiotic was named streptomycin after *Streptomyces*, the group of actinomycetes that produced sporulating aerial mycelia. Waksman and his colleagues screened more than ten thousand different soil microbes before streptomycin was isolated. Streptomycin was capable of destroying the tubercle bacillus and was considered safe enough to test in humans. Subsequent clinical trials proved that streptomycin cured several types of tuberculosis and that it was safe enough to prescribe for a variety of gram-negative bacterial infections.

Within a decade, ten antibiotics were isolated and characterized in Professor Waksman's laboratories, three of them with important clinical applications: actinomycin (1940), streptomycin (1943), and neomycin (1948). He proposed the now standard term "antibiotics" for this class of natural growth inhibitors. Eighteen antibiotics were eventually discovered under Waksman's direction. With each new phase in the development of the antibiotics program in Waksman's laboratory, progress was made in understanding the type of antibiotic that was necessary to treat a specific pathogen, and in methods for its production and isolation.

In response to his concerns about fascism in Europe, Waksman created an association with the Oceanographic Institute in Woods Hole, Massachusetts. He established a laboratory there for the study of marine microbiology. One study there, for the U.S. Navy and Coast Guard, was concerned with fouling of oceangoing vessel bottoms. Waksman was appointed marine bacteriologist at the institute, where he served until 1942. He was then elected as a trustee, and later a life trustee. He and several students worked at Woods Hole each summer over the next decade or more.

Industry and research organizations began to study actinomycetes for their ability to produce antibiotics and vitamins. To meet the growing interest, Professor Waksman published in 1953 a volume entitled *Guide to the Classification and Identification of the Actinomycetes and Their Antibiotics*. With his discovery of streptomycin in 1943, Waksman initiated a professional relationship with Merck and Company, which developed liquid culture methods for bulk production of microbial products.

Waksman patented and licensed his antibiotics, and he donated 80 percent of his patent earnings to Rutgers University. In 1951, Rutgers University established an Institute of Microbiology and made Waksman its first director. The institute was endowed and supported by the assignment of Waksman's streptomycin patent royalties to Rutgers. Waksman established the Foundation for Microbiology in 1951 and assigned one-half of his personal royalties for its support.

Impact

In Waksman's day, microorganisms were considered significant to medicine primarily as causes of disease. Microbes were also noteworthy in terms of public health in connection with water contamination and purification, and in food processing and agriculture. Soil microorganisms were recognized as critical for the decomposition of plant and animal remains, returning elements such as carbon, nitrogen, oxygen, and others to the air and soil via a range of biogeochemical cycles. Microbes, however, had yet to be shown to be of value in the industrial production of vitamins, enzymes, and antibiotics.

Waksman's work transformed the actinomycetes from interesting laboratory creatures to organisms of highly practical significance, which yield chemical substances used for combating numerous infections of humans, animals, and plants. Professor Waksman, together with his students and associates, isolated a range of new antibiotics including actinomycin (1940), streptothricin (1942), streptomycin (1943), grisein (1946), neomycin (1948), clavacin, fradicin, candicidin, candidin, and others. Two of these, streptomycin and neomycin, have found extensive application in the treatment of numerous infectious diseases of humans, animals, and plants. The patent on streptomycin has been designated as one of the ten "patents that shaped the world."

During his lifetime, Waksman received numerous awards and honorary degrees for his scientific work. He was elected to the National Academy of Sciences in 1942. He was awarded the Nobel Prize in Physiology or Medicine in 1952 "for his discovery of streptomycin, the first antibiotic effective against tuberculosis." This distinction earned him the title of the "father of antibiotics."

Waksman has emphasized that fundamental scientific investigations will sooner or later lead to practical applications: "It is essential to gain fundamental knowledge; the application will come sooner or later."

Madam C. J. Walker

American entrepreneur and hair stylist

Walker created hair care products that have been used by thousands of women both in the United States and abroad. More significantly, she developed business and marketing strategies that allowed women, particularly African American women, to become financially independent.

Born: December 23, 1867; Delta, Louisiana
Died: May 25, 1919; Irvington-on-Hudson, New York
Also known as: Sarah Breedlove McWilliams Walker (full name); Sarah Breedlove (birth name); Madam Charles Joseph Walker
Primary field: Business management
Primary invention: Hair care products

Early Life

Madam C. J. Walker was born Sarah Breedlove to Owen and Minerva Anderson Breedlove; she was the fifth of six children. She was the couple's first child born outside slavery. Sarah became an orphan at the age of seven. She and her sister survived by working in cotton fields in both Louisiana and Mississippi. Sarah had very little formal education, but she improved her reading and writing skills through tutoring by women at the African Methodist Episcopal church she attended in St. Louis. At the age of fourteen, she married Moses McWilliams, largely to escape abuse from her sister's husband. When McWil-

Madam C. J. Walker, the first female self-made millionaire in the United States. (Michael Ochs Archives/Getty Images) liams died two years later, she moved to St. Louis with her only child, Lelia (born June 6, 1885), to join her four brothers, who were establishing themselves as barbers. Making only $1.50 per day, she managed to educate her young daughter. She also took jobs as a washerwoman and a cook to help support herself and Lelia.

Life's Work

During the 1890's, Sarah began to suffer from a scalp ailment that caused her to lose most of her hair. She began to experiment with both homemade remedies and store-bought products. In 1905, she moved to Denver, Colorado, where she married Charles Joseph Walker, and she became known as Madam C. J. Walker. Eventually, she created Madam Walker's Wonderful Hair Grower from a recipe she claimed had been revealed to her by a man in a dream. Her husband felt that she should be satisfied with making ten dollars per day; she disagreed, and the two were divorced. Madam Walker began to build her company: She was solely responsible for the sales, marketing, development, and distribution of her hair and skin care products—a feat unheard of at the time for any woman, let alone an African American woman.

While Walker's hair grower was a great invention, it was not the first of its kind. Walker worked for a short period for Annie Malone, an African American entrepreneur who had a hair care product before Walker invented her own. Walker's product line eventually expanded beyond her hair grower: She invented other hair care products as well as skin creams. She ended up with a complete line of beauty products to fit the needs of black women throughout the world. Understanding that her beauty products need to be utilized appropriately, Walker made sure that her sales force trained women in the proper use of her products, creating the "Walker System." She emphasized customer service, wanting her clients to feel pampered and important. Walker's products included not only locally available ingredients but also ingredients imported from all over the world, including African countries. Unique to Walker's enterprise were the business and marketing strategies she implemented in the sale of her products. She started by selling her line door-to-door, demonstrating the proper use of her beauty products to black women in the southern and southeastern United States. This market had previously been ignored or misunderstood, and these women appreciated not only products designed for their needs but also the attention of a beautifully coifed black woman capable of showing them how to use the products. Walker's success grew.

Independent Business Operation

Madam C. J. Walker is noted to have invented the concept of independent business operators, whom she called hair culturists. These women independently sold products in the community in which they lived. As a result, Walker's products reached a broad market while retaining the sense of being a local product. This early version of "thinking globally and acting locally" created a strong following for Walker's products: Those who purchased Walker's hair care line and beauty creams learned how to use them in their own homes.

Madam Walker trained her culturists well and emphasized their participation in the company by holding the Madam C. J. Walker Hair Culturist Union of America Convention, the first national meeting of businesswomen in the United States. The convention sought not only to motivate the saleswomen but also to encourage their political and social activism within their communities.

Another benefit of this type of product distribution is the development of brand loyalty. By owning the product formula, the factories that produced the products, the schools utilized to train sales associates in the use and sale of the products, and the salons in which individuals could have the products professionally applied could always be assured of receiving a genuine Madam C. J. Walker hair tonic or cream, not an impostor. They were welcome to tour the factory and watch "their" products being created. They knew that they were getting the "real thing," and they had the sense that it was created just for them. This type of brand management and brand loyalty became the foundational principle of the marketing of all sorts of products, from automobiles to breakfast cereals.

In 1908, Walker moved to Pittsburgh, Pennsylvania, where she opened Lelia College. There she trained individuals she named "hair culturists," who began to sell her products. In 1910, she moved to Indianapolis, Indiana, where she built a factory, hair and manicure salon, and another training school. By creating the sales force and venues through which her products would be sold, Walker increased brand loyalty.

Walker then organized her independent sales agents in local and state clubs, a practice still utilized today be companies such as Mary Kay, Tupperware, and Avon. The agents not only sold the products but also used the products themselves. As walking endorsements of the Walker line, these saleswomen built brand loyalty; as homemakers and single mothers—women who had much in common with the women to whom they sold Walker's line—they demonstrated the feasibility of earning one's own money and making a living. These sales agents were not simply employees of Walker's company; they were themselves entrepreneurs who could enjoy the fruits of business ownership. Hence, Walker's direct-marketing method became a popular small-business strategy, used to this day. The women Walker recruited and trained became part of a national sales force, who then went on to recruit and train other women to establish beauty shops in their homes, keep business records, and practice exceptional customer service.

A visionary when it came to protecting her brand, Walker owned the formulas for making her hair care products, the factories in which they were made, the training facilities to teach her hair culturists to use and sell the products, and the salons in which her products could be used. This created "two brands in one": Walker's hair care products could be used both at home, by the layperson, and by professionals who set the example of how the products should be used to give women an elegant look.

In a move employed by many of the largest companies in the world today, in 1917 Walker held a convention of the Madam C. J. Walker Hair Culturist Union of America in Philadelphia, considered the first national meeting of businesswomen in the United States. At this convention, Walker went beyond simply motivating her hair culturists to sell more of the Walker line of products. She also encouraged them to get engaged in political and social activism in the communities in which they lived. Walker led by example in this area, visiting the White House after a white mob had lynched three African Americans in Illinois. She donated one thousand dollars to the building fund of a "colored" YMCA in Indianapolis, and she contributed five thousand dollars to the antilynching movement of the National Association for the Advancement of Colored People (NAACP). In another brilliant marketing strategy, Walker popularized the use of famous spokespersons by having her product used and touted by Josephine Baker, one of the most popular African American entertainers in the world at that time.

Walker's company was in operation from 1905 to 1985, when the right to manufacture products using the Walker name was sold to another company. She died from complications of hypertension on May 25, 1919, in New York State at the relatively young age of fifty-one. She left a sizable estate and a business that continued to function and provide good jobs for more than six decades after her death.

Impact

Walker is often quoted as saying, "I got my start by giving myself a start." She took this concept further by not only giving herself a start but also giving a start to countless other African Americans through her innovative business practices and high-quality products that produced the results they promised. She brought beauty into the lives of women who where often working hard just to make ends meet. Some complained that she was trying to make African American women's hair look like that of white women. Walker retorted that she was simply trying to promote the proper care of hair for women.

While Walker invented a number of products and developed many business and marketing strategies, she is often credited with inventions that were not hers. She did not, for example, invent the straightening comb, although she did popularize its use. She did not create the first African American hair care product available for purchase; she in fact got her start working for an earlier inventor of hair care products for African Americans.

Walker is, however, noted as the first self-made female millionaire in the United States. At her death, her estate had an estimated value of between $600,000 and $700,000 (approximately $6 million to $7 million today). The value of her personal and business assets combined is believed to have exceeded $1 million. She also achieved such prominence that she counted such eminent social and political figures as W. E. B. Du Bois among her acquaintances.

The impact of Walker's work on the field of business is threefold. First, she changed the practice of direct marketing. Bypassing the "middleman," Walker brought the supplier directly to the customer and vice versa. This allowed feedback on the product line that led to quick corrections of product flaws as well as new products tailored to changing customer demands. Walker's second area of influence included the creation of a large galley of "business owners" and the concept of franchising products, as opposed to having a large cadre of employees. The result was not only financial independence and wealth for a large number of people but also the Walker company's freedom to focus on business products and services as opposed to employer-employee issues. Walker's third major contribution was the concept of woman-as-owner, a contribution that went beyond business to improve society as a whole. In a time when few women, and fewer African Americans, owned a business, Walker not only owned a company but also helped others to do so.

Sir Alan Walsh

English physicist and chemist

Walsh invented atomic absorption spectroscopy to identify the presence of chemical elements in samples and determine their concentration. This method was quick, easy, accurate, highly sensitive, and free from interference. It revolutionized quantitative analysis and was widely applied to a variety of diverse areas.

Born: December 19, 1916; Hoddlesden, Lancashire, England
Died: August 3, 1998; Melbourne, Australia
Primary fields: Chemistry; physics
Primary invention: Atomic absorption spectroscopy

Early Life

Alan Walsh was born in England, approximately twenty miles north of Manchester, in Hoddlesden, a small borough of Darwen, Lancashire. His father, Thomas Haworth Walsh, managed a small family cotton mill in Hoddlesden. His mother, Betsy Alice Walsh (née Robinson), was a very warm and gracious woman. At ten years of age, Walsh attended the local grammar school in Darwen. He passed the Northern Universities Matriculation Examination in 1933. At sixteen, eyestrain persuaded Walsh to concentrate on mathematics, chemistry, and physics. He completed his Higher School Certificate Examination in 1935, and his physical science prowess won him an honors course in physics at the University of Manchester.

Walsh flourished at the University of Manchester. While there, he attended a lecture by Sir Lawrence Bragg, who had won the Nobel Prize in Physics in 1915 for his work on X-ray crystal structure analysis. Bragg's lecture captivated and energized the young Walsh and influenced him to pursue a research career. Walsh graduated from Manchester in 1938 and was awarded a research scholarship to pursue postgraduate research in physics. He initially worked on the structure of mineral crystals but later switched to crystal structures of beta-carotene, a chemical from plants that serves as a precursor to vitamin A. He only spent one year at the Manchester College of Technology, since the onset of World War II compelled Walsh to refocus his efforts. During the war, Walsh worked for the British Non-Ferrous Metals Research Association (BNF). Walsh continued to work on the beta-carotene project in his spare time after he moved to the BNF.

While at the BNF, Walsh analyzed metals from German war planes that had been shot down. He devised several methods for the rapid and accurate identification of aluminum, copper, and zinc alloys. In 1944, Walsh completed his work on beta-carotene and was awarded a master of science degree in 1944 for a thesis entitled "An X-ray Examination of Beta-carotene."

THE ATOMIC ABSORPTION SPECTROPHOTOMETER

The original atomic absorption spectrophotometer relied on a basic principle of atoms that have been heated so that they are in the gaseous state: Atomic vapors emit light at particular wavelengths and also absorb light at some of the same wavelengths. Of those emitted wavelengths of light, one of them will usually be much brighter than all the others. This is called the "peak wavelength," and if a light source is shone through the atomic vapor, the quantity of light absorbed at the peak wavelength will cause the brightness of that wavelength to diminish. Furthermore, the amount of reduction in the brightness of the peak wavelength depends on how many atoms of that element are present in the vaporized sample.

Vaporizing the sample requires a small furnace to burn it. Graphite furnaces that use electrical heating are widely used in contemporary atomic absorption spectrophotometers to vaporize the sample. Alternatively, a solution of the material could be sprayed into the flame to generate the vapor. In this case, organic solvents such as alcohol or heptanes work far better than noncombustible solvents such as water as diluents for samples.

A light source is shone into the atomic vapor, and the best light source is a hollow-cathode lamp. These lamps consist of a quartz or glass envelope with two electrodes, one of which, the cathode, is cup-shaped and composed of several metals. The lamp is filled with a low-pressure noble gas. Application of an electrical current across the electrodes will cause the emission of a particular spectrum of wavelengths of light that will pass through the atomic vapor to the detection machinery of the spectrophotometer.

Atoms at such high temperatures emit light, which can contaminate the light from the lamp that is shone through the atomic vapor to the detector. Therefore, the machine must distinguish between this emitted light and the peak wavelengths emitted from the lamp that is shone through the vapor. Originally, Alan Walsh used a device called a "chopper wheel," which is a circular disk, a third of which is opaque, another third mirrored, and the last third cut away to allow light to pass through. The wheel is located between the cathode lamp and the atomic vapor and rotates as light moves through it. The wheel subtracts some of the wavelengths of light shone through the atoms so that only the peak wavelength hits the atomic vapor. The second feature that solved the light contamination problem was a tuned amplifier that amplified only those peak wavelengths from the light source and extraneous wavelengths emitted by the atomic vapor. Modern devices tend to use a "monochromator," an optical device that selectively transmits only specific wavelengths of light.

Once the light strikes the detector, a photomultiplier generates the desired signal, which passes to an amplifier/rectifier combination, and finally to a recorder, which provides the output. In between the vapor and the detector, a series of lenses precisely bend the light so that it can accurately find its way to the detector.

Walsh's original atomic absorption spectrophotometers were somewhat simple in principle, but they required enormous troubleshooting in order to make them work at optimal efficiency and sensitivity. Improved light sources increased the number of elements the machine could analyze. Improved electronic components improved the sensitivity and accuracy of the machine.

LIFE'S WORK

In January, 1945, Walsh became the chief spectroscopist at the BNF and oversaw all spectrographic research. He developed a technique for detecting impurities in uranium metal. In May, 1946, Walsh immigrated to Australia to work in the Chemical Physics Section of the Division of Industrial Chemistry at the Council for Scientific and Industrial Research (CSIR), which became the Commonwealth Scientific and Industrial Research Organization (CSIRO) in 1949. At CSIR/CSIRO, Walsh experienced a near scientific utopia. Instrumentation in the CSIRO laboratories was state of the art, and bureaucratic red tape was kept to a minimum. Investigators were given tremendous freedom to work on their own, and the atmosphere was highly collegial and collaborative. His first project involved installing the new Perkin-Elmer Model 12B spectrometer. He noted that this machine could not resolve the spectra of larger molecules. Therefore, he designed the "double-pass monochromator" to improve the resolution of the machine, which he patented in 1950.

In March, 1952, Walsh experienced a flash of insight while working in his garden. Chemical analyses at this time were conducted in one of two ways. The first method placed the material under analysis between two discharging electrodes. The light emitted by the material under these conditions provided the means of identifying the elements that composed the material and, by comparison to standard samples, the amount of the elements present in the material as well. A second procedure examined the light given off when a solution of the material was sprayed into a flame. Both procedures were fraught with problems that limited their application. Walsh realized that an atomic vapor absorbs light energy at wavelengths peculiar to its chemical composition. The problem was that a vaporized compound emitted light at the same wavelengths at which it absorbed. However, by detecting the decrease in light emission at the most robust wavelength, an investigator could not only identify the presence of a particular element but also determine the amount of that element present in the sample. The other wavelengths of light emitted by the vaporized material could be eliminated by using amplifiers that were tuned to only the desired wavelength. Walsh went to work the next day and performed a trial experiment with sodium atoms and succeeded. This and other follow-up experiments formed the basis of atomic absorption spectroscopy.

After solving problems and substantially improving his new technique, Walsh filed his final patent specification on October 21, 1954, and published his new technique in 1955 in the journal *Spectrochimica Acta*. The reaction to his work by the scientific community was subdued, since many saw it as a scientific curiosity rather than a practical analytical method. However, an Australian company, Hilger and Watts, entered into an exclusive license agreement with CSIRO to make a commercial atomic absorption machine. Unfortunately, they were unable to produce one that was viable.

In 1958, Walsh was elected a fellow of the Australian Academy of Science. That same year, he was invited to give his first presentation on American soil about atomic absorption spectroscopy. At the Louisiana State University Symposium on Analytical Chemistry, Walsh met spectroscopist James W. Robinson from Esso Research, Baton Rouge. Robinson's excitement about atomic absorption spectroscopy inspired him to collaborate with Walsh. In 1962, Robinson and his colleagues demonstrated that atomic absorption spectroscopy had widespread application in the analysis of most metals and metalloids. This work demonstrated the industrial uses of atomic absorption spectroscopy and the need for commercially produced machines that could effectively use it. Walsh also met a representative from the scientific instrumentation manufacturer Perkin-Elmer. This interaction motivated Perkin-Elmer to form a research group dedicated to developing an atomic absorption instrument in 1960. In 1963, the company shipped its first atomic absorption instrument, the Model 303. This was followed by the Australian company, Tektron, which had collaborated with Walsh and CSIRO since 1958, producing the first Australian atomic absorption instrument in 1964.

During the 1960's and 1970's, Walsh and his collaborators worked to improve atomic absorption instruments and extend their applications to various fields. In 1969, Walsh was elected a fellow of the Royal Society of London. In 1970, he was awarded an honorary doctor of science degree from Monash University, Melbourne. In 1977, Walsh retired from CSIRO, where he had served as chief research scientist and assistant chief of the division. Soon thereafter, Walsh was knighted for his services to science. Even during retirement, he continued to work as an honorary research fellow and a consultant for several years. Walsh died in Melbourne in 1998.

Impact

Without a doubt, atomic absorption spectroscopy is the most significant advance in elemental analysis in the twentieth century. With the production of the first atomic absorption machines, chemists had an easy and fast method of determining the presence and concentrations of more than sixty-five of the chemical elements in the periodic table. Furthermore the accuracy and sensitivity of this method drove all "wet-chemical" methods into obsolescence. This method also found applications in fields as diverse as medicine, agriculture, food analysis, mineral exploration, metallurgy, enology, environmental science, forensics, and biochemistry. It is not an overstatement to say that all significant chemistry laboratories in the world possess an atomic absorption spectrophotometer. The use of this technology is universal.

Walsh lived and worked at a time when spectroscopy—the study of the interaction of matter with light—was flourishing. Given the rapid advances in the field, no one would have thought that the field needed a new way of looking at problems. Yet Walsh possessed the rare combination of being brilliant, practical, and exceptionally creative. Even during his years at the BNF, Walsh thought that spectroscopy would not advance much further without "a completely new line of attack." Even though virtually none of his colleagues shared his point of view, Walsh proceeded to gnaw away at the problem until it gave in. The result of his relentless pursuit was a completely new way of determining chemical compositions.

—Michael A. Buratovich

Ernest Thomas Sinton Walton

Irish physicist

Walton, working with John Cockroft in Ernest Rutherford's laboratory at Cambridge University, built the first high-energy particle accelerator and with it produced the first human-made nuclear reaction.

Born: October 6, 1903; Dungarvan, County Waterford, Ireland
Died: June 25, 1995; Belfast, Northern Ireland
Primary field: Physics
Primary invention: Cockroft-Walton particle accelerator

Early Life

Ernest Thomas Sinton Walton was born in Dungarvin in the county of Waterford, Ireland, on October 6, 1903. His father, the Reverend John Walton, was a Methodist minister from County Tipperary. The Irish church frequently moved its clergy from one parish to another, so Ernest attended a number of different elementary schools. When he was older, he was sent to boarding school in Belfast, where he became an outstanding student. He was passionate in his studies of science and mathematics and especially liked to build things. He carried a toolbox with him and became proficient at using the tools.

After his studies in Belfast, Walton moved to Trinity College in Dublin and graduated in 1926 with firsts in mathematics and science. He stayed on at Trinity to work toward a master's degree and was given the problem of explaining why a liquid moving past a cylinder creates twin groups of vortices in the liquid. Walton designed and built apparatuses to study this phenomenon and was able to photograph the whirlpools as they were formed. He was awarded his master's degree in 1927.

The most exciting area in physics at the time was the study of the atomic nucleus, and the place to study this was the Cavendish Laboratory in Cambridge under Ernest Rutherford. Walton seized the opportunity of a scholarship mainly reserved for students from the Dominions and moved to Cambridge in October, 1927, to work toward a Ph.D. in Rutherford's laboratory.

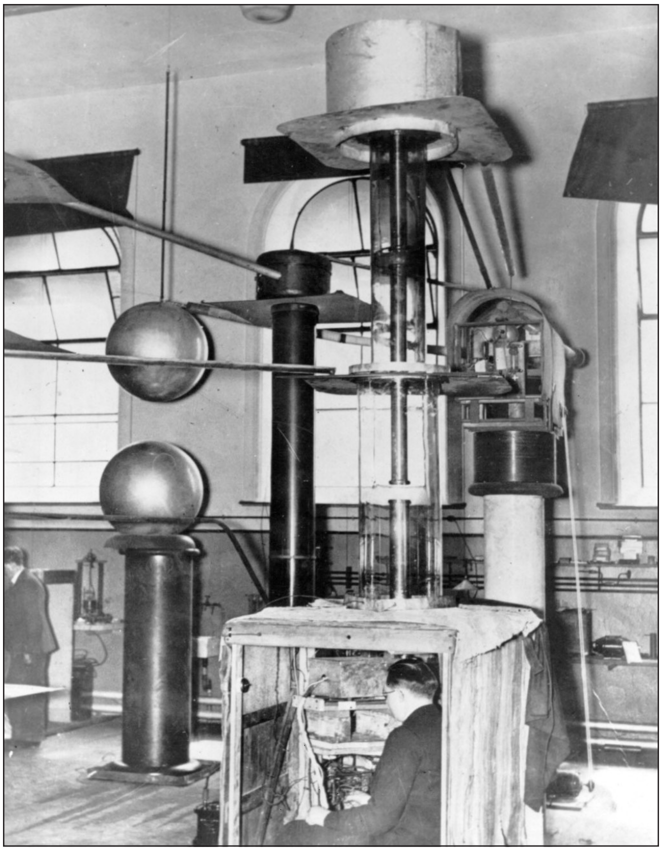
Life's Work

Walton's mechanical abilities were immediately recognized by Rutherford, and Walton was given a project to build a device that would accelerate protons to high enough energies to overcome the repulsion of the positively charged nucleus and penetrate within. Rutherford had discovered in 1911 that the atom had a heavy positively charged nucleus surrounded by electrons. His experiments were done with alpha particles from a radioactive source, but he recognized that to study inside the nucleus would require more intense beams of smaller charged particles such as protons. The Russian scientist George Gamow, using the new wave mechanics, had calculated that protons with energies of 300,000 electronvolts (300 kiloelectronvolts) would be sufficient to overcome the charge on the nucleus of light elements and produce transmutations in the nucleus.

Walton's first two attempts to build a proton accelerator were failures. He first tried to build an accelerator similar to a transformer, in which protons in an evacuated chamber between the poles of a magnet would be accelerated by an increasing magnetic field. He was never able to obtain a focused beam by this method, so he tried a linear accelerator in which the protons would be accelerated down a long vacuum tube by a series of electrodes, each of which give a kick to the protons and increase their energy. This device also failed to give a measurable beam, because the protons were lost in the walls of the beam tube.

Walton was persistent and would not give up the problem. He had heard of a voltage-doubler circuit that used current rectifiers and capacitors to turn alternating current from a transformer into direct current at twice the voltage of the output of the transformer. He thought that, by putting a number of these voltage doublers together, he could obtain high enough direct-current voltages to accelerate protons that could probe into the nucleus.

Most of the experiments in physics research of the time were done with desktop equipment that could be made in a small machine shop. The accelerator that would be necessary to study the interior of the nucleus would be a much larger undertaking requiring an entire room and the expenditure of considerable money and effort. Rutherford approved Walton's plans and found a room in the basement of the laboratory that was large enough to build the high-voltage machine safely.



The Cockroft-Walton accelerator, used by Ernest Thomas Sinton Walton and his colleague John Cockroft at the Cavendish Laboratory at Cambridge University. The men were awarded the 1951 Nobel Prize in Physics for their atomic research. (Getty Images)

To build the accelerator, Walton teamed up with John Cockroft, a physicist with a background in electrical engineering who had stayed on at the Cavendish Laboratory after his Ph.D. and become interested in nuclear transmutation. Together they designed an accelerator that rectified and multiplied the output of a transformer four times to obtain a steady voltage of 800,000 volts. This was used to accelerate protons from a discharge in hydrogen at the top of the machine into an evacuated glass cylinder and unto a target.

By April, 1932, they had constructed the accelerator and were ready for the first experiment. They sealed a thin target of lithium inside the accelerator tube at 45° to the beam and a thin mica window on the side of the tube. With a potential of 125,000 volts, scintillations were seen outside the mica window. After various other experiments, the scintillations were seen to be due to alpha particles from the breakup of the lithium nuclei. This was widely reported by the press and became a worldwide sensation. The accelerator immediately became an important tool for studying the nucleus and was widely copied around the world.

After the glory days of the early 1930's, the young men who had made the nuclear revolution began to drift away from the Cavendish Laboratory to other organizations. Walton was offered a fellowship by his old college and returned to his roots in Trinity College in Dublin. He knew that there would be little money for research but believed that the most important contribution he could make would be to encourage and support science in Ireland. Although he attempted to do further nuclear research when money for equipment could be obtained, his primary successes were in teaching. His lectures were known for their clarity, and his laboratory demonstrations caught the imagination of his students.

During World War II, Walton was asked by Sir James

The Cockroft-Walton Accelerator

Ernest Thomas Sinton Walton and his colleague John Cockroft were the first to build a charged-particle accelerator with enough energy to penetrate into the atomic nucleus. Although other types of accelerators quickly followed with higher energies, the advantages of simplicity of the technology and precision of the energy obtainable make the electrostatic machine of Walton and Cockroft useful to the present day.

The basic invention that made the Cockroft-Walton accelerator possible was the voltage-multiplier circuit that takes alternating current from a transformer and converts it into direct current at much higher voltage. The voltage multiplier is an arrangement of rectifiers that allow current to pass in only one direction with capacitors that are in series to obtain the high voltage.

The positive output of the voltage multiplier was attached to the top of an evacuated column where hydrogen ions (protons) were produced. The positively charged protons were repelled by the high positive voltage at the top of the column and accelerated down the tube into the target area.

Cockroft and Walton built their accelerator to study the nucleus. The accelerator's first use was to split a lithium nucleus into two alpha particles. Because of the breakdown of air at high voltages, this type of accelerator is limited to about 2 million electronvolts, but there continue to be many nuclear studies at lower energies where the Cockroft-Walton accelerator excels. In addition, these accelerators continue to be used as preaccelerators for injection of protons into the huge accelerators at the Fermi National Accelerator Laboratory in Illinois and the European Organization for Nuclear Research (known as CERN) near Geneva, Switzerland.

The voltage-multiplier circuit invented by Cockroft and Walton is used in many other applications in the home and industry, where it is necessary to convert alternating current at low voltage into high-voltage direct current. Industry uses a Cockroft-Walton-type accelerator to implant ions into semiconductors to manufacture the chips widely used today. Any home that has a TV or a computer cathode-ray-tube monitor makes use of a voltage multiplier to obtain the high-voltage direct current needed.

Chadwick, head of the British contingent in the Manhattan Project, to join what he described as war work in the United States. Walton declined because he felt an obligation to Trinity College, where there would be only two professors left to teach physics if he left.

In 1946, Walton was made Erasmus Smith's Professor of Natural and Experimental Philosophy, and he spent the rest of his career at Trinity College. Even after his retirement in 1974, he was part of the college and attended seminars and Physics Department teas to keep in touch with the students.

Walton received many honors during his career, the first being the Hughes Medal of the Royal Society of London with Cockroft in 1938. He and Cockroft were awarded the Nobel Prize in Physics in 1951 for their "work on the transmutation of atomic nuclei by artificially accelerated atomic particles." After his retirement, Walton also received many honorary degrees from both British and American institutions.

He had a long happy marriage with his wife, Freda, whom he had married in 1934 after his successes at the Cavendish Laboratory. They had five children, several of whom followed in their father's footsteps and became physicists. Walton lived until the age of ninety-one and died in Belfast in 1995.

Impact

Walton and Cockroft were able to show with their accelerator that charged-particle beams could be produced with specific controlled energies and at much higher intensity than the radioactive sources that were used for nuclear research at the time. They were the first to show that quantum tunneling into the nucleus as predicted by the new wave mechanics occurred, and their measurements of the energy of the alpha particles produced by the splitting of lithium verified Albert Einstein's mass-energy relation, $E = mc^2$.

The Cockroft-Walton accelerator had an immediate and profound effect on nuclear research. It was the first of the thousands of accelerators to study the interior of the atom. It was also the first accelerator to show that an atomic nucleus could be split by human-made high-energy charged particles. It and other accelerators that followed galvanized the study of nuclear physics, and within a year hundreds of physicists had switched to the study of the nucleus. Within five years, 30 percent of the articles in the leading American physics journal, *Physical Review*, were devoted to research in nuclear physics.

A Cockroft-Walton accelerator was used in World War II as part of the research leading to the atomic bomb, and it was later used to study nuclear reactions occurring in the Sun and stars. In recent years, the Cockroft-Walton accelerator's primary use in physics research is as a preaccelerator to inject charged particles into the higher-energy machines used to study the particles and forces within the nucleus.

Voltage multipliers of the type pioneered by Cockroft and Walton are now used for many other applications besides nuclear physics research. They are used in the high-voltage power supplies in electron microscopes, X-ray systems, air ionizers, television sets, bug zappers, and many other applications that require high-voltage direct current.

An Wang

Chinese American electrical engineer

Wang invented the magnetic memory device that dominated the storage capacity of computers for twenty years, until the development of semiconductor technology. He became a major American entrepreneur in the area of calculators, word processors, and computers.

Born: February 7, 1920; Shanghai, China
Died: March 24, 1990; Boston, Massachusetts
Primary fields: Computer science; physics
Primary invention: Pulse transfer controlling device

Early Life

An Wang's parents named their son with an expression meaning "peaceful king." His father taught English in an elementary school and was a firm disciplinarian. His mother was far less strict and very loving. Wang lived either in Shanghai or Kun San, where his father taught, until the age of twenty-one. A very bright boy, Wang began school in the third grade at the age of six. Although he was very proficient in mathematics, he did less well in other subjects, which were taught by rote memorization. In many ways, his curriculum was like that American students confronted at the time, and since some of the textbooks were written in English, he was faced with the challenge of learning English as well. Outside school, he learned much about Chinese thought and literature from his grandmother, who also introduced him to the philosophy of Confucius.

As he progressed in his education, Wang spent much time reading about scientific thinkers such as Leonardo da Vinci, Galileo, and Sir Isaac Newton. He attended Shanghai Provincial High School (which had an eminent reputation), graduated at sixteen, and entered an excellent college, Chiao Tung University, also in Shanghai, where he studied electrical engineering. He also edited a scientific digest compiled by students at the university. During these years of the 1930's, Japan increased military pressure on China and in 1937 began to occupy its territory. By November of that year, the Chinese army had been driven out of the Shanghai area. When Wang graduated as valedictorian (1940), he stated that there was war "all around him."

Life's Work

After a year as a teaching assistant in electrical engineering at Chiao Tung, Wang took a job building transmitters and radios, which the government could use in the war effort. This work had to be done hundreds of miles inland from Shanghai in Kweilin. In World War II, his parents died in ways unknown to him, and although his sisters and brothers survived the war, he did not see any of them again for forty years.

In 1945, Wang took advantage of a program that was sending well-trained Chinese engineers to the United States. The goal of the Chinese government was to allow particularly talented young engineers to learn American technology and help rebuild postwar China. Wang entered Harvard University and in 1948 completed the requirements for a Ph.D. in applied physics. He decided not to return to China but to work in the United States.

The experience that led to his later achievements was his work at the Harvard Computation Laboratories. At the time, he was thinking of this work not as a step in computing but as a job that he needed as a husband and father, for in 1949 he married Lorraine Chu, and within a few years they had three children. At a time when computer technology was just beginning to develop, Wang began to work on the problem of storing information in a computer. At that time, it was understood that computers would use a binary system containing only two digits rather than the usual ten digits. The speed of a computer depended on how fast the circuit could change from one digit, the 1, to the other, the 0. Working on the problem of how to design a means by which computers would have rapid access to data, Wang found that there were several possible types of storage of information. Magnetism seemed to offer the best solution. He decided that he had to find a way to read and store information without mechanical motion, which slowed the process.

Having progressed in his effort, Wang decided to leave Harvard and form Wang Laboratories in 1951 in Boston. Despite its plural name, his business was first established over a garage in Boston's South End. He began the business with capital of $600, no orders, no contracts, and no office furniture. His business grew when he was able to convince scientists that he could design applications that would facilitate their work. One of his customers was International Business Machines (IBM); after a series of difficult negotiations, he assigned a patent to IBM for $500,000. Wang also developed his own line of products, one of which was Linasec (1963), a semiautomatic typewriter. Wang's company was now becoming important. His LOCI desk calculator, introduced in 1964, not only could do ordinary mathematical problems but also could quickly generate exponential values. Scientists and engineers, who until that time had to rely on a mainframe computer, could now work from their office desks.

Wang's word-processing machine, in-

The Pulse Transfer Controlling Device

The most important of An Wang's forty inventions was what he called in his patent a "pulse transfer controlling device." It established a way to record and read magnetically stored information without mechanical motion and thus enormously increased the speed of operation. The information could be stored without mechanical motion by magnetizing material in either a positive or negative magnetic direction.

Wang's invention is based on a magnetic core, which was an arrangement of iron rings connected by wires. Every memory operation requires a recording cycle and a reading cycle. The transfer of information could be controlled by setting the core at a state of residual magnetic flux density that would either allow or prevent the transfer. If a negative pulse is applied to a winding on such a core, there will be little or no flux change at the core and no power will be transferred. At a positive state of residual magnetism, a large change will occur and power will be transferred to the core.

The problem in reading such a text was that it reversed the direction of the flux and destroyed the information that it stored. The insight that allowed Wang to develop the memory core was his realization that the information could be rewritten immediately afterward, a process that would take only a few thousandths of a second. The polarity of the residual magnetism of the core could be controlled to a desirable state by applying a pulse. For the core to operate efficiently, the rings had to be very small. At high speeds, the wires of the core could heat up, their resistances could change, and the drive currents could fluctuate and cause internal interference. The cores were first assembled by hand, but the demand for smallness eventually made hand assembly too difficult. Machines were developed that could knit the core rings together.

Wang's invention became the basis for all high-speed computer memory. Using core memory, Wang Laboratories became an important manufacturer of early desktop computers. Wang's core memory continued to serve as the basis for information storage in computers until the development of solid-state memory began to replace it in the 1970's.

vented in 1971, sparked the development of a word-processing system in 1976. His word-processing system had its own microprocessor and the capacity to function as part of a network; thus, Wang was one of the early developers of a local area network (LAN), which could bring users together to share documents and applications. In two years, Wang Laboratories was the largest maker of stand-alone word processors in the world. These word processors for science, business, and industry anticipated their later use by the millions of people with access to personal computers.

Successful as Wang Laboratories were in the 1970's, the firm began to encounter the problems peculiar to a proprietary business that had grown into a large company. By 1981, Wang had surrendered his ruling function to a management committee. His son Frederick and John F. Cunningham were named vice presidents. Two years later, Cunningham was named president and chief operating officer. A drop in earnings the next year resulted in layoffs of workers and other types of cost reduction. Cunningham resigned, and Wang again took charge of the company. Soon, however, Frederick Wang was named its president, and Wang Laboratories declined in the late 1980's.

Wang held forty patents and received twenty-three honorary degrees. He was named a member of the National Inventors Hall of Fame. He also made his mark as a philanthropist. He donated handsomely to Boston's Performing Arts Center, to Harvard University, and to Wellesley College, and he created the Wang Institute of Graduate Studies, partly intended to benefit China scholars. He died in 1990.

Impact

From a tiny operation, Wang Laboratories grew to an organization employing thirty thousand people. Wang's work advanced the development of computers for use by the government, science, business, and eventually private citizens. When Wang began his work, computers capable of doing the work now done routinely by mere laptops had to be mainframes, which were too large and expensive to be used by any offices or businesses of ordinary size. His development of magnetic core memory made desk-sized calculators possible, and after other scientists developed solid-state technology, he applied it to the production of minicomputers and word processors. Wang Laboratories became a leader in word processing in the 1970's.

Wang's accomplishments as an inventor encouraged other Asian Americans and thus enlarged the ranks of the men and women in technological invention. He designed many technological applications for fellow scientists and established an important link between engineering science and industry. These applications ranged widely. As modified by Jay Wright Forrester at the Massachusetts Institute of Technology, Wang's core memory design was used by the U.S. Air Force to control flight simulation. Wang benefited the newspaper industry by designing the first electronic typesetter system. Another design resulted in the electronic scoreboard in Shea Stadium, the home of the New York Mets baseball team.

Wang's development of the largest minority-owned business in the United States proved that the Horatio Alger success story—in which vision, energy, determination, and the courage to compete with larger and richer operations (in his case, IBM) could raise a person to prominence—was possible. Wang's philanthropy also contributed to educational and cultural activities for many people, particularly in the Boston area.

Taylor Gunjin Wang

Chinese American physicist

Wang's inventions moved from novel methods of acoustic manipulation of matter to the design of new encapsulations for cells used in bioengineering, with practical applications in the fight of diseases such as diabetes. His innovative design of drop dynamics experiments in zero gravity made him the first Chinese American astronaut.

Born: June 16, 1940; Shanghai, China
Also known as: Taylor Gun-Jin Wang; Wang Ganjun (Pinyin)
Primary fields: Biology; medicine and medical technology; physics
Primary invention: Cell encapsulation

Early Life

Taylor Gunjin Wang (wahng) was born in Shanghai, China, during World War II. He was the oldest son of businessman Zhang Wang and his wife, homemaker Jiehong Yu. His parents would have two more boys and one girl. In 1943, the Wang family fled from the Japanese invaders to the seat of the Chinese nationalist government in Chongqing. At age three, Wang fell into the raging Jialing River. Clinging to a bamboo pole, he was saved from drowning. His family interpreted his survival as a sign that his life would be special.

Wang's family returned to Shanghai at the end of World War II in 1945. Wang's first boyhood experiment involved winding up a valuable mantel clock beyond breaking point. He did this to try to find out if time passed faster if the clock was wound up more than usual. His inquisitive spirit never left him.

After their father fled to Taiwan when the communists conquered mainland China in 1949 and their mother was able to join him there in the same year, Wang and his siblings sought to escape to Hong Kong in 1950. The smuggler hired to pass the four children beyond communist lines was ready to betray them at the border. However, a kindly English journalist intervened and saved them from communist border guards. The Wang family was reunited in Taiwan in 1950.

At age twelve, Wang decided to become a scientist. This was against the wishes of his father, who wanted Wang to inherit the family business. In 1961, Wang graduated from the Affiliated Senior High School of National Taiwan Normal University in Taipei. He assumed that his intelligence alone would ensure him entrance to a Taiwanese university. Surprisingly, as he neglected diligent study, he failed the Taiwan college entrance exams. Dedicating himself to his studies during two years in Hong Kong, in 1963 Wang was admitted to the University of California, Los Angeles (UCLA), and moved to the United States. There Wang married Xueping Feng in 1965, and their first son, Kenneth, was born the next year.

Life's Work

In 1967, Wang graduated from UCLA with a bachelor of science degree in physics. He obtained his master of science degree in physics from UCLA in 1968, focusing on fluid mechanics. In 1970, Wang's second son, Eric, was born. Wang obtained his Ph.D. in physics from UCLA in 1971; his thesis was on solid-state physics.

In 1972, Wang was appointed senior scientist in the Physics Section of the Jet Propulsion Laboratory (JPL) at Pasadena's California Institute of Technology. His research on fluid dynamics of drops and bubbles in a containerless environment attracted the attention of the National Aeronautics and Space Administration (NASA). NASA accepted one of Wang's proposed space experiments in 1974. He became a U.S. citizen the following year. On October 4, 1977, Wang's first patent was granted. It was for an invention in acoustic energy shaping, discovered by Wang and two other scientists.

In 1979, Wang became manager of the Microgravity Science and Applications Program at JPL. In 1982, NASA began to look for astronaut-scientists to conduct experiments in space. Since Wang's research on the dynamics of drops and bubbles in microgravity (an almost weightless environment) was very suited for space research, he applied for the program. Against considerable competition, Wang was chosen as a payload specialist astronaut on June 5, 1983.

On April 29, 1985, Wang lifted off on the STS-51-B *Challenger* space shuttle flight, which lasted until May 6. Wang spent seven days and eight minutes in space. Wang was principal investigator of the Spacelab 3 drop dynamics experiments. Mortified when his first experiment failed on the second day of the mission, he pleaded with NASA bureaucrats to give him extra time to fix his setup despite an ultratight time schedule. When NASA refused, he threatened not to return to Earth, alarming mission control. Supported by his fellow astronauts, he was finally given extra time. Wang repaired his experiments' compartment and successfully finished his research. In addition to contributing to pure science, his space experiments had positive implications for finding a cure for diabetes.

Upon his return to Earth as the first ethnic Chinese astronaut, Wang was awarded the NASA Space Flight Medal and celebrated the Taylor G. Wang Recognition Day on October 11, 1985, in Washington, D.C. Many more public awards followed.

In 1988, Wang became Centennial Professor of Materials Science and Engineering at Vanderbilt University in Nashville, Tennessee, and the director of the Center for Microgravity Research and Applications. His research and subsequent patents for his inventions focused on drop dynamics in containerless environments. In 1992, Wang's experiments for drops in zero gravity were carried out by scientists aboard the space shuttle carrying the U.S. Microgravity Laboratory 1. In 1993, Wang was appointed director of the Applied Physics Program at Vanderbilt. In 1995, Wang's experiments in designing encapsulations for living cells were performed in the space shuttle's U.S. Microgravity Laboratory 2.

Over the next years, Wang's inventions gradually moved from the field of pure physics to applications in bioengineering. Wang focused on ways to create stable shells for cells, embedded in drops that could carry capsules with beneficial islets to combat the disease of diabetes. The primary challenge was to create custom-designed capsules that protected the cells inside them and that did not trigger a body's immune system to attack and destroy them. Here, Wang's inventions yielded him three more patents, granted in 1995-1996. An application for a patent for his invention of a multimembrane immunoisolation system for cellular transplants was filed in 2006. A patent for capsule patches for cellular transplantation without immunosuppression was filed in 2008.

Wang continued to teach and conduct research at Vanderbilt University and did not plan to retire until his experiments were finished successfully. He continued to work on inventing new designer capsules for cells that can deliver their beneficial content to a diabetes patient without causing the body's immune system to destroy them before their healing mission is accomplished.

Cell Encapsulation

Taylor Gunjin Wang's encapsulation system for the immunoisolation of living cells was discovered with five other scientists on his research team. The system enabled the customized creation of protective capsules for cells that carry beneficial hormones and proteins that they release when transplanted into the body of a patient suffering a disease resulting from a deficiency of certain hormones or proteins, as is the case with diabetes. The problem Wang faced was that a host's body immune system fights transplanted cells and quickly destroys them unless the immune system is suppressed, which results in many negative side effects. Before Wang's invention, the capsules used to immunoprotect cells could not be customized and optimized for specific applications and were of limited practicability.

Wang's novel encapsulation system creates a new multicomponent polymer capsule that permits individual modification of its size, the thickness of its wall, its mechanical strength, its two-way permeability, and a variety of its surface characteristics. With Wang's system, cells with beneficial content can be put into customized capsules in which they are transplanted into the diseased body. Such encapsulated cells are not rejected by the host's immune system, and because of their specific design, the capsules optimize the inflow of molecules that the beneficial living cell inside needs to survive and function. The outflow of the desired beneficial cellular products, such as specific hormones or proteins, can be fine-tuned for each case and application.

Wang and his team analyzed more than one thousand different chemical combinations of polyanions and polycations to create working capsules. Only thirty-three combinations were discovered to work as desired. These capsules consist of a special mix of agents—namely, high-viscosity sodium alginate, cellulose sulfate, and a polycation. The capsules are created in a novel reactor that allows for customization of the cells by carefully altering the ingredients of the eventual combination.

In their first practical application, Wang's capsules carried beneficial cells that consisted of rat pancreatic islets that emitted cellular products that reversed and cured the diabetes of living mice. Eventually, Wang's capsules may carry beneficial cells to cure diabetes and other diseases in human patients. His invention falls in the fields of endocrinology, protein chemistry, and biomedical engineering. His work is an example of how physics can aid medical advances.

Impact

Wang has been an outstanding scientist who realized early that experiments in space could contribute greatly to new knowledge and inventions in his field of fluid mechanics and solid-state physics. He was a visionary who designed new experiments leading to new knowledge when successfully carried out aboard the space shuttle. His personal courage and determination to become an astronaut-scientist added adventure to his endeavors as physicist. He inspired many young people both to embark on a scientific career and to participate in space exploration. He has been awarded many prizes for his contributions as scientist, inventor, and citizen. In 2007, Wang was honored as a White House state ceremony participant and received the Distinguished Science and Technology Award at the Asian American Engineer of the Year Award ceremony of the National Engineers Week Foundation.

Once Wang invented new ways of engineering customized capsules for cells transported in drops and bubbles, he successfully joined his research in pure physics to the field of bioengineering. He sought to ensure that his capsules were useful in future medicine and contributed to the fight against diabetes. His work came to stand at the nexus of physics and medicine.

By 2008, Wang held twenty-six patents and had two more in the application process. By that time, he had authored one book, edited another, contributed four textbook chapters, and published more than two hundred scientific articles that contributed greatly to the understanding of the mechanics of drops and bubbles in a microgravity environment and novel protective cell capsules.

—R. C. Lutz

Felix Wankel

German mechanical engineer

Wankel was an imaginative, self-trained engineer and inventor whose most memorable contribution was the development of the rotary engine that bears his name—the Wankel engine—and operates by using orbiting triangular rotors that function much as pistons do in conventional gas-powered engines.

Born: August 13, 1902; Lahr, Germany
Died: October 9, 1988; Lindau, West Germany (now in Germany)
Primary fields: Automotive technology; mechanical engineering
Primary invention: Wankel rotary engine

Early Life

Felix Wankel (FEE-lihks WAHN-kuhl) was born in the Upper Rhine River Valley in the Swabian town of Lahr. Lahr is close to Stuttgart, the home of such automobile companies as Daimler and Benz. Wankel first conceived the idea of the rotary engine that bears his name when he was twenty-two years old.

The young man's father, Rudolf Wankel, died in World War I, leaving Felix's widowed mother, Martha, with few financial resources. Felix was twelve when his father died. What limited income his mother had was soon wiped out by Germany's staggering inflation during the 1920's. There was no possibility for her only son, a withdrawn and reclusive youth, to pursue a university education or enter into an apprenticeship. When Felix did attend school, he was bored by it. His active mind moved more rapidly than the minds of his classmates and teachers.

Inherently curious and mechanically gifted, Felix learned a great deal about technology by studying on his own. Out of his well-disciplined program of self-education came his earliest realization that rotors could replace pistons in engines, thereby reducing their size and weight while decreasing their manufacturing cost and substantially increasing their reliability. Such engines, seldom requiring repairs and needing only routine maintenance, delivered a remarkably smooth performance.

Most automotive engineers in the mid-1930's, nearly all of them with more impressive academic credentials than Wankel, were convinced that the conventional reciprocating engine was the most desirable source of power for motor vehicles. Wankel was not convinced, and he quietly went about experimenting with alternative power sources that resulted in his development of the rotary engine.

Pressed to support himself and his mother, Felix, in 1921, took a job in a bookstore in the university town of Heidelberg, where his main responsibility was scientific publications. When he developed a kidney condition, the bookstore's management transferred him from the printing room, where high concentrations of lead were affecting his health, to the storeroom, which he quickly reorganized to make it more efficient.

Life's Work

During the three years that he spent working in the bookstore in Heidelberg, Felix found ample time to read the scientific sources that were his chief responsibility. He also attended night school and took correspondence courses to help build his knowledge base in the scientific

Felix Wankel with his rotary engine, an alternative to the conventional piston-driven engine. (Popperfoto/Getty Images)

Wankel's Rotary Engine

Felix Wankel's rotary engine is housed in a uniquely shaped combustion chamber of an automotive engine, its triangular rotor replacing the pistons that are characteristic of most internal combustion engines. The stages through which the rotor passes are, respectively, intake, compression, expansion, and exhaust.

During the intake stage, air is taken in and mixed with fuel that is drawn into the motor through the tiny intake opening. In the next stage, the rotor compresses the mixture of fuel and air as the rotor passes the intake opening. During the next stage, a spark plug ignites the mixture, which causes the burning gases to expand. This, in turn, causes the rotor to move around the output shaft. Finally, the burnt gases are expelled through the exhaust port as soon as the rotor tip uncovers it. When this four-stage cycle has been completed, it automatically repeats itself, resulting in a smooth infusion of power into the engine.

The most important parts of the rotary engine is the triangular rotor and the uniquely shaped chamber in which it rotates. The tips of the rotor are in continuous contact with the chamber's walls and, because of the rotor's triangular structure, separate the chamber into three specific areas. In the four-stroke cycle gasoline engine, each piston has to move back and forth two times and stop four times to go through its cycle. The rotary engine, on the other hand, operates continuously, completing three cycles of combustion with each complete rotation of its rotor. The single-rotor engine produces one power stroke for each turn of its output shaft, whereas the more conventional piston engine produces one power stroke every time the piston moves down its cylinder. Thus, the dual-rotor engine is able to generate a number of power strokes equal to that of a four-cylinder piston engine.

Because all the motion in a Wankel engine is rotary, its operation is remarkably efficient. Whereas in the piston engine the reciprocating vertical motion has to be converted to rotary motion, in the Wankel engine there is no need for such a conversion. Every revolution of the rotor results in three impelling power forces.

areas that most interested him. In 1924, he first conceived the notion of an engine whose pistons would be replaced by rotors, and he embarked intermittently on the work that would become his lifelong passion and would result in his invention of the Wankel rotary engine.

Clearly possessed of a unique intelligence—some of the people who knew him well called it genius—Wankel approached inventing with a childlike excitement. Once he had overcome the basic obstacles lying in the path of his research, however, rather than pursuing it to the end, he tended to abandon it in order to turn to other projects that excited him. In 1927, Wankel became a partner in an engineering company and soon afterward opened his own research laboratory, in which he engaged in considerable experimentation on internal combustion engines, but with special emphasis on the rotary engine. This experimentation lasted well into the 1930's.

In early 1933, Adolf Hitler was elected chancellor of Germany. Soon afterward, Wankel, who was an outspoken opponent of Hitler, was imprisoned for several months because of what the German government considered his subversive political views. Upon his release, with World War II looming ominously in the future, Wankel's expertise was needed as Germany prepared for war. He was employed by the German Air Ministry to develop seals and rotary valves for the Luftwaffe, the German air force. He also worked for the German navy on developing seals and valves for torpedoes. Between 1936 and 1945, he worked for the Deutsche Versuchsanstalt für Luft-fahrt (DVL), the German aeronautical research establishment, on developing rotary valves. When the war ended in 1945, the occupying Allied forces imprisoned Wankel for several months, forcing him to close his laboratory. The Allies in charge of his imprisonment confiscated his scientific work and ordered him to discontinue his experiments.

Unable to pursue his interest in the rotary engine for several years, Wankel was finally employed in 1951 by the NSU Motorenwerke AG to continue his work on developing a rotary engine, which NSU hoped to use in manufacturing its motorcycles. Wankel completed the first design for a rotary-piston engine in 1954 and, on February 11, 1957, completed the first prototype of his rotary engine that turned in slightly over twenty horsepower.

Wankel continued to refine this engine for Kreiskolbenmotor (KKM) AG. In July, 1958, he tested his new and improved engine. By now, considerable interest had develop worldwide for the innovations that Wankel had created. In 1967, the Japanese automobile maker Mazda introduced the Cosmo Sport, one of the world's first dual-rotor rotary engine cars. The company manufactured many rotary engine sports cars that were much in demand because of their dependable power and the infrequency with which they required repairs. Many such vehicles are still in use. In 1978, Japan manufactured the Mazda RX-7 largely for distribution in the United States.

On December 5, 1969, in recognition of his singular contributions to the field of automotive engineering, Wankel was awarded an honorary doctorate in engineering by the Technische Universität München. Ever reclusive, Wankel continued to reside in the Swabian area of Germany in which he was born and raised. He developed a private testing facility and laboratory there. Even as his long life inched toward its end, he spent a great deal of time working in his laboratory, which he named The Institute. Despite his monumental contributions to automotive engineering, it is said that he never obtained a driver's license for himself. He died in Lindau, West Germany, at the age of eighty-six.

Impact

In 1957, shortly after Wankel unveiled the prototype of his rotary engine, automobile manufacturers throughout the world and particularly in Japan and the United States became extremely interested in this new approach to powering vehicular engines, most notably those used to power automobiles, trucks, and motorcycles.

Rotary engine automobiles, like piston engine automobiles, require a battery, a starter motor, and a distributor to engage the engine. They also require cooling and lubrication systems to make their engines work efficiently. To this extent, they are similar to automobiles with more conventional engines. One of the major selling points of the Wankel rotary engine is that it has less than half the moving parts of conventional piston engines, meaning that there are fewer parts that can malfunction.

Despite the obvious virtues of rotary engines, they came on the market at an unfortunate time. In 1971, there was an international energy crisis that discouraged people from purchasing vehicles whose energy efficiency was questionable. The early enthusiastic celebrity that the Mazda vehicles had evoked soon cooled as the American economy took a downturn. Nevertheless, Mazda continued to experiment with the rotary engine and to refine it in many ways. By the end of the 1970's, the Japanese manufacturer concentrated on producing sports cars with rotary engines for European and American markets, where such sports cars were received enthusiastically. Mazda ran an extensive advertising campaign for its RX-7, released in 1978, and buyers flocked to showrooms to learn more about this innovative automobile that promised sustained, trouble-free operation.

LEWIS WATERMAN

American insurance broker

Waterman invented the first leak-proof fountain pen that could be relied on to perform properly. He founded the L. E. Waterman Company, which set the standard for quality pens and was instrumental in creating the market for fountain pens.

Born: November 20, 1837; Decatur, New York
Died: May 1, 1901; New York, New York
Also known as: Lewis Edson Waterman (full name)
Primary fields: Business management; household products
Primary invention: Waterman fountain pen

An advertisement for Lewis Waterman's fountain pens, published in the November 21, 1908, issue of The Graphic. (Getty Images)

EARLY LIFE

Lewis Edson Waterman was born in Decatur, New York, on November 20, 1837. He grew up on a farm and had a number of jobs before he invented his capillary feed fountain pen. The facts of his life during this period remain somewhat enigmatic. Waterman himself told different stories about his work during this time. He apparently taught school for a year or two, worked as a book agent for some ten years, and then worked as a life insurance agent for about fifteen years. He was also employed at one time by the *Railroad Gazette* and a trade publication, *National Car Builder*.

The commonly told story of what brought about his invention of the leak-proof fountain pen is generally considered a fabricated tale. According to the story, Waterman was working as an insurance broker, meeting with a client who was to sign a very lucrative contract with him. Waterman supposedly bought a new fountain pen for the client to use to sign the contract. The signing turned into a disaster when the pen leaked ink all over the contract. From this point, the story has two conclusions. One states that the client interpreted this as an ill omen and refused to sign the contract. The second ending recounts that Waterman hurried off to get another contract and upon his return found that the client had signed with another agent. Some versions of the story also state that Waterman went to his brother's farm in upstate New York and invented his innovative ink feed, which he then placed in a pen his brother had made from a wagon wheel spoke. The story, which is highly disputed and is probably myth, at least in part, continues to be included in much of the material written about Waterman and his pen. It should be noted, however, that while many historians deny and scoff at the story, other reliable experts accept it.

Because of his various lines of work, Waterman, it seems, had developed the habit of carrying several fountain pens with him and at times selling some of his extra ones. He had become interested in fountain pens and made a detailed study of pens before becoming a pen manufacturer.

Life's Work

Whether or not the story of the ruined contract is true, Waterman was working as a life insurance salesman in the early 1880's. It was at this time that he began working on his idea of making a fountain pen with a feed using the principle of capillary action. After several less-than-successful experimental pens, he produced the pen he had envisioned. In 1883, Waterman applied for a patent, which he received on February 12, 1884. Inspired by his success in getting his invention patented, he closed his life insurance business and devoted himself to the making of pens.

He established the L. E. Waterman Company. At first, his company was a one-person operation located in a cigar store on Fulton Street in New York City. His sign advertised Waterman's Ideal Fountain Pen. Each pen carried a written guarantee against defects for five years. Working by himself at a table in the back of the shop, Waterman managed to manufacture two hundred pens the first year and five hundred the second. Waterman's business was small and enabled him to have a personal relationship with each customer. He kept a list of the names and addresses of his customers. However, his profits did not provide enough money to support him.

Faced with the problem of either increasing his sales or losing his company, Waterman accepted the advice and offer of E. T. Howard, an advertising agent. He proposed that Waterman advertise his pen in a popular magazine with a large circulation. Howard offered to loan him money for the advertisement. Taking Howard's advice proved to be one of the best decisions Waterman ever made. Sales increased dramatically. Waterman was able to move his company to a large building at the corner of Broadway and Courtland Street and to hire a large staff both to handle the business aspects of the company and to manufacture the pens. This building housed the sales and business offices of the company, a warehouse, and a repair shop. Waterman also established two factories: one in Seymour, Connecticut, where the rubber pen parts were made, and one in New York City, where the gold pen nibs were produced. The company sold pens in both the wholesale and retail markets. It also sold ink and pen pockets.

Waterman was an astute and shrewd businessman. His advertising campaign continued to emphasize the quality and reliability of his pens. A Waterman pen was an investment in a quality writing instrument. Waterman was also selective in the people he chose to employ. For example, he hired William I. Ferris to perfect machines for making the pens, thereby reducing hand labor and increasing production.

In 1893, Waterman's Ideal Fountain Pen won a first prize at the Chicago World's Fair. This award was followed by the Medal of Excellence at the Paris Exposition of 1900. The company expanded first throughout the

The Waterman Fountain Pen

Fountain pens were in use as early as the tenth century. However, until Lewis Waterman developed his feed with capillary action based on the principle of capillary attraction, fountain pens were not very practical writing instruments. With an irregular flow of ink, they tended either to skip because of an inadequate amount of ink reaching the nib or to leave puddles of ink on documents because of an excessive quantity of ink reaching the nib. Working alone and using only a pocket knife, a saw, and a file, Waterman succeeded in creating a feed system that regulated the flow of ink and made the fountain pen a practical and enjoyable writing instrument.

His feed system utilized the principle of capillary attraction. As ink left the reservoir, air entered it, avoiding the creation of a vacuum. This was accomplished by letting the ink flow through a channel feed that had fine cuts in it, thus permitting a quantity of air equal to the outflowing quantity of ink to enter the reservoir. Waterman devised a shallow square channel with three fissures. He cut a fissure alongside each wall of the channel and a third fissure in the middle of the channel. This highly successful system, called the three-fissure feed, was the system of ink control used for the next fifty years.

Waterman also designed his pen to provide comfort to the user. His first model had a ridge on the grip. In his second model, he replaced this ridge with a taper, which greatly improved the comfort of the pen's user. Convenience was another important feature of the Waterman pen. It was the first pen to have a clip on the cap.

In addition to making pens that were practical, reliable, and comfortable to use, Waterman made his pens attractive. The first pens were made of hard black rubber. He soon added pens made of hard red rubber and of mottled red and black rubber. He developed and patented a method for machining decorative chasing onto the hard rubber barrels. Many of his pens had elaborate metal overlays. The nibs were gold.

During Waterman's lifetime and until the 1930's, the Waterman pen, synonymous with quality and reliability, was the leader of the fountain pen industry.

United States and then abroad. In 1899, the company built a factory in Montreal, Canada. Soon after, the L. E. Waterman Company had sales representatives in Europe. By 1901, the company was selling one thousand pens per day. Lewis Waterman died in New York City on May 1 of that year.

Upon Waterman's death, his nephew Frank D. Waterman became head of the company, which continued to be the leader in the manufacture of fountain pens through the 1920's and enjoyed continued global expansion. It was during this period that the company enjoyed its greatest success and prestige. In the 1930's, competitors who were more open to innovations in style and technical advances took a considerable share of the market from the company. The 1930's and 1940's saw the L. E. Waterman Company lose even more ground in the pen market. The invention of the ballpoint pen was the major cause of the demise of the business, which ceased production in 1956. The L. E. Waterman Company was eventually sold to Bic in 1959. However, in 1926 Jules Fagard, a French sales representative, had founded a subsidiary known as JiF Waterman, so pens bearing the name Waterman continued to be produced. Waterman pens continue to be available.

IMPACT

Waterman developed the capillary feed system, which successfully controlled the ink flow to the nib of the fountain pen. Before Waterman's invention, fountain pens had been considered impractical because of their unreliability and tendency to either release too much or not enough ink. His invention of this feed system and manufacture of pens using the system founded a new industry in the United States and eventually worldwide. In addition to producing a reliable pen, he also produced an attractive pen. Fountain pens became a status symbol for individuals and a profitable business for entrepreneurs.

SIR ROBERT ALEXANDER WATSON-WATT

Scottish physicist

Watson-Watt is often described as the "father of radar." His experiments and research established the foundational physics of radar, while his administrative efforts and persuasiveness were instrumental in the development of a radar-based air defense system. While Watson-Watt's work focused on the military applications of radar, the wartime development of miniaturized radar made possible the radar-based technologies in navigation, traffic control, meteorological prediction, and tracking that so pervade the modern world.

Born: April 13, 1892; Brechin, Forfarshire (now Angus), Scotland
Died: December 5, 1973; Inverness, Inverness-shire, Scotland
Primary fields: Military technology and weaponry; physics
Primary invention: Radar-based air defense system

EARLY LIFE

Robert Alexander Watson-Watt was born in Brechin, Scotland, to Patrick and Mary Watt. Robert was raised in a practical family whose head, Patrick, worked as a carpenter and a joiner. Robert was a successful student at the University of St. Andrews in Dundee, Scotland. While Robert enrolled in the pragmatic field of engineering, his principal interest was in physics, a field in which he excelled. When he graduated in 1912, his placement in the top of his class garnered for him a position as a teaching assistant in the physics faculty. He remained in academia until Great Britain began to mobilize its intellectual resources during World War I.

In 1915, Watt's physics skills secured him employment in the Meteorological Office. This was the first in a series of government service positions he would hold until 1952. World War I saw the evolution of airplanes from fragile curiosities to important weapons of war whose use significantly affected battles. This was partially the result of technological innovations such as bigger engines and structurally improved airframes, but equally consequential was the creation of the infrastructure needed to supply and support aerial operations. This infrastructure was essential in the formation of the Royal Air Force (RAF). This included not only pilots, mechanics, and armorers but also specialists such as meteorologists who could track and predict weather, since storms often interfered with or delayed operations. Watt's experiments focused on using radio waves to detect storms, for early on he discovered that the electrical discharges in storms interfered with radio transmissions. At about the same time, scientists in the United States noted that this interference showed up as a visible pattern of disturbance on a cathode-ray-tube display, and Watt understood that these disturbances offered a visible and quantifiable way to identify and track storms.

In the postwar years, Watt continued to work as a researcher in the Air Ministry. By the 1930's, his work was well respected within the scientific community, so when scientists in the ministry began to investigate the implications of research on radio waves, Watt was an obvious person to consult.

Life's Work

One aspect of aerial combat in World War I that resonated with Britain's population was what would later be termed "strategic bombardment"—the use of bombers to attack and destroy an enemy's war industries. While both sides launched air raids on cities, the best-known attacks were those made by German dirigibles against London. Although these attacks caused little actual damage and insignificant casualties, they had a huge impact on the British public, who saw the RAF's inability to stop raids as an admission of British vulnerability. Consequently, the interwar years saw Britain invest great effort into developing defenses against aerial attacks. While much of this effort built upon scientific engineering such as the development of fast all-metal monoplane fighters, no scheme seemed too absurd if it seemed to offer safety from aerial attack. Thus, even ideas that sounded like science fiction were investigated. A few of the more esoteric proposals that were seriously investigated were death rays and aerial mines attached to parachutes that would be dropped in front of attacking bombers.

A Radar-Based Air Defense System

An air defense system must overcome the following problems: monitoring the incoming bombers, identifying their target(s), massing the defending fighters before the target at altitudes that maximize their effectiveness against the bombers, and inflicting enough casualties among the bombers to force them to either abort the attack or to bomb ineffectively. Prior to pre-World War II British efforts, air warning was based on sound detection or visual identification—both of which suffered from the technological limits of short range. Likewise, air defense was based on manually aimed antiaircraft guns and fighters circling over likely targets in perpetual air patrols. The first method was inaccurate, and the latter degraded the fighter pilots' effectiveness as they burned fuel and exhausted themselves in long patrols.

The air defense system based on Robert Alexander Watson-Watt's Chain Home (CH) radar system (a network of radar stations that initially dotted the south and east coasts of England) and the Biggin Hill experiments was a multifaceted system whose effect was a synergetic combination of technologies. The CH towers were set in a grid so that long-range echoes of incoming aircraft could be identified from numerous towers and triangulation could establish their routes and probable targets. This information would then be telephoned to a plotting room where the data could be processed and appropriate fighter squadrons alerted. The fighters, once airborne, could then be vectored by radio to the correct target and altitude—or be easily rerouted. The fresh fighters with full tanks of gas could then ambush the bombers and their fighter escorts near the end of their range after long over-water flights. This gave the defending fighters a great advantage in almost every encounter. As a result, the ratio of losses during the Battle of Britain (1940) ran against the Germans. The failure of the Luftwaffe to subdue the Royal Air Force was Nazi Germany's first major defeat of the war.

It was the improbable quest for a death ray that propelled Watt into his role in the creation of radar. In 1934, an Air Ministry committee tasked with the development of new technologies for air defense approached Watt and asked him to evaluate a proposal for the creation of a death ray to be used against aircrew. Watt then instructed his subordinate, Arnold "Skip" Wilkins, to calculate the power needed to raise eight pints of water from 98° Fahrenheit to 105° Fahrenheit, a fatal body temperature. Wilkins's figures demonstrated that the power demands of such a weapon made it impractical.

In February, 1935, Watt reported these findings in a memo, *Detection and Location of Aircraft by Radio Methods*. Watt claimed that while a death ray was not viable, a detection system based on radio echoes was feasible, if funding for research was provided. Watt's memo was one of the first items addressed by the newly created Committee for the Scientific Survey of Air Defense, unofficially called the Tizard Committee after the name of its chair, Henry Tizard. The Tizard Committee was to be a coordinator of scientific research, a facilitator of government funding, and a "cheerleader" with government leaders such as Winston Churchill. Through the Tizard Committee's support, a group of scientists, including Watt, were gathered to study what they called radio direction finding (RDF) and to create the machinery that would turn RDF from concept into what is now commonly called radar (an American acronym for "radio detection and ranging").

Detecting incoming aircraft was only half the battle. To make radar useful, a system had to be created to link radar with defending fighters. Air Marshal Hugh Dowding was a member of the Tizard Committee; in 1937, he authorized a series of field tests known as the Biggin Hill experiments. Biggin Hill was an RAF fighter base, and the experiments addressed how to couple radar detection of incoming aircraft with fighter planes. These experiments worked out how to use a centralized plotting team to analyze radar data to predict the target of incoming bombers and then communicate this data to airfields near the target in time to allow effective response. Forewarned defending fighters could rapidly scramble and be vectored directly to the oncoming bombers. This system appears complex, but offered the advantage of allowing defending fighters to be ready, rested, and fully fueled until the last moment—which was a very real advantage since the bombers would be fighting near the end of their radius of action. This system was unprecedented for its sophistication and unmatched by any other nation. Historians of World War II's aerial campaigns ascribe Britain's victory in the Battle of Britain to this radar-based system.

During and after the war, Watt portrayed himself as the innovator and leader of this effort, claiming, "I modestly believe myself to be the father of radar." Watt was central to this effort in part because he recruited a number of the talented scientists involved in the research. In addition, Watt was assigned increasingly important roles as the administrator of crucial research bodies such as the Radio Research Station; eventually, he became the director of communications development, a generically named position that disguised the military nature of his work.

While Watt styled himself as the "father of radar," there were many fathers. The Tizard Committee, for example, brought together scientists, engineers, and administrators such as Watt, Tizard himself, Wilkins, Edward "Taffy" Bowen, and Dowding. Each man's efforts contributed to the creation of Britain's multifaceted and effective air defense system. Parliament's funding resulted in the creation of a series of radar stations along the coast known as the Chain Home (CH) system.

While the CH system allowed Britain to be the first nation to deploy an effective and coordinated radar-based air defense system, other nations' scientists had also been aware of the use of radio waves to detect aircraft and had been working on their own versions of radar. What gave legitimacy to Watt's claims to be the "father of radar" was that he was one of the first to take out patents—albeit secret patents—on radar technology, and he ultimately headed a number of organizations that researched and developed the radar hardware used by Britain during the war. It was under Watt's direction, for example, that Taffy Bowen worked to create radar that would fit an airplane. While Watt's ideas and persuasiveness continued to drive radar research, some of the difficulties faced by the British were the unintended results of Watt's initial work. Watt's early storm-tracking apparatus worked best when the radar operated on the long wavelength of approximately 1.5 meters. Long wavelengths required huge receivers, and the CH stations stood over 200 feet high. Such large receivers could not be made mobile or be mounted in aircraft, so much of Bowen's efforts at creating an airborne radar set were focused on the creation of a radar set that would operate at centimetric wavelengths.

Both the Tizard Committee and the government recognized the importance of Watt's ideas and leadership, and in 1942 Watt was knighted. In response to his new station, Watt hyphenated his last two names and became Watson-Watt. With his promotion to the post of director of communications development, Watson-Watt controlled radar research throughout the war. It was in this position that he also was responsible for sharing British radar research with the Americans so that their research could be accelerated and their productive capacity could meet Britain's increasing demand for radar sets.

Impact

Watson-Watt's initial observations and ideas had been significantly enhanced by the work of a number of scientists, many of whom he had recruited. His enthusiasm and drive made him a booster of the technologies, while his self-serving efforts resulted in his holding a number of leadership positions in the British radar program. From these positions, he coordinated others' ideas, which resulted in such advancements as airborne mounted radar, radar navigation, and the sharing of radar technologies with the Americans. These advances, when tied to the initial radar-based air defense system, proved to be pivotal parts of the successful Allied aerial campaigns in World War II. Following the war, radar technologies were used in navigation, identification of airplanes for air traffic control, and eventually meteorological studies. In these capacities, radar has reshaped the world.

James Watt

Scottish mechanical engineer

Watt's improvements to existing steam engines, including the introduction of a separate condenser that allowed a faster rate of operation and a significant saving in fuel, revolutionized the mining and textile industries in England and the world in the late eighteenth and into the nineteenth century.

Born: January 19, 1736; Greenock, Renfrewshire, Scotland
Died: August 25, 1819; Heathfield Hall, Warwick, England
Primary fields: Manufacturing; mechanical engineering
Primary invention: Improved steam engine

Early Life

James Watt was born in a small Scottish fishing village, Greenock, on the Firth of Clyde on January 19, 1736, the fourth of five children. His paternal grandfather, Thomas Watt, was an instructor in navigational mathematics, and his father, James, was a carpenter, surveyor, merchant, shipbuilder, and town official. James senior married Agnes Muirhead, a woman from an old, distinguished family, with relatives at the University of Glasgow. The young James showed an interest in mathematics at an early age, but because of ill health, he was educated by his parents at home. He spent his spare time at his father's workbench, constructing models of various mechanisms in wood and metal. At the age of thirteen, James was sent to the village school, but at this time he did not show any propensity for genius.

When James was eighteen years old, he went to Glasgow to learn the trade of a mathematical instrument maker, but there was not a competent master craftsman in that town with whom he could pursue an apprenticeship. In 1755, he was advised to move to London, the seat of scientific instrument making, where he would find the proper instruction. He worked for a year with John Morgan, who charged James twenty guineas to teach him the trade, and returned to Glasgow intent on pursuing his new craft. Unfortunately, since he did not serve his apprenticeship in Glasgow, the trade guilds would not allow him to open a shop in the town. He was then employed by Dr. Robert Dick of the University of Glasgow to clean and repair several scientific instruments brought to the university from the West Indies.

Life's Work

As early as the seventeenth century, experimenters were working with steam apparatuses to achieve various purposes with varied results. In 1679, a French physician, Denis Papin, invented the pressure cooker, a steam-powered cooking implement that utilized the heat of steam under pressure to speed up the cooking of meat and vegetables. With modifications including the addition of a piston, Papin produced a rudimentary steam engine. Thomas Savery, an Englishman, developed a "fire engine" (1698) for raising water from mines. He was hampered, however, by the limits of the technology of that time, which did not allow the creation of a permanent vacuum that would produce the high boiler pressures necessary to raise water to a practical level in flooded coal mines. By 1718, John Theophilus Desaguliers had improved upon the Savery engine by designing a jet-spray head that introduced cooling water directly into the cylinder of this apparatus to initiate a vacuum more rapidly than had been possible before. In 1712, Thomas Newcomen, another Englishman, improved the Savery engine by designing a piston in an enclosed cylinder and a separate boiler that, along with other innovations, made this the most successful steam engine for raising water from mines up to that time.

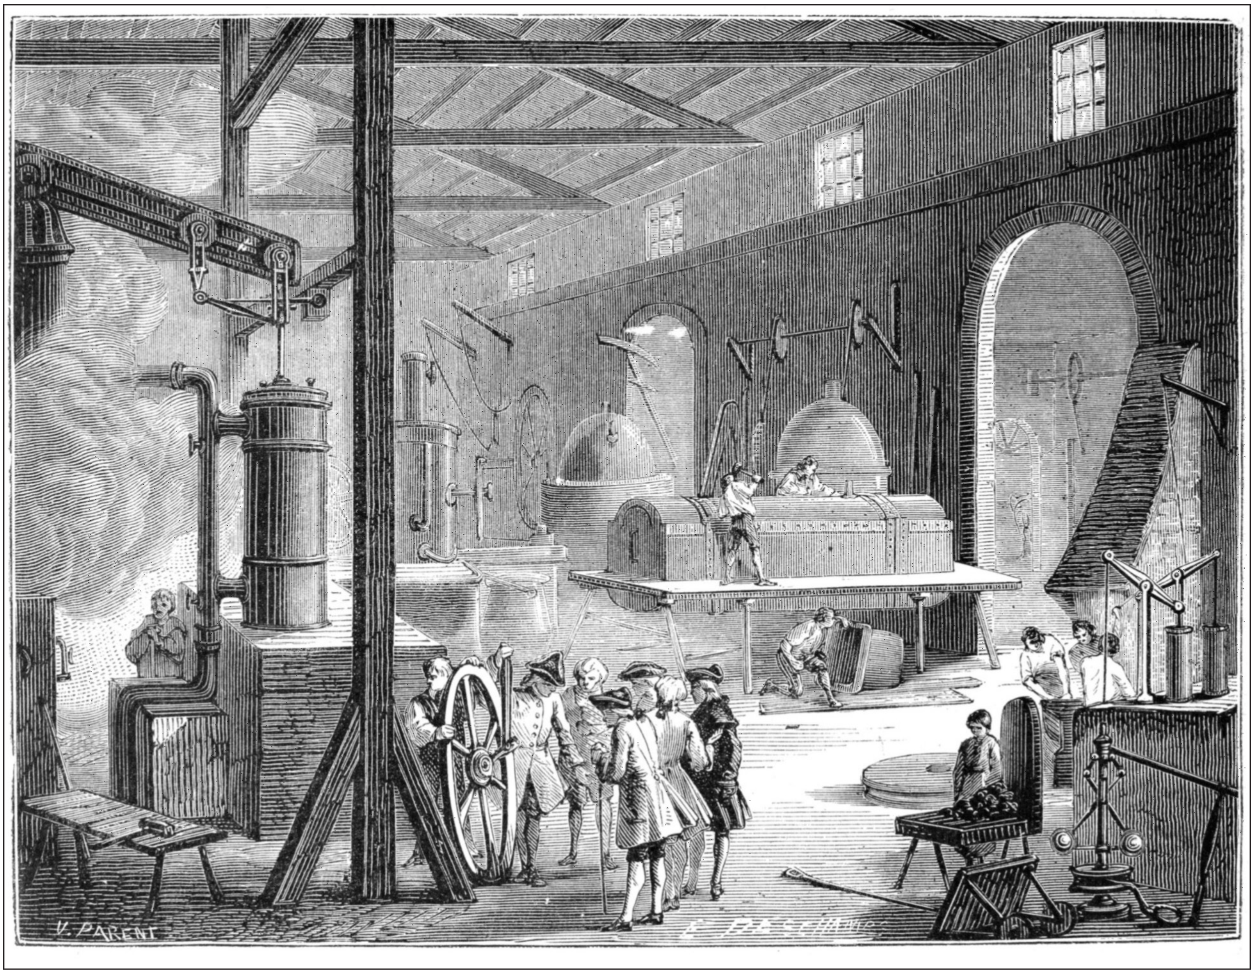
In 1763, Dr. John Anderson, professor of natural philosophy at Glasgow, assigned Watt the task of repairing a model of a Newcomen engine belonging to the university. By 1764, Watt had the machine in working order, but he was shocked at the amount of steam loss and fuel consumption due to the heating and then cooling of the cylinder. Watt had studied chemistry, was familiar with the work of Savery, Newcomen, and Desaguliers, and used this knowledge to continue experimenting and improving his engine. Soon, Dr. Joseph Black introduced Watt to John

The Improved Steam Engine

James Watt realized that to reduce the consumption of fuel, the cylinder of a steam engine must be maintained at a high temperature, but to achieve maximum power, the cylinder must be cooled down to produce a vacuum. The inventor, during a contemplative Sunday walk, hit upon the idea of a separate vessel, a condenser that would remain cool and into which the hot steam would be introduced. The cylinder with the piston would remain hot, a vacuum would be produced in the condenser with a pump to expel air, steam would rush in and condense, and the piston in the still-hot cylinder would be forced up. Watt constructed an experimental apparatus with a steam jacket around the cylinder that gave such good results that he decided to produce a full-size engine.

The first commercial-grade Watt steam engine with a fifty-inch cylinder was completed in 1776 and successfully put into service at the Bloomfield Colliery in Staffordshire, England. The engine consumed only about 25 percent of the fuel of a typical Newcomen engine and provided three times the power. The Matthew Boulton and Watt partnership charged a royalty to mine owners using their engines based upon one-third of the savings in fuel compared to the Newcomen engines then in service. Within a few years, improvements to the basic engine included a larger boiler, a more efficient plug rod connected to the horizontal beam to open and close the three main valves of the system, a more efficient stuffing box through which the piston rod passed, more insulation provided to the top of the cylinder, an improved internal water jet head to condense the steam and to create a vacuum below the piston, and a piston ring of tallow-soaked hemp to reduce leakage between the piston and the cylinder wall.

The partnership did not provide a ready-to-run engine to its coal mine customers. Rather, the client provided most of the material at his cost to build the engine, with the exception of the valves, and Boulton and Watt supplied the drawings and a construction supervisor to oversee the project. This arrangement was modified somewhat for textile mill operators. The firm of Boulton and Watt prospered over the next quarter century, earning wide recognition as one of the premier business concerns in Europe.



Soho Manufactory in Birmingham, England, where James Watt and his partner, Matthew Boulton, manufactured steam engines from 1775 to 1800. (The Granger Collection, New York)

Roebuck from Birmingham, the owner of the Carron Iron Foundry in Scotland.

In 1767, Roebuck agreed to assume Watt's debts in return for a two-thirds interest in the improved steam engine. The work on a new model proved so encouraging that Watt went to London in 1768 and successfully applied for a patent, which was granted the following year. In 1768, Watt returned to Scotland and built a large engine at Roebuck's house at Kimmeil with a cylinder of eighteen inches in diameter and a stroke of five feet. This engine showed promise, but the poorly bored cylinder leaked profusely, and Watt was not able to find a material that would provide a steam-tight seal around the piston. As a result, work on this engine stopped as Roebuck's financial situation steadily deteriorated.

Fortunately, while he was returning from London after submitting the patent application, Watt stopped in Birmingham and met the wealthy industrialist Matthew Boulton, the owner of the famous Soho Manufactory. Later, Boulton agreed to assume Roebuck's debts in return for the two-thirds share of Watt's invention, and in 1774 Watt relocated with his engine and his two young children to Soho. His wife, Margaret Miller, had died of a sudden illness several months before. The problem of the imperfect cylinder was solved when John Wilkinson of Bersham manufactured an improved boring machine and produced for Watt a nearly perfect product that did not allow steam to escape around the piston.

Boulton realized that the fifteen-year 1769 patent would expire before a profit could be realized, so he insisted that Watt apply for a patent extension. The extension was granted for a period of twenty-five years in

1775, giving the new partnership of Boulton and Watt a virtual monopoly on steam engines until the year 1800. The partners vigorously contested patent encroachments for the next twenty-five years.

Other inventions ancillary to the steam engine followed in rapid succession between 1775 and 1785: the sun-and-planet gear wheels that allowed for rotary motion in Watt's steam engines, the utilization of the expansive properties of steam, the double-acting steam engine, a counter that recorded the number of strokes that an engine made, the fly-ball governor, and the glass water gauge.

By 1800, both Boulton and Watt were aged, and somewhat feeble, but had grown quite wealthy from the royalties realized from their patents. By this time, the partners were ready to turn their business over to their two sons who had been groomed for years to assume the responsibilities of the enterprise. Boulton continued to participate in business ventures until his death at the age of eighty on August 17, 1809; Watt retired to his attic workshop at his home at Heathfield and for the remaining years of his life amused himself in tinkering with gadgets and being cared for by his second wife, Ann McGregor, a meticulous housekeeper who reputedly trained her two dogs to wipe their paws on a doormat before they entered the house.

As a result of his accomplishments, Watt was afforded numerous honors in his later years. He was elected a fellow of the Royal Society of Edinburgh in 1784 and a fellow of the Royal Society of London in 1785. In 1806, the University of Glasgow awarded him an honorary LL.D., and in 1814 the Académie des Sciences in Paris elected him as one of its only eight foreign associates.

Watt was sickly for most of his working life. However, when he retired, his health slowly improved, and he enjoyed good health until one month before his death at Heathfield, on August 25, 1819. A marble statue of Watt was erected in 1824 in Westminster Abbey, a fitting tribute from the people of England who owed him so much.

Impact

Watt did not invent the steam engine. The previous inventions of Savery and Newcomen were not efficient because of the large amount of fuel they consumed, but they laid the foundation for the improvements that Watt initiated after years of experimentation. With Watt's idea that a separate condenser would save fuel costs, the stage was set for the production by his partnership of more than five hundred steam engines that revolutionized the conversion of heat energy to mechanical power. Watt's steam engine became the major power source around the world during the nineteenth century. It was used in manufacturing and transportation, both on land and on the ocean. The success of the British textile industry was due, in large part, to the dependable power provided by the rotary motion of steam engines. For the first time in history, mills could be located away from the undependable water-power sources of rivers and streams.

The theory behind steam power was not fully understood in the early days of the construction of the first steam engines. Only over the course of many years of trial and error were the most economical fuel and pressure settings discovered by the members of that newest profession, the engineers. Steam engines were replaced after two hundred years of service in factories by electric motors, but since electricity is still produced by steam turbines and generators, it is fair to say that steam power is still very much a part of the modern world.

George Westinghouse

American engineer

Westinghouse's invention of dependable braking systems for trains, controlled from the locomotive by the engineer or from railcars by conductors, brought him recognition and enormous wealth. Westinghouse received patents for 361 inventions during his career, and by the beginning of the twentieth century he had organized more than fifty companies, thirty of which he served as president.

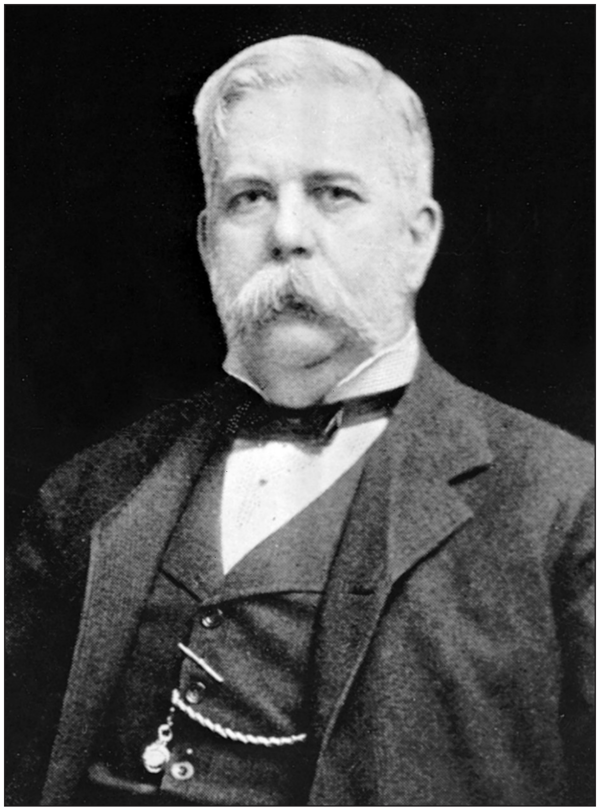
Born: October 6, 1846; Central Bridge, New York
Died: March 12, 1914; New York, New York
Primary fields: Manufacturing; railway engineering
Primary inventions: Railway air brakes; railway signaling system

Early Life

George Westinghouse was a restless child, hard to control and given to tantrums. He was an inattentive student whom his teachers considered lazy and virtually unteachable, although he demonstrated ability in mathematics and freehand art. The seventh of ten children born to George and Emmeline Vedder Westinghouse and the second youngest of the eight who survived, George was reserved and solitary, living in his own world, the often misunderstood world of the active imagination.

George, Sr., was a resourceful farmer who taught himself carpentry and understood how things worked mechanically. He ran a farm machinery repair shop where he manufactured machines to increase the efficiency of planting and of harvesting crops. He held patents for seven of the implements he invented. In 1856, the Westinghouse family moved to Schenectady, New York, where George, Sr., expanded his repair shop under a new name: George Westinghouse and Company. His shop prospered, and the family became comfortable financially. During the summer of 1859, George, Jr., working in his father's shop, developed a rotary engine for which he obtained a patent at age fifteen. George, Sr., assigned his son many menial tasks, such as sweeping the shop's floor.

One day, when the men working in the shop were permitted to go home, George, Sr., assigned his son the seemingly meaningless task of cutting a huge pile of metal pipes into equal lengths. George, Jr., who probably wanted to end his day and go home as the other workers had, knew better than to complain. He did the next best thing: He used his mechanical skill and imagination to complete the task expertly. Although it would have taken several days to finish this job had George taken each length of pipe, measured it, and cut it to specification, he invented a method using a steam-powered lathe to do the



George Westinghouse. (NARA)

job in a couple of hours and with such precision that each length of pipe was virtually identical to the others.

When the Civil War began in 1861, Westinghouse, lying about his age, joined the Union Army, but when his deception was uncovered, he was sent home. In 1863, now old enough to serve, he enlisted in the Army. After a year, Westinghouse, at his own request, was reassigned to the Navy as an assistant engineer on two ships assigned to enforce the blockade of southern seaports. Returning from the war, Westinghouse enrolled in Schenectady's Union College, acceding reluctantly to his father's wish that he continue his formal education. Totally bored by the experience, he dropped out after three months and embarked on his life as an inventor.

Life's Work

In 1867, back in Schenectady, Westinghouse married Marguerite Walker, with whom he had one child. Pursuing his interest in rail transportation, he invented a device that could set derailed trains back on the track. He also invented a railway switch that was more durable than previous switches. By 1868, Westinghouse had moved to Pittsburgh after abortive attempts to market these new devices. By the following year, however, he had invented an air brake system for railways that was vastly superior to the unwieldy braking systems then in general use. Westinghouse was granted a patent for the air brake on April 13, 1869.

A savvy businessman, Westinghouse subsequently established the Westinghouse Air Brake Company. Although he continued to produce air brakes and to work on a variety of other inventions, his monumental fortunes were not assured until 1893, when the United States Congress passed the Railway Safety Appliance Act mandating the use of air brakes on all railway cars in the United States.

Having created means by which American railroads could operate more safely and faster, Westinghouse now turned his efforts to perfecting remotely controlled railroad signaling and switching devices. He acquired patents that he combined with his own inventions to improve devices in these areas. In 1881, he established the Union Signal and Switch Company to manufacture signaling and switching devices and to accommodate railroads hungry for such advanced and sophisticated implements.

Early in the 1880's, Westinghouse found that his electrical signaling and switching devices worked better on alternating current (AC) than on direct current (DC). Direct current could be used only within a radius of two or three miles, whereas alternating current could be transmitted over considerable distances. Westinghouse's claim ran counter to that of Thomas Alva Edison, who considered alternating current dangerous.

Railway Air Brakes

Central to George Westinghouse's prominence as both inventor and businessman was his invention of greatly improved air brakes that eventually, through an act of Congress, were required on all railway cars in the United States. Previous braking systems required that brakemen engage a train's brakes individually for each railway car. Westinghouse's invention enabled the locomotive engineer or the conductor to engage all of the brakes simultaneously and bring their trains to a halt.

Whereas many early trains consisted of few cars and operated over relatively flat surfaces, later trains could consist of dozens of cars and often were operated in mountainous areas, making it essential that they could be stopped quickly to prevent collisions and possible derailments. Initially a straight air system was employed. In this system, compressed air is released to push on a piston housed in a cylinder. Through its connection with pistons on other railway cars, pressure is exerted on each car's brakes, creating the friction needed to reduce the train's speed dramatically and quickly. The mechanical connection thus achieved distributes the force from one cylinder to many wheels. The pressurized air required for such an operation is supplied by an air compressor housed in the locomotive and controlled by the engineer. It is sent from its source to all of the train's cars through pipes installed beneath each carriage and connected to other railway cars through hoses that join them. The only significant problem with such a system is that if the hose connecting the cars become disconnected, the pressure needed to apply friction to the brakes can be lost, resulting in derailment or collision.

Westinghouse addressed this problem by inventing a control valve for railway cars. It consisted of three parts: a diaphragm-operated feeding reservoir to feed compressed air to the brake cylinder, the reservoir charging valve that assures equalization of pressure, and the brake cylinder release valve that is engaged when a train's speed has to be reduced or when the train has to be brought to an immediate stop. This system uses a decrease in air pressure on the train line to engage the brakes. The engineer can thereby control from the locomotive the braking system for an entire train, which makes it unnecessary for railways to hire a cadre of brakemen to engage individual braking systems for each railway car.

Westinghouse, however, developed a meter that greatly reduced the danger from alternating current. He also invented a similar meter that took much of the danger out of the transmission of highly explosive natural gas. Despite this, much of the public sided with Edison, who was regarded as the elder statesman in matters involving electricity.

When the state of New York reached the decision to punish those condemned to death for committing capital crimes by electrocuting them, it mandated that the state's electric chair should operate on alternating current, which was used in 1890 when William Kemmler became the first person to be executed in this manner. Nevertheless, in time it became evident that alternating current was more practical, in most situations, than direct current.

As early as 1882, when Westinghouse learned that Lucien Gaulard and John D. Gibbs had developed AC generators and transformers to regulate the voltage of alternating current, he bought their patents and studied their implements extensively. In 1884, he established the Westinghouse Electric Company, a corporation that manufactured a variety of electrical devices powered by alternating current. It took seven years for Westinghouse to perfect an induction meter that would enable alternating current to be used domestically and safely.

Westinghouse was a visionary who realized the potential of electrical power. Earlier than most of the scientists and inventors of his day, he knew that the limitations of direct current would severely impede its practical application. Realizing that alternating current posed safety problems, he set about finding a means to control these problems.

Westinghouse employed Nikola Tesla and other eminent scientists and inventors to help him build safe AC motors so that high-tension current could be transmitted in a carefully controlled and safe manner. With a virtual stable of such high-powered inventors, he set about harnessing the hydroelectric power of Niagra Falls, which produced enough power for the whole of Buffalo, New York.

The Westinghouse Electric Company's chief competitor was the General Electric Company. Westinghouse was clearly the more inventive company. In 1896, General Electric reached an agreement to use many of Westinghouse's patents. By the dawn of the twentieth century, the Westinghouse Electric Company was among the preeminent corporations in the United States, with a workforce exceeding fifty thousand. The company continued to prosper until 1907, when a nationwide financial panic threatened the U.S. economy, forcing Westinghouse Electric into bankruptcy, from which it emerged the following year. George Westinghouse was deeply shaken by this event. In 1911, now sixty-six years old, he ended his direct association with the company.

During his last three years, Westinghouse devoted himself to public service endeavors. The directors of the bankrupt Equitable Life Assurance Society enlisted Westinghouse's help to save their company. Working feverishly to bring this corporation back from bankruptcy, Westinghouse, by the time he died, had transformed it into the vibrant company it had been before its collapse.

Impact

Westinghouse is at the forefront of legions of inventors and scientists who transformed American society in the last half of the nineteenth century from agriculture to industry. It would be difficult for anyone living in the twenty-first century to go through a day without being in some way affected directly by several of the innovations Westinghouse brought to the public.

Although the automotive industry was in its infancy, Westinghouse experimented with air springs to use in automobiles and received patents for such devices. He continued to experiment with steam turbines as generators of electrical power.

Without the advances he made with electricity, the space age would have been impossible. On a practical level, rail transportation of both freight and passengers was greatly enhanced by Westinghouse's invention of air brakes and of signaling devices.

Ever mindful of safety, Westinghouse assessed problems relating to the distribution of electricity and natural gas and set out to overcome these problems. The meters he developed to control the flow of such energy resulted in the safe distribution of these energy resources domestically and industrially.

Westinghouse's impact upon American society was broadly recognized and honored. Although he is said to have spent only a year and a half in school after age thirteen, he was the recipient of many honorary doctoral degrees, including one from Union College, where, during 1866, he had spent three months as a student before dropping out.

Don Wetzel

American computer programmer

Wetzel conceptualized and helped design the first successful automated teller machine (ATM). Though other ATMs had been developed before the Wetzel ATM, he developed the management ideas that made the invention a success, showing banks how to generate a population of clients who used the machines.

Born: 1928; New Orleans, Louisiana
Also known as: Donald Claude Wetzel (full name)
Primary field: Mechanical engineering
Primary invention: Automated teller machine (ATM)

Early Life

Donald Claude Wetzel was born and reared in New Orleans, Louisiana. He attended Jesuit High School and was the star shortstop on the baseball team. He played professional baseball in the New York Giants farm system for three years while attending the University of Loyola in New Orleans. He graduated in 1951 with a bachelor's degree in foreign trade and was offered a job at Service Bureau Corporation, a subsidiary of International Business Machines (IBM). Realizing that he would not make the major leagues, he accepted the position. The company processed data such as payroll, accounts receivable, and sale analyses for companies that did not have IBM machines. Wetzel worked five years in New Orleans before moving to Fort Worth, Texas, to become a branch manager. After several years, he became a systems engineer in San Antonio. Before computers, he was the person to wire the panels, write the procedures, and train the personnel. After computers became available, he started programming. In 1958, he moved to sales, and in 1960 he became a "special representative" for IBM. His duties centered on assisting salesmen in securing orders with banks. In 1963, he moved to Houston as a sales manager responsible for five industries: financial, insurance, communication, utilities, and transportation (FICUT). In 1968, IBM wanted Wetzel to move to New York, but he instead accepted a job as vice president of product planning with the Docutel Corporation in Dallas, the company that developed automated baggage-handling equipment.

Life's Work

While standing in line at a bank, Wetzel realized that a machine could do almost all the tasks of a teller. Mentioning this at one of the weekly company meetings, Wetzel received enough encouragement to generate a feasibility study. The company had to know how many machines could be sold and how many people would use them. Docutel convinced a University of Dallas graduate program to do a study as well. The studies found that people preferred speed and convenience to personal, face-to-face service. With these positive studies, a proposition was made to the board of directors of Recognition Equipment, Docutel's parent company. The board agreed to invest $4 million in the development of an automated teller machine (ATM).

To be a stand-alone (offline) machine—that is, having no communication with the bank's computer system—the ATM needed some information about the client before it could dispense money. A data card similar to a credit card was used by the client to provide information to the machine. In addition to the card reader, the machine needed two others parts: a cash dispenser and a printer to make a record of the transaction for the bank and a copy for the customer. Similar devices had already been developed, but Wetzel and the development team had to produce or significantly modify each device for the teller machine.

The first ATM was installed at New York's Chemical Bank, which had loaned money to Docutel. The bank advertised that it would open on that morning in September, 1969, "and never close again": Since there was an ATM open twenty-four hours a day, seven days a week, it would be as if the bank were always open. Though the first machine was only a cash dispenser (the full-service teller machine was a few years in the future), it was a success. Banks began to buy and advertise ATMs, and qualified bank customers received ATM cards. At one time, Docutel had so many orders that it did not have enough money to buy all the supplies needed to build the machines.

In 1973, a patent for the machine was issued to Wetzel, Tom Barnes, the mechanical engineer, and George Chastain, the electrical engineer. They had started plans for a full-service teller machine when Wetzel resigned from the company to be able to spend more time with his family. His first wife, Gladys, died of cancer in 1970. In 1972, he married Eleanor, a widow with eight children. With his four children and her eight all at home, Wetzel decided that his job at Docutel required too much travel. That year, he started his first business, Financial Systems and Equipment. He became a manufacturer's representative for all kinds of bank equipment except computerized equipment. The company was a success. In 1978, Wetzel and another former Docutel employee started Electronic Banking Systems (EBS), a consulting business for banks in the ATM business. According to Wetzel, EBS was the first company to place ATMs in supermarkets. The ATMs by this time were full-service machines connected to the bank's computer. EBS would buy an ATM and program it to charge a small fee for each transaction, and EBS and the supermarket would split the money. The company was so successful that it was bought out by Docutel in 1984. Part of the terms of the sale was that Wetzel and his partner would work for Docutel for a period of time.

In 1979, Wetzel started a third company, Autosig Systems, which sold electronic signature verification systems. Wetzel retired in 1989, although he remained on

The Automated Teller Machine

The ATM was developed by Don Wetzel and the Docutel Corporation and was first installed at a bank in 1969. The ATM had three main components: the card reader, the cash dispenser, and the printer. The card reader read the bank-issued card that contained the customer's data, including checking, savings, and credit card account numbers, the bank's routing and transit number, and the number of times per day that the card could be used. All this data was placed on a magnetic strip on the data card. It was encrypted so that no one could read the magnetic strip without the encryption codes. A client could withdraw a certain amount of money with each transaction and only so many times per day. Wetzel and his team had to build a module to be placed inside the machine that would rewrite the magnetic code each time the card was used. Then they had to design a module to produce the cards for the banks to replace lost cards.

Designing the cash dispenser was a greater issue. The dispenser had to give out the right amount of money, so it had to dispense one bill at a time. Also, engineers had to ensure that the dispenser would not jam, else the machine would record a transaction though the customer would not get money. It was determined that the cash had to be new or almost new, fairly crisp bills for the dispenser to work correctly and continuously.

The printer had to print a record of the transaction, including the account number, amount of money withdrawn, date, time, and the bank's routing and transit number, as well as make a copy for the customer. The bank's copy had to be written so that the bank's mainframe computer could read the transaction. Numbers printed on paper with normal ink were not readable by a computer, so the transaction record had to be written in magnetic ink character recognition (MICR) format. The MICR format was developed for the processing of checks. Besides having a certain font, the characters were printed with an ink that contained magnetic particles, usually iron oxide. The printer could not only print the transaction record correctly every time for both bank and customer but also print the bank copy in the MICR format. This feature made the printer more sophisticated than was originally anticipated.

All the parts were fit into a mechanical box whose stainless steel frame was ⅝ inch thick. This frame provided sufficient security: It would have taken several hours for a thief using a blowtorch to cut into the box to steal the money. In addition, heat sensors were installed on the machine to melt any ice that formed there.

the board of Autosig Systems. In 2003, Jesuit High School recognized him as alumnus of the year.

Impact

Wetzel helped change the way people bank. Wetzel and Docutel's studies indicated that bank customers preferred speed and convenience over face-to-face service, and Wetzel met this demand with the automated teller machine. Instead of entering the bank, customers can go to an outside ATM and deposit or withdraw money, pay the mortgage, or transfer money from one account to another at any time, twenty-four hours a day, any day of the week. Between 1995 and 2008, the number of ATMs in the United States grew from 187,000 to 406,000.

Charles Wheatstone

English physicist

Wheatstone was a prolific inventor in the fields of acoustic and electric technology. He is best known for his invention of new musical instruments and his contributions to the development of telegraphy.

Born: February 6, 1802; Barnwood, Gloucestershire, England
Died: October 19, 1875; Paris, France
Also known as: Sir Charles Wheatstone
Primary fields: Communications; music; physics
Primary inventions: Enchanted lyre; electric telegraph

Early Life

Charles Wheatstone was the second of four children and the younger son of William Wheatstone, a shoemaker, and his wife, Beata. In 1806, the family moved to Pall Mall in London, where the elder Wheatstone became a music teacher; his pupils included Princess Charlotte. Charles attended several private schools, finding the experience uncomfortable because of his chronic shyness. At the age of fourteen, he was apprenticed to his uncle, also named Charles Wheatstone, who had a business in the Strand manufacturing musical instruments. The young Charles found that experience as uncongenial as school and returned home, immersing himself in books—including a treatise on electricity by Alessandro Volta, which he translated from French with the aid of a dictionary.

Wheatstone's brief experience of working with his uncle cultivated a fascination with acoustic science and made a considerable impression when he exhibited an "acoucryptophone," or "enchanted lyre." The instrument suspended from the ceiling played by itself as if by magic, though it was actually resonating with the sounds (transmitted by wire) of musical instruments played in another room. The idea occurred to him of using electrical wires to carry signals over much longer distances, making broadcast music possible. Though it never came to fruition, the idea inspired him to coin the term "telephone" to describe such a device. His coinage "microphone," describing a device for augmenting feeble sounds—what would nowadays be called an amplifier—also failed to catch on.

When Charles Wheatstone the instrument maker died in 1823, his nephew William took over the business, and the young Charles returned to the Strand, apparently feeling able to work with his older brother. He published a paper in the *Annals of Philosophy* on his early experiments with sound, and he developed a "kaleidophone," in which a bead suspended on the end a steel wire was caused to describe elaborate patterns of movement in harmonic response to different patterns of vibration in the wire. In 1825, he designed a mouth organ whose reeds were controlled by a small keyboard. On June 19, 1829, Wheatstone took out one of his very few patents, on a bellows-driven concertina, which remained a familiar instrument throughout the twentieth century. He also developed a portable harmonium, which won him a prize at the Great Exhibition of 1851.

On the basis of his experiments in acoustics—and his first significant contribution to acoustic theory, published in the *Philosophical Transactions of the Royal Society* in 1833—Wheatstone was offered the post of professor of experimental philosophy at King's College in London. This proved to be a crucial career move; as a lecturer, he was a disaster, unable to adapt to public speaking, but he made very productive use of the college's laboratory facilities, becoming one of Great Britain's first notable academic research scientists.

Life's Work

In 1835, Wheatstone read a paper on "The Prismatic Analysis of Electric Light" to the annual meeting of the British Association for the Advancement of Science. The paper paved the way for a means of detecting minute proportions of metals in alloys by the spectroscopic analysis of electric sparks. The method, deployed by other researchers, ultimately revealed the existence of the previously undiscovered metals rubidium and thallium and helped astronomers determine the composition of stars. In 1836, he was elected a fellow of the Royal Society. In 1838, he discovered the principle of stereopsis, or binocular vision, and invented a stereoscope to combine two-dimensional pictorial images so as to give an impression of depth. Wheatstone's stereoscope, which used mirrors as well as lenses, was subsequently simplified by David Brewster. Wheatstone also invented a "pseudoscope," which had a contrary effect, making three-dimensional objects seem flat.

Like many other researchers, Wheatstone began experiments in telegraphy when the machine developed by Baron Pavel Schilling was widely demonstrated in 1836. On February 27, 1837, Wheatstone met another researcher in that field, William Fothergill Cooke, and was persuaded to go into partnership with him. Wheatstone, as an academic researcher, had intended to make the results of his own work freely available, but Cooke wanted to make a fortune. When Wheatstone had solved the problem of long-distance transmission, the partners were able to produce their first workable system, patented on June 10, 1837.

The first Cooke-Wheatstone telegraph used five signaling needles to set up sufficient signal combinations to encode the twenty-six letters of the alphabet. They developed a two-needle model in 1838, but it was still too cumbersome to be economically viable. The American inventor Samuel F. B. Morse had been a year behind them in filing his initial patent, but his rapid adoption of a binary code developed in Germany by Carl August von Steinheil enabled him to develop a single-needle system first. It was not until Cooke and Wheatstone began using a single-needle apparatus in 1845 that their system be-

The Enchanted Lyre

There is no single invention whose description can summarize the awesome breadth of Charles Wheatstone's achievements. Still, his acoucryptophone (Greek for "hearing a hidden sound"), better known as the enchanted lyre, offers eloquent testimony to his inventive ingenuity.

The principle of sonic resonance had been known for more than two thousand years, but the idea of using a wire to transmit the sonic impulses required to produce sounds—including pieces of music—at a distance had not occurred to anyone before Wheatstone produced his seemingly magical instrument. In September, 1821, at the age of nineteen, he demonstrated his acoucryptophone at his father's shop in Pall Mall, London. A replica of an ancient lyre was suspended from the ceiling by a brass wire that connected to the soundboards of instruments—a harp, piano, and dulcimer—being played in the room above. To visitors, the lyre appeared to play on its own, though it was in fact just a sounding box. Wheatstone's device attracted attention from scientific circles and the general public. Although it was a simple device, primarily interesting as an amusement, the enchanted lyre demonstrated how sound waves travel more readily through solids than air.

came economically viable. It was then quickly adopted by all the railway companies in Britain. In 1841, however, Cooke and Wheatstone had fallen out over the question of who was primarily responsible for the invention. The matter was referred for arbitration to Sir Marc Isambard Brunel and Professor John Frederic Darnell, whose carefully mediated decision that Wheatstone and Cooke were equally responsible satisfied neither of the contending parties.

The argument between Cooke and Wheatstone flared up again when Cooke set up the Electric Telegraph Company in 1846. A parliamentary commission had to be appointed to sort out various claims for compensation, including one from Alexander Bain. Cooke's patents were eventually bought by the company for £120,000, while Wheatstone only received £33,000; Wheatstone then refused to have anything further to do with the company. The dispute heated up again when Cooke published a combative pamphlet in 1854 entitled *The Electric Telegraph: Was It Invented by Professor Wheatstone?* Wheatstone's reply prompted further assertive publications from Cooke.

In the meantime, Wheatstone continued to produce new devices for use in the context of telegraphy. In 1840, he developed a dial telegraph; in 1841, a type-printing telegraph. He also developed an automatic transmitting and receiving system independently of Cooke. Wheatstone became very interested in submarine telegraphy and conducted a significant series of experiments in Swansea Bay in 1844 with the collaboration of J. D. Llewellyn. He also worked in cryptography, developing a cipher that he named for his friend Lord Playfair; the Playfair cipher was still in use by the British army in World War II, although a method for cracking it had been developed earlier in the twentieth century.

Wheatstone's work in other fields included contributions to the development of the electrical generator, including the combination of armatures so as to produce a continuous current. He developed several devices for managing electrical resistance, including the rheostat. Ironically, the Wheatstone bridge for measuring and balancing electrical currents was only rediscovered by him in 1843, having been invented by Samuel Hunter Christie in 1833. Wheatstone also developed an ingenious method of measuring the velocity of electricity in a wire, using a spark gap and a rotating mirror, but obtained the wrong result, producing a figure in excess of the velocity of light. The "chronoscope" he invented in 1840, which measured minute intervals of time, proved more successful. A "polar clock" he invented for measuring time by the Sun, even when the Sun was obscured by cloud, was of little practical value but was also ingenious.

On February 12, 1847, Wheatstone married Emma West, the daughter of a Taunton tradesman, in Christchurch, Maylebone; they had two sons and three daughters. Although the flow of his inventions abated somewhat thereafter, his reputation continued to grow, especially among fellow scientists who thought that he had been shabbily treated by Cooke. He received honorary doctorates from the universities of Oxford (1862) and Cambridge (1864). He was knighted on January 30, 1868, a year ahead of Cooke. His reputation was international, and he was highly regarded in France. He was appointed a Chevalier of the Legion of Honor in 1855 and became a foreign associate of the French Academy of Sciences in 1873. He was in Paris when he died during an attack of bronchitis in 1875, but his body was shipped home so that he could be buried in Kensal Green Cemetery. Although Cooke made far more money in telegraphy than he did, Wheatstone managed his rewards much more wisely; he left an estate worth £70,000, while Cooke—like Alexander Bain—died penniless.

Impact

Wheatstone's achievements were somewhat confused, and perhaps blighted, by disputes over priority. It was inevitable, however, when electrical science was in its infancy and hundreds of researchers were working on the same conspicuous problems, that different researchers would make similar discoveries independently. His reputation outshone those of his detractors in his own day, and most subsequent historians have sided with him for two reasons. First, he was a shining example of zeal and skill in turning scientific theory into practical technology on a prolific and wide-ranging scale. Second, and perhaps more important, he never set out to exploit any of his discoveries commercially with the kind of ruthlessness that William Fothergill Cooke demonstrated; he was interested in discovery for its own sake and was always as ready to lend his work to others as he was to borrow from them. The manner in which he used the opportunities provided by his professorship at King's College provided an important new model of the raison d'être of academic scientists.

Eli Whitney

American mechanical engineer and manufacturer

Whitney is credited with inventing the cotton gin, a machine that separated cottonseed for the short-staple cotton fiber. He is also credited with devising a method by which muskets could be manufactured with interchangeable parts.

Born: December 8, 1765; Westboro, Massachusetts
Died: January 8, 1825; New Haven, Connecticut
Primary fields: Agriculture; military technology and weaponry
Primary inventions: Cotton gin; musket manufacture using interchangeable parts

Early Life

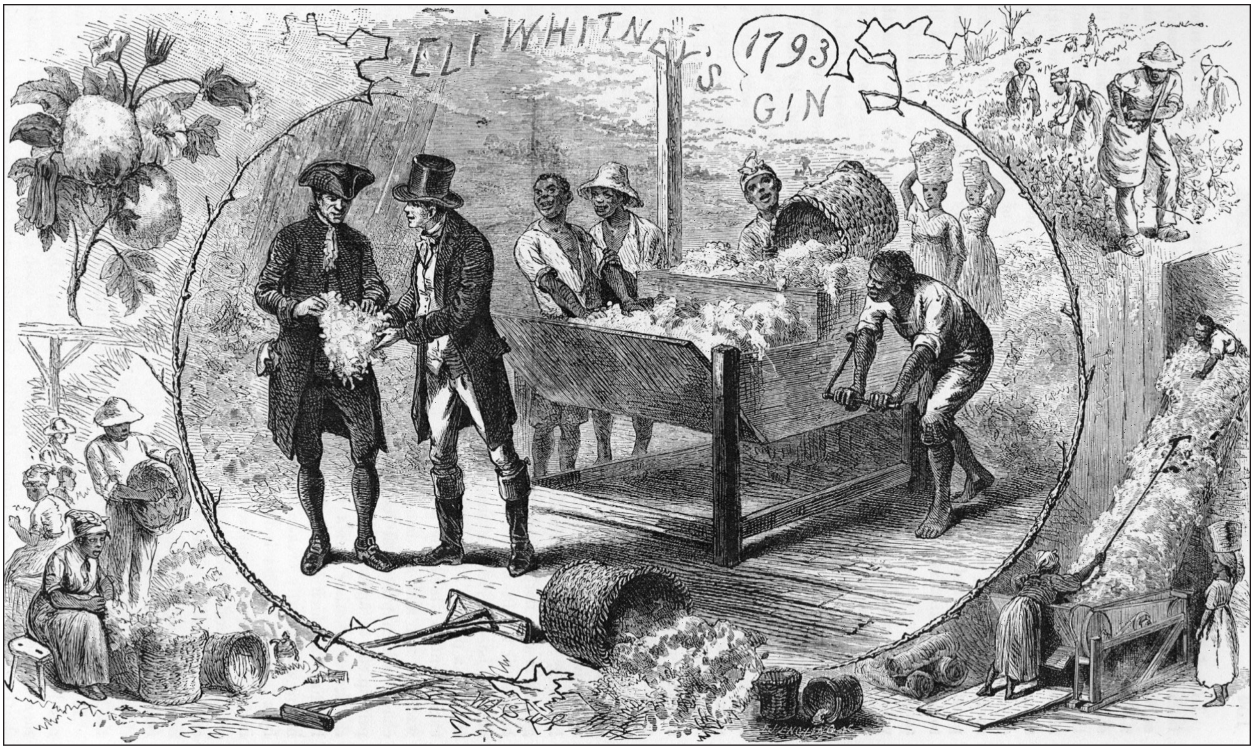
Eli Whitney was born on the family farm in Westboro, Massachusetts, in 1765. As a young man, he worked on the farm and as a blacksmith. When Whitney was fifteen years old, his father purchased tools for him that the boy used to build a nail-making machine. Later, Whitney made hat pins and walking sticks. While he was discouraged from going to college, Whitney saved money he made from the profits of the product he sold and from the income he made teaching in a village school. At the age of twenty-three, Whitney moved to Durham, Connecticut, to be tutored by the Reverend Elizur Goodrich. In May, 1889, Whitney was accepted to Yale University. Three years later, he graduated Phi Beta Kappa from Yale.

Whitney obtained a job as a private tutor in Georgia. Before moving there, he was inoculated against smallpox, but he contracted a severe case of the disease. When he finally traveled south, he met Catherine Greene, the widow of Revolutionary War hero Nathanael Greene. She invited him to stay at her plantation near Savannah while he recovered from his illness. It was there that Whitney's career as an inventor began to develop.

Life's Work

When Whitney moved south, cotton was not a major American commodity. Most cotton was grown in India and manufactured into products in England. These products were then imported to the United States, where they were considered luxuries. Cotton production was also a labor-intensive process. It took a worker approximately one day to separate one pound of short-staple cotton from seeds.

Whitney, working with plantation manager (and fellow Yale graduate) Phineas Miller, set up a workshop for the purpose of creating a machine that would separate the cotton staple from its seed. By 1793, Whitney had invented a cotton engine, or cotton gin, that accomplished



Eli Whitney's cotton gin not only made cotton production more efficient but also led to increased demand for slave labor in the American South. (C. A. Nichols & Company)

this feat. Whitney received a patent for his invention on March 14, 1794. He then created a business partnership with Miller and moved back to New Haven, Connecticut, to set up a factory to manufacture the machines. Their original plan was to establish their own ginning mills throughout the South where demand existed and to charge farmers for cleaning their cotton. Within the factory, Whitney utilized an approach whereby each worker would make only one part of the gin, such as the crank or the spindle, in order to assemble them faster. However, he encountered numerous problems in the manufacturing process ranging from a lack of skilled labor to a lack of materials such as wire. As a result, the partners were unable to keep up with the demand for the machines. In addition, patent infringement became a major problem, and within two years there were two variations of Whitney's cotton gin being produced and sold by others. Finally, in March, 1795, Whitney's factory was destroyed by fire, and within two years his cotton gin manufacturing company was out of business. Whitney finally secured a legal ruling in 1807 that protected his patent, but it was too late to save his business. In 1812, he was denied a patent renewal for his invention.

Whitney's next manufacturing venture entailed the production of firearms. Until 1797, the U.S. Department of War had armed its military with weapons left over from the Revolutionary War. At that time, gun making was considered a complex craft, with each gun being produced by a single craftsman. Production was slow, and the best American arms producers had never built more than three thousand muskets per year. Despite the fact that he had never manufactured firearms, Whitney bid on a contract to supply forty thousand muskets to the Department of War. In January, 1798, he received a contract to produce ten thousand muskets. Under the terms of the contract, Whitney was to deliver four thousand muskets within one year and the other six thousand within two years.

Whitney then built a firearms factory at Mill Rock, Connecticut, where he had purchased a grist mill in order to have running water for his machinery. Using his experience with the cotton gin plant, he set up a new manufacturing process using water-driven machinery, a division of labor, and interchangeable parts for the muskets. This approach to arms production was revolutionary, and Whitney did not initially grasp or appreciate the implications of utilizing this new manufacturing technique. He experienced numerous problems tooling up for this new process, and he had to design and make much of the machinery for his factory himself. He also had to train his own labor force to use this new equipment and technique. In addition, he had to develop a method for contracting supplies and having them delivered in advance of their need for the production process. As a result, Whitney did not meet his contractual deadline.

In 1801, Whitney persuaded President John Adams and the military that his innovative system of manufacturing uniform parts would work. He was granted an extension on his contract. While production was slow, Whitney delivered the last of the ten thousand muskets in January, 1809, ten years after the initial contract was drawn.

Whitney died on January 8, 1825. His factory continued to be operated by his nephews. In 1841, his son, Eli Whitney, Jr., graduated from Princeton University and assumed control of the factory. He soon received a contract from the federal government to manufacture twenty thousand rifles. Later, he manufactured the Whitneyville Walker Colts for the Texas Rangers. Over time, the factory was used by a variety of industries. In 1979, the Eli Whitney Museum and Workshop was established as a nonprofit historical site in New Haven, Connecticut.

Impact

Whitney is best known for his invention of the cotton gin. This invention had a tremendous impact on the economic, political, and social life of the United States, both North and South. As a result of this invention, cotton became the most important crop in the agricultural economy of the South. There was a ready market for cotton in Europe, and this resulted in the growth of the textile industry in New England. Finally, the increased demand for cotton resulted in an increased demand for slaves to grow the crop, and the economy of the South became more dependent on a slave-based system. Politically, the divisions between North and South increased as cotton became king and slavery became more entrenched, eventually leading to the Civil War.

Whitney also made significant contributions to the manufacturing process in the United States through other inventions and innovations. He invented the filing jig, which guided the worker's file. He designed a stencil with as many as twelve holes, which helped bore in exact places. He developed mechanical stops for his lathe to ensure that pieces were precisely turned. He also built the first milling machine, which precisely shaped metal parts, and he developed gauges in order to assure the uniformity of parts. Whitney not only built the tools but also developed the machines that used water to power the tools. His use of interchangeable parts revolutionized the small-arms industry, and, over time, these production techniques were applied to many different objects made of metal moving parts. These included bicycles, clocks, watches, sewing machines, typewriters, and, in the twentieth century, the automobile. Whitney's inventions and

The Cotton Gin

Eli Whitney was an inventor, innovator, and entrepreneur in the manufacturing process in the United States. He is credited with the invention of the cotton gin, a device that had a significant impact on American history and politics. While Southern planters could easily separate long-staple cotton from its seeds, that cotton could be grown only along the immediate coastal region of the country. Short-staple cotton, which was grown inland, had sticky seeds that were difficult to separate from the cotton bolls. The cottonseeds had to be removed by hand. The cotton gin Whitney invented in 1793 was the first device able to clean the short-staple cotton. This machine consisted of spiked teeth mounted on a boxed revolving cylinder that pulled the cotton fiber through small openings that separated the seeds from the lint. Then, a rotating brush, operated by a belt and pulleys, removed the lint from the projecting spikes. This device could clean up to fifty-five pounds of cotton a day. Originally, the cylinder was turned by a crank. Later, the gins were powered by horses or water.

Whitney's cotton gin transformed the agrarian economy of the South. The cotton gin greatly increased the production of cotton by lowering the cost of the product. Cotton production doubled each decade after 1793, and cotton soon became the number-one-selling textile. By the middle of the nineteenth century, the United States was producing 70 percent of the world's supply of cotton. Sixty percent of the United States' exports came from the South, most of which was cotton. The cotton gin also contributed to the growth of slavery in the South as cotton farming became more profitable in the interior part of the South and Southwest. Large plantations were created throughout the South, and the institution of slavery expanded. The number of slave states increased from six in 1790 to fifteen by the middle of the nineteenth century, and approximately one of every three southerners was a slave.

innovations contributed greatly to the economic development of both the American South and North. Because of his accomplishments, he is considered, along with Thomas Alva Edison and Alexander Graham Bell, one of the most notable American inventors of the eighteenth and nineteenth centuries.

However, while Whitney is remembered by most people for his invention of the cotton gin, he also made significant contributions to the manufacturing process. When Whitney secured his contract to produce muskets for the federal government, he spent two years building and equipping a factory. He designed and built machine tools for the production of muskets using interchangeable parts, and he recruited and trained an unskilled workforce to use those tools. He even built houses for the workers to live in near his factory. He also had to develop techniques for procuring supplies in a timely manner. Whitney's innovations revolutionized the manufacturing process and the system of industrialization in the United States.

Sir Frank Whittle

British American aviation engineer

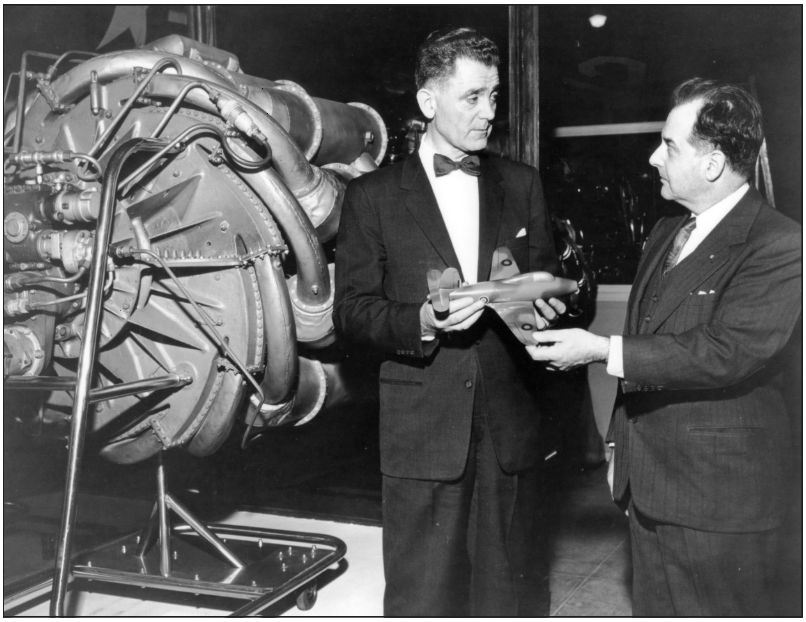
Whittle designed and built the engine that revolutionized aviation and ushered in the modern age of the jet aircraft. His engine has been called the greatest engineering development ever to occur in aviation.

Born: June 1, 1907; Coventry, Warwickshire, England
Died: August 8, 1996; Columbia, Maryland
Primary field: Aeronautics and aerospace technology
Primary invention: Jet engine

Early Life

Frank Whittle was born in Coventry, England, to Moses Whittle, a mechanic and inventor. As a child, Frank's favorite toy was a model Blériot airplane powered by a clock spring and suspended from the ceiling, where it would fly in a circle above his head. He was fascinated by airplanes and was especially excited when a local pilot made a forced landing near his home. Frank began his education at the age of five at Earlsdon Council School. Coming from a working-class background, he had somewhat limited educational opportunities. When he was nine years old, his father moved the family to Leamington Spa, where Moses purchased the Leamington Valve and Piston Ring Company. Young Frank was enrolled in the Milverton Council School and was awarded a scholarship to Leamington College for Boys.

The end of World War I had a negative effect on his father's income. Because of the family's reduced economic circumstances, Frank was not able to take advantage of a scholarship to a grammar school. He was not proving to be an outstanding student, and he decided to enlist in the Royal Air Force (RAF) as a boy apprentice. His first two attempts at enlistment were unsuccessful because of his small stature. On his third attempt, he neglected to mention the previous rejections and was accepted as a mechanic apprentice at the age of sixteen. He did very well in classes and displayed an aptitude for engineering. In 1926, he was accepted for flight training, in which he proved to be a very competent pilot. He also became somewhat of a daredevil, a trait that was to cause him some difficulty during his military career. By 1930, he was a fighter pilot, test pilot, and a flight instructor. On May 24, 1930, he married Dorothy Mary Lee.



Sir Frank Whittle, left, stands by a turbine engine he designed for use in Great Britain's first jet-propelled aircraft. (Smithsonian Institution)

Life's Work

By 1928, Whittle had become interested in the problem of high-speed flight at high altitude. He observed that, although a plane could fly faster at high altitude because of the decrease in atmospheric pressure, that same pressure decrease caused piston engine and propeller performance to degrade. He began writing his thesis "Future Development in Aircraft Design," in which he proposed alternatives to piston-powered, propeller-driven aircraft. He theorized that high-speed, long-range flight would require aircraft to fly at very high altitudes. At these altitudes, air pressure and drag would be reduced relative to the speed of the aircraft. He argued that propeller efficiency was the major limiting factor for this type of operation and that it required some type of jet propulsion. He completed this thesis at the age of twenty-one.

Whittle designed an engine with a turbine that would turn the compressor. The high-pressure gases not used to power the compressor would be expelled as thrust. He theorized that this type of engine would not suffer from performance loss due to the reduced air pressure. Whittle would spend the next thirteen years fighting for acceptance of his ideas.

In 1929, Whittle presented his work to the Air Ministry, which rejected his ideas as overly optimistic and impractical. The ministry questioned the existence of materials that could handle the extremely high temperature and rotational speeds required for the engine to operate. The ministry also concluded that Whittle's performance estimates were grossly in error. Nevertheless, Whittle was awarded a patent on May 24, 1930. He contacted a number of private manufacturers in the hope of generating financial support, but no company was willing to make the sizable investment required. Persevering in the attempt to generate interest in his project, he wrote a paper for the Royal Aeronautical Society on superchargers outlining his radical ideas for a new type of compressor. This was followed by another paper that dealt with gas turbines. None of this effort was rewarded, and it was not until 1936 that Whittle obtained a limited amount of support.

During this period, Whittle continued to perform his duties as an RAF officer. While he could gain no official sponsorship for his project, his initiative and ability were recognized by the Air Ministry. In 1932, he graduated from the officers' engineering course and was posted to Cambridge University to study mechanical sciences. Engineering had replaced flight as his primary passion. Throughout this period, he continued to refine his ideas, although he was still unable to build the engine.

In 1936, a small group of former RAF pilots suggested to Whittle that they form a corporation. The partners secured a bank loan to begin operations. That year, Power Jets, Ltd., was born and work on the jet engine began in earnest. The Air Ministry approved Whittle's involvement as chief engineer but restricted his activities to a maximum of six hours per week. The company eventually received limited support from British Thomson-

The Turbojet Engine

Sir Frank Whittle was the man who solved the problem of jet propulsion. Rather than utilizing a propeller to accelerate a mass of air, he designed a turbojet engine. It consisted of a double-sided centrifugal compressor rotating in excess of 17,750 revolutions per minute, which drew in large quantities of air, approximately 1,500 pounds of air per minute. This generated a tip speed of 1,500 feet per second with all of the associated stresses. The compressor generated an air pressure equivalent to four atmospheres and routed this high-pressure air into a series of ten combustion chambers mounted around the engine core, where fuel was introduced and ignited. The heated and compressed air accelerated through a single-stage turbine wheel whose blades deflected the gases and provided the energy to rotate the turbine wheel. The turbine was connected by a shaft to the compressor, thereby rotating the compressor at the same speed. In this way, the accelerated gases extracted only enough energy to turn the compressor at the desired speed. The remaining energy supplied by the hot gases passed out through an exhaust nozzle in the form of thrust.

One of the major difficulties that had to be overcome was the manufacture of these components. They required materials that could withstand the heat and stresses produced by the engine. This resulted in the design and production of many high-strength stainless-steel alloys. It was believed that these alloys could not be welded successfully because of the requirement for very thin parts manufactured to extremely close tolerances. The combustion chamber, for example, was only $1/64$ of an inch thick. Whittle proved that it could indeed be welded, and Power Jets became a leader in stitch welding of very thin exotic metals.

Whittle's engine differed in both design and function from all existing engines of the day. Unlike reciprocating engines, his turbojet engines were efficient at altitudes up to about forty thousand feet. This altitude was unachievable by a propeller-driven aircraft. By relying on the acceleration of gases rather than a propeller to produce the thrust, Whittle eliminated the problem of loss of efficiency at high altitude and high speeds. The use of a high-speed turbine wheel to turn a compressor that in turn supplied high-pressure air in tremendous amounts for combustion was the radical part of Whittle's theory that made efficient jet propulsion possible.

Houston (BTH), a company that manufactured industrial turbines. However, this was a mixed blessing: Whittle challenged some of BTH's design and manufacturing practices, and friction developed. Eventually, BTH traded its interest to Rolls-Royce. Even with the limited support of BTH and the Rover Automobile Company, adequate financing was lacking. In spite of these difficulties, Whittle and his dedicated team constructed the Whittle Unit (WU). On April 12, 1937, the first test run was undertaken. By June, 1937, Power Jets was almost entirely out of money and contemplating halting work on the engine.

The approach of World War II generated increased interest in Whittle's engine by the Air Ministry, which declared Whittle's project a high priority. In 1939, the ministry contracted for construction of a flight engine. This engine was installed in a specially built Gloster Pioneer aircraft. The aircraft made its first flight on May 15, 1941, and proved so successful that the government committed to production. Unfortunately for Whittle and his team, the British government decided that Power Jets be relegated to research and testing, while production was to be handled by the established aircraft engine manufacturing companies, primarily Rolls-Royce. Power Jets was ordered to surrender all pertinent drawings and materials. Whittle and his team eventually resigned, and Power Jets faded from existence.

Whittle had dedicated his life to developing his engine, and he had succeeded in spite of numerous obstacles, only to have the fruits of his labor stripped away. However, Whittle continued to be an active participant in aviation. He was knighted in 1948 and ended his career holding twenty-seven different patents, having worked as a technical adviser to British Overseas Airways Corporation (BOAC), Shell Research, Bristol Siddely Engines, and as a research professor at the U.S. Naval Academy. The "father of jet propulsion" died in Columbia, Maryland, on August 8, 1996.

Impact

Whittle was a visionary who refused to become discouraged when he could find little support for his ideas. His design of the jet engine was so revolutionary that few could fully comprehend the concept, much less see the potential consequences of such a design. Even the professor who read his thesis admitted that he could not fully understand it but could find nothing wrong with it. At a time when the fastest military fighter aircraft operated at a speed of about 150 miles per hour at twenty thousand feet, Whittle was envisioning speeds in excess of 500 miles per hour at much higher altitudes. While it took thirteen years to demonstrate conclusively that his radical ideas were indeed valid, the technology he invented completely revolutionized aviation.

Whittle developed the first jet engine for the Royal Air Force, and he was sent to Boston to work with the General Electric Company to produce an engine for the United States. Whittle was again successful, and his work resulted in the production of the first jet-powered fighter aircraft in the U.S. inventory, the Bell XP-59A Airacomet, which flew on October 2, 1942. Civil air transport owes a similar debt to Whittle, as jet engines now power virtually all of the large commercial aircraft. One man's dogged determination and persistence truly changed the face of aviation. The jet engine was the most significant technological development of the World War II era, and it was entirely the product of one man's vision.

Otto Wichterle

Czech chemist

Wichterle discovered the hydrogel polyhydroxyethyl methacrylate (poly-HEMA), a synthetic polymer (plastic) that could absorb and retain water, and developed a method for molding it into flexible, soft contact lenses. He patented dozens of types of plastics and methods for their use or manufacture, and he wrote extensively on organic and inorganic chemistry, polymer science, and medical uses for plastics.

Born: October 27, 1913; Prostějov, Austro-Hungarian Empire (now in Czech Republic)
Died: August 18, 1998; Sdradisko, Czech Republic
Primary field: Chemistry
Primary invention: Soft contact lenses

Early Life

Otto Wichterle (OT-oh VIHK-tur-leh) was the youngest of five children born to Karel, co-owner of a farm machinery plant, and Slávka, a well-educated housewife. When he was six years old, Wichterle nearly drowned after falling into an open sewer, and afterward remained ill; diagnosed with an enlarged heart, he was expected to die within the year. Thinking him too sick to attend school, his parents arranged for him to be tutored at home. Two years later, Wichterle seemed healthy enough to return to school; in 1922, at the age of eight, he passed entrance examinations that placed him in classes with children three years older than himself. Wichterle endured some bullying but quickly adjusted, becoming involved in school sports and taking music lessons in addition to his regular studies.

After graduating from high school, Wichterle planned to study mechanical engineering at the Czech Technical University in Prague, but a friend advised him that he would have more opportunity to do research, and to study with better scientists, in the university's chemical engineering department. In 1936, he obtained his Ph.D. in chemistry from the university and remained there as a lecturer until November, 1939, when the Germans occupied Czechoslovakia and closed all its universities.

Life's Work

Realizing that German forces were arresting university professors, Wichterle left the university but continued his research at the Baťa Chemistry Research Institute in Zlín, where he developed a method for spinning synthetic nylon fibers that could be used in textile production. After World War II, he returned to Czech Technical University and was appointed a professor of macromolecular chemistry there in 1949. Always concerned with the quality of education in chemistry, Wichterle soon clashed with the administration over his teaching methods, the subjects he covered in classes, and the very purpose of education.

In 1952, Wichterle, then on the faculty of Prague's new University of Chemical Technology, met by chance a government official who worked on finding medical uses for plastics. Their brief conversation inspired Wichterle with several ideas for using hydrophilic polymers (plastics that could hold water) as substitutes or enhancements for human tissue. Wichterle immediately filed a patent on these types of water-permeable plastics and their possible uses, including an idea that they could be used to make soft contact lenses.

The next year, Wichterle and his colleague Drahoslav Lim patented polyhydroxyethyl methacrylate (poly-HEMA) gel, a transparent plastic that was nearly half water. Wichterle worked with ways to form the gel into a usable contact lens and in 1957 was able to briefly wear a thick, ragged-edged prototype lens in his own eye.

The University of Chemical Technology's communist administration fired Wichterle in 1958, and he immediately was offered the directorship of a new research institution, the Institute of Macromolecular Chemistry, at the Czechoslovak Academy of Sciences. He was not allowed to continue his research on hydrophilic plastics at the institute, so Wichterle moved his project to a separate laboratory, where soft contact lenses with smooth edges were formed in glass molds, although the methods were time-consuming. In 1959, several patients were

Soft Contact Lenses

Contact lenses, or contacts, are small, transparent disks worn directly on the cornea of the eye to correct vision by focusing light properly on the retina of the eyeball. Contacts can be worn as an alternative to eyeglasses to correct near- or farsightedness, presbyopia (aging of the eye), or astigmatism (an irregularly shaped cornea). Contacts can be used to reshape the cornea, correcting conditions that cannot be treated with conventional eyeglasses.

Scientists and inventors since Leonardo da Vinci (1452-1519) had imagined contact lenses; the first glass contact lens that could be used in the human eye was created in 1887 by German physiologist Adolf Eugen Fick (1829-1901). Later lenses were made from clear plastic, but these prevented oxygen from reaching the eye, until researchers developed new types of plastic that could be penetrated by oxygen.

Contact lenses are worn for cosmetic reasons, providing an option of correcting poor vision without eyeglasses. In addition to changing the wearer's appearance, contacts can give the user a wider range of vision and will not, as eyeglasses will, slide on the user's nose, cause pain at pressure points on the nose or ears, or steam up because of changes in temperature.

Soft contact lenses created using Otto Wichterle's methods are more popular than rigid, or hard, lenses because they are less likely to cause irritation by their movement over the surface of the eye, or to cause pain if airborne irritants come in contact with the eye or lens. Soft lenses also provide an option for wearers who find it difficult to adjust to using rigid lenses, which can be felt in the eye and can be uncomfortable for some time before the eye adapts to them. Soft lenses can be placed in, or removed from, the eye with greater ease and worn with greater comfort.

Soft contact lenses are sometimes worn to change the appearance of eyes that do not have the look of a normal eye, or simply to change the eye color for the wearer's enjoyment. It is even possible to create a temporary special effect with soft contact lenses, such as the look of a cat's eye.

A wide range of soft contact lenses have been developed, such as extended-wear lenses, which users can leave in their eyes while they sleep, and disposable lenses, designed to be worn for a single day, reducing the risk of infection that may develop when contacts are worn for extended periods.

experimentally fitted with the lenses. Wichterle coauthored an article about his groundbreaking work with water-retaining plastics in the journal *Nature* in January, 1960; however, that year the Ministry of Health ceased funding for the project because the lenses could not yet be mass-produced.

Wichterle continued his research at home. Combining pieces of laboratory equipment taken from the University of Chemical Technology, parts from an erector set belonging to his children, and a generator from his son'sbicycle, he developed a method for "spin casting" the lenses, forming them from softened plastic on rotating molds. On Christmas Day of 1961, he tested four of his homemade lenses on hospital patients and found that, although their vision was not improved, the patients could wear the lenses easily and could at least see through them.

Wichterle upgraded his homemade equipment, replacing the bicycle generator with parts from a record player, and exposing the lenses to ultraviolet rays filtered through a piece of glass taken from one of his bookshelves. Between January and April of 1962, Wichterle and his wife, Linda, a physician, made approximately fifty-five hundred contact lenses. As these lenses were tested and government officials learned of the project's economic potential, Wichterle was invited to resume his research at the Institute of Macromolecular Chemistry. In 1963, looking for a way to manufacture contact lenses on the same type of machinery used to made rigid lenses, Wichterle created and patented a xerogel, a plastic that could be formed into lenses while dry, then allowed to absorb water.

In 1964, Wichterle traveled to the United States to promote the soft contact lens; as part of his presentation, he would take a soft lens from his own eye, drop it on the floor, step on it, put it in his mouth to clean it with saliva, and then replace it in his eye. In 1965, an American investment company, the National Patent Development Corporation (NPDC), partnered with Wichterle and were licensed to mass-produce soft lenses once the product and manufacturing process were perfected. In 1966, the NPDC licensed Bausch and Lomb to produce the lenses, and soft contacts were first offered to the American public in 1971.

In 1968, Wichterle became director of the Macromolecular Division of the International Union of Pure and Applied Chemistry and traveled extensively, looking for further medicinal applications for hydrogels. The same year, during the Prague Spring reform movement, Wichterle was among sixty Czech activists who signed the "Two Thousand Words" manifesto, a document of protest against Czechoslovakia's communist leadership. In August, 1968, the Soviet Union occupied Czechoslovakia; to avoid arrest, Wichterle left the country. He returned to Prague in September, only to be removed once again from his professional position.

Wichterle's activities and contacts were limited, and he continued working in isolation, receiving the International Eye Research Foundation Prize (1978) and the American Optical Society Wood Prize (1983). In 1989, at the age of seventy-six, Wichterle was elected president of Czechoslovakia's Academy of Sciences and received the American Society of Plastic Engineers Hyatt Prize (1989). He retired from the Academy of Sciences after three years. Wichterle died in his sleep in 1998 at the age of eighty-four, having suffered a heart attack and a stroke during the previous year.

Impact

Wichterle was a pioneer in his approach to pure and applied sciences, simultaneously developing scientific theories and practical applications. He also pioneered the idea that synthetic materials could be made to imitate living tissues and used for medical implants.

Inspired by chance to work with plastics for medical applications, Wichterle laid a foundation for future developments in biomedical materials. He persevered in developing his ideas in spite of academic rivalries, political opposition, lack of funding for research, and loss of personal income. In pursuit of a product that seemed to serve only cosmetic purposes, Wichterle produced contact lenses that could be used in situations where rigid lenses or eyeglasses were impractical; his brilliant and innovative use of materials at hand to manufacture thousands of prototype lenses proved that mass manufacture of the lenses was possible. Soft contact lenses are invaluable in professional sports, occupations that place wearers in humid or particle-heavy environments and in military operations where specialized headgear and equipment prevent the use of eyeglasses. At the time of Wichterle's death, an estimated 100 million people worldwide were using soft contact lenses.

Sheila Widnall

American aerospace engineer

The first woman to serve on the U.S. Joint Chiefs of Staff, Widnall became an internationally renowned expert in fluid dynamics who revolutionized the field with her work on aircraft turbulence, vortices, and spiraling airflows.

Born: July 13, 1938; Tacoma, Washington
Also known as: Sheila Evans Widnall (full name); Sheila Evans (birth name)
Primary fields: Aeronautics and aerospace technology; mathematics
Primary invention: Flexible tailored elastic airfoil section

Early Life

Sheila Evans Widnall was born the oldest of two girls on July 13, 1938, in Tacoma, Washington. Her father, Rolland John Evans, lost his Colorado ranch during the Depression and became a rodeo cowboy and ranch hand. He then worked as a foreman in the shipyards, while attending college. Later, he was a production planner for Boeing Aircraft Company and finally a teacher after earning a master's degree. Her mother, Genevieve Alice, was a social worker and juvenile probation officer.

As a child, Widnall became interested in mathematics and science. She helped her father with painting, rewiring, plumbing, and building projects. The family lived near McChord Air Force Base, so at an early age Widnall became fascinated with the airplanes that flew over her home.

From elementary through high school, she attended all-female Catholic schools and excelled in science and mathematics. In her junior year of high school, she won first prize for a science fair project on the radioactive decay of uranium. In September, 1956, Widnall entered the Massachusetts Institute of Technology (MIT). She was one of twenty women in a freshman class of approximately nine hundred. In 1960, she received her bachelor of science degree in aeronautics and astronautics. Only ten of the original twenty women graduated. During the summers of 1957-1959 and 1961, she worked for Boeing, and she spent the summer of 1960 at the Aeronautical Research Institute of Sweden.

Widnall stayed at MIT to earn a master of science degree in 1961 and a Ph.D. in 1964. From 1961 to 1962, she worked as a research staff engineer, and from 1962 to 1964 she was a research assistant in MIT's Department of Aeronautics and Astronautics. During these years, she met and married William S. Widnall, also an aeronautical engineer. They had two children, William and Ann.

The Flexible Tailored Elastic Airfoil Section

Practical applications of Sheila Widnall's theories emerged both in the design of equipment to evaluate the forces and in the design of technology to control them. One of the many challenges involved in the study of turbulence in fluid mechanics was the problem of being able to measure fluctuations in pressure under unsteady conditions. In 1970, with C. G. Heller, Widnall described the use of piezoelectric transducers to measure high-frequency force changes caused by airflow causing bending in an airfoil, rods, and bars. She continued this research, contributing to the design of wind tunnels used for testing at the Massachusetts Institute of Technology (MIT).

Widnall applied for a patent in 1992 jointly with her husband, William S. Widnall, as well as William Gorgen and Jeffrey Evernham, with the patent assigned to Flex Foil Technology, Inc. The patent was awarded in 1993, and research proceeded into specific ways of dynamically modifying the shape of the leading edge of blades moving through various fluids. The patent was written to cover many kinds of conditions and functions, with special attention to aircraft wings and stabilizers as well as other applications. Previous designs for flaps on the wings of aircraft required control mechanisms or pilot intervention to change the angle of the flaps by rotating them from the points at which they are joined to the larger structures, but the shapes of the flaps themselves were not changed.

The main advantage over previous rigid designs is that greater lift and side force can be gained by delaying the separation of the flow of the medium, therefore minimizing the effects of the turbulence. The desired flexibility can be achieved by using flexible material that can expand and contract around a stiff central spine. There can be axle cavities inside the skin of the devices to allow for changes in the geometry of the surface. In general, relative stiffness is distributed between the leading and trailing edges, spine, and various segments of the devices.

Widnall's revolutionary designs for the reduction of turbulence in moving through fluids, based on decades of research, have an incredibly broad range of applications. In both air and water, the vortices created near the sides and back of a blade or wing cutting through the given medium are sources of instability, vibrations, and noise. Controlling these disturbances increases the safety, fuel efficiency, flexibility, and durability of many types of vehicles, and increases the capabilities of air- and water-based turbines and fans, as well as provides more lift and control in all kinds of aircraft, including helicopters.

Life's Work

Immediately after receiving her doctorate in 1964, Widnall became an assistant professor in mathematics and aeronautics at MIT. In 1970, she became an associate professor, and then a full professor in 1974. From 1975 to 1979, Widnall was head of the Division of Fluid Mechanics; from 1979 to 1990, she was director of the Fluid Dynamics Laboratory. In 1988, she became the president of the American Association for the Advancement of Science. From 1992 to 1993, she served as the associate provost at MIT.

In 1993, she was appointed secretary of the Air Force, thus becoming the first woman to be in charge of a military branch. During this time, she was responsible for 400,000 active-duty forces and 185,000 reservists, as well as allocating and planning a $62 billion budget. In October, 1997, she stepped down from the Air Force post and resumed her teaching career at MIT. She took part in the Lean Aerospace Initiative, which determined that any enterprise must identify and create value in order to be successful. In November, 1998, she was appointed institute professor, the highest honor awarded to MIT faculty. There are only fifteen institute professors, who are considered the very best of MIT. They have the freedom to follow intellectual pursuits without the obligation to teach courses.

Widnall has become internationally known for her life's work—computational, analytical, and experimental—in aerodynamics. Her field is fluid dynamics, with a specialty in aircraft turbulence, vortex stability, and spiraling airflows, all of which affect the performance of aircraft, hydro-craft, and high-speed ground transportation vehicles. Testing these complex phenomena required very specialized equipment, including wind tunnels, which she helped to design as part of her work at MIT. The anechoic wind tunnel, which suppresses the reflection of sound waves, was used to study noise associated with aircraft that can make short vertical take-offs and landings, especially useful in military and emergency situations with minimal space for runways. Other wind tunnel experiments were used to test material surfaces used in aviation.

Widnall's theoretical and experimental work centered on the study of vortices in relation to fluid dynamics. In the course of this work, she found that waves would expand around rings in vortices. This phenomenon became known as the "Widnall instability," and it was an important breakthrough in her field. In particular, her research has encompassed unsteady lifting surfaces in aircraft, the effect of unsteady air forces on shaking cylinders under both subsonic and supersonic conditions, the separation of leading-edge vortices from slender delta wings, the aerodynamics of tip vortices, noise in helicopters, the stability of vortices, the aerodynamics of ground transport vehicles moving at very high speeds, unsteady hydrodynamic loads on supercavitating hydrofoils (hydrofoils that reduce drag by creating a large bubble of gas, usually air, inside a liquid, usually water), the stability of boundary layers, the turbulence in the wake of aircraft, and more. The instability and noise associated with the swirling vortices created at the trailing edges and ends of spinning helicopter blades was a special focus, since these phenomena impact the safety of the vehicle.

After the tragic loss of the *Columbia* space shuttle in 2003, Widnall served on the Columbia Accident Investigation Board, which made recommendations addressing both the technical and organizational issues that led to the disaster. She has served as a trustee, council member, board member, guest lecturer, and/or consultant for numerous foundations, academic institutions, corporations, and government agencies. She is also active as an author and has served as an associate editor for scientific journals, including the *Journal of Aircraft*, *Physics of Fluids*, and the *Journal of Applied Mechanics*.

Impact

Through her excellence as a scientist, researcher, educator, inventor, and writer, Widnall became a role model for women. In recognition of her encouragement of women in the sciences and engineering, MIT in 1986 awarded her the Abby Rockefeller Mauzé chair, an endowed professorship. She was inducted into the Women in Aviation Pioneer Hall of Fame in 1996. The Women's International Center (WIC) recognized her achievements with its 1998 Living Legacy Award. In October, 2003, Widnall was inducted into the National Women's Hall of Fame.

A world-famous pioneer in the field of aerospace engineering, Widnall holds three U.S. patents and is a prolific author who has published more than seventy scientific papers. Her inventions and discoveries are breakthroughs in dealing with aerodynamic noise, aircraft turbulence, and vortex instability for either air or water vehicles. Improved performance, safety, flexibility, and energy savings support advanced models for the twenty-first century. Her work has contributed greatly to understanding helicopter rotor blade noise generation and aerodynamics, and the deterioration of aircraft wave vortices. In November, 2002, *Discover* magazine named Widnall one of the fifty most important women in science, for her discovery of the Widnall instability, which had a profound effect on the field of fluid dynamics.

Paul Winchell

American television entertainer

Though better noted as a television personality and entertainer than as an inventor, Winchell developed innovations that ran the gamut from dramatic medical breakthroughs to novelties to unobtrusive everyday articles. His greatest accolades came as a result of his invention of the artificial heart, which purportedly became the model for the Jarvik-7 heart.

Born: December 21, 1922; New York, New York
Died: June 24, 2005; Moorpark, California
Also known as: Paul Wilchin (birth name)
Primary fields: Entertainment; household products; medicine and medical technology
Primary invention: Artificial heart

Early Life

Paul Wilchin was born to Jewish Americans Sol and Clara (née Fuchs) Wilchin, who had apparently shortened their surname Wilchinski before their son was born. Paul was the second of three siblings, with an elder sister, Ruth, and a younger sister named Rita. His father worked as a tailor, and the family lived in modest rented accommodations on the lower East Side of Manhattan.

Winchell's childhood was troubled. He had an especially stormy, even physically and verbally abusive, relationship with his strong-willed mother, and he harbored extremely bitter feelings about this phase of his life for years to come. However, according to his own account, this seemed to serve, in the long run, as a spur that would motivate him to excel in defiance of the odds. In 1928, at the age of six, Winchell was stricken with polio but, undertaking intensive weight exercising, was able to survive without severe or permanent physical impairment. Among the personal obstacles he faced was an abnormal shyness, coupled with a speech impediment (stuttering and stammering), which he overcame by developing and honing his speaking style, finally succeeding to the point that he was able to master the art of ventriloquism.

In this effort, in which Winchell was almost entirely self-taught, he had as a hero and role model the famed celebrity ventriloquist Edgar Bergen, whose performances with his dummies Charlie McCarthy and Mortimer Snerd during the 1930's through the 1950's pioneered voice throwing as an entertainment form. Young Winchell's immediate source of inspiration came from attending a live performance of Bergen in New York. Begging money from his sister Ruth's boyfriend, Winchell was able to purchase a pamphlet on ventriloquism. He not only cured himself of his speech impediment but also (using dummies that he had learned to fashion with

Ventriloquist Paul Winchell, seen here with his puppet Jerry Mahoney in 1949, was also a prolific inventor. His artificial heart invention, patented in 1963, was donated to the University of Utah for research. (Getty Images) the help of his father) began making a name for himself by giving comedy ventriloquist routines for classmates and teachers.

Life's Work

Winchell's first true break into show business came in 1936, when his art school principal arranged for him to appear on the *Major Bowes Original Amateur Hour* radio show. It was then that he was first introduced under the professional name by which he would thereafter be known: Paul Winchell. (This was the idea of his sister Ruth's boyfriend, who believed that the pseudonym would make the young man's act more marketable to audiences.) Winchell's routine with his dummy, originally named Terry, was so well received that he won the cash prize and launched into his career as an entertainer. Taking part for several years in the vaudeville tour, he had the good fortune to be on hand for the advent of television.

One of the trailblazing shows of the early mass-media television era was *The Bigelow Show*, which ran on the Columbia Broadcasting System (CBS) and the National Broadcasting Company (NBC) networks from 1948 to 1949 and featured Winchell and his most famous ventriloquist dummy, Jerry Mahoney. From 1950 to 1968, Winchell performed, and usually starred, in children's and variety shows such as *The Spiedel Show*, *The Winchell-Mahoney Show*, and *Circus Time* with Jerry Mahoney and his second great dummy characterization, the slow but good-hearted Knucklehead Smiff.

Though Winchell was already one of the best-known names in the entertainment world, it was in 1962 that he diverged into a career as a voice-over artist. From 1968 to 1999, Winchell acted as the voice behind the animated cartoon character Tigger in the Walt Disney cartoon series *Winnie the Pooh*, the voice-over impression for which he is best known. Achieving great success, he branched into a series of voice-over roles as diverse as those of Dick Dastardly in *Wacky Races*, Gargamel in *The Smurfs*, Boomer in *The Fox and the Hound* (1967),

The Artificial Heart

A celebrity dance contest organized by dance impresario Arthur Murray set into motion a chain of events for noted TV ventriloquist-entertainer Paul Winchell. Winchell won the prime-time TV contest and at a subsequent reception at Murray's home met Dr. Henry Heimlich (who would later stake his own claim to fame as the originator of the life-saving Heimlich maneuver). Out of this meeting came Heimlich's offer to Winchell—who was at that time also a medical student—to observe surgical procedures at New York's Montefiore Hospital. There, Winchell was deeply affected when a patient died on the operating table during heart surgery.

At Heimlich's suggestion, and with his technical advice and assistance, Winchell undertook the task of designing a model for an artificial heart that could sustain a patient through a complex surgical procedure by temporarily performing the heart's routine bodily functions. (Only later was the idea of a more permanent heart implantation seriously considered.) By Winchell's own account, the process involved was somewhat akin to the design and construction of some of the ventriloquist dummies that he had previously created, with comparable moving parts and compartments. Winchell's idea was based on the construction of a mechanically, externally driven substitute, or even replacement, heart, made of material such as nylon that would be durable and as noninvasive as possible. The device would have two internal chambers, the top chamber being capable of containing five ounces of blood; the lower one, four ounces. The blood would be circulated through the body by means of a special squeezing mechanism. The external motor mechanism was designed to be strapped and held in place to the patient's outer chest wall by means of a harness.

Winchell was granted a patent for his artificial heart design on July 16, 1963. Some nine years later, Dr. Willem Johan Kolff, director of the Medical Center for the Institute for Biomedical Engineering at the University of Utah, whose Division of Artificial Organs had been developing artificial hearts (which were then undergoing trials on animals), requested that Winchell donate his patent to the university. Winchell assented, handing over the patent on November 22, 1972.

Winchell, Heimlich, and others asserted that the University of Utah biomedical engineer Dr. Robert Jarvik largely borrowed from and refined Winchell's artificial heart design in creating the Jarvik-7 heart. The Jarvik-7 was first successfully implanted by a cardiovascular surgeon, William Castle DeVries, into a human recipient, Barney Clark, on December 2, 1982. The claims put forward by Winchell and Heimlich have been challenged in some quarters; it has been asserted that Jarvik's primary model on which he made the improvements that culminated in the Jarvik-7 device was an earlier powered model called the Kwann-Gett heart.

Fleegle in *The Banana Splits*, and Zummi in *Disney's Adventures of the Gummi Bears*. In 1974, Winchell received the Grammy Award for Best Recording for Children. He appeared in roles for various Hollywood productions, among them *Stop! Look! and Laugh!* (1960), *Vernon's Volunteers* (1969), *Which Way to the Front?* (1970), and *The Treasure Chest Murder* (1975), but these roles never became a substantial part of his career.

Winchell's career as an amateur inventor took him in many directions. He became a premed student at Columbia University. Studying there from 1959 to 1974, he ultimately earned his doctorate in acupuncture. He also became a proficient hypnotherapist, working part-time at Mount Vernon Hospital in New York. Dr. Henry Heimlich invited Winchell to observe and assist at Montefiore Hospital. There Winchell conceived the idea of an artificial coronary device that could be implanted during surgery and possibly increase the heart patient's chances of survival. Winchell completed his artificial heart device in 1956, when he applied for a U.S. patent, and was finally granted a patent on July 16, 1963 (U.S. Patent number 3,097,366). On November 22, 1972, Winchell donated the patent to the University of Utah's Institute for Biomedical Engineering. Dr. Robert Jarvik, who worked at the university, was said to have refined and adapted the model to develop his Jarvik-7 artificial heart. Thereafter, it appears that relations between Winchell and Heimlich on one hand and Jarvik and Dr. Willem Johan Kolff, Jarvik's department chair, on the other became strained. Over the ensuing years, a debate surfaced as to the extent of the influence exerted upon Jarvik's mechanism by Winchell's prototype.

Winchell filed for many other patents, including a retractable-tipped fountain pen (3,071,113, filed January 30, 1961); a jewelry pendant (D216371, November 27, 1968); an electric heater for a container (3,079,486, May 22, 1961); a lens cover (3,133,149, September 23, 1960); a warning indicator for interrupted power supply for freezers (3,063,225, February 3, 1961); a tandem sifter for flour and other products (3,063,563, January 30, 1961); an inverted novelty mask (3,129,001, May 22, 1961); a nonbulging garter fastener (3,128,477, February 3, 1961); a pouring expediter for sugar, salt, and the like (3,110,424, January 30, 1961); a nonvisible garter for hosiery (3,097,407, December 1, 1961); and a hand pump for transferring liquids (3,120,192, December 22, 1961). One prototype he developed, but for which he did not bother to file, to his later regret, was for the disposable razor.

During the 1970's, Winchell worked with alternative energy advocate Dr. Keith E. Kenyon of Northrop University on developing an electric motor for automobiles. The 1980's saw Winchell, Heimlich, Senator Ted Kennedy, and certain entertainment industry notables team up to form the Africa Tomorrow organization and to conceive a scheme whereby hunger in Africa might be alleviated by teaching Africans how to raise and harvest the prolific and hardy tilapia fish. However, they were unable to secure U.S. congressional support for its funding, and the project petered out.

Winchell married three times: His first marriage was to Dottie Morse (by whom he had two children, Stephanie and Stacy Paul); his second, to Nina Russel (the couple had a daughter named April Terri); and the third, to Jean Freeman (the mother by a previous marriage of two sons, Larry and Keith, whom Winchell adopted). His personal life was turbulent, though the full extent of this was not generally known until he published his controversial autobiography, *Winch*, in 2004. In the book, Winchell blamed his mother and his ex-spouses for most of his emotional and psychological problems. Some see the autobiography as an attempt to ease the painful memories that were still plaguing him. Others, and most openly his daughter April, took exception to this view and lay more of the responsibility on Winchell himself, alleging problems such as marital infidelity, verbal abuse, and fits of anger—and stating that Winchell as a family man was a far different persona than the television kid's show idol with whom most of the baby-boom generation was familiar. Apart from his autobiography, Winchell was the author of the books *Ventriloquism for Fun and Profit* (1954) and *Pressure Points: Do it Yourself Acupuncture Without Needles* (1979; with Kenyon). Toward the end of his life, he was active in the Universal Church ministry, establishing a Web site called ProtectGod.com (now defunct). On the night of June 24, 2005, Winchell died in his sleep of apparent heart failure.

Impact

Winchell's most revolutionary and enduring innovation is the artificial heart. However, debate continues over who should receive what amount of credit for the development of the device. It has been alleged that Robert Jarvik did not incorporate portions of Winchell's designs—nor did they even influence him—in the making of the Jarvik-7 artificial heart. Henry Heimlich consistently maintained that the design set forward by Winchell in the patent that he donated to the University of Utah was totally incorporated into the Jarvik-7 and that Jarvik himself must have been familiar with it. The question over the extent (if at all) to which Jarvik made use of Winchell's research has been bandied about long after Winchell's death and shows no sign of being resolved. Regardless, Winchell must rank as one of the most versatile, and unusual, inventive geniuses of the mid-to-late twentieth century, and a model to nonspecialists with avant-garde ideas.

Alexander Winton

American automobile manufacturer

Winton was a leading pioneer in the automobile industry, and his Winton Motor Carriage Company was one of the first American companies to sell automobiles. He also invented the first American diesel engine and the first engines with marine applications.

Born: June 20, 1860; Grangemouth, Stirling, Scotland
Died: June 21, 1932; Cleveland, Ohio
Primary fields: Automotive technology; manufacturing
Primary invention: Automobile components

Early Life

Alexander Winton was born in Grangemouth, Stirling, Scotland, to Alexander and Helen Fea Winton. He was a bright student and demonstrated mechanical talent at an early age. At age nineteen, he immigrated to the United States and worked for the first few years at the Delameter Iron Works in New York and in a factory making marine engines. These experiences gave Winton a practical education that remained with him throughout his life. At about age twenty-three, Winton moved to Cleveland, Ohio, where he lived for the rest of his life.

In 1891, Winton received his first patent, for a bicycle, and he organized the Winton Bicycle Company to manufacture his new invention. Although the business was successful, Winton was restless. After five years, he began to turn his attention to the creation of a new mechanical wonder that promised to revolutionize transportation: the automobile. He completed his first motorcar in 1896 and incorporated the Winton Motor Carriage Company in 1897.

Life's Work

Early automobile makers often tested their new machinery in what were called reliability (or endurance) tests. On July 28, 1897, Winton began the first reliability run in the United States by making a nine-day trip from Cleveland to New York. The trip attracted a great deal of attention and led to a sufficient amount of new investment that allowed Winton to build four new automobiles later that year. In late March, 1898, he sold his first car—believed to be the first automobile sales transaction in the United States for a standard-model gasoline-powered vehicle—to Robert Allison of Port Carbon, Pennsylvania. Allison decided to buy the car after seeing an advertisement in *Scientific American* magazine. Later that year, Winton sold twenty-one automobiles. One of these was sold to a future competitor, James Packard, whom Winton may have inadvertently pushed into the automobile business. When Packard complained about the performance of the car Winton had sold him, Winton challenged Packard to see whether he could do better. Packard went on to create the Packard automobile, which remained in production until the 1960's, long after the Winton automobile had ceased to be manufactured.

In 1899, Winton made a second, even better advertised, reliability run from Cleveland to New York, cutting the travel time almost in half by making the trip in just five days. This trip stimulated so much interest that Winton sold more than one hundred cars that year, making his company the largest manufacturer of gasoline-powered automobiles in the United States. This success in turn led Winton to authorize the first automobile dealership in the United States, opened by H. W. Koler in Reading, Pennsylvania, in 1899. In 1901, after ten years in the bicycle business while experimenting with automobiles on the side, Winton began to manufacture automobiles full time.

Winton also raced his automobiles. He pitted his cars against the first vehicles produced by Henry Ford, losing to Ford at Grosse Pointe, Michigan, in 1901 and vowing to improve in 1902. For the second match with Ford, Winton created a new vehicle, named the Bullet, which set an unofficial record of 70 miles per hour. Despite this achievement, Winton's driver was unable to best Ford's illustrious Barney Oldfield in the 1902 race. Winton built two more Bullet-type racing cars, which also failed to win. Nevertheless, racing remained an important form of advertising for automobile manufacturers.

Winton long worked to make his vehicles durable. In 1903, he cooperated with Dr. Horatio Nelson Jackson to stage what was then the ultimate reliability run: a trip across the United States from San Francisco to New York. Jackson and his mechanic made the journey in sixty-four days, which included time for breakdowns and the delivery of repair parts. These exploits enabled Winton to sell his custom-built upscale cars to the wealthy until the 1920's. These various models included five-passenger touring cars and a large limousine. One version of the limousine used an engine mounted in the middle of the vehicle. Although this design did not become standard for American automobiles, it was an indication of Winton's willingness to innovate.

Winton diversified, calling on his early training with marine transportation, by creating the Winton Engine Company in 1912 to manufacture marine engines. By 1913, Winton had produced the first diesel engine in the United States. This diversification was important because Winton's sales of automobiles declined in the 1920's and the Winton Motor Carriage Company stopped making cars in 1924.

Winton continued to manufacture various engines, including diesel and marine engines, until 1930, when he sold the company to General Motors, which turned it into the Winton Engine Corporation. As such, it created the first practical two-stroke-cycle diesel engines powerful enough to drive diesel locomotives and U.S. Navy submarines. In 1935, the section of the Winton Engine Corporation that made diesel locomotives became a part of the Electro-Motive Corporation, a division of General Motors that was still operating in the early twenty-first century. The remaining portion of the Winton Engine Corporation manufactured almost exclusively Navy, marine, and stationary diesel engines. In 1937, General Motors converted this into the Cleveland Engine Division, which continued operation until 1962.

Alexander Winton. (The Granger Collection, New York)

Winton was married and widowed twice. His first wife, Jeanie Muir McGlashan, bore him six children and died in 1903. Three years later, he married LaBelle McGlashan, with whom he had two more children before her death in 1924. In 1927, he married Marion Campbell, a marriage that ended in divorce in 1930. Finally, he married Mary Ellen Avery in 1930. Winton died in 1932 and was buried in the Lakeview Cemetery in Cleveland, Ohio.

Impact

Although Winton is not particularly well remembered today, he was a significant American automotive pio-

Winton's Innovations

The holder of more than one hundred automotive patents, Alexander Winton was a significant leader in the development of the automobile. Among his innovations were his brake and steering systems for automobiles. In 1901, Winton gave one of his complete steering mechanisms to Henry Ford because he was convinced that the system Ford was using was extremely dangerous. Ford used this innovation in the vehicle he manufactured to defeat Winton's car in one of their early races. Winton could take consolation in the fact that he helped advance automobile safety.

If the history of invention is that of one innovation building on another, this process is visible in Winton's lifelong career. Since the earliest automobiles were not much more than double bicycles with engines, Winton's first patent, for a bicycle innovation, presaged his later automotive career. His early employment at a company making marine engines led to a career in this field lasting longer than the three decades he spent making automobiles. His work on marine engines led to the development of the first American diesel engine, later developed to power the largest vehicles in the U.S. Merchant Marine and the Navy. Once such large diesel engines were available, they could be transformed into the power plants of railroad locomotives.

neer. With more than one hundred patents in automobile design, he clearly had a large role in the development of cars. Beyond the technical innovations, Winton popularized the industry with his auto racing and his reliability testing. The historic journey of Jackson driving a Winton automobile from San Francisco to New York went a long way toward creating the popular understanding that the automobile was not a toy but had the potential to become a prominent form of transportation. Winton's diesel engines were ultimately developed into the power plants for Navy warships and the Merchant Marine. Winton also should be credited for taking the first steps toward powering trains with diesel engines.

Granville T. Woods

American machinist and mechanical engineer

Woods invented many electrical and electromechanical devices related to railway technology and telecommunications systems. He also invented the egg incubator and improvements to inventions such as safety circuits, phonographs, telegraphs, and telephones. Altogether, he had approximately sixty patents to his credit.

Born: April 23, 1856; Columbus, Ohio
Died: January 30, 1910; New York, New York
Also known as: Granville Trey Woods (full name)
Primary field: Railway engineering
Primary invention: Synchronous multiplex railway telegraph

Early Life

Granville Trey Woods, son of Tailer and Martha Woods, was born on April 23, 1856, in Columbus, Ohio. Because of the Northwest Ordinance, a law passed in 1787, he was born a free African American. Woods attended school until the age of ten, when he began a machine shop apprenticeship. He learned trades that enabled him to repair railroad equipment and machinery and to also work as a blacksmith. Intrigued by electrical power, Woods studied other workers as they dealt with different machines and paid those workers to teach him electrical concepts. To improve his academic skills, he also went to night school and took private lessons. Woods left Columbus when he was sixteen years old and traveled around the country working on railroads and in steel rolling mills. His academic and employment experiences helped to prepare him for formal engineering coursework. His natural talents, inquisitive nature, persistence, and determination prepared him for the life of a very productive inventor.

Although the Civil War had ended, certain areas of the United States were embroiled in racial turmoil. Many African American workers were unable to get lucrative factory jobs because they were undereducated, unskilled, or simply because of their skin color. Those who were qualified for such jobs were limited to a narrow range of careers and often prohibited from joining increasingly powerful unions. Woods sought ways to overcome racial barriers to his success.

Life's Work

In 1872, Woods began working as a fireman on the Iron Mountain Railroad in Missouri. He eventually became an engineer for that company. In his spare time, he studied electronics and experimented with electricity. In 1874, Woods moved to Springfield, Illinois, and worked in a steel rolling mill. In 1876, he moved eastward, worked six half-days in a machine shop, and took college courses in electrical and mechanical engineering during afternoons and evenings. In 1878, Woods took a job aboard the British steamer *Ironsides*, sailing around the world and ultimately becoming chief engineer of the steamer. Two years later, he obtained employment as a conductor of a steam locomotive with Danville and Southern Railroad. In spite of his increased education and experience, he was denied opportunities and promotions because of racial prejudice. He eventually realized that in order to successfully utilize his talents to the fullest, he would have to be self-employed.

Woods settled in Cincinnati, Ohio, in 1881. Three

The Synchronous Multiplex Railway Telegraph

One of the most important inventions developed by Woods Electric was the synchronous multiplex railway telegraph, a variation of the induction telegraph. The system was developed to improve communications between train crews and station dispatchers. To develop the synchronous multiplex railway telegraph, Granville T. Woods utilized one of the basic laws of physics and electricity, Faraday's law of electromagnetic induction. This law states that a current sent through a coil-shaped wire will generate a magnetic field around the coil. When a wire moves through the magnetic field, a current like that in the coil is induced in the wire. When the wire stops moving or when there is no current in the coil, no current is induced in the wire.

From inside a train car, an electric current from telegraph equipment passed through a coiled cable. The end of the cable was suspended underneath the train car and generated a magnetic field around the train car. As the train car traveled along the tracks, the magnetic field moved with it and induced a similar current in the telegraph lines already running along the tracks, even though the train cable and the telegraph lines were eight to ten inches apart and parallel to each other. The power of the induced current was strong enough to be received by the telegraph equipment at a nearby station or on other trains. In a similar manner, electrical currents generated by the telegraph at a train station and passed into the ground wire between rails could be picked up by the cable underneath the train car. This phenomenon of electromagnetic induction allowed station dispatchers to pinpoint the locations of all trains in their area at any given time. It also allowed train crews and dispatchers communicating with one another via telegraph to share details about oncoming trains and information about hazardous conditions. This communication helped make both commercial and passenger railways safer. The synchronous multiplex railway telegraph permitted two hundred telegraph operators to simultaneously use one wire. Although messages were going in opposite directions, they did not conflict with one another.

Although Woods received a patent for his special railway telegraph in 1887, his patent was challenged in court by two other inventors, Thomas Alva Edison and Lucius Phelps. Woods was declared to be the rightful patent holder and permitted to sell his patent to the Westinghouse Air Brake Company, which also specialized in electrical signaling. Unfortunately for Woods, much of the money he made from the sale of his patents went to pay legal fees rather than going into research and development at the Woods Electric Company. The Woods brothers eventually closed their business.

years later, he and his brother Lyates formed the Woods Railway Telegraph Company, which later became the Woods Electric Company. The company developed, manufactured, and sold telephone, telegraph, and electrical equipment. Among the company's first patented inventions were an improved steam boiler furnace and an improved telephone transmitter with superior clarity of sound and longer-range transmission.

In 1885, Woods patented a product that was a combination of a telephone and a telegraph, a "telegraphony." His invention allowed a telegraph operator to send either voice or telegraph messages over a single wire. The device was so successful that he later sold it to the American Bell Telephone Company. The lucrative sale enabled Woods to become a full-time inventor.

Woods patented a synchronous multiplex railway telegraph in 1887. A variation of the induction telegraph, it allowed for messages to be sent between moving trains, and between trains and railway stations. With this device, dispatchers could know the location of each train, telegraph information about equipment conditions and hazardous weather, and take necessary precautions to make railway travel safer. In the robust railroad industry of the late nineteenth century, this invention was so successful that Woods found himself fighting patent suits filed by Thomas Alva Edison and Lucius Phelps. Woods successfully defended himself, proving that there were no existing devices upon which he could have modeled his invention. Persistent in winning Woods and his expertise, Edison offered Woods a prominent position in the engineering department of Edison Electric Light Company in New York. Woods refused, preferring to remain independent.

As a prolific inventor, Woods soon developed other inventions for electric railways. His patents included electromechanical and electromagnetic brakes (1887), an overhead electrical conducting system for trolleys (1888), and an automatic safety cutout for electric circuits (1889). For a while, he manufactured and sold his inventions through the Woods Electric Company, but he later sold his patent rights to the General Electric Company.

In 1890, Woods moved to New York City to develop more electrical equipment for subways and trolleys. In collaboration with his brother Lyates, he patented emergency braking systems and devices relating to third-rail power. Woods used his knowledge of electrical systems to devise the method of supplying electricity to a train without any exposed wires or secondary batteries. Approximately every twelve feet, electricity would be passed to the train as it passed over an iron block. In 1892, he demonstrated the device as a complete Electric Railway System at Coney Island amusement park in New York City. The Woods Electric Company closed in 1893, but Granville Woods continued working to meet the need for more electrical products.

At the turn of the century, Woods patented an air brake, an egg incubator, and devices for regulating and controlling electrical devices and motors. He continued to develop and patent better railway systems and equipment during the last decade of his life. When he died on January 30, 1910, at Harlem Hospital in New York City, he had become an admired and well-respected inventor, having sold many patents to such corporations as Westinghouse Air Brake Company, General Electric, American Bell Telephone, and American Engineering.

Impact

Many of Woods's inventions attempted to increase efficiency, safety, and profitability of the burgeoning railway communications, commerce, and industry of his time. Because he explored the many advantages and possibilities in utilizing clean electrical energy over horse power, coal, and steam, he is among the forerunners of modern proponents of environmentally friendly energy sources.

Over the course of his lifetime, Woods obtained approximately sixty patents for his inventions, including an electromechanical brake, an electromagnetic brake, an automatic air brake, an electrical railway system, and an egg incubator. He also had patents for improvements to other inventions, such as safety circuits, telegraphs, phonographs, and telephones. Among Woods's better-known contributions are inventions introducing third-rail electrical power in mass-transit subway systems and overhead electrical power for trolley cars. Many subway, elevated, and commuter-rail systems still use third-rail electrical power. His development of the synchronous multiplex railway telegraph system allowed messages to be sent to and from moving trains, enabling train conductors and engineers to avoid collisions and to report information about hazardous conditions. This invention is one of the forerunners of modern communications networks. Woods is among the inventors who have inspired creative integration of science, engineering, and technology to solve a variety of business and industrial problems.

Woods struggled as a relatively small businessman encountering opposition from big corporations with competitive advantages. Although selling some of his patents yielded him initial profits, Woods came to realize that a product sometimes resulted in higher-than-anticipated demand. Yet because he sold his patents, he received no additional profits and little if any public recognition for their development. Even when challenges to his patents forced him into legal disputes, Woods demonstrated the fortitude needed to consistently defend his patent rights.

Granville T. Woods overcame many obstacles related to being an African American genius and a prolific inventor during an era when most African Americans could obtain neither a basic education nor viable employment. Public schools in New York City, Chicago, and suburban New Orleans were later named in his honor.

Steve Wozniak

American computer engineer

Wozniak produced several key technical innovations of the microcomputer era, including chip designs and circuit boards that used electronics more efficiently than previously thought possible.

Born: August 11, 1950; San Jose, California
Also known as: Stephen Gary Wozniak (full name)
Primary field: Computer science
Primary inventions: Personal computer (PC); *Breakout* (video game)

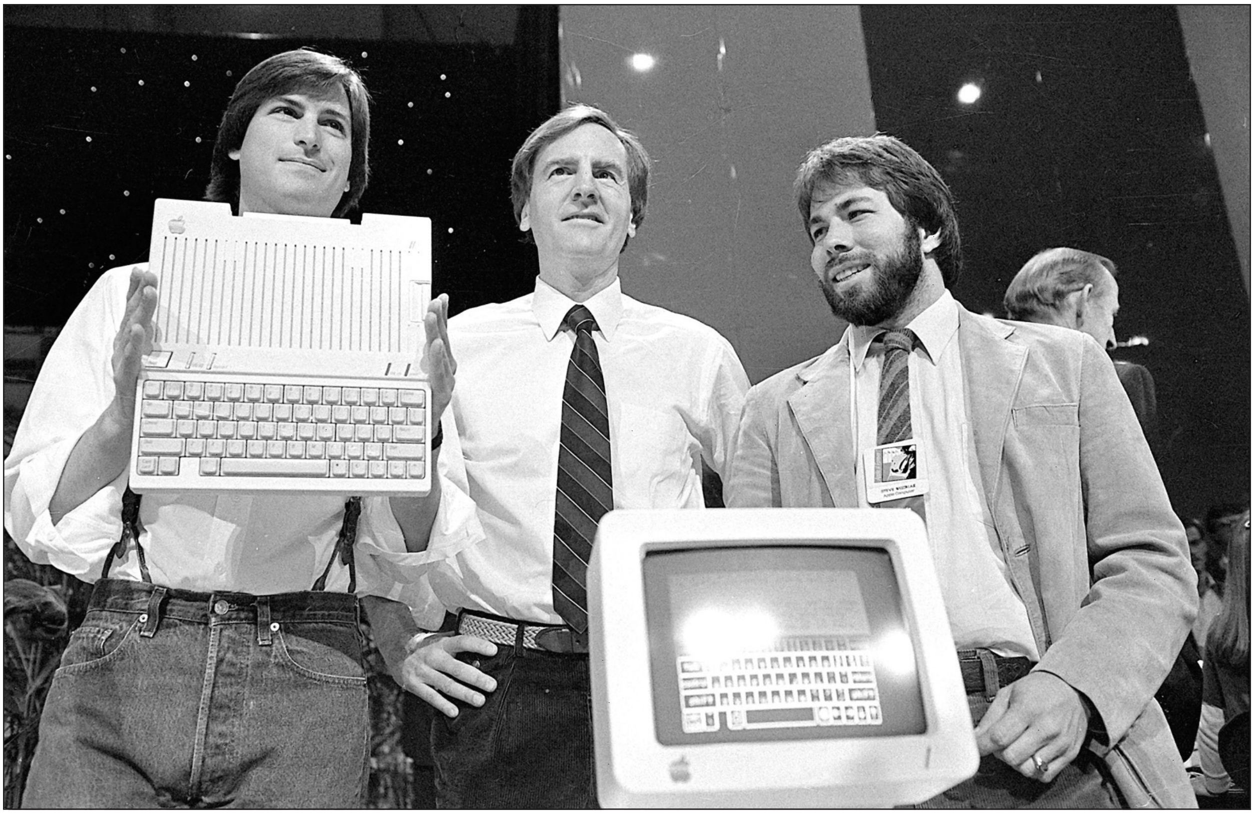
Early Life

Stephen Gary Wozniak (WOZ-nee-ak) was born in San Jose, California, the son of an electrical engineer. His father, Jerry, worked for the National Aeronautics and Space Administration (NASA) and other government agencies during Steve's childhood. When young Steve asked his father questions about work, the elder Wozniak would always answer that he was a man of his word. Steve eventually figured out that his father was working on secret projects and had promised not to talk about them. This understanding instilled in Steve a powerful ethic of honesty.

However, the young Wozniak differentiated between lies and pranks. His nimble technical mind allowed him to come up with very complex pranks that could even fool adults. For instance, he once designed a very convincing fake bomb using two old-fashioned stick batteries and an electronic oscillator that produced a realistic ticking sound. When he planted it in a friend's locker, intending to startle the unwitting friend, he instead created a panic. The school principal, thoroughly convinced that the device posed a deadly threat to his students, scooped it up and sprinted to the football field, where he disassembled the device. Wozniak was quite surprised to be arrested and put in juvenile hall for his prank, since he regarded it as an example of his skill with electronics rather than anything truly dangerous.

While still in high school, Wozniak got an internship at GTE Sylvania, a company producing microwave relay systems for telephone networks. There he worked with his first computer, an IBM 1130 mainframe that ran on punch cards and occupied a case the size of a refrigerator. Wozniak appreciated the privilege of being able to work with this computer; the experience taught him to move beyond purely hardware approaches and to understand the importance of the instructions that made a computer work. (The term "software" was relatively new at that time.) He learned FORTRAN, one of the earliest computer languages, and how to write programs for the 1130.

After dropping out of the University of Colorado, Wozniak met a new friend, Steve Jobs. The two young men shared interests and, like many computer geeks, considered technical know-how the currency of status within their subculture. The two men soon became in-



From left: Steve Jobs, chairman of Apple Computer; John Sculley, president and chief executive officer; and Steve Wozniak, cofounder of the company, unveil the new Apple IIc computer in San Francisco, California, in April, 1984. (AP/Wide World Photos)

volved in phone phreaking, building "blue boxes" to spoof telephone switching systems and gain free calls. Once they had a close call with a suspicious police officer, but Jobs convinced him that the illegal device was a music synthesizer.

Life's Work

In 1973, Wozniak left school to get a job with the electronics company Hewlett-Packard (HP). A year later, Jobs found work with the video game manufacturer Atari. Jobs was asked to design a new game, *Breakout*, and soon pulled Wozniak into the work, agreeing to split the money. In fact, Jobs had been promised a hefty bonus for certain design features, which he quietly pocketed. Wozniak would not find out about this for more than a decade, when he was helping a researcher write a history of Apple Computer (later Apple). Wozniak was not so upset about the money—he would have done the job for free just to be able to work on such an intellectual challenge—but the deception and betrayal stung bitterly.

At the time, Wozniak was simply happy to have successfully completed the challenge. He became involved in the Homebrew Computer Club, a group of computer hobbyists, in his spare time, and he designed an innovative microprocessor-based machine, originally to impress his friends. However, Jobs saw commercial potential in it, and both men sold a personal prized possession to raise capital: Wozniak, his HP programmable calculator; Jobs, his Volkswagen bus. On April 1, 1976, they officially founded Apple Computer, and a few months later they delivered their first shipment of assembled circuit boards to the Byte Shop, an early Silicon Valley computer store.

Their first computer's relatively crude appearance appealed only to dedicated hobbyists, so Jobs and Wozniak designed a successor, the Apple II, which came in a tan plastic case, in order to appeal to the general public. Wozniak did most of the circuit design, while Jobs concentrated on developing Apple's new logo, a rainbow-colored apple with a bite out of it. When users of the earliest Apple II model complained about the slow loading of programs from cassette tapes, Wozniak designed a controller for a floppy disk drive, and the Apple II became one of the first microcomputers to boast floppy disks. The Disk II system allowed the Apple II to run business programs.

When Jobs launched the Macintosh project, Wozniak was instrumental in developing the disk controller for it, the Integrated Wozniak Machine (IWM) chip. However, the discovery of Jobs's betrayal over the *Breakout* money and other issues with Jobs's management style drove Wozniak away from the company he had helped found. Still, he remained active in the electronics industry, developing such diverse items as the first programmable universal television remote control and wireless Global Positioning System (GPS) equipment. He concentrated largely upon practical devices that help improve the lives of ordinary people.

Wozniak also became involved in various charitable causes and social activities. He sponsored two US Festivals, free concerts held in Southern California in 1982 and 1983. He used his engineering expertise to work out a realistic approximation of how many portable toilets would be needed for the expected attendance. He also made both financial and intellectual contributions to the Children's Discovery Museum in San Jose. The street in front of the museum was subsequently renamed Woz Way in his honor.

Wozniak was an early adopter of the Segway personal transport, and he became involved in a game known as Segway polo, showing that his quirky sense of humor has not diminished as he has aged. The top prize in this new sport is the Woz Challenge Cup, named in his honor. His sense of humor and good nature were underscored by his appearance as a competitor on the television talent show *Dancing with the Stars* in 2009.

Breakout

The earliest video game was *Pong* (released in 1972), an adaptation of table tennis, or Ping-Pong, in which players used handheld controllers to move rectangular "paddles" back and forth on a television screen in order to bounce the ball back and forth. The primitive state of electronics at the time made it impossible for programmers to create a computer-controlled player, so a single person wanting to play alone was out of luck. This was a minor annoyance for owners of the home console but represented a considerable amount of lost revenue for arcade owners.

Thus, Atari founder Nolan K. Bushnell was interested in developing a single-player version of the game. He visualized something like handball, in which the player would bounce the ball off the walls, but that seemed rather simplistic. To add additional challenges for the player, he suggested that the object of the game would be to remove several rows of colored bricks by striking them with the ball.

Bushnell initially turned to Steve Jobs, who was working as one of his technicians at the time. Seeing that the task was beyond his skills, Jobs recommended Steve Wozniak, who was skilled in circuit design. Wozniak gladly took the challenge and soon produced a design that used far fewer chips than anything else Atari had produced. However, his design was so elegant that it was difficult to manufacture, and it had to be modified in order to allow the chip-fabricating technology of the time to produce it.

In spite of its relative simplicity (the original *Breakout* had only two screens of bricks, and once all of them were knocked out, the player could advance no further), the video game quickly became a hit at video arcades across the country. Atari took the revenue to design more advanced versions of *Breakout* that included a potentially infinite number of screens of bricks, as well as increasing challenges as the game went on. For instance, the on-screen paddle would shrink after a certain number of levels were cleared, or the ball would begin moving more rapidly.

As a result of these changes, new versions of *Breakout* became open-ended. In one *Breakout* version, the ball smashed through whole rows of bricks instead of destroying a single one with each bounce. Other variations added narrative elements or additional complications. For example, *Arkanoid*, popular in the late 1980's as both an arcade game and a computer game, was built around a story of a spaceship full of refugees fleeing an enemy and having to make its way through a series of fields of hostile aliens. In this game, each level's field of bricks was arranged in a different way, and some of the bricks produced "pills" that gave special power-ups. At the top of the field were two "gates" that would open to admit small aliens that could destroy the player's on-screen paddle if they touched it. *Arkanoid* also replaced the open-ended format with a set collection of thirty-two fields and a thirty-third round in which the player had to kill the master alien by bouncing the ball off its one vulnerable point, at which point a victory screen was displayed.

Because the basic form of *Breakout* is so simple, the game was later included as a surprise, or "Easter egg," in a number of computer programs. It later became available in numerous forms as shareware, often as a desktop application.

Impact
Although Wozniak was less interested in business than was his friend and collaborator Steve Jobs, his technical expertise was critical in the founding of Apple Computer and its early success, even into the Macintosh era. He designed computers that needed fewer chips than previous models, and his simple, elegant designs laid the groundwork for future product lines.

Frank Lloyd Wright
American architect

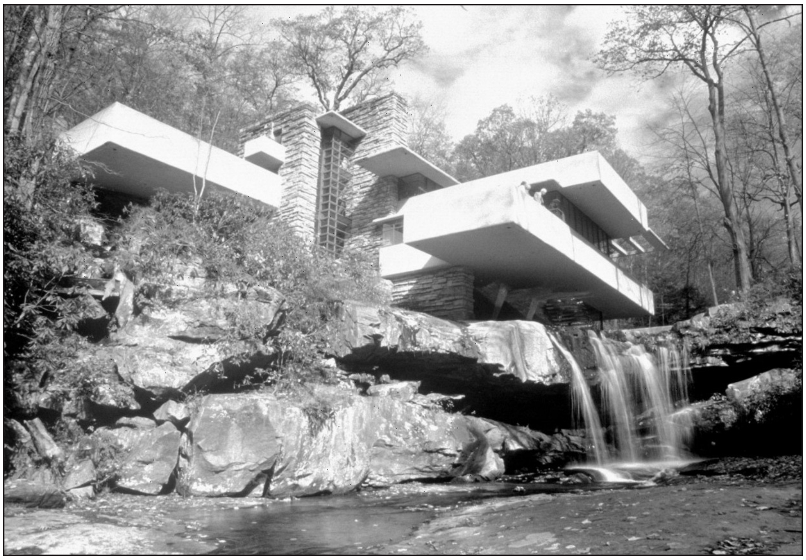
Wright is considered by many to be the greatest architect of the twentieth century. During his long career, he was responsible for a great many innovations in structure, materials, and design.

Born: June 8, 1867; Richland Center, Wisconsin
Died: April 9, 1959; Phoenix, Arizona
Also known as: Frank Lincoln Wright (birth name)
Primary field: Architecture
Primary inventions: Innovative architectural design (open planning, outdoor rooms, water features) in such signature projects as Taliesin, Fallingwater, the S. C. Johnson building, and Usonian and Prairie homes

Early Life
Frank Lloyd Wright was born in Richland Center, Wisconsin, on June 8, 1867, and given the middle name of Lincoln. Frank's mother, Anna Lloyd Jones Wright, was a schoolteacher and the daughter of prosperous Welsh immigrants. Frank's father, William Carey Wright, was a New Englander who became a Baptist preacher. In 1863, William's first wife, Permelia, died in childbirth, leaving three children. Three years later, William and Anna were married.

Though William was likeable and dynamic, he was impractical; he kept accepting calls to churches that could not pay him enough to support his growing family—for Frank was soon joined by two younger sisters. After three years in Richland Center, William moved to McGregor, Iowa; Pawtucket, Rhode Island; and Weymouth, Massachusetts. In 1877, he accepted a call to a Unitarian church in Madison, Wisconsin. William's indifference toward Anna and his children by her made her understandably hostile toward him. In 1885, William and Anna were divorced. William left Madison, and Frank never saw his father again. About this time, Frank changed his middle name to Lloyd, thus claiming his mother's family and her Welsh heritage.

Despite the family problems, Frank had a relatively happy youth. He always had playmates and friends. Moreover, his mother, who was always certain that he would be a great architect, devoted a great deal of time to his education. She utilized the progressive ideas of the German educator Friedrich Wilhelm August Fröbel, who believed in balancing physical and mental activity,



Fallingwater, designed by architect Frank Lloyd Wright as a weekend cottage for Edgar J. Kaufmann, is an example of organic architecture. The house sits above the falls and blends with the environment. (AP/Wide World Photos)

encouraging creativity through the use of geometric designs, and developing a reverence for nature. Though Frank attended the Second Ward Grammar School in Madison, his real education took place at home, where he could let his imagination run free, reading, painting, drawing, or just dreaming. In order to toughen him up physically, every summer from 1878 on Wright was sent to work on an uncle's farm.

Since his father would not support Anna and her children, Frank dropped out of Madison High School in March, 1885, and began working in an architectural office. He also attended the University of Wisconsin for two semesters, but in the spring of 1887 he went to Chicago, which had become an important architectural center.

LIFE'S WORK

At his first job, in the drafting office of the architect J. Lyman Silsbee, Wright began to develop skill in domestic architecture. His employer's high estimate of Wright is evident in the fact that within a year, he was making enough to bring his mother and his younger sister, Maginel Wright, to live with him in suburban Oak Park. On his own time, he built the Hillside Home School in Spring Green, Wisconsin, for two of his aunts. Wright then obtained a position with Adler and Sullivan, an architectural firm that was always on the cutting edge of design. There he worked on the massive Auditorium Building, thus expanding his knowledge of engineering. He also learned a great deal from Louis H. Sullivan, who was noted for his innovative designs. Sullivan thought so highly of Wright that he made the young man his assistant.

On June 1, 1889, Wright married Catherine Lee Tobin, and they moved to a house in Oak Park that he had designed and built for her. The next year, their first child was born; five more would follow. As the family expanded, Wright built onto his home. A spacious playroom constructed in 1895 had a floor patterned with the shapes Wright remembered from his Fröbel training; its extensive use of natural light and its open plan foretold designs to come.

In 1893, Wright left Sullivan and formed a partnership with his friend Cecil Corwin. Three years later, Wright became independent. He constructed a number of low, horizontal homes in and near Oak Park that became known as "Prairie houses." In them, he eliminated interior walls as much as possible, substituting large open spaces with multiple uses; he also used porches to eliminate the break between indoors and outdoors. These ideas would reappear in his designs for larger homes and even for public buildings such as the Larkin Administration Building in Buffalo, New York (1902-1906), and the Unity Temple in Oak Park (1905-1908).

However, Wright's marriage had collapsed. In 1909, he eloped to Europe with a married woman, Mamah Borthwick Cheney. After they returned, Wright installed his mistress at Taliesin, the house at Spring Green that was to be his home, his studio, and later the location of his Fellowship. On August 14, 1914, tragedy struck. Without warning, a newly hired cook ran amok, killing seven people, including Mamah and her two children, and setting fire to the living quarters, which burned to the ground. Wright was devastated. His only salvation was his work.

Wright had already begun planning one of his most ambitious projects, the Imperial Hotel in Tokyo (1922). Aware of the danger of earthquakes, he designed the building in separate sections, each of which was attached to a base that floated on the mud below, and he also placed pools of water throughout the structure, thinking that they could be useful in case of fire. The Imperial Hotel was one of the few buildings in Tokyo to survive the catastrophic 1923 earthquake.

During the years that followed, Wright designed and built "Usonian homes" for people of modest means; lavish private residences like Fallingwater in Bear Run, Pennsylvania (1935); and public structures such as the S. C. Johnson and Son Administration Building in Racine, Wisconsin (1936), and the Solomon R. Guggenheim Museum in New York City (1959). At a rebuilt and expanded Taliesin, he founded the Fellowship, a system in which students, or apprentices, pursued their artistic interests while living a communal life. He later added a second campus, Taliesin II, located in the Paradise Valley near Phoenix, Arizona.

After Mamah's death, Wright had become involved with Miriam Noel, a sculptor. However, he postponed obtaining a divorce from Catherine until 1922. His subsequent marriage to Miriam lasted only a few months. In 1928, Wright married Olgivanna Ivanova Lazovich Hinzenberg, a dancer from Montenegro. They had one daughter, Iovanna. Wright died in a Phoenix hospital on April 9, 1959, and was taken to Wisconsin to be buried in the family graveyard. However, after Olgivanna died in 1985, Iovanna insisted that her mother had wanted Wright to be buried with her. His body was exhumed and cremated, and his ashes were taken to Taliesin West.

Impact

Though during his lifetime a great many architectural fashions came and went, Wright paid little attention to them. Instead, he drew his inspiration from his own inner sense of what was good and beautiful. This freedom from tradition, from fashion, and indeed from all outside influences enabled him to invent structures that were totally new and different—an office building without separate cubicles, for example, or a house with a concealed entrance. Wright could also use whatever materials he wished in whatever combination he liked. He could place something as modern as reinforced concrete in close proximity to traditional building materials like wood or stone and produce a structure that seemed at the same time as ancient as its

Fallingwater

Fallingwater, a house Frank Lloyd Wright built in 1935 in Bear Run, Pennsylvania, has been called the most famous private residence in the world. It was commissioned by Edgar J. Kaufmann, the president of a Pittsburgh department store, and was intended as a weekend retreat, where his guests would have a good view of the falls. However, Wright had his own vision of what the building should be. In keeping with his theory of organic architecture, Wright decided to build the house over the falls, making it appear to jut out from the rocky slope over which the falls flow so that it would seem to be an integral part of its natural surroundings. Not surprisingly, this unusual structure cost some $75,000, or $40,000 more than the limit that Kaufmann had originally set.

Fallingwater reflects both the horizontal and the vertical planes of the site. Two cantilevered terraces cross above the falls, mirroring the horizontal ledge over which the water flows, while the tall chimney that rises above the massive stone fireplace echoes the vertical lines of the waterfall. Some of the natural materials Wright used were local; the Pottsville sandstone, for example, came from a quarry near Harrisburg, Pennsylvania. However, Wright also paid tribute to the new technology, for example, by utilizing reinforced concrete for his pillars.

The floor plan of Fallingwater exemplifies another of Wright's theories: that the interior space in a house should make confinement or separation almost impossible. There are very few walls in the house. Most of the first floor is taken up by a huge living and dining room. The bedrooms on the second and third floors are relatively small; much of the space on those floors is taken up by large, stone-paved terraces.

Unfortunately, Fallingwater was so far ahead of its time that some of the materials and the techniques that would have made it more stable were not yet developed. Over the years, the original owner's son, Edgar Kaufmann, Jr., did his best to maintain Fallingwater. In 1963, he presented the house and the land around it to the Western Pennsylvania Conservancy. By the 1990's, it was evident that a major overhauling was necessary. The most urgent task was to repair the concrete cantilevers, which were threatening to collapse because they had not been sufficiently reinforced; in addition, the house needed to be rewired and new heating and plumbing systems installed. With these and other repairs completed, Fallingwater was once again secure.

In 2000, the American Institute of Architects voted Fallingwater the Building of the Century. However, though Fallingwater is a unique architectural achievement, it has also influenced the direction of domestic architecture. Many home buyers now look for a house that suits its site, that has an open plan, and that uses expanses of glass, outdoor rooms, and terraces to bring the outdoors in. Thus, Wright's ideas, as embodied in Fallingwater, have become accepted by ordinary Americans.

natural surroundings and as new as the spacecraft of the future.

Wright's genius was also evident in the fact that he never repeated himself. Every building he designed was unique, and as decade followed decade, he was constantly pursuing new paths, while at the same time remaining true to those principles by which he had always been guided, among them his insistence on fitting a structure to its site.

Wright's designs are responsible for much that is taken for granted today: for example, open planning, outdoor rooms, and the use of water features in homes, hotels, and convention centers. His works and the free spirit that produced them continued to influence both domestic and commercial architecture throughout his life span and into the twenty-first century.

Wilbur and Orville Wright

American aeronautical engineers

The Wright brothers developed the first successful heavier-than-air flying machine that incorporated wings to create lift; propulsion to produce forward thrust; and movable surfaces to control pitch, roll, and yaw, thus making modern aviation possible.

Wilbur Wright

Born: April 16, 1867; near Millville, Indiana
Died: May 30, 1912; Dayton, Ohio

Orville Wright

Born: August 19, 1871; Dayton, Ohio
Died: January 30, 1948; Dayton, Ohio
Primary field: Aeronautics and aerospace technology
Primary invention: First successful heavier-than-air aircraft, the Wright Flyer

Early Lives

Wilbur and Orville Wright were born in 1867 and 1871, respectively, to Milton and Susan Koerner Wright. Wilbur was born near Millville, Indiana, shortly before the Wright family moved to Dayton, Ohio, where Orville was born. They had five brothers and sisters. Their father was a bishop in the United Brethren Church; he was a strong, self-confident man who believed utterly that, with enough hard work, a person could achieve anything he or she set out to do. He encouraged his children to explore whatever made them curious. Wilbur and Orville often credited this early environment with allowing them to pursue their passion, flying, and with giving them the work ethic to persist until they were successful.

Wilbur was an outstanding student, and there were plans to send him to Yale. However, when he was eighteen, he was struck in the face by a stick during a game of hockey. He lost several teeth, and he also developed a heart condition. Whereas he had been an outgoing young man before the accident, after it he became withdrawn and very quiet. He did not attend college, instead choosing to stay at home and nurse his mother, who subsequently died of tuberculosis in 1889. Upon her death, Wilbur and Orville's sister Katharine took over the task of caring for the family. Except for the four years she spent at Oberlin College, she was a homemaker for Orville, Wilbur, and their father, a role she continued for Orville until 1926, long after the deaths of Wilbur and her father.

Wilbur (left) and Orville Wright. (Library of Congress)

Orville did not finish high school. During his junior year, he left school to open his own printing business, publishing his first newspaper in 1889. Wilbur joined him in this endeavor; although the newspaper business failed quickly, the print shop prospered. At about the same time, however, the brothers became interested in bicycles, and soon they were not only riding bikes but also repairing bicycles for their friends. In 1892, the brothers founded the Wright Cycle Company, and they were very successful in this venture. In 1899, however, they began work on what became the passion of their lives: the quest for flight.

Lives' Work

Across the world, many engineers and scientists were racing to develop the first heavier-than-air flying machine. In Europe, Otto Lilienthal was the best known, and his work with hang gliders aroused intense public scrutiny. In 1896, however, one of his gliders went into a stall, and Lilienthal crashed to the ground, mortally wounded. His work, and his death, aroused the interest of the Wrights. In their search for information, they contacted the Smithsonian Institution and received books and brochures describing the work of two Americans, Samuel Pierpont Langley, the head of the Smithsonian Institution, and Octave Chanute.

The brothers recognized almost at once that the key to solving the problems of mechanical flight were threefold: They would need sturdy yet flexible wings to provide lift; they would need some sort of engine to provide forward motion, or thrust; and they would need to be able to control the machine in flight. The Wrights were careful engineers who were able to identify and borrow the technology developed by others. Their own experiments began with a biplane glider with a wingspan of five feet. They flew this model as a kite and tested their idea that wing warping would allow them greater control than straight wings.

Once they had the basic design of the glider, they

The Wright Flyer

Wilbur and Orville Wright spent the years from 1899 to 1905 experimenting with the three basic problems of mechanical flight: lift, propulsion, and control. The Wright Flyer, a biplane flown at Kitty Hawk, North Carolina, on December 17, 1903, was the first heavier-than-air machine that solved these problems, demonstrated by sustained forward, piloted flights and landings at points at the same or higher elevation from the takeoff point.

The Flyer was constructed of ash and spruce, both light woods, and then covered by muslin. An important feature of the wing covering was that the framework could move slightly within the pockets of the muslin. The overall effect was that the structure of the plane was flexible and strong. The shape of the wings helped to provide the lift needed for the plane to get off the ground.

Propulsion, or thrust, is necessary to provide forward movement to an airplane. The Wrights' source of thrust was a device consisting of twin propellers attached to a hub, in turn attached to a four-cylinder, twelve-horsepower engine using a sprocket chain drive—technology the Wrights learned from their work with bicycles. The propulsion device was designed to be lightweight as well as reliable and strong. The engine turned the chain, which turned the wings at a high rate of speed, drawing air through them and moving the aircraft forward.

The Wrights correctly understood that control was the most important element of flight necessary for a practical machine. There are three axes around which an airplane moves. Pitch refers to the up-and-down movement of the nose of the aircraft. Yaw refers to a side-to-side movement of the nose, while roll is the up-and-down movement of the wing tips. All three movements must be under control. The Wrights placed a rudder at the rear of the Flyer to control yaw and used wing warping to control roll. The pilot controlled the aircraft through the use of a movable cradle attached to the bottom wing and connected to the wing tips and rudder by wires. The pilot lay prone in the cradle and shifted his weight, thus moving the rudder and warping the wings. In addition, an elevator at the front of the plane could be controlled with a wooden stick by the pilot. This brought the nose up or down and controlled pitch.

While modern aircraft uses fixed rather than flexible wings, and ailerons rather than wing warping, the basic premises that guided the Wrights in their development of the 1903 Flyer still underpin modern aeronautics. Every aircraft flying the skies today is a direct descendant of the aircraft flown by Orville Wright on that windy December day on the Outer Banks of North Carolina.

knew they had to build one large enough to hold a human pilot and to find a location with specific requirements to allow them to test it. They needed a lot of wind and plenty of open space. Through correspondence with the U.S. Weather Bureau, they determined that Kitty Hawk, North Carolina, would fill their needs. Once the glider was constructed, Wilbur determined to go ahead and make arrangements for them. It was a long journey. Located on the Outer Banks of North Carolina, Kitty Hawk could only be reached by boat, since there were no bridges. Nevertheless, by the end of September, 1900, both brothers and their glider were at Kitty Hawk. They had very successful tests with the glider.

The Wrights returned to the Outer Banks in 1901 with a new and improved glider, but all in all it was a very discouraging season for them. After a near catastrophic wreck, the brothers returned to Dayton, not at all sure that they would accomplish their goal.

The Wrights vigorously analyzed their data. They built a wind tunnel to test out a variety of wing constructions. In 1902, they returned to the Outer Banks. This time, they met success as they tested the new glider. All that remained was to design an engine that could fly the plane. Their own bicycle shop mechanic Charles E. Taylor successfully accomplished this task, and by the winter of 1903 they were ready to return to Kitty Hawk. On December 17, 1903, the Wright brothers took off into history. They completed a total of four flights, the longest one covering a distance of two hundred feet at an altitude of ten feet.

In the years that followed, the Wrights were very quiet about their ongoing testing and improvements to their aircraft as they were attempting to patent their machine. They did not want others to steal their technology because they believed that there was a great future in aviation. By 1906, patent in hands, they began public demonstrations of their craft. In 1908, the Wrights quieted all scoffers when Wilbur demonstrated the improved Wright Flyer in France.

In 1909, the brothers incorporated the Wright Company, setting up an airplane manufacturing factory and a flight school in Dayton. With the first commercial flight in 1910, the Wrights demonstrated the potential of their invention.

Wilbur Wright contracted typhoid fever in 1912 and died at age forty-five. His brother grieved deeply, and within three years he sold the Wright Company. Orville's last flight was in 1918. He became a spokesperson for aviation, ultimately serving on the board of the agency that became the National Aeronautics and Space Administration (NASA). He died of a heart attack in 1948.

Impact

The Wright brothers did not invent the airplane by themselves. They built on the work of other aviation pioneers, who sometimes even sacrificed their lives to further the study of human flight. The Wrights were, however, the first experimenters to approach the study of flight in such a systematic way. Through rigorous testing and endless attention to detail, the Wrights were the first of the early aviators to define the essential problems of flight.

The Wright brothers correctly identified control as the key problem to solve, and they did so. Since 1903, aeronautics has continued to build on their painstaking tests with their Dayton wind tunnel and their Kitty Hawk flights. In addition, the Wright brothers understood even in 1903 that machine-powered flight was not just some curiosity but rather the wave of the future. They knew that once developed, flying machines would change the course of civilization. Their vision made possible the first steps of aviation history. It is fitting that Neil Armstrong, the first astronaut to step on the Moon, carried with him a piece of the fabric from the 1903 Wright Flyer.

Rosalyn Yalow

American medical physicist

Yalow won the Nobel Prize in Physiology or Medicine in 1977 for the discovery of the radioimmunoassay (RIA) method for detecting small concentrations of compounds, especially hormones, in body fluids. RIA allowed scientists to study the action of hormones and other compounds in the body.

Born: July 19, 1921; Bronx, New York
Also known as: Rosalyn Sussman Yalow (full name); Rosalyn Sussman (birth name)
Primary field: Physics
Primary invention: Radioimmunoassay technique

Early Life

Rosalyn Sussman Yalow (YAH-loh) was born in New York City to Simon and Clara Sussman, a Jewish couple with little formal education but who had a thirst for knowledge. Clara had only a sixth-grade education but read every book that her children brought home from school. Simon had completed only the eighth grade, but he too read avidly. He owned a twine and paper business. Rosalyn had a brother, Alexander, who was five years her senior. Learning to read at an early age, Rosalyn became a member of the local library on the day she turned five. Alexander was responsible for supervising the weekly trip to the library to turn in the last week's books and get new ones. By the eighth grade, Rosalyn had become enthralled with mathematics. She graduated from high school at age fifteen by skipping grades, and in 1937 she entered Hunter College to study chemistry.

Rosalyn Yalow. (©The Nobel Foundation)

The chemistry classes were large, and Yalow received little attention from the instructors. The smaller Physics Department had instructors who showed an interest in Yalow and encouraged her. In January, 1941, she graduated magna cum laude with the first physics degree issued to a woman from the newly established department. Although she strongly desired to go to graduate school, Yalow was told that no school would accept a Jewish girl as a physics student; therefore, she made plans to work as secretary to a professor who would allow her to take physics classes. The military draft had so depleted the number of people wanting to do graduate work that the University of Illinois College of Engineering accepted her. She was the only woman in her class of four hundred. By January, 1945, she had earned her Ph.D. in nuclear physics and had met and married her husband, Aaron Yalow. She then returned to New York to teach at Hunter College. She took on the responsibility of establishing the radioisotope laboratory at the Bronx Veterans Administration Hospital because she missed research and teaching did not occupy enough of her time.

Life's Work

At the Bronx Veterans Administration Hospital, Yalow turned a janitor's closet into a radioisotope lab and began to work with doctors in treatment and research. In two years, eight publications had resulted from her work with other physicians. In January, 1950, she resigned from teaching at Hunter College. At this time, Yalow realized that she needed someone with more medical background than she possessed, so she developed a working relationship with an internist, Dr. Solomon Berson, in the spring of that year. The pair worked closely together for the next twenty-two years, until Berson's untimely death on April

11, 1972. He taught her medicine, and she taught him physics and mathematics. They worked so closely that they could anticipate each other's thoughts. They also worked at a feverish pace, often through the night.

Yalow wanted to be not only a superb researcher and wife but also an excellent mother. In 1952, at age thirty-one, she had a son, Benjamin. Her daughter, Elanna, was born in 1954. The rules at the Bronx Veterans Administration Hospital required that women leave at the end of their fifth month of pregnancy, but Yalow had become so important to the hospital that no one told her she had to quit. On weekends, when Yalow took care of the lab animals, she took her children with her to work. Even with her exhaustive work schedule, Yalow kept up with her children's activities. Both Benjamin and Elanna attended public schools and would go on to earn their doctorates.

At the lab, Yalow and Berson began working with radioisotopes to measure the body's volume of blood, then the size of each body compartment. Using radioactive iodine 131, they studied thyroid physiology. A study using albumin labeled with a radioactive isotope led to knowledge of the rate of production of body albumin and other serum proteins. A study of insulin degradation led to the discovery that type II (adult-onset) diabetes is caused not by a lack of insulin production but by the inefficient use of insulin by the body. They also found that even a small protein such as insulin would cause an antigen to form. An antigen is any substance (such as bacteria or another foreign substance) that provokes the body's immune response. To facilitate the analysis of samples, Yalow and Berson combined chromatography and electrophoresis. Their method allowed samples to be analyzed in a half hour instead of overnight.

In a 1956 research paper, Yalow and Berson described a new method of analysis using radioisotopes to measure the concentration of an organic compound. It required three years of work to refine the idea into a practical test. This method, called radioimmunoassay (RIA), meant that compounds could be detected using a drop, instead of a cup, of blood. RIA was not quickly accepted by the scientific community, but Yalow and Berson continued to do outstanding research using the method and also began to train others to use the method. They did not patent the idea, instead sharing with the medical community what they considered to be a valuable technique to study the body.

By 1970, RIA had become a successful, standard laboratory technique. When Berson died, Yalow was devastated, but she pushed forward. Her already large number of work hours increased, and in four years her lab produced sixty papers. In 1977, she was awarded the Nobel Prize in Physiology or Medicine. Yalow retired from the Bronx Veterans Administration Hospital in 1991.

Those who knew Yalow agree that she was a very determined medical physicist. In her lab, she was often terse with colleagues. At meetings, she was known to be critical of substandard research but fiercely protective of the people who worked for her. Many have been put off by her aggressive, less-than-tactful manner. However, according to her admirers, she had no time for niceties because there was research to be done.

The Radioimmunoassay

Radioimmunoassay (RIA) is a method to test for antigens, which are compounds that enter the body and cause it to produce antibodies during the body's immune response. The RIA method is extremely sensitive, and it is also specific for each antigen. The procedure uses known amounts of a radioisotope-labeled antigen (antigen made radioactive) mixed with a known amount of the antibody to that antigen. The two types of molecules—antigen and antibody—bind to each other.

Next, a blood sample from a patient containing an unknown amount of "cold" (not radiolabeled) antigen is added to the mixture. As more of the patient's sample is added, the cold antigen displaces the bound radiolabeled antigen, leaving the radiolabeled antigen free. Ultimately the bound antigen-antibody is separated from the unbound radiolabeled antigen, and the radioactivity of the unbound antigen can be measured and compared to a standard "binding curve." The final result tells the researcher exactly how much antigen, and of what specific type, is present in the patient's blood serum.

RIA testing has some disadvantages: Although very specific and requiring very small blood samples, it is nevertheless expensive, requiring sophisticated equipment and special precautions to protect against radioactivity. Today, another technique for identifying antigens—known as enzyme-linked immunosorbent assay (ELISA)—has largely supplanted the RIA method. Unlike RIA, ELISA does not use radioisotopes.

Impact

Radioimmunoassay has changed the way that research on body systems is done. Before RIA, many of the body's compounds were present in too small a concentration to be detected. The RIA procedure allowed scientists to study hormones in the blood. Medical uses for RIA have included studies on high blood pressure, infertility, nutrition, human growth hormone, infectious diseases, cancer, vitamins, and enzymes. The list of compounds that can be tested with RIA is almost as long as the list of compounds in the body. This noninvasive procedure can detect a billionth of a gram. No radiation touches the patient; the test is done on a small amount of blood (one drop) drawn from the patient. With RIA, a pediatrician can take a drop of blood from a newborn and detect problems at a very early point in the infant's development; blood banks can scan the blood supply for different diseases; and forensic scientists can analyze drugs and poisons.

Ferdinand von Zeppelin

German aircraft designer

The fund-raiser and driving visionary behind building giant rigid balloon airships, Zeppelin built a craft that flew three years before the Wright brothers' airplane. Problems of safety and maintenance made Zeppelin's airships unsuccessful, however, though his legacy remains in blimps and novelty aircraft.

Born: July 8, 1838; Konstanz, Baden (now in Germany)
Died: March 8, 1917; Charlottenburg, Germany
Also known as: Ferdinand Adolf August Heinrich von Zeppelin (full name); Count Zeppelin
Primary fields: Aeronautics and aerospace technology; military technology and weaponry
Primary invention: Rigid airship (dirigible)

Early Life

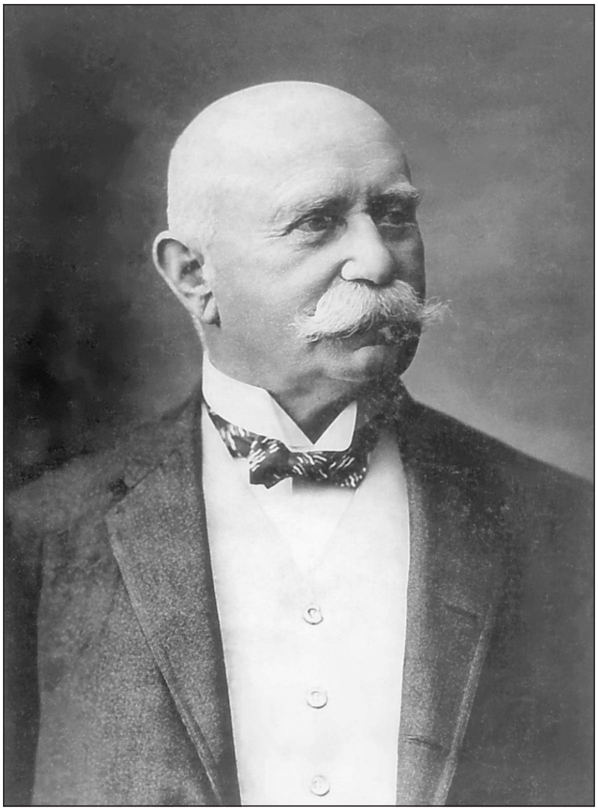
Ferdinand Adolf August Heinrich von Zeppelin (ZEHP-uh-lihn) was born near the Swiss border on Lake Constance (Bodensee in German). His father was councilor to the duke of Hohenzollern-Sigmaringen and his mother was from a family of wealthy textile manufacturers. Given an excellent private education and having an adventurous disposition, Zeppelin decided on a military career. He graduated from Ludwigsburg Military Academy and joined the Württemberg army in 1857. In 1863, he was given permission by Abraham Lincoln to observe the Civil War from Union lines, where he witnessed tethered observation balloons in army service. A short time later, he went on an adventure seeking the headwaters of the Mississippi River in Minnesota. While there, he took his first balloon flight.

Zeppelin fought in the Austro-Prussian War in 1866, which established Prussian military dominance over German-speaking Europe. In 1869, he married the Livonian baroness Isabella von Wolff and had a daughter—their only child. During the Franco-Prussian War in 1870, Zeppelin served in the cavalry and became famous for a nasty skirmish at Schirlenhof Inn, in which he was the only German not killed or captured. Later in the war, Prussia besieged Paris, and the French used balloons to communicate with the outside world. Zeppelin read of this in 1874 and was struck by the potential of steerable balloons for military and commercial use. In 1885, he was appointed military attaché for Württemberg in Berlin—the wrong man for the job. Zeppelin was not happy with Prussian domination of the German army and made enemies on the general staff. He was forced into retirement in 1891 as a brigadier general. He decided to build a practical balloon airship to fulfill his vision of the future, and to safeguard Germany from being overtaken technologically by the French. Zeppelin was not an engineer, however, and was totally reliant upon those he hired.

Life's Work

By the late nineteenth century, airships (*Luftschiffe*) as symbols of the coming age fired people's imaginations. European nations of the day were competing for military and economic dominance. Balloon aviators became romantic and patriotic figures, their achievements synonymous with national pride and the arms race. Three balloon types were experimented with: nonrigid, semirigid, and rigid. Rigid types had a girder framework that formed the aerodynamics necessary for steering.

The French successfully flew the nonrigid airship *La France* in 1884 and captured world attention. In 1887,



Ferdinand von Zeppelin. (Library of Congress)

The Dirigible

The word "dirigible" means "able to be steered." Zeppelins were dirigibles constructed of tough fabric stretched over a hollow frame (either wood or metal), into which lighter-than-air hydrogen was pumped under pressure. Steam was the common power source of the day to turn propellers, butit was impractical for balloons. Electric engines were available but underpowered and unreliable. Zeppelins used German-made gasoline engines. Zeppelin fabric was treated with flammable "dope," making it airtight. Aluminum was added to its outside to reflect heat so that the gas would not expand. Although hydrogen was quite combustible, it was available in quantity through the "water-gas shift method" of production: blowing steam through a bed of hot, glowing coke, then siphoning off the rising gas. Hydrogen was held in separate balloon compartments that resembled segments of an orange—but with a long, hollow area inside. If cells leaked or were ruptured, the ship remained aloft from the buoyancy of other cells. In later models, the hollow interior was crisscrossed with catwalks, ladders, and trapdoors to the outside. On top of the zeppelin was a valve permitting leaked hydrogen to vent into the atmosphere rather than build up inside the combustible cloth.

Helium was a better choice than hydrogen as a lifting agent: Although not quite as buoyant, it does not burn. However, helium was a laboratory curiosity until 1917, when American scientists discovered how to extract it from natural gas wells in the United States and Canada. Texas became the main source for it, and the United States held a monopoly on it for two decades, refusing to sell it to the Germans. Consequently, all zeppelins were filled with explosive hydrogen even into the late 1930's.

To further the civilian use of his dirigibles, Ferdinand von Zeppelin founded the German Airship Transportation Company (DELAG) in 1909, the first commercial airline in history. It folded when World War I began. In 1919, Hugo Eckener saved the company from ruin by restarting DELAG. He had only the LZ120, which flew successful passenger service until it was seized by Italy as war reparations in 1921. France seized Zeppelin's newly built LZ114 and LZ121. The U.S. Navy then gave Zeppelin's company a contract to build a U.S. dirigible to be named *Los Angeles*. In 1924, Eckener personally flew it across the Atlantic to the United States, where its hydrogen was pumped out and replaced with helium. The Goodyear company later entered into a partnership with Zeppelin to build airships for the U.S. Navy. The *Akron* (1931) and the *Macon* (1933) were built in Germany and helium-filled in the United States, but both wrecked within two years of their construction as a result of weather.

Zeppelin wrote the king of Württemberg about the need to match this technology. By 1891, when the count was forced into retirement, he believed it was his patriotic duty to safeguard Germany by developing the airship. He hired engineers to draw up blueprints. In time, his most famous assistant would be Dr. Hugo Eckener.

In 1894, Zeppelin's requests for government development funds were rejected for poor design and planning, but he nevertheless patented his blueprints. In 1898, he sought capital to build a dirigible himself. He erected a huge shed floating on pontoons on Lake Constance. His prototype LZ1 was 39 feet in diameter and 420 feet long, with two passenger gondolas, each with two propellers run by gasoline engines. A stability weight dangled beneath, and there were top and bottom rear rudders. On the evening of July 2, 1900, when winds were mild, the LZ1 flew for twenty minutes. An engine crankshaft bent the airframe, but the ship landed safely. The LZ1 flew twice more before Zeppelin ran out of money and closed operations, in 1901. In 1902, he found no backers, although many were sympathetic. They saw Zeppelin's airships as contraptions and Zeppelin as an old hero with a harebrained idea, a bittersweet Don Quixote.

After Wilbur and Orville Wright's historic flights in December, 1903, at Kitty Hawk, North Carolina, public interest in airships increased. Zeppelin ran a lottery and mortgaged his wife's estate to fund the LZ2, which flew in early 1906. Compared to the LZ1, the LZ2 had more powerful engines and sliding midsection weights to control trim. Its engines stalled, however, and when it landed, winds blew it to pieces. That same year, Kaiser Wilhelm II founded the Society for the Study of Powered Flight to close the airship gap with France. Zeppelin raised funds to build the LZ3, which flew more than thirty miles per hour in October, 1906. It had tail and rudder improvements copied from the French, making it stable enough to discard midsection weights. Zeppelin's daughter and the crown prince were passengers in the airship. The airship once stayed aloft for eight hours. Following the success of the LZ3, the German government allocated funds and ran a lottery to build the LZ4. Meanwhile, the French airship *Patrie* carried Premier

Georges Clemenceau over the Eiffel Tower in July, 1907. German unease increased over French airship technology.

The LZ4 was 146 feet long, had more powerful engines and larger rudders than its predecessor, and had a fuel-storage cabin halfway between two gondolas. In July, 1908, it flew for twelve hours, crossing into Switzerland and back. The king and queen of Württemberg flew in it over Lake Constance. In August, 1908, the airship force-landed in the German village of Echterdingen, where a crowd gathered around it and spontaneously sang the national anthem. Later, a storm destroyed it by dragging it into trees. Germans sent Zeppelin money to build the LZ5, and there were now government funds as well. Zeppelin became a national hero for ignoring public opinion and Prussian indifference to build his invention for Germany. In 1909, the LZ5 flew to Berlin, where it was greeted by the German emperor.

That same year, Louis Blériot flew across the English Channel in an airplane, but Germans loved "zeppelins" too much to be mindful of Blériot's feat. During 1910-1911, four zeppelins were destroyed on the ground by winds. The German general staff realized that zeppelins were vulnerable but nevertheless ordered seventeen of them in 1912 because of rumors of a French airship fleet. By World War I, in 1914, Germany had twelve airships and twenty-six airfields, and the Zeppelin works had a rival: The Schütte-Lanz Company had begun building dirigibles for government and civilian use in 1909, although all rigid balloons of the day were commonly referred to as zeppelins.

Airship bombing raids of Great Britain and France commenced in 1915. At first, there was shock and fear in the populace, but in time people got used to them. By 1916, the Allies were shooting zeppelins down with incendiary bullets and antiaircraft fire. In response, zeppelins flew above the clouds to be out of range. This necessitated lowering an observer in a cable car (*Spähkorb*) below cloud level to telephone when a zeppelin was over its target. By 1917, zeppelins had a range of almost 7,500 miles and had antifreeze coolants and oxygen masks for high altitudes. However, they were regularly shot down or crashed before they reached their objectives. The German military flew 111 *Luftschiffe* raids, dropped 311,500 pounds of bombs, killed more than 500 people, but had a loss rate of about 70 percent from combat and accidents. During the war, Zeppelin advocated all-out aerial bombing of Allied cities in order to bring victory. He died of pneumonia in Berlin on March 8, 1917, at age seventy-nine.

Impact

Military zeppelins never fulfilled their promise. They were equivalent to the megacannon "Big Bertha"—a terror weapon inconsequential to victory. Zeppelin raids made populations angry rather than frightened. After the initial fear of them subsided, city dwellers actually sat on park benches to watch for Zeppelins caught in Allied searchlights. In his own country, Zeppelin became a national icon—an old cavalry hero from 1870 with the spirit of a young aeronaut. He was photogenic in his visored cap and white handlebar moustache, smiling for the camera or looking determinedly off into the distance. He appeared on postcards and stamps, was quoted in newspapers, was drawn in political cartoons, and decorated by the emperor. Average Germans were so zeppelin-mad for a time that they overlooked disastrous smashups and crashes that claimed lives and cost money. When world war came in 1914, the dirigible's effectiveness was less than the danger and manpower required to fly and maintain it. Preoccupied as Germans were with great airships, it was perhaps no accident that the best early German warplanes were designed by a non-German: Antony Fokker from the Netherlands.

After the war, Germany's dirigibles were taken as war reparations. Interest in commercial flights rekindled in the 1920's. By far the most successful zeppelin was the *Graf Zeppelin*—built and piloted by Hugo Eckener and named after his former boss. It flew commercially across the Atlantic with passengers, and in 1929, around the world. There followed a brief golden age of zeppelin transatlantic flights. The United States built the *Shenandoah* (crashed in Ohio in 1925, killing fourteen), the *Akron* (crashed into the Atlantic in 1933, killing seventy-three), and the *Macon* (crashed into the Pacific in 1935, killing two). The British effort ended with the crash of the R101 (crashed in France in 1930, killing forty-eight). The spectacular filmed explosion of the *Hindenburg* (killing thirty-six) in Lakehurst, New Jersey, in 1937 was the death blow for zeppelins.

Richard Zsigmondy

Austrian German chemist

Zsigmondy did much of the early work to explain and characterize colloids, mixtures in which particles of a substance are dispersed throughout another. He developed the ultramicroscope as a tool to study colloids.

Born: April 1, 1865; Vienna, Austrian Empire (now in Austria)
Died: September 24, 1929; Göttingen, Germany
Also known as: Richard Adolf Zsigmondy (full name)
Primary field: Chemistry
Primary invention: Ultramicroscope

Early Life

Richard Adolf Zsigmondy (ZHIHG-mawn-dee) was the fourth child born to Adolf Zsigmondy and Irma von Szakmary. Adolf was a well-respected, innovative dentist and head of Vienna General Hospital's surgical department. Adolf died when Richard was fifteen years old. Richard went to Vienna's public school in the Josefstadt District, receiving his secondary school degree in 1883. He then began studies at the Vienna Institute of Technology. In 1885, he published a paper with one of his teachers, Rudolf Benedict, on the detection of glycerin. In 1887, he moved to the Technical University of Munich to study organic chemistry. His dissertation, on the synthesis of indene derivatives, was accepted, and he received his Ph.D. from the University of Erlangen in 1889.

At about the same time, Zsigmondy published some of his first papers on the coloring of glass, a subject that would be important to him for his entire career. This research involved silver salts and silver particles, which caused the coloring of the glass and which could be recovered by using hydrofluoric acid to dissolve the glass. In 1891 and 1892, Zsigmondy was an assistant to physicist August Kundt. During this time, Zsigmondy researched the diathermaneity (the property of transmitting radiant heat) of glasses and ferrous salts. His research in this area brought him into contact with Otto Schott, whose laboratory in Jena was doing research in glasses. Zsigmondy and Schott would later collaborate, studying the thermal transmittance of different glasses and producing a glass that would not transmit heat rays.

Life's Work

In 1893, Zsigmondy became a teaching assistant at the Graz University of Technology. That summer, he presented a colloquium and lecture that were praised by the professors at the school and earned him a teaching qualification (habilitation). Zsigmondy taught at Graz from 1893 to 1897. He was an outstanding lecturer, and during this time he began his in-depth study of colloids. His first study was a glass dye generated by gold particles, known as "purple of Cassius" (named for its discoverer, the seventeenth century alchemist Andreas Cassius). At that time, there were two views on the nature of purple of Cassius: One stated that it was a chemical compound, a view held by the prominent Swedish chemist Jöns Jakob Berzelius; the other held that it was a "mixture of finely divided gold and stannic acid." Zsigmondy's experiments determined that the latter view was correct.

In October of 1897, Schott offered Zsigmondy a position at the Schott Glass Manufacturing Company in Jena. Zsigmondy worked there until 1900 and had many outstanding accomplishments in both the study of colloids and the practical application of the knowledge in the coloring of glasses. His Jena milk glass and his work with colored and turbid glasses earned Zsigmondy a sterling reputation. When he left Schott's company, he became a private researcher in Jena.

In 1903, Zsigmondy built and introduced the ultramicroscope to study particles smaller than could be seen in a regular microscope. The ultramicroscope was a result of collaboration with H. F. W. Siedentopf, a physicist with the Zeiss Company of Jena. In June of that year, Zsigmondy married Laura Luise Müller, with whom he had two daughters, Annemarie and Käthe. Zsigmondy introduced the immersion ultramicroscope, an improvement to the original ultramicroscope, ten years later. During his time in Jena, he wrote two noteworthy overviews of colloids. In 1907, he was offered an associate professorship at the University of Göttingen. In 1908, he was named director of the Institute of Inorganic Chemistry, a position he held until his retirement in 1929, and became a full professor in 1919. For several years after World War I, inflation was so bad that the institute ran short of the necessary materials for top-quality research.

Zsigmondy was awarded the 1925 Nobel Prize in Chemistry "for his demonstration of the heterogenous nature of colloid solutions and for the methods he used." When he won his Nobel Prize, he stated the work that he did at Graz was the beginning of his knowledge of colloids. He was searching for glass dyes, and his experimental results could not be explained by the current knowledge of chemistry.

Thomas Graham (1805-1869) had been the first to differentiate between crystalloid and colloid solutions. He observed that crystalloid solutions quickly diffused through parchment paper, leaving no residue, whereas colloid solutions such as gelatin hardly diffused through the membrane. Zsigmondy found that sometimes the same substance formed a colloid solution under one set of conditions and a crystalloid solution under a different set of conditions.

Zsigmondy was interested in making colored glass and ceramics of a consistent color. Some of his work in glass involved making a glass, noting its color, dissolving it in hydrofluoric acid, and measuring the amount of particles in the glass. Using his ultramicroscope, he was able to detect particles in the colloid solutions that were not visible with a regular microscope. He determined that the difference in the two types of solutions was the particle size of the molecules, which were larger in colloid solutions. Thus, he confirmed that colloid solutions were not homogeneous.

Zsigmondy discovered that different size particles of the same material produced different colors in glass. Using the ultramicroscope, he was able to calculate the size of the particles by counting the number of particles in a volume. For particles that were too small to see with the ultramicroscope, Zsigmondy invented the nucleus method, which was first applied to gold particles. The colloid particles were placed in a reducing solution in which metal was precipitated; the precipitating metal then settled on the colloid particles until they could be seen in the ultramicroscope. With this process, gold colloidal particles as small as one ten-millionth of a millimeter were visible in sunlight. The study of different size particles led Zsigmondy to develop a theory of coagulation, the formation of colloids by small particles aggregating together. He measured the speed of coagulation and the final size of a particle, among other variables.

Richard Zsigmondy. (©The Nobel Foundation)

During his time in Göttingen, Zsigmondy developed membrane filters with Wilhelm Bachmann. In 1922, the ultrafine filter was developed as an improvement to the membrane filters. Zsigmondy also worked on different types of colloidal solutions, including silicic acids and soap gels. His work with gold sols helped him to develop his theory of coagulation. Zsigmondy published a textbook about colloids, *Lehrbuch der Kolloidchemie* (1912), which was revised several times, and reviewers praised his writings for their clear explanations. Zsigmondy taught at Göttingen until 1929, retiring because of acute arteriosclerosis. He died a few months later.

Impact

Zsigmondy led in the study of colloids and their uses. He conclusively demonstrated that colloids are not the homogeneous solutions that they were thought to be. He also helped explain why some colloidal solutions do not have the same properties of others: The particles are coagulated instead of behaving as individual particles. Zsigmondy developed the methods to study colloids, such as ultramicroscopy and the nuclear method.

Colloids are prevalent in the world. They can occur in gaseous, liquid, or solid states. Colloid particles are larger—a micrometer to a nanometer in diameter—than most individual molecules. Examples of colloids are fog, whipped cream, mayonnaise, marshmallows, Jello, jellies, detergents in water, starch, proteins, water glass, glue, albumin, and rubber. Depending on the colloid particle and the state of the solution, colloid solutions may be called aerosol, foam, emulsion, sol, gel, or colloidal solid. Zsigmondy's research has been especially beneficial in fields of biochemistry and bacteriology.

—C. Alton Hassell

The Ultramicroscope

In the early twentieth century, Richard Zsigmondy and H. F. W. Siedentopf were investigating the Tyndall effect, the visible scattering of light by colloidal particles. An example of this is headlights shining through fog. Someone from the side can see the light beams because the light is reflected off the fog particles. Zsigmondy utilized this effect in his ultramicroscope, which was built in 1903.

A normal microscope does not make very small particles visible. Zsigmondy and Siedentopf decided that there were two criteria for making tiny particles visible. First, the light source needed to be the most intense possible but directed such that no light from the light source was seen by the observer. If the observer could see the light, he or she would not be able to see the light reflected off the particles. It would be like trying to see stars in the daylight. Second, the field of view needed to be as dark as possible so that the light reflected off the particles would be visible.

To produce the light source, rays from the Sun are reflected through an iris diaphragm into a dark room and onto a lens that is focused onto a slit. The light goes through the slit and through another iris diaphragm, an objective lens, and a condensing lens to be projected onto the material in the view of the microscope. The light comes from the side of the microscope, and any excess light is carefully blocked from the observer's view. For solids, a table was devised so that the sample could be moved in small steps across the view of the microscope. For liquid samples, a quartz viewing tube was attached in the view of the microscope. The viewing tube was attached to a funnel and to a drain tube. Liquid samples could be viewed and drained, the viewing tube washed out, and a new sample put into place without removing the viewing tube.

For some samples, the light needed to be polarized. A polarizer could be placed between the slit and the iris diaphragm. For an immersion sample, a plate to block the bottom part of the light would be placed between the iris diaphragm and the last objective lens.

The ultramicroscope allowed particles as small as 4 nanometers to be visible on bright, sunny days. The limit of visibility of particles was about 15 nanometers when using artificial light.

Konrad Zuse

German computer engineer

Zuse designed and built early computers, including the Z3, the world's first general-purpose, program-controlled, reliable computer. He also wrote the first book about digital physics.

Born: June 22, 1910; Berlin, Germany
Died: December 18, 1995; Hünfeld, Germany
Primary fields: Computer science; physics
Primary invention: Z3 programmable computer

Early Life

Born in Berlin, Germany, to Emil and Maria Zuse, Konrad Zuse (KAHN-raht TSEW-zuh) showed high intelligence as a boy. Much later, he wrote that he thought visually and therefore showed little interest in music and in the once popular hobby of building radios. He did, however, exercise a genuine talent in drawing and painting.

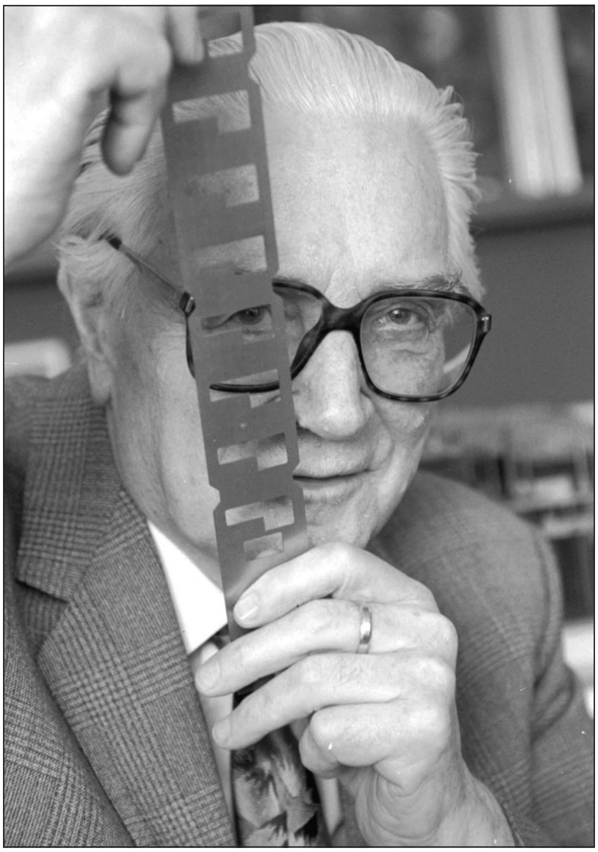
Soon after he passed an examination in 1928, Zuse enrolled in the Technische Hochschule in Berlin-Charlottenburg, where he finally majored in civil engineering. Meanwhile, besides participating in stage plays, he kept active intellectually in ways beyond what his formal studies strictly required. He designed, for instance, a futuristic city, and he gave serious thought to self-replicating machinery in outer space.

In addition, Zuse thought about how he could avoid the tedium and risk of error in the calculations that engineering required. His experience had taught him that a burdensome task in big calculations was recording intermediate answers correctly and later using them appropriately. Whether he worked with a mechanical adding machine or a slide rule, he still faced that task. To handle intermediate answers with less trouble, Zuse printed boxes on paper. Numbers in boxes together in a horizontal row would be multiplied together, and numbers in boxes together in a vertical column would be added together. The idea of the printed boxes led Zuse to his idea that he could use the patterns indicated on the paper forms to join mechanical calculators to solve complex problems. From that idea, he realized by 1934 that a machine that could calculate automatically needed only three main parts: one each for arithmetic, memory, and control.

Receiving his university degree in 1935, Zuse began work as a structural engineer for the Henschel aircraft company but soon, to his parents' dismay, quit to concentrate on building a computer. As his workplace, he chose his parents' Berlin apartment, especially the living room, and received financial help from his family and several of his friends.

Life's Work

Working at home with friends as his assistants, Zuse planned and constructed several computers that he designated by the letter *V* and by a numeral to indicate the particular model. His first computer was therefore the V1, for *Versuchsmodell* 1 (experimental model 1). It was not until after World War II that he replaced the *V* in each of his model names with a *Z*, to avoid confusion with the famous V-1 and V-2 rockets, which were *Vergeltungswaffen* (retaliatory weapons). From the time of the



Konrad Zuse holds an original part of his Z1 computer. Zuse built the first general-purpose, programmable computer in 1941, the Z3, but it was destroyed by Allied bombing raids during World War II. (AP/Wide World Photos) change of designating letters, Zuse usually referred to his early computers by using a *Z*.

Not being an expert on the mechanical calculators of the 1930's, Zuse relied on his own thinking for the Z1 and thus decided not on the commonly used decimal system, with wheels of ten positions each, but on a binary system (in which there are only two digits, 0 and 1). In 1936, when Zuse applied for a patent in Germany, he was also unfamiliar with the work of Charles Babbage, the nineteenth century British pioneer in computer science, and with the monumental paper "On Computable Numbers," which the British mathematician Alan Mathison Turing submitted that year for publication.

Actually finished in 1938, the Z1 was almost all mechanical. It worked, but not well. The trouble lay in the two arithmetic units, the one for the 16-bit significand and the other for the 7-bit exponent. As Zuse realized, the complexity of the arrangement of gears and levers needed for transmitting signals led to failures. Knowing that, in contrast, electric wires could easily carry signals around corners, Zuse started planning the Z2 before he and his coworkers had finished the Z1.

Although his friend Helmut Schreyer actually built a model section of the Z2 with vacuum tubes, Zuse intended to use electromechanical relays instead, because he could more easily visualize how they worked and because they were easier to acquire. Needing thousands of relays, Zuse, Schreyer, and others rebuilt previously used ones. In 1939, when Zuse had almost finished the Z2, the German army drafted him. He spent months as a soldier before friends managed to have him released to civilian duty. Even so, that duty was to work again for the Henschel aircraft company. Zuse had to complete the Z2 in his spare time.

The Z2 had the same mechanical memory as the Z1, but its control and arithmetic units used relays. When Zuse finished this improved computer, he demonstrated it for the German Aeronautical Research Institute. The researchers who saw the Z2 at work realized that it was too unreliable for practical use, but they were impressed enough to offer Zuse money to pay for his work on his next computer, the Z3.

The money Zuse received did not, however, pay for conventional laboratory space, so he and his friends continued their living-room work as the Z3 took shape from 1939 until December 5, 1941, when it was finished. It worked well within its built-in limitation of a tiny memory, but that limitation led the German Aeronautical Research Institute to decide that the usual methods were better for solving the systems of linear equations on which it had planned to use the Z3. Zuse therefore had to store his computer in his parents' apartment, where Allied bombing of Berlin destroyed the machine in 1944.

Soon after he had finished the Z3, Zuse was working on the Z4, despite

The Z3 Programmable Computer

The first general-purpose, programmable computer, the Z3, like the Z1 and the Z2, used 35-millimeter film instead of punched paper tape, a keyboard with four decimal places for input that was converted to base-2 (binary), and an electric lamp for the display of output, which was converted back from base-2 to base-10 with four decimal places. In contrast to the Z1 and the Z2, however, the Z3 had electromechanical relays in the control, the arithmetic, and the memory units. In all, Konrad Zuse used about 2,600 relays in the Z3, including about 1,400 for the memory. Because he knew that sparking would wear out relays, Zuse used a metal-coated drum that revolved in contact with carbon brushes. He designed the Z3 so that the sparking would occur at the places where the brushes touched the drum but not at the relay contacts. The brushes, he realized, would wear out, but he could replace them more easily than he could the relays.

Employing the floating-point system, the binary memory could hold sixty-four words, each of which could be as long as twenty-two bits: one for the sign, fourteen for the significand, and seven for the exponent. In the arithmetic unit, Zuse used two devices that operated in parallel, one for significands and the other for exponents. Zuse designed the arithmetic unit so that it could add, subtract, multiply, divide, and determine square roots. To save calculating time, Zuse hard-wired the Z3 to solve several common problems in multiplication.

Although the Z3 was accurate to only four digits in the decimal system, its use of the floating-point system enabled it to represent huge numbers. Its speed was about that of the Harvard Mark I, designed by Howard Aiken and his team in the United States. The Z3 took between four and five seconds to multiply two numbers together and between one-fourth and one-third of a second to add numbers together.

By the standards of the twenty-first century, the Z3 was very slow and had a minuscule memory. It was, however, the first machine of its kind. Its design and construction under adverse conditions is a tribute to Konrad Zuse's unrelenting work and intellectual brilliance.

serving briefly again as a soldier before he was released once more to return to his official job with Henschel. During the building of the Z4, Zuse changed the location of his laboratory, but he had to endure the hardships of working in Germany when World War II had turned against his homeland. Amid wartime deprivation, on January 6, 1945, he married Gisela Brandes. Then, as the Soviets advanced toward Berlin, he and his associates laboriously moved the massive Z4 to the Experimental Aerodynamics Institute in Göttingen. It was not long, however, before Zuse had to arrange again to move the Z4, this time because of the threat of the Western Allies. Eventually, Zuse hid the Z4 in a cellar at the Bavarian village of Hinterstein, where it remained after the German surrender until Zuse and others moved it to a stable in the town of Hopferau. Yet, after Zuse cleaned and repaired the Z4, it worked just as he had thought it would, and in 1950 it found a home at the Swiss Federal Institute of Technology. At that time the only computer working on the European mainland, it now rests in the German Museum at Munich.

Meanwhile, shortly after the war's end, Zuse turned his attention to a computer language, the *Plankalkül* (plan calculus), on which he had started work in the 1930's. He finished his manuscript in 1946, but the circumstances of life in his homeland made publication difficult then. It was not until 1972 that Zuse's ideas about what he considered the initial algorithmic language reached print. Unfortunately for Zuse, by 1972 other computer languages had become so popular that few programmers used the *Plankalkül*.

Nevertheless, Zuse enjoyed success for years in postwar Europe as a founder of the computer-manufacturing company Zuse KG. Because, however, he had to spend most of his time as a businessman, not an inventor, he felt relief, along with failure, when debt led to corporate changes and he became merely a consultant after his own company in 1967 became part of Siemens AG.

With more time for his artistic and scientific passions, Zuse painted numerous pictures and, developing an idea from his youth, wrote *Rechnender Raum* (1969; calculating space), the seminal book on digital physics, in which he presented his theory that discrete laws govern the physical universe. The universe, he said, is the output of a computation on a cellular automaton; in other words, an enormous grid of cells, acting as a network of computers working in parallel, has determined everything that is or will be. Whether or not such is the case, Zuse died in Hünfeld on December 18, 1995, when he was eighty-five years old.

Impact

By the time he died, Zuse had received several honorary doctorates and other awards, including the Computer Pioneer Award of the Institute of Electrical and Electronics Engineers and the first Konrad Zuse Medal. Working in wartime Germany with almost no knowledge of what inventors in the United States and Great Britain were doing in his field and, for that matter, no knowledge of what work Germans beyond his team were doing, he designed and, with his associates, built the Z3, the first successful computer controlled by a program and used for general calculation. In computer science, he developed an early algorithmic language. Extending his thoughts to cosmology, he presented an idea that, while it remains unproven, has prompted discussions and stirred imaginations.

In *The Computer—My Life* (1993), Zuse implied that he did not receive the recognition he deserved as a founder of computer science and engineering. His years spent as a business executive contributed to his scientific obscurity relative to his accomplishments, as did his isolation in Germany in the years just before, during, and even just after World War II. Furthermore, his slowness in turning to electronic components put him behind a number of other pioneers. It may be true that the line of development of computers in English-speaking countries does not pass through Zuse's work on the Z3 or the *Plankalkül*, but Zuse deserves credit for what he did before anyone else had done it.

—Victor Lindsey

Vladimir Zworykin

Russian American electronics engineer

Known as "the true inventor of television" (a claim sometimes disputed), Zworykin developed the iconoscope, the standard television camera until 1946, as well as the kinescope, its receiver. He also pioneered practical, noncommunication uses for the technology, such as the electron microscope.

Born: July 30, 1889; Murom, Russia
Died: July 29, 1982; Princeton, New Jersey
Also known as: Vladimir Kosma Zworykin (full name)
Primary fields: Communications; electronics and electrical engineering
Primary inventions: Iconoscope; kinescope; electron microscopy

Early Life

Vladimir Kosma Zworykin (VLA-dee-meer KOZ-mah TSVOR-ee-kihn) was born to a prosperous merchant in Murom, Russia. In 1910, he entered the St. Petersburg Institute of Technology to study with physicist Boris Rosing, who three years earlier had completed and demonstrated his first cathode-ray tube television. The young Zworykin's work in Rosing's laboratory led to an improved design that Rosing demonstrated in 1911. World War I interrupted Zworykin's research in 1914: His skill in electronics made him valuable to the Russian Signal Corps, which assigned him to detached service with Russian Marconi, evaluating communications equipment for the Russian army. When the Russian Revolution (1917) began co-opting all research, especially in such a vital industry as communications, Zworykin sought to leave his country. His exact itinerary is difficult to establish (he apparently went back to Russia at one point), but he may have spent a year in Paris studying X rays under Paul Langevin in 1918 before settling in the United States the following year. He became a U.S. citizen in 1924.

Zworykin began working for Westinghouse Electric in Pittsburgh while pursuing graduate study in physics at the University of Pittsburgh. By 1926, he had completed his Ph.D. and demonstrated a television system based on the cathode-ray tube (CRT). Westinghouse management told him to stick to more practical projects. In 1929, he successfully demonstrated his kinescope, a CRT receiver that was the basis for all picture tubes in the twentieth century. The demonstration impressed David Sarnoff of the Radio Corporation of America (RCA), who hired Zworykin for his new laboratory in Camden, New Jersey. There Zworykin developed an electronic scanner that he called an iconoscope, to deliver the image to a kinescope. It was Zworykin's basic design that the Germans used to televise the Berlin Olympics in 1936. Zworykin continued to develop applications for his iconoscope and kinescope, particularly electron microscopy, which was under development in Germany in the 1930's, until his retirement from RCA in 1954.

Life's Work

When introduced as the "father of television" in 1951, Vladimir Zworykin scorned the title. With a disparaging remark about the children's show *Howdy Doody*, he remarked that he would not want his own children to watch what the medium had become. Zworykin had expected his invention to serve science and industry, not merely entertain. His confidence in the importance of industry is ironic, since management at Westinghouse gave very little encouragement to his early experiments in television. His 1923 patent application was still pending in the fall of 1925 when he demonstrated his improvements on the design. Because the image he broadcast was still—a simple *X*—management, not understanding the technical achievement, was unimpressed and ordered him to concentrate on other projects. However, the demonstration led to a new patent application that included a key element in television camera design: the creation of a "mosaic" pattern on the image plate. Zworykin's 1923 patent had spoken of a "layer" of photoelectric material, but subsequent experiments proved the need to have discrete areas (what are now called "pixels") electrically insulated from one another.

Following the letter of Westinghouse's ban on his television research, Zworykin continued to develop hardware that could be used in television but that had other commercial applications. One success in this area was his mercury-arc light valve, which would later be the basis for his kinescope. He also produced a photoelectric cell in a vacuum tube that was a great deal more sensitive than previous cells. Westinghouse billed it as an optical smoke detector. Also, since photocells became desensitized with use, Zworykin in 1926 developed potassium-based photocells that outlasted the sodium cells then in use. While banned from direct television research, Zworykin was still free to apply for patents, and his 1928 patent for a cathode-ray television system caught the eye of one of the leaders in television research, A. A. Campbell Swinton, who convinced Westinghouse management of the viability of Zworykin's television work. Consequently, Zworykin was free to develop the kinescope, which he demonstrated in 1929.

Hired away from Westinghouse by David Sarnoff at RCA, Zworykin at last had the freedom (and funding) to pursue his television research. In 1931, he produced a working version of the iconoscope, though his success was marred by the fact that other researchers had beat him to the patent office, even though he was the first to prove "operability," a key criterion in patent disputes. In 1932, RCA demonstrated Zworykin's iconoscope in a broadcast from the Empire State Building, viewed by fifty top radio and electronics manufacturers. The Depression made Sarnoff hesitant to develop commercial applications for Zworykin's work, though he continued to support it, albeit under tight secrecy. By 1933, however, Sarnoff decided to publicize the iconoscope, and a picture of it appeared in the Sunday *New York Times* of July 2. Zworykin's scholarly paper on the iconoscope was reported by the newspaper as front-page news. The U.S. State Department allowed Zworykin at this time to return to Russia and deliver his paper to scientists there. Shortly after, and, it is likely, in no small part due to this trip, the United States and the Soviet Union resumed diplomatic relations for the first time since the 1917 revolution.

In 1936, RCA staged a second demonstration of its now-improved television system broadcast from the Empire State Building. However, there were only three receivers in the city, and the highest stated ambition was to have one hundred sets in operation in New York. The home market for receivers, announced in 1932, had not materialized. A repeat demonstration in 1937 was reported to have greater clarity, though the contrast was higher than that of film. A 1938 demonstration showed a higher percentage of gray tones. At the opening of the New York World's Fair in April of 1939, RCA began the first public television service, with Zworykin's iconoscope cameras and kinescope receivers.

In 1940, Zworykin demonstrated his improvements on the electron microscope, and he gave a scholarly paper on the subject. He also published his classic book, *Television: The Electronics of Image Transmission*, which detailed the state of the art at that time. For his work on electron microscopy, Zworykin was awarded the Rumford Medal by the American Academy of Arts and Sciences in 1941. During the war years, Zworykin was influential in the development of the infrared snoop-

Vladimir Zworykin holds his iconoscope, the first practical television camera tube. (The Granger Collection, New York)

The Iconoscope

Although Vladimir Zworykin's most indisputable claims in the invention of television—the kinescope and the iconoscope—have been disputed by zealous historians, Zworykin's version of the iconoscope was vital to the earliest television camera. His iconoscope's design elements pervade all modern video. The initial part of the iconoscope is little different from a film camera: A series of lenses focuses the image on an image plate. Instead of being chemically treated like a film plate, however, the image plate is connected to photoelectric cells. A cathode-ray tube sweeps the image on the plate with a charged beam. (The plate itself was one of Zworykin's innovations.) By baking silver dusted through a ruled screen onto a mica plate, Zworykin's team produced a four-inch-square mass of minute sections of highly conductive silver oxide—each section insulated from the others in what is now known as a "pixel." It is this part of the process that makes the iconoscope similar to Philo T. Farnsworth's image dissector, which was key to Farnsworth's battle for patent priority. The greater the intensity of light in a given pixel, the greater the charge that goes to the cells. Thus, a light image is converted to an electronic image. The electronic information is then amplified.

The advantage of Zworykin's scope over Farnsworth's image dissector (and the earlier iconoscope of Kálmán Tihanyi) was its ability to store charges, allowing the camera to be used with lower intensity studio light. Another Zworykin improvement (even over his own earlier attempts at an electronic camera) was having the cathode ray scan the same side of the plate on which the image fell, though a later patent dispute proved that Tihanyi had invented the single-sided plate. The innovation is obvious in retrospect, but engineers at the time feared that the electron gun would damage the plate. The two-sided design, however, had a host of its own problems: pinholes in the plate causing images to spot, short circuits, and insufficient insulation. Zworykin's design eliminated all three problems. From 1936 to 1946, the heart of all commercial television cameras was the Zworykin iconoscope. Even when the iconoscope was replaced in 1946 with the image orthicon tube, the latter retained the image plate with photoelectric receptors and the electron scan of Zworykin's design—though it also incorporated Farnsworth's dissector.

erscope, once being stopped by the police in Princeton, New Jersey, for driving without headlights to test the infrared "night vision" effect. Because he was driving around the RCA Laboratories, the police suspected that he was a spy.

After the war, Zworykin went to work on a large-screen color television, which he demonstrated publicly for the first time in March of 1947. By this time, he had been promoted to vice president of RCA Laboratories. By the time he retired in 1954, color television was on its way to American homes, and every camera and receiver depended at least in part on a Zworykin invention. Zworykin died on July 29, 1982, at the Princeton Medical Center, at the age of ninety-two.

Impact

Although RCA's claim for Zworykin as the "father of television" may be a bit exaggerated, Zworykin surely contributed as much as any one inventor to the development of video technology. Furthermore, his pioneer work on the electron microscope, and his wartime development of television-guided missiles, which Zworykin had proposed as early as 1934, were major contributions to the Allied war effort. During the war, Zworykin served as a member of the Ordnance Advisory Committee on Guided Missiles, and he was a scientific adviser to the commanding general of the U.S. Army Air Force. In the 1950's, the Institute of Electrical and Electronics Engineers (IEEE) named its highest award in video technology the V. K. Zworykin Award. In November of 1980, ninety-one-year-old Zworykin was awarded the Fellowship Citation Plaque of the Royal Television Society of London at the 122nd technical conference of the Society of Motion Picture and Television Engineers (SMPTE). In 1984, he received a posthumous Emmy, the Trustees Award of the National Academy of Television Arts and Sciences, for his seventy-year career in television research. Robert B. Frederick, the president of RCA, accepted the Emmy in Zworykin's honor. In addition to directing what was in the 1940's the largest broadcast laboratory in the world, Zworykin wrote six informative books on the subject of television that became standard reading.

History of U.S. Patent Law

A patent is an exclusive legal protection granted to inventors. It protects the intellectual property of those who create a new and useful invention against duplication by third parties for a fixed term of years. Under U.S. patent law, "invention" is a term of art broadly referring to technological, design, and aesthetic innovations or improvements. It also refers to new industrial and scientific processes as well as certain discoveries and manipulations of the natural world. However, principles of mathematical and natural science and mere ideas of any kind are not patentable. Patent law encourages and rewards the creativity of inventors with exclusive legal protection, while serving to eventually place all inventions in the public domain. Patent law has been instrumental in the growth of American business and in technological and scientific excellence. The law of patents is closely related to that of copyright and trademark. Copyright protects the creative works of authors and artists. Trademark protects the marks, brands, and insignias used by commercial enterprises to identify their products and foster good will.

The first modern patents arose in the flourishing commercial and guild culture of medieval Venice. In the fifteenth century, the Senate of Venice enacted a statute authorizing the Guild Welfare Board to grant exclusive privileges for ten years to inventors of new industrial methods. Venetian patents were granted for stoves, printing, and corn and flour mills. The idea of a patent was well known to English common law. The Crown granted monopolistic and charter privileges to merchants and traders, as a mark of favor and patronage, to raise revenue and to further English excellence and commerce in industry. In 1623, Parliament passed the Statute of Monopolies, which abolished royal prerogatives to grant monopolies but allowed for patents for terms of fourteen years for manufacturing inventions. Several of the North American colonies of Great Britain enacted their own versions of a patent law. The colony of Massachusetts enacted a loosely phrased patent statute in 1641, and the colony of Connecticut did likewise in 1672. Apparently, the first patent in the American colonies was granted to Samuel Winslow of Massachusetts in 1641 for inventing a new method of manufacturing salt for fisheries.

Federal Patent Law

After America declared independence from Great Britain, states continued to grant patents. However, the framers of the U.S. Constitution realized that the development of a national economy required the newly created federal government to possess the exclusive power to grant patents. Under Article I, section 8, clause 8 of the Constitution, Congress is given the power "to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." Congress has passed patent laws on a steady basis, some acts completely revising patent law and some representing a mere refinement of existing law. The goal of patent law is to encourage and reward imagination and industry while ensuring fair competition and the widest dissemination of the fruits of human ingenuity. Patent jurisprudence has alternated between generous awarding of patents to reward inventors and restricting the number of patents so as to increase competition and lower entry costs to business.

Given the constitutional mandate, U.S. patent law is governed by federal statutes. The first patent act was passed in 1790 in the first congressional session. This Patent Act of 1790 authorized the granting of patents to the "first inventor or discoverer" of an invention if the invention was new and determined by a board consisting of the attorney general, the secretary of war, and the secretary of state to be sufficiently significant. The first federal patent granted was to Samuel Hopkins on July 31, 1790, for a new method of making industrial potash. However, it was soon realized that the examination of patents required of the cabinet officers was a burden to their other duties. A reform patent act was passed in 1793 allowing for the secretary of state to grant patents good for fourteen years. Most important, the act eliminated the examining board and allowed for a patent to be obtained by simple registration. This merely clerical system resulted in numerous useless and even fraudulent patents. As a result, perhaps the most important patent act was passed in 1836, establishing the modern patent system. It created a United States Patent Office as a bureau of the Department of State, headed by a commissioner of patents. As with the original 1790 board, the Patent Office was obligated not only to issue patents but also to investigate the merits of the applications, determining if the discovery or invention represented a true and useful innovation.

The Patent Act of 1836 also created the patent numbering system used to this day. Finally, an appeals board was instituted to hear claims from denied applicants. In 1842, the act was amended to provide for design patents, which are patents that protect the ornamental features of manufactured items. In 1870, the act was revised to require the applicant to present a more detailed description of the invention, as well as a more explicit claim of the subject-matter protection the inventor seeks. In 1897, patent protection was barred for inventions described in a printed publication in the United States or a foreign country. The Plant Patent Act of 1930 allowed for the patenting of laboratory-derived hybrid plants that reproduce asexually.

With the Great Depression, there arose greater public and judicial hostility to patents, as constituting restraints on business competition and trade. In the 1940's, the courts began to require that a patent show more than mere novelty and usefulness. In *Cuno Engineering Corporation v. Automatic Devices Corporation* (1941), the U.S. Supreme Court suggested that a patentable invention needed to show a "flash of genius." In *Mercoid Corp. v. Mid-Continent Investment Co*. (1944), the Court broadened its strictures on the misuse of patents. In *Great Atlantic & Pacific Tea Co. v. Supermarket Equipment Corporation* (1950), the Supreme Court disfavored patents that were new combinations of old parts. The community of investors, patent lawyers, and established businesses reacted against these trends. The Patent Act of 1952 invalidated these judicial doctrines and restored a more generous view of the granting of patents. It also updated the statutory language to make explicit that patents were provided for inventions and "processes." Processes are defined as the method or steps in achieving a useful technological result. The Atomic Energy Act of 1954 excludes the patenting of any invention that chiefly pertains to nuclear material or weapons.

In line with this trend, modern law has seen a major expansion in the types of things and methods that can be patented. In 1982, Congress created the United States Court of Appeals for the Federal Circuit to hear, consolidate, and provide expertise on the increasing volume of patent cases. In 1995, the length of patent protection was changed from a term of seventeen years from the issue date to a term of twenty years from the filing date. The American Inventors Protection Act of 1999 provided for the publication of patent applications. The Patent and Trademark Office Authorization Act of 2002 broadened the appellate rights of applicants. The United States has also signed three international agreements that have shaped patent law. The 1883 Paris Convention for the Protection of Industrial Property internationalized patent rights. The 1970 Patent Cooperation Treaty simplified the process for obtaining multinational patents. The Uruguay Round Agreements Act of 1994, implementing the Agreement on Trade-Related Aspects of International Property Rights, internationalized the twenty-year patent term. Many of the recent developments in patent law concern the scope of patentable subject matter in computer programming, biotechnology, and medical treatments.

How Patents Work

A patent is a valuable economic monopoly that allows the patent holder to exclude competitors from making use of, selling, or importing an invention for a fixed period of time. The Patent Act is found in Title 35 of the U.S. Code. Under section 101 of Title 35, "any new and useful process, machine, manufacture, composition of matter, or any new and useful improvement thereof" is patentable. Abstract ideas, natural phenomena, and laws of nature are not. Three types of patents may be obtained: utility patents, for new products or processes; design patents, for new design features of manufactured products; and plant patents, for new varieties of asexually reproduced plants. Under the current patent statute, a patent expires twenty years after the filing date. To obtain a patent, the inventor must submit a detailed description of the invention or process for publication upon grant by the government. This publication both protects the inventor's intellectual property while placing the invention or process in the public domain upon the expiration of the patent.

To acquire a patent for an invention or improvement, the inventor first files an application with the Patent and Trademark Office. The process of applying for a patent is called patent prosecution; it is an often lengthy, technical, and expensive procedure. A provisional patent is a simplified process for retaining patent rights for one year before a regular patent application is filed. The patent application must contain a "specification," which refers to a written description and a claim. The written description usually includes a survey of the "prior art" that is the problem or opportunity facing the inventor, and related inventions in the field. The application also includes a summary of the invention or process and how it resolves the problem or opportunity. A detailed, technical description of the invention or process, usually accompanied by drawings or illustrations, is included. The description must be sufficient to disclose to a person skilled in the relevant field how to make and use the invention.

Thus, patent law not only encourages and rewards the inventor for his or her industry and imagination but also seeks to ensure that his or her ideas and methods are eventually open to public dissemination and competition. The claim defines the scope of the patent protection by describing what would constitute an infringement of the patent. The applicant must also sign an oath or declaration that he or she is the first inventor of the invention or improvement. Finally, the applicant must pay a filing fee.

Once a complete application is submitted, an expert examiner from the Patent Office examines the application for compliance with the requirements of the Patent Act. Under current law, to receive a patent grant, an invention must meet three requirements. First, the invention must be novel or new as compared with prior art—that is, not previously known or used in the United States or a foreign country. If the subject matter of the application has been in public use for more than a year, it is not new or novel. Second, it must be useful. To satisfy the requirement of usefulness, the invention must work as indicated and confer some utility or benefit to society. Third, it must be nonobvious—that is, not readily apparent on the basis of the prior art by a person of ordinary skill. If the patent application is judged to meet these three requirements, a patent is granted. If not, the examiner may object to the application or reject it. In response, the applicant may amend the application. If the application receives a final rejection, the applicant may file an appeal with the Patent Office Board of Appeals.

If the patent is granted, it is valid for twenty years from the date of the filing of the application. (A design patent is valid for fourteen years.) If the patent is infringed by a third party during this period, the patent holder may sue to recover money and perhaps punitive damages or enjoin the infringed use of the invention. The scope of patent rights, however, is often settled outside civil lawsuits by patent licensing contracts. Ownership rights to a patent may also be assigned to another party.

Ptolemy (c. 100 C.E.-c. 178 C.E.)

Middle Ages, 476-1400

Al-Khwārizmī (c. 780 C.E.-c. 850 C.E.)
ʿAbbas ibn Firnas (810 C.E.-887 C.E.)
Al-Jazarī (c. 1150-c. 1220)
Roger Bacon (c. 1220-c. 1292)
Johann Gutenberg (1394-1399-probably February 3, 1468)

1401-1600

Leonardo da Vinci (April 15, 1452-May 2, 1519)
Gerardus Mercator (March 5, 1518-December 2, 1594)
John Napier (1550-April 4, 1617)
Faust Vrančić (1551-January 17, 1617)
Sir John Harington (1561-November 20, 1612)
Santorio Santorio (March 26 or 29, 1561-February 22 or March 6, 1636)
Galileo (February 15, 1564-January 8, 1642)
Hans Lippershey (c. 1570-September, 1619)
Giovanni Branca (April 22, 1571 [baptized]-January 24, 1645)
Zacharias Janssen (c. 1580-c. 1638)

1601-1700

Otto von Guericke (November 20, 1602-May 11, 1686)
Evangelista Torricelli (October 15, 1608-October 25, 1647)
Blaise Pascal (June 19, 1623-August 19, 1662)
Christiaan Huygens (April 14, 1629-July 8, 1695)
Antoni van Leeuwenhoek (October 24, 1632-August 26, 1723)
Robert Hooke (July 18, 1635-March 3, 1703)
James Gregory (November, 1638-October, 1675)
Sir Isaac Newton (December 25, 1642-March 20, 1727)
Gottfried Wilhelm Leibniz (July 1, 1646-November 14, 1716)
Thomas Savery (c. 1650-May, 1715)
Bartolomeo Cristofori (May 4, 1655-January 27, 1732)
Thomas Newcomen (January or February, 1663-August 5, 1729)

1701-1800

1801-1900

1901-1950

1951-

Time Line

The time line below lists more than five hundred milestones in the history of technology: major inventions and their approximate dates of emergence, along with key events in the history of science. These developments appear in boldface, followed by the name or names of the inventors in parentheses, where these individuals are known. A brief description of the significance of the milestone follows.

—Charles W. Rogers, Southwestern Oklahoma State University, Department of Physics

Date	Invention/Milestone
2,500,000 B.C.E.	**Stone tools**: Stone tools, used by *Homo habilis* and perhaps other hominids, first appear in the Lower Paleolithic age (Old Stone Age).
400,000 B.C.E.	**Controlled use of fire**: The earliest controlled use of fire by humans may have been about this time.
200,000 B.C.E.	**Stone tools using the prepared core technique**: Stone tools made by chipping away flakes from the stones from which they were made appear in the Middle Paleolithic age.
100,000-50,000 B.C.E.	**Widespread use of fire by humans**: Fire is used for heat, light, food preparation, and driving off nocturnal predators. It is later used to fire pottery and smelt metals.
100,000-50,000 B.C.E.	**Language**: At some point, language became abstract, enabling the speaker to discuss intangible concepts such as the future.
16,000 B.C.E.	**Earliest pottery**: The earliest pottery was fired by putting it in a bonfire. Later it was placed in a trench kiln. The earliest ceramic is a female figure from about 29,000 to 25,000 B.C.E., fired in a bonfire.
10,000 B.C.E.	**Domesticated dogs**: Dogs seem to have been domesticated first in East Asia.
10,000 B.C.E.	**Agriculture**: Agriculture allows people to produce more food than is needed by their family, freeing humans from the need to lead nomadic lives and giving them free time to develop astronomy, art, philosophy, and other pursuits.
10,000 B.C.E.	**Archery**: Archery allows human hunters to strike a target from a distance while remaining relatively safe.
10,000 B.C.E.	**Domesticated sheep**: Sheep seem to have been domesticated first in Southwest Asia.
9000 B.C.E.	**Domesticated pigs**: Pigs seem to have been domesticated first in the Near East and in China.
8000 B.C.E.	**Domesticated cows**: Cows seem to have been domesticated first in India, the Middle East, and sub-Saharan Africa.
7500 B.C.E.	**Mud bricks**: Mud-brick buildings appear in desert regions, offering durable shelter. The citadel in Bam, Iran, the largest mud-brick building in the world, was built before 500 B.C.E., and was largely destroyed by an earthquake in 2003.
7500 B.C.E.	**Domesticated cats**: Cats seem to have been domesticated first in the Near East.
6000 B.C.E.	**Domesticated chickens**: Chickens seem to have been domesticated first in India and Southeast Asia.
6000 B.C.E.	**Scratch plow**: The earliest plow, a stick held upright by a frame and pulled through the topsoil by oxen, is in use.
6000 B.C.E.	**Electrum**: The substance is a natural blend of gold and silver, pale yellow in color like amber. The name "electrum" comes from the Greek word for amber.
6000 B.C.E.	**Gold**: Gold is discovered—possibly the first metal to be recognized as such.
6000-4000 B.C.E.	**Potter's wheel**: The potter's wheel is developed, allowing for the relatively rapid formation of radially symmetric items, such as pots and plates, from clay.

DATE	INVENTION/MILESTONE
5000 B.C.E.	**Wheel**: The chariot wheel and the wagon wheel evolve—possibly from the potter's wheel. One of humankind's oldest and most important inventions, the wheel leads to the invention of the axle and a bearing surface.
4200 B.C.E.	**Copper**: Egyptians mine and smelt copper.
4000 B.C.E.	**Moldboard plow**: The moldboard plow cut a furrow and simultaneously lifted the soil and turned it over, bringing new nutrients to the surface.
4000 B.C.E.	**Domesticated horses**: Horses seem to have been domesticated first on the Eurasian steppes.
4000 B.C.E.	**Silver**: Silver can be found as a metal in nature, but this is rare. It is harder than gold, but softer than copper.
4000 B.C.E.	**Domesticated honeybees**: The keeping of bee hives for honey arises in many different regions.
4000 B.C.E.	**Glue**: Ancient Egyptian burial sites contain clay pots that have been glued together with tree sap.
3500 B.C.E.	**Lead**: Lead is first extruded from galena (lead sulfide), which can be made to release its lead simply by placing it in a hot campfire.
3000 B.C.E.	**Bronze**: Bronze, an alloy of copper and tin, is developed. Harder than copper and stronger than wrought iron, it resists corrosion better than iron.
3000 B.C.E.	**Cuneiform**: The method of writing now known as cuneiform began as pictographs but evolved into more abstract patterns of wedge-shaped (cuneiform) marks, usually impressed into wet clay. This system of marks made complex civilization possible, since it allowed record keeping to develop.
3000 B.C.E.	**Fired bricks**: Humans begin to fire bricks, creating more durable building materials that (because of their regular size and shape) are easier to lay than stones.
3000 B.C.E.	**Pewter**: The alloy pewter is developed. It is 85 to 99 percent tin, with the remainder being copper, antimony, and lead; copper and antimony make the pewter harder. Pewter's low melting point, around 200 degrees Celsius, makes it a valuable material for making vessels that hold hot substances.
2700 B.C.E.	**Plumbing**: Earthenware pipes sealed together with asphalt first appear in the Indus Valley civilization. Greeks, Romans, and others provided cities with fresh water and a way to carry off sewage.
2650 B.C.E.	**Horse-drawn chariot** (Huangdi): Huangdi—a legendary patriarch of China—is possibly a combination of many men. He is said to have invented—in addition to the chariot—military armor, ceramics, boats, crop rotation, and more.
2600 B.C.E.	**Inclined plane**: Inclined planes are simple machines and were used in building Egypt's pyramids. Pushing an object up a ramp requires less force than lifting it directly, although the use of a ramp requires that the load be pushed a longer distance.
1750 B.C.E.	**Tin**: Tin is alloyed with copper to form bronze.
1730 B.C.E.	**Glass beads**: Red-brown glass beads found in South Asia are the oldest known human-formed glass objects.
1600 B.C.E.	**Mercury**: Mercury can easily be released from its ore (such as cinnabar) by simply heating it.
1500 B.C.E.	**Iron**: Iron, stronger and more plentiful than bronze, is first worked in West Asia, probably by the Hittites. It could hold a sharper edge, but it had to be smelted at higher temperatures, making it more difficult to produce than bronze.
1500 B.C.E.	**Zinc**: Zinc is alloyed with copper to form brass, but it will not be recognized as a separate metal until 1746.
1000 B.C.E.	**Concrete**: The ancient Romans build arches, vaults, and walls out of concrete.
1000 B.C.E.	**Crossbow**: The crossbow seems to come from ancient China. Crossbows can be made to be much more powerful than a normal bow.
700 B.C.E.	**Magnifying glass**: An Egyptian hieroglyph seems to show a magnifying glass.

DATE	INVENTION/MILESTONE
350 B.C.E.	**Compass**: Ancient Chinese used lodestones and later magnetized needles mostly to harmonize their environments with the principles of feng shui. Not until the eleventh century are these devices used primarily for navigation.
350-100 B.C.E.	**Scientific method** (Aristotle): Aristotle develops the first useful set of rules attempting to explain how scientists do science.
300 B.C.E.	**Screw**: Described by Archimedes, the screw is a simple machine that appears to be a ramp wound around a shaft. It converts a smaller turning force to a larger vertical force, as in a screw jack.
300 B.C.E.	**Lever**: Described by Archimedes, the lever is a simple machine that allows one to deliver a larger force to a load than the force with which one pushes on the lever.
300 B.C.E.	**Pulley**: Described by Archimedes, the pulley is a simple machine that allows one to change the direction of the force delivered to the load.
215 B.C.E.	**Archimedes' principle** (Archimedes of Syracuse): Archimedes describes his law of displacement: A floating body displaces an amount of fluid whose weight is equal to the weight of the body.
200 B.C.E.	**Astrolabe**: A set of engraved disks and indicators becomes known as the astrolabe. When aligned with the stars, the astrolabe can be used to determine the rising and setting times of the Sun and certain stars, establish compass directions, and determine local latitude.
40 C.E.	**Ptolemy's geocentric system** (Ptolemy): A world system with the Earth in the center with the Moon, Venus, Mercury, Sun, Mars, Jupiter, Saturn, and fixed stars surrounding it, the geocentric Ptolemaic system would remain the most widely accepted cosmology for the next fifteen hundred years.
90 C.E.	**Aeolipile** (Hero of Alexandria): The aeolipile—a steam engine that escaping steam causes to rotate like a lawn sprinkler—is developed.
105	**Paper and paper making** (Cai Lun): Although papyrus paper already existed, Cai Lun creates paper from a mixture of fibrous materials softened into a wet pulp that is spread flat and dried. The material is strong and can be cheaply mass-produced.
250	**Force pump** (Ctesibius of Alexandria): Ctesibius develops a device that shoots a jet of water, like a fire extinguisher.
815	**Algebra** (al-Khwārizmī): al-Khwārizmī develops the mathematics that solves problems by using letters for unknowns (variables) and expressing their relationships with equations.
877	**Maneuverable glider** (ʿAbbas ibn Firnas): A ten-minute controlled glider flight is first achieved.
1170	**Water-raising machines** (al-Jazarī): In addition to developing machines that can transport water to higher levels, al-Jazarī invents water clocks and automatons.
1260	**Scientific method** (Roger Bacon): Bacon develops rules for explaining how scientists do science that emphasize empiricism and experimentation over accepted authority.
1284	**Eyeglasses for presbyopia** (Salvino d'Armate): D'Armate is credited with making the first wearable eyeglasses in Italy, with convex lenses. These spectacles assist those with farsightedness, such as the elderly.
1439	**Printing press** (Johann Gutenberg): Gutenberg combined a press, oil-based ink, and movable type made from an alloy of lead, zinc, and antimony to create a revolution in printing, allowing mass-produced publications that could be made relatively cheaply and disseminated to people other than the wealthy.
1450	**Eyeglasses for the nearsighted** (Nicholas of Cusa): Correcting nearsightedness requires diverging lenses, which are more difficult to make than convex lenses.
1485	**Dream of flight** (Leonardo da Vinci): On paper, Leonardo designed a parachute, great wings flapped by levers, and also a person-carrying machine with wings to be flapped by the person. Although these flying devices were never successfully realized, the designs introduced the modern quest for aeronautical engineering.

DATE	INVENTION/MILESTONE
1543	**Copernican (heliocentric) universe**: Copernicus publishes *De revolutionibus* (*On the Revolutions of the Heavenly Spheres*), in which he refutes geocentric Ptolemaic cosmology and proposes that the Sun, not Earth, lies at the center of the then-known universe (the solar system).
1569	**Mercator projection** (Gerardus Mercator): The Mercator projection maps the Earth's surface onto a series of North/South cylinders.
1594	**Logarithms** (John Napier): Napier's logarithms allow the simplification of complex multiplication and division problems.
1595	**Parachute** (Faust Vrančić): Vrančić publishes a book describing sixty new machines, one of which is a design for a parachute that might have worked.
1596	**Flush toilet** (Sir John Harington): Harington's invention is a great boone to those previously assigned to empty the "chamber pots."
1604	**Compound microscope** (Zacharias Janssen): Janssen, a lens crafter, experiments with lenses, leading to both the microscope and the telescope.
1607	**Air and clinical thermometers** (Santorio Santorio): Santorio develops a small glass bulb that can be placed in a person's mouth, with a long, thin neck that is placed in a beaker of water. The water rises or falls as the person's temperature changes.
1608	**Refracting telescope** (Hans Lippershey): Lippershey is one of several who can lay claim on developing the early telescope.
1609	**Improved telescope** (Galileo Galilei): Galileo grinds and polishes his own lenses to make a superior telescope. Galileo will come to be known as the father of modern science.
1629	**Steam turbine** (Giovanni Branca): Branca publishes a design for a steam turbine, but it requires machining that is too accurate to be built in his day.
1644	**Barometer** (Evangelista Torricelli): Torricelli develops a mercury-filled barometer, in which the height of the mercury in the tube is a measure of atmospheric pressure.
1650	**Vacuum pump** (Otto von Guericke): After demonstrating the existence of a vacuum, von Guericke explores its properties with other experiments.
1651	**Hydraulic press** (Blaise Pascal): Pascal determines that hydraulics can multiply force. For example, a 50-pound force applied to the hydraulic press might exert 500 pounds of force on an object in the press.
1656	**Pendulum clock** (Christiaan Huygens): Huygens discovers that, for small oscillations, a pendulum's period is independent of the size of the pendulum's swing, so it can be used to regulate the speed of a clock.
1663	**Gregorian telescope** (James Gregory): The Gregorian telescope produces upright images and therefore becomes useful as a terrestrial telescope.
1666	**The calculus** (Sir Isaac Newton): Newton (and independently Gottfried Wilhelm Leibniz) develop the calculus in order to calculate the gravitational effect of all of the particles of the Earth on another object such as a person.
1670	**Spiral spring balance watch** (Robert Hooke): Hooke is also credited as the author of the principle that describes the general behavior of springs, known as Hooke's law.
1672	**Leibniz's calculator** (Gottfried Wilhelm Leibniz): Leibniz develops a calculator that can add, subtract, multiply, and divide, as well as the binary system of numbers used by computers today.
1674	**Improvements to the simple microscope** (Antoni van Leeuwenhoek): Leeuwenhoek, a lens grinder, applies his lenses to the simple microscope and uses his microscope to observe tiny protozoa in pond water.
1698	**Savery pump** (Thomas Savery): Savery's pump was impractical to build, but it served as a prototype for Newcomen's steam engine.

Date	Invention/Milestone
1700	**Piano** (Bartolomeo Cristofori): Cristofori, a harpsichord maker, constructs an instrument with keys that can be used to control the force with which hammers strike the instrument's strings, producing sound that ranges from *piano* (soft) to *forte* (loud)—hence the name "pianoforte," later shortened to "piano."
1701	**Tull seed drill** (Jethro Tull): Before the seed drill, seeds were still broadcast by hand.
1709	**Iron ore smelting with coke** (Abraham Darby): Darby develops a method of smelting iron ore by using coke, rather than charcoal, which at the time was becoming scarce. Coke is made by heating coal and driving off the volatiles (which can be captured and used).
1712	**Atmospheric steam engine** (Thomas Newcomen): Newcomen's engine is developed to pump water out of coal mines.
1714	**Mercury thermometer, Fahrenheit temperature scale** (Daniel Gabriel Fahrenheit): Fahrenheit uses mercury in a glass thermometer to measure temperature over the entire range for liquid water.
1729	**Flying shuttle** (John Kay): On a loom, the shuttle carries the horizontal thread (weft or woof) and weaves it between the vertical threads (warp). Kay develops a shuttle that is named "flying" because it is so much faster than previous shuttles.
1738	**Flute Player and Digesting Duck automatons** (Jacques de Vaucanson): De Vaucanson builds cunning, self-operating devices, or automatons (robots) to charm viewers.
1745-1746	**Leiden jar** (Pieter van Musschenbroek and Ewald Georg von Kleist): Von Kleist (1745) and Musschenbroek (1746) independently develop the Leiden jar, an early type of capacitor used for storing an electric charge.
1746	**Clinical trials prove that citrus fruit cures scurvy** (James Lind): Others had suggested citrus fruit as a cure for scurvy, but Lind gives scientific proof. It still will be another fifty years before preventive doses of foods containing vitamin C are routinely provided for British sailors.
1752	**Franklin stove** (Benjamin Franklin): Franklin develops a stove that allows more heat to radiate into a room than what goes up the chimney.
1752	**Lightning rod** (Benjamin Franklin): Franklin devises an iron-rod apparatus to attach to houses and other structures in order to ground them, preventing damage during lightning storms.
1756	**Wooden striking clock** (Benjamin Banneker): Banneker's all-wood striking clock operates for the next fifty years. Banneker also prints a series of successful scientific almanacs during the 1790's.
1757	**Nautical sextant** (John Campbell): When used with celestial tables, Campbell's sextant allows ships to navigate to within sight of their destinations.
1762	**Marine chronometers** (John Harrison): An accurate chronometer was necessary to determine a ship's position at sea, solving the pressing quest for longitude.
1764	**Spinning jenny** (James Hargreaves): Hargreaves develops a machine for spinning several threads at a time, revolutionizing the textile industry and laying a foundation for the Industrial Revolution.
1765	**Improved steam engine** (James Watt): A steam condenser separate from the working pistons make Watt's engine significantly more efficient than Newcomen's engine of 1712.
1767	**Dividing engine** (Jesse Ramsden): Ramsden develops a machine that automatically and accurately marks calibrated scales.
1767	**Spinning machine** (Sir Richard Arkwright): Arkwright develops a device to spin fibers quickly into consistent, uniform thread.
1770	**Steam dray** (Nicolas-Joseph Cugnot): Cugnot builds his three-wheeled *fardier à vapeur* to move artillery; the prototype pulls 2.5 metric tons at 2 kilometers per hour.
1772	**Soda water** (Joseph Priestley): Priestley creates the first soda water, water charged with carbon dioxide gas. The next year, he develops an apparatus for collecting gases by mercury displacement that would otherwise dissolve in water.

DATE	INVENTION/MILESTONE
1776	**Bushnell's submarine** (David Bushnell): Bushnell builds the first attack submarine; used unsuccessfully against British ships in the Revolutionary War, it nevertheless advances submarine technology.
1781	**Uranus discovered** (Sir William Herschel): Herschel observes what he first believes to be a comet; further observation establishes it as a planet eighteen times farther from the Sun than the Earth is.
1782	**Hot-air balloon** (Étienne-Jacques and Joseph-Michel Montgolfier): Shaped like an onion dome and carrying people aloft, the Montgolfiers' hot-air balloon fulfills the fantasy of human flight.
1783	**Parachutes** (Louis-Sébastien Lenormand): Lenormand jumps from an observatory tower using his parachute and lands safely.
1784	**Improved steam engine** (William Murdock): In an age when much focus was on steam technology, Murdock works to improve steam pumps that remove water from mines. He will go on to invent coal-gas lighting in 1794.
1784	**Bifocals** (Benjamin Franklin): Tired of changing his spectacles to see things at close range as opposed to objects farther away, Franklin designs eyeglasses that incorporate both myopia-correcting and presbyopia-correcting lenses.
1784	**Power loom** (Edmund Cartwright): Cartwright's power loom forms a major advance in the Industrial Revolution.
1785	**Automated flour mill** (Oliver Evans): Evans's flour mill lays the foundation for continuous production lines. In 1801, he will also invent a high-pressure steam engine.
1790	**Steamboat** (John Fitch): Fitch not only invents the steamboat but also proves its practicality by running a steamboat service along the Delaware River.
1792	**Great Clock** (Thomas Jefferson): Jefferson's clock, visible and audible both within Monticello and outside, across his plantation, is designed to maintain efficiency. He also invented an improved portable copying press (1785) and will go on to invent an improved ox plow (1794).
1793	**Cotton gin** (Eli Whitney): Whitney's engine to separate cotton seed from the fiber transformed the American South, both bolstering the institution of slavery and growing the "cotton is king" economy of the Southern states. Five years later, Whitney develops an assembly line for muskets using interchangeable parts.
1796	**Rumford stove** (Benjamin Thompson): The Rumford stove—a large, institutional stove—uses several small fires to heat the stove top uniformly.
1796	**Smallpox vaccination** (Edward Jenner): Jenner's vaccine will save millions from death, culminating in the eradication of smallpox in 1979.
1799	**Voltaic pile/electric battery** (Alessandro Volta): Volta creates a pile—a stack of alternating copper and zinc disks separated by brine-soaked felt—that supplies a continuous current and sets the stage for the modern electric battery.
1804	**Monoplane glider** (George Cayley): Cayley develops a heavier-than-air fixed-wing glider that inaugurates the modern field of aeronautics. Later models carry a man and lead directly to the Wright brothers' airplane.
1805	**Electroplating** (Luigi Brugnatelli): Brugnatelli develops the method of electroplating by connecting something to be plated to one pole of a battery (Voltaic pile) and connecting a bit of the plating metal to the other pole of the battery, placing both in a suitable solution.
1806	**Steam locomotive** (Richard Trevithick): After James Watt's patent for the steam engine expires in 1800, Trevithick develops a working steam locomotive. By 1806 he has developed his improved steam engine, named the Cornish engine, which sees worldwide dissemination.
1807	**Paddle-wheel steamer** (Robert Fulton): Fulton's steamboat becomes far more commercially successful than those of his competitors.

Date	Invention/Milestone
1808	**Law of combining volumes for gases** (Joseph-Louis Gay-Lussac): Gay-Lussac discovers that, when gaseous elements combine to make a compound, the volumes involved are always simple whole-number ratios.
1810	**Preserving food in sealed glass bottles** (Nicolas Appert): Appert answers Napoleon's call to preserve food in a way that allows his soldiers to carry it with them: He processes food in sealed, air-tight glass bottles.
1810	**Preserving food in tin cans** (Peter Durand): Durand follows Nicolas Appert in preserving food for the French army, but he uses tin-coated steel cans in place of the breakable bottles.
1815	**Miner's safety lamp** (Sir Humphry Davy): Davy devises a miner's safety lamp in which the flame is surrounded by wire gauze to cool combustion gases so that the mine's methane-air mixture will not be ignited.
1816	**Macadamization** (John Loudon McAdam): McAdam designs a method of paving roads with crushed stone bound with gravel on a base of large stones. The roadway is slightly convex, to shed water.
1816	**Kaleidoscope** (Sir David Brewster): The name for Brewster's kaleidoscope comes from the Greek words *kalos* (beautiful), *eidos* (form), and *scopos* (watcher). "Kaleidoscope," therefore, literally means "beautiful form watcher."
1816	**Stirling engine** (Robert Stirling): The Stirling engine proves to be an efficient engine that uses hot air as a working fluid.
1819	**Stethoscope** (René-Théophile-Hyacinthe Laënnec): Laënnec invents the stethoscope to avoid the impropriety of placing his ear on the chest of a female heart patient.
1820	**Dry "scouring"** (Thomas L. Jennings): Jennings discovered that turpentine would remove most stains from clothes without the wear associated with washing them in hot water. His method becomes the basis for modern dry cleaning.
1821	**Braille alphabet** (Louis Braille): Braille develops a tactile alphabet—a system of raised dots on a surface—that allows the blind to read by feel.
1821	**Diffraction grating** (Joseph von Fraunhofer): Fraunhofer's diffraction grating separates incident light by color into a rainbow pattern. The various discrete patterns reveal the structure of specific atomic nuclei, making it possible to identify the chemical compositions of various substances.
1822	**Difference engine** (Charles Babbage): Babbage's "engine" was a programmable mechanical device used to calculate the value of a polynomial—a precursor to today's modern computers.
1823	**Waterproof fabric used in raincoats** (Charles Macintosh): Macintosh patents a waterproof fabric consisting of soluble rubber between two pieces of cloth. Raincoats made of the fabric are still often called mackintoshes (macs), especially in England.
1824	**Astigmatism-correcting lenses** (George Biddell Airy): Airy develops cylindrical lenses that correct astigmatism. An astronomer, Airy will go on to design a method of correcting compasses used in ship navigation and the altazimuth telescope. He becomes England's astronomer royal in 1835.
1825	**Electromagnet** (William Sturgeon): Sturgeon builds a U-shaped, soft iron bar with a coil of varnished copper wire wrapped around it. When a voltaic current is passed through wire, the bar becomes magnetic—the world's first electromagnet.
1825	"**Steam waggon**" (John Stevens): Stevens builds the first steam locomotive to be manufactured in the United States.
1825	**Bivalve vaginal speculum** (Marie Anne Victoire Boivin): Boivin develops the tool now widely used by gynecologists in the examination of the vagina and cervix.
1827	**Matches** (John Walker): Walker coats the ends of sticks with a mixture of antimony sulfide, potassium chlorate, gum, and starch to produce "strike anywhere" matches.
1829	**Rocket steam locomotive** (George Stephenson): Stephenson builds the world's first railway line to use a steam locomotive.

DATE	INVENTION/MILESTONE
1830	**Steam locomotive** (Peter Cooper): Cooper's four-wheel locomotive with a vertical steam boiler, the *Tom Thumb*, demonstrates the possibilities of steam locomotives and brings Cooper national fame. His other inventions and good management enable Cooper to become a leading industrialist and philanthropist.
1831	**Mechanical reaper** (Cyrus Hall McCormick): McCormick's reaper can harvest a field five times faster than earlier methods.
1831	**Alternating current (AC) generator** (Michael Faraday): Faraday constructs the world's first electric generator.
1832	**Electromagnetic induction** (Joseph Henry): Henry discovers that changing magnetic fields induces voltages in nearby conductors.
1835	**Colt revolver** (Samuel Colt): The Colt revolver becomes known as "one of the greatest advances of self-defense in all of human history."
1835	**Photography** (Nicéphore Niépce): Niépce codevelops photography with Louis-Jacques-Mandé Daguerre.
1837	**Steam hammer** (James Hall Nasmyth): Nasmyth develops the steam hammer, which he will use to build a pile driver in 1843.
1837	**Steel plow** (John Deere): Previously plows were made of cast iron and required frequent cleaning. Deere's plow is effective in reducing the amount of clogging farmers experienced when plowing the rich prairie soil.
1837	**Electric telegraph** (William Fothergill Cooke and Charles Wheatstone): Wheatstone and Cooke devise a system that uses five pointing needles to indicate alphabetic letters.
1838	**Fuel cell** (Christian Friedrich Schönbein): Schönbein's fuel cell might use hydrogen and oxygen and allow them to react, producing water and electricity. There are no moving parts, but the reactants must be continuously supplied.
1839	**Nitric acid battery** (Sir William Robert Grove): The Grove cell delivered twice the voltage of its more expensive rival, the Daniell cell.
1839	**Daguerreotype** (Louis Jacques Daguerre): Improving on the discoveries of Nicéphore Niépce, Daguerre develops the the first practical photographic process, the daguerreotype.
1839	**Vulcanized rubber** (Charles Goodyear): Adding sulfur and lead monoxide to rubber, Goodyear processes the batch at high temperature. The process, later called vulcanization, yields a stable material that does not melt in hot weather or crack in cold.
1840	**Electrical telegraph** (Samuel F. B. Morse): Others had already built telegraph systems, but Morse's system was superior and soon replaced all others.
1841	**Improved electric clock** (Alexander Bain): With John Barwise, Bain develops an electric clock with a pendulum driven by electric impulses to regulate the clock's accuracy.
1843	**Rotary printing press** (Richard March Hoe): Patented in 1847, the steam-powered rotary press is far faster than the flatbed press.
1843	**Multiple-effect vacuum evaporator** (Norbert Rillieux): Rillieux develops an efficient method for refining sugar using a stack of several pans of sugar syrup in a vacuum chamber, which allows boiling at a lower temperature.
1845	**Sewing machine** (Elias Howe): Howe develops a machine that can stitch straight, strong seams faster than those sewn by hand.
1845	**Suspension bridges** (John Augustus Roebling): A manufacturer of wire cable, Roebling wins a competition for an aqueduct over the Allegheny River and goes on to design other aqueducts and suspension bridges, culminating in the Brooklyn Bridge, which his son, Washington Augustus Roebling, completes in 1883.

Date	Invention/Milestone
1846	**Neptune discovered** (John Galle): German astronomer Galle observes a new planet, based on irregularities in the orbit of Uranus calculated the previous year by England's John Couch Adams and France's Urbain Le Verrier.
1847	**Telegraphy applications** (Werner Siemens): Siemens refines a telegraph in which a needle points to the alphabetic letter being sent.
1851	**Sewing machine** (Isaac Merrit Singer): Singer improves the sewing machine and successfully markets it to women for home use.
1851	**Foucault's pendulum** (Léon Foucault): Foucault's pendulum proves that Earth rotates.
1851	**Ophthalmoscope** (Hermann von Helmholtz): Helmholtz invents a device that can be used to examine the retina and the vitreous humor. In 1855, he will invent an ophthalmometer, an instrument that measures the curvature of the eye's lens.
1855	**Bessemer process** (Sir Henry Bessemer): Bessemer creates a converter that leads to a process for inexpensively mass-producing steel.
1855	**Bunsen burner** (Robert Wilhelm Bunsen): In 1859 Bunsen—along with Peter Desaga, an instrument maker, and Henry Roscoe, a student—develops a high-temperature laboratory burner, which he and Gustav Kirchhoff use to develop the spectroscope (1859).
1857	**Safety elevator** (Elisha Graves Otis): Otis's safety elevator automatically stops if the supporting cable breaks.
1858	**Internal combustion engine** (Étienne Lenoir): Lenoir's engine, along with his invention of the spark plug, sets the stage for the modern automobile.
1858	**Transatlantic cable** (Lord Kelvin): Kelvin helps design and install the under-ocean cables for telegraphy between North America and Europe, serving as a chief motivating force in getting the cable completed.
1859	**Signal flares** (Martha J. Coston): Coston's brilliant and long-lasting white, red, and green flares will be adopted by the navies of several nations.
1860	**Web rotary printing press** (William Bullock): Bullock's press has an automatic paper feeder, can print on both sides of the paper, and could cut the paper into sheets, and fold them.
1860	**Electric incandescent lamp** (Joseph Wilson Swan): Swan produces and patents an incandescent electric bulb; in 1880, two years after Edison's light bulb, Swan will produce a more practical bulb.
1861	**Machine gun** (Richard Gatling): Gatling develops the first machine gun, called the Gatling gun. It has six barrels that rotate into place as the operator turns a hand crank; the shells were automatically chambered and fired.
1861-1862	**USS *Monitor*** (John Ericsson): Ericsson develops the first practical ironclad ship, which will be used during the Civil War. He goes on to develop a torpedo boat that can fire a cannon from an underwater port.
1862	**Pasteurization** (Louis Pasteur): Pasteur's germ theory of disease leads him to develop a method of applying heat to milk products in order to kill harmful bacteria. He goes on to develop vaccines for rabies, anthrax, and chicken cholera (1867-1885).
1865	***Pioneer* (Pullman) sleeping car** (George Mortimer Pullman): Pullman began working on sleeping cars in 1858, but the *Pioneer* is a luxury car with an innovative folding upper berth to allow the passenger to sleep while traveling.
1867	**Dynamite** (Alfred Nobel): Nobel mixes clay with nitroglycerin in a one-to-three ratio to create dynamite (Nobel's Safety Powder), an explosive whose ignition can be controlled using Nobel's own blasting cap. He goes on to patent more than three hundred other inventions and devotes part of the fortune he gained from dynamite to establish and fund the Nobel Prizes.

DATE	INVENTION/MILESTONE
1867	**Steam velocipede motorcycle** (Sylvester Roper): Roper spent his lifetime making steam engines lighter and more powerful in order to make his motorized bicycles faster. His velocipede eventually reaches 60 miles (100 kilometers) per hour.
1867	**Flat-bottom paper bag machine** (Margaret E. Knight): Knight designs a machine that can manufacture flat-bottom paper bags, which can stand open for easy loading.
1867	**Baby formula** (Henri Nestlé): Nestlé combines cow's milk with wheat flour and sugar to produce a substitute for infants whose mothers cannot breast-feed.
1869	**Air brakes for trains** (George Westinghouse): In 1867, Westinghouse developed a signaling system for trains. The air brake makes it easier and safer to stop large, heavy, high-speed trains.
1869	**Periodic table of elements** (Dmitry Ivanovich Mendeleyev): The periodic table, which links chemical properties to atomic structure, will prove to be one of the great achievments of the human race.
1871	**Fireman's respirator** (John Tyndall): The respirator grows from Tyndall's studies of air pollution.
1872	**Blue jeans** (Levi Strauss): Miners tore their pockets when they stuffed too many ore samples in them. Strauss makes pants using heavy-duty material with riveted pocket corners so they will not tear out.
1872	**Burbank russet potato** (Luther Burbank): Burbank breeds all types of plants, using natural selection and grafting techniques to achieve new varieties. His Burbank potato, developed from a rare russet potato seed pod, grows better than other varieties.
1872	**Automatic lubricator** (Elijah McCoy): McCoy uses steam pressure to force oil to lubricate the pistons of steam engines.
1873	**QWERTY keyboard** (Christopher Latham Sholes): After patenting the first practical typewriter, Sholes develops the QWERTY keyboard, designed to slow the fastest typists, who otherwise jammed the keys. The basic QWERTY design remains the standard on most computer keyboards.
1873	**Barbed wire** (Joseph Glidden): Barbed-wire fences make farming and ranching of the Great Plains practical. Without effective fences, animals wandered off and crops were destroyed.
1874	**Medical nuclear magnetic resonance imaging** (Raymond Damadian): Damadian and others develop magnetic resonance imaging (MRI) for use in medicine.
1876	**Four-stroke internal combusion engine** (Nikolaus August Otto): In order to deliver more horsepower, Otto's engine compresses the air-fuel mixture. His previous engines operated near atmospheric pressure.
1876	**Telephone** (Elisha Gray): Gray files for a patent for the telephone the same day that Alexander Graham Bell does so. While the case is not clear-cut, and Gray fought with Bell for years over the patent rights, Bell is generally credited with the telephone's invention.
1876	**Ammonia-compressor refrigeration machine** (Carl von Linde): Breweries need refrigeration so they can brew year-round. Linde refines his ammonia-cycle refrigerator to make this possible.
1878	**Loose-contact carbon microphone** (David Edward Hughes): Hughes's carbon microphone advances telephone technology. In 1879, he will invent the induction balance, which will be used in metal detectors.
1878	**First practical light bulb** (Thomas Alva Edison): Twenty-two people have invented light bulbs before Edison and Joseph Swan, but they are impractical. Edison's is the first to be commercially viable. Eventually, Swan's company merges with Edison's.
1879	**Saccharin** (Ira Remsen): Remsen synthesizes a compound that is up to three hundred times sweeter than sugar; he also establishes the important *American Chemical Journal*, serving as its editor until 1915.
1880	**Milne seismograph** (John Milne): Milne invents the first modern seismograph for measuring earth tremors. He will come to be called the father of modern seismology.
1881	**Improved incandescent light bulb** (Lewis Howard Latimer): Latimer develops an improved way to manufacture and to attach carbon filaments in light bulbs.

Date	Invention/Milestone
1882	**Induction motor** (Nikola Tesla): Tesla's theories and inventions make alternating current (AC) practical.
1882	**Two-cycle gasoline engine** (Gottlieb Daimler): Daimler builds a small, high-speed two-cycle gasoline engine. He will also build a successful motorcycle in 1885, and (with Wilhelm Maybach) an automobile in 1889.
1883	**Shoe-lasting machine** (Jan Ernst Matzeliger): The machine sews the upper part of the shoe to the sole and reduces the cost of shoes by 50 percent.
1884	**Fountain pen** (Lewis Waterman): The commonly told story is that Waterman was selling insurance and lost a large contract when his pen leaked all over it, prompting him to invent the leak-proof fountain pen.
1884	**Roll film** (George Eastman): Roll film replaces heavy plates, making photography both more accessible and more convenient. In 1888, Eastman and William Hall invent the Kodak camera. These developments open photography to the masses.
1884	**Steam turbine** (Charles Parsons): Designed for ships, Parsons's steam turbine is smaller, more efficient, and more durable than the steam engines in use.
1884	**Census tabulating machine** (Herman Hollerith): Hollerith's machine uses punched cards to tabulate 1890 census data. He goes on to found the company that later becomes International Business Machines (IBM).
1884	**Vector calculus** (Oliver Heaviside): Heaviside develops vector calculus to represent Maxwell's electromagnetic theory with only four equations instead of the usual twenty.
1885	**First gasoline-powered automobile** (Carl Benz): Benz not only manufactures the first gas-powered car but also is first to mass-produce automobiles.
1885	**Machine gun** (Hiram Stevens Maxim): Maxim patents a machine gun that can fire up to six hundred bullets per minute.
1886	**Dishwasher** (Josephine Garis Cochran): Like modern washers, Cochran's dishwasher cleans dishes with sprays of hot, soapy water and then air-dries them.
1886	**Linotype machine** (Ottmar Mergenthaler): Pressing keys on the machine's keyboard releases letter molds that drop into the current line. The lines are assembled into a page and then filled with molten lead.
1886	**Electric-traction system** (Frank J. Sprague): Sprague's motor can propel a tram up a steep hill without its slipping.
1886	**Gramophone** (Emile Berliner): A major contribution to the music recording industry, Berliner's gramophone uses flat record discs for recording sound. Berliner goes on to produce a helicopter prototype (1906-1923).
1886	**Coca-Cola** (John Stith Pemberton): Originally developed as a pain reliever less addictive than available opiates, the original Coca-Cola contains cocaine from cola leaves and caffeine from kola nuts. It achieves greater success as a beverage marketed where alcohol is prohibited.
1886	**Hall-Héroult electrolytic process** (Charles Martin Hall and Paul Héroult): The industrial production of aluminum from bauxite ore made aluminum widely available. Prior to the electrolytic process, aluminum was a precious metal with a value about equal to that of silver.
1886	**Yellow pages** (Reuben H. Donnelly): Yellow paper was used in 1883 when the printer ran out of white paper. Donnelly now purposely uses yellow paper for business listings.
1887	**Distortionless transmission lines** (Oliver Heaviside): Heaviside recommends that induction coils be added to telephone and telegraph lines to correct for distortion.
1887	**Radio transmitter and receiver** (Heinrich Hertz): Hertz will use these devices to discover radio waves and confirm that they are electromagnetic waves that travel at the speed of light; he also discovers the photoelectric effect.

DATE	INVENTION/MILESTONE
1887	**Synchronous multiplex railway telegraph** (Granville T. Woods): Woods patents a variation of the induction telegraph that allows messages to be sent between moving trains and between trains and railway stations. He will eventually obtain sixty patents on electrical and electromechanical devices, most of them related to railroads and communications.
1887	**Olds horseless carriage** (Ransom Eli Olds): Olds develops a three-wheel horseless carriage using a steam engine powered by a gasoline burner.
1888	**Cordite** (Sir James Dewar): Dewar, with Sir Frederick Abel, invents cordite, a smokeless gunpowder that is widely adopted for munitions.
1888	**Pneumatic rubber tire** (John Boyd Dunlop): Dunlop's pneumatic tires revolutionize the ride for cyclists and motorists.
1889	**Electric drill** (Arthur James Arnot): Arnot's drill is used to cut holes in rock and coal.
1889	**Bromine extraction** (Herbert Henry Dow): Dow's method for extracting bromine from brine enables bromine to be widely used in medicines and in photography.
1890	**Improved carbon electric arc** (Hertha Marks Ayrton): The carbon arc produces an intense light that is used in streetlights.
1890	**Pneumatic (air) hammer** (Charles B. King): A worker with a pneumatic hammer can break up a concrete slab many times faster than can a worker armed only with a sledgehammer.
1890	**Smokeless gunpowder** (Hudson Maxim): Hudson (perhaps with brother Hiram) develops a version of smokeless gunpowder that is adopted for modern firearms; he goes on to develop a smokeless cannon powder that will be used during World War I.
1891	**Rubber automobile tires** (André and Édouard Michelin): The Michelin brothers manufacture air-inflated tires for bicycles and later automobiles, which leads to a successful ad campaign, featuring the Michelin Man (Bibendum).
1891	**Carborundum** (Edward Goodrich Acheson): Attempting to create artificial diamonds, Acheson instead synthesizes silicon carbide, the second hardest substance known. He will develop an improved graphite-making process in 1896.
1892	**Calculator** (William Seward Burroughs): Burroughs builds the first practical key-operated calculator; it prints entries and results.
1892	**Dewar flask** (Sir James Dewar): Dewar invents the vacuum bottle, a vacuum-jacketed vessel for storing and maintaining the temperature of hot or cold liquids.
1893	**Color photography plate** (Gabriel Jonas Lippmann): Also known as the Lippmann plate for its inventor, the color photography plate uses interference patterns, rather than various colored dyes, to reproduce authentic color.
1893	**Alternating current calculations** (Charles Proteus Steinmetz): Steinmetz's calculations make it possible for engineers to determine alternating current reliably, without depending on trial and error, when designing a new motor.
1894	**Cereal flakes** (John Harvey Kellogg): Kellogg, a health reformer who advocates a diet of fruit, nuts, and whole grains, invents flaked breakfast cereal with the help of his brother, Will Keith Kellogg. In 1906, Kellogg establishes a company in Battlefield, Michigan, to manufacture his breakfast cereal.
1895	**Victrola phonographs** (Eldridge R. Johnson): Johnson develops a spring-driven motor for phonographs that provides the constant record speed necessary for good sound reproduction.
1895	**Streamline Aerocycle bicycle** (Ignaz Schwinn): Through hard work and dedication, Schwinn develops a bicycle that eventually makes his name synonymous with the best of bicycles.
1895	**Cinématographe** (Auguste and Louis Lumière): The Lumière brothers' combined motion-picture camera, printer, and projector helps establish the movie business. Using a very fine-grained silver-halide gelatin emulsion, they cut photographic exposure time down to about one minute.

Date	Invention/Milestone
1896	**Aerodromes** (Samuel Pierpont Langley): In 1896 Langley's "Aerodrome number 6," using a small gasoline engine, makes an unmanned flight of forty-eight hundred feet.
1896	**Four-wheel horseless carriage** (Ransom Eli Olds): Olds patents his internal combustion engine and applies it to his four-wheel horseless carriage, naming it the "automobile."
1896	**Wireless telegraph system** (Guglielmo Marconi): Marconi is the first to send wireless signals across the Atlantic Ocean, inaugurating a new era of telecommunications.
1896	**High-frequency generator and transformer** (Elihu Thomson): Thomson produces an electric air drill, which advances welding to improve the construction of new appliances and vehicles. He will also invent other electrical devices, including an improved X-ray tube.
1896	**X-ray tube** (Wilhelm Conrad Röntgen): After discovering X radiation, Röntgen mails an X-ray image of a hand wearing a ring and paves the way for the medical use of X-ray imaging—one of the most important discoveries ever made for medical science.
1897	**Oscilloscope** (Karl Ferdinand Braun): The oscilloscope is an invaluable device used to measure and display electronic waveforms.
1897	**Modern submarine** (John Philip Holland): Holland's submarine is the first to use a gasoline engine on the surface and an electric engine when submerged.
1897	**Diesel engine** (Rudolf Diesel): Diesel's internal combustion engine rivals the efficiency of the steam engine.
1897	**Jenny coupler** (Andrew Jackson Beard): Beard's automatic coupler connects the cars in a train without risking human life. The introduction of automatic couplings reduces coupling-related injuries by a factor of five.
1897	**Automobile components** (Alexander Winton): The Winton Motor Carriage Company is incorporated, and Winton begins manufacturing automobiles. His popular "reliability runs" help advertise automobiles to the American market. He will produce the first American diesel engine in 1913.
1897	**Escalator** (Charles Seeberger): Before Seeberger built the escalator in its now familiar form, it was a novelty ride at the Coney Island amusement park.
1897	**Electron discovered** (J. J. Thomson): Thomson uses an evacuated tube with a high voltage across electrodes sealed in the ends. Invisible particles (later named electrons) stream from one of the electrodes, and Thomson establishes the particles' properties.
1898	**Flashlight** (Conrad Hubert): Joshua Lionel Cowen suggested that a battery-powered light would look nice with a houseplant. Hubert combines three parts—a battery, a light bulb, and a metal tube—to produce a flashlight.
1898	**Mercury vapor lamp** (Peter Cooper Hewitt): Hewitts's mercury vapor lamp proves to be more efficient than incandescent lamps.
1899	**Alpha particle discovered** (Ernest Rutherford): Rutherford detects the emission of helium 4 nuclei (alpha particles) in the natural radiation from uranium.
1900	**Gamma ray discovered** (Paul Villard): Villard discovers gamma rays in the natural radiation from uranium. They resemble very high-energy X rays.
1900	**Dirigibles** (Ferdinand von Zeppelin): Zeppelin flies his airship three years before the Wright brothers' airplane.
1901	**String galvanometer (electrocardiograph)** (Willem Einthoven): Einthoven's device passes tiny currents from the heart through a silver-coated silicon fiber, causing the fiber to move. Recordings of this movement can show the heart's condition.
1901	**Acousticon hearing aid** (Miller Reese Hutchison): Hutchison invents a battery-powered hearing aid in hopes of helping a mute friend speak.
1901	**Vacuum cleaner** (H. Cecil Booth): Booth patents his vacuum cleaner, a machine that sucks in and traps dirt. Previous devices, less effective, had attempted to blow the dirt away.

DATE	INVENTION/MILESTONE
1902	**Airplane engine** (Charles E. Taylor): Taylor begins building engines for the Wright brothers' airplanes.
1902	**Air conditioner** (Willis Carrier): Whole-house air-conditioning becomes possible.
1902	**Lionel electric toy trains** (Joshua Lionel Cowen): Cowen publishes the first Lionel toy train catalog. Lionel miniature trains and train sets become favorite toys for many years, prized by collectors to this day.
1903	**Windshield wipers** (Mary Anderson): At first the driver operated the wiper with a lever from inside the car.
1903	**Safety razor with disposable blade** (King Camp Gillette): Gillette's razor used a disposable and relatively cheap blade, so there was no need to try to sharpen it.
1903	**Wright Flyer** (Wilbur and Orville Wright): The Wright Flyer is the first heavier-than-air machine to solve the problems of lift, propulsion, and steering for controlled flight.
1903	**Ultramicroscope** (Richard Zsigmondy): Zsigmondy builds the ultramicroscope to study colloids, mixtures in which particles of a substance are dispersed throughout another substance.
1903	**Space-traveling projectiles** (Konstantin Tsiolkovsky): Tsiolkovsky publishes "The Exploration of Cosmic Space by Means of Reaction-Propelled Apparatus," in which he includes an equation for calculating escape velocity (the speed required to propel an object beyond Earth's field of gravity). He is also recognized for the concept of rocket propulsion and for the wind tunnel.
1903	**Spinthariscope** (Sir William Crookes): Crookes invents a device that sparkles when it detects radiation. He also develops and experiments with the vacuum tube, allowing later physicists to identify alpha and beta particles and X rays in the radiation from uranium.
1903	**Crayola crayons** (Edwin Binney): With his cousin C. Harold Smith, Binney invents dustless chalk and crayons marketed under the trade name Crayolas.
1905	**Special relativity** (Albert Einstein): At the age of twenty-six, Einstein uses the constancy of the speed of light to explain motion, time, and space beyond Newtonian principles. During the same year, he publishes papers describing the photoelectric effect and Brownian motion.
1906	**Klaxon horn** (Miller Reese Hutchison): Hutchison files a patent application for the electric automobile horn.
1906	**Hair care products** (Madam C. J. Walker): Walker trains a successful sales force to go door-to-door and sell directly to women. Her saleswomen, beautifully dressed and coifed, are instructed to pamper their clients.
1906	**Broadcast radio** (Reginald Aubrey Fessenden): In broadcast radio, soundwave forms are added to a carrier wave and then broadcast. The carrier wave is subtracted at the receiver, leaving only the sound.
1907	**Sun valve** (Nils Gustaf Dalén): Dalén's device uses sunlight to activate a lighthouse beacon. His other inventions make automated acetylene beacons in lighthouses possible.
1908	**Cellophane** (Jacques Edwin Brandenberger): Brandenberger builds a machine to mass-produce cellophane, which he has earlier synthesized while unsuccessfully attempting to develop a stain-resistant cloth.
1908	**Helium liquefaction** (Heike Kamerlingh Onnes): Kamerlingh Onnes produces liquid helium at a temperature of about 4 kelvins. He will also discover superconductivity in several materials cooled to liquid helium temperature.
1908	**Electrostatic precipitator** (Frederick Gardner Cottrell): The electrostatic precipitator is invaluable for cleaning stack emissions.
1908	**"Tin Lizzie" (Model T) automobile** (Henry Ford): Ford's development of an affordable automobile, manufactured using his assembly-line production methods, revolutionizes the U.S. car industry.

Date	Invention/Milestone
1908	**Vacuum cleaner** (James Murray Spangler): Spangler receives a patent on his electric sweeper, and his Electric Suction Sweeper Company eventually becomes the Hoover Company, the largest such company in the world.
1908	**Geiger-Müller tube** (Hans Geiger): Geiger invents a device, popularly called the Geiger counter, that is a reliable, portable radiation detector. Later his student, Walther Müller, helps improve the instrument.
1908	**Audion** (Lee de Forest): De Forest invents a vacuum tube used in sound amplification. In 1922 he will develop talking motion pictures, in which the sound track is imprinted on the film with the pictures, instead of on a record to be played with the film, leading to exact synchronization of sound and image.
1909	**Synthetic fertilizers** (Fritz Haber): Haber also invents the "Haber process" to synthesize ammonia on a small scale.
1909	**Maxim silencer** (Hiram Percy Maxim): The silencer reduces the noise from firing the Maxim machine gun.
1910	**Chlorinator** (Carl Rogers Darnall): Major Darnall builds a machine to add liquid chlorine to water to purify it for his troops. His method is still widely used today.
1910	**Neon lighting** (Georges Claude): Brightly glowing neon tubes revolutionize advertising displays.
1910	**Bakelite** (Leo Hendrik Baekeland): Bakelite is the first tough, durable plastic.
1911	**Gyrocompass** (Elmer Ambrose Sperry): Sperry receives a patent for a nonmagnetic compass that indicates true north.
1911	**Colt .45 automatic pistol** (John Moses Browning): Commonly called the Colt Model 1911, an improved version of the Colt Model 1900, the Colt .45 is the first autoloading pistol produced in America. Among Browning's other inventions are the Winchester 94 lever-action rifle and the gas-operated Colt-Browning machine gun.
1911	**Ochoaplane, a plane with collapsible wings** (Victor Leaton Ochoa): Ochoa also developed an electricity-generating windmill.
1911	**Ductile tungsten** (William David Coolidge): He also invented the Coolidge tube, an improved X-ray-producing tube.
1911	**Atomic nucleus identified** (Ernest Rutherford): Rutherford discovered the nucleus by bombarding a thin gold foil with alpha particles. Some were deflected through large angles, showing that something small and hard was present.
1912	**Automatic traffic signal system** (Garrett Augustus Morgan): Morgan also invents a safety hood that served as a rudimentary gas mask.
1913	**Erector set** (Alfred C. Gilbert): Erector sets provide hands-on engineering experience for countless children.
1913	**Gyrostabilizer** (Elmer Ambrose Sperry): Sperry develops the gyrostabilizer, a device to control the roll, pitch, and yaw of a moving ship. He will go on to invent the flying bomb, which is guided by a gyrostabilizer and by radio control.
1913	**Zipper** (Gideon Sundback): While others had made zipper-like devices but had never successfully marketed them, Sundback designs a zipper in approximately its present form. He also invents a machine to make zippers.
1913	**Industrialization of the Haber process** (Carl Bosch): Bosch scales up Haber's process for making ammonia to an industrial capacity. The process comes to be known as the Haber-Bosch process.
1913	**Improved electric light bulb** (Irving Langmuir): Langmuir fills his light bulb with a low-pressure inert gas to retard evaporation from the tungsten filament.
1913	**Bergius process** (Friedrich Bergius): Bergius develops a high-pressure, high-temperature process to produce liquid fuel from coal.

DATE	INVENTION/MILESTONE
1914	**Backless brassiere** (Caresse Crosby): The design of a new women's undergarment leads to the expansion of the U.S. brassiere industry. Caresse was originally a marketing name that Mary Phelps Jacob eventually adopted as her own.
1915	**General relativity** (Albert Einstein): Einstein refines his 1905 theory of relativity (now called special relativity) to describe the theory that states that uniform accelerations are almost indistinguishable from gravity. Einstein's theory provides the basis for physicists' best understanding of gravity and of the framework of the universe.
1915	**Jenny** (Glenn H. Curtiss): The Jenny becomes a widely used World War I biplane, and Curtis becomes a general manufacturer of airplanes and airplane engines.
1916	**By-products of sweet potatoes and peanuts** (George Washington Carver): In 1916 Carver publishes his famous bulletin on 105 ways to prepare peanuts.
1919	**Proton discovered** (Ernest Rutherford): After bombarding nitrogen gas with alpha particles (helium 4 nuclei), Rutherford observes that positive particles with a single charge are knocked loose. They are protons.
1920	**Microelectrode** (Ida H. Hyde): Hyde's electrode is small enough to pierce a single cell. Chemicals can also be very accurately deposited by the microprobe.
1923	**Improved telephone speaker** (Georg von Békésy): Békésy's studies of the human ear lead to an improved telephone earpiece. He will also construct a working model of the inner ear.
1923	**Quick freezing** (Clarence Birdseye): Birdseye's quick freezing process preserves food's flavor and texture better than previously used processes.
1924	**Coincidence method of particle detection** (Walther Bothe): Bothe's method proves invaluable in the use of gamma rays to discover nuclear energy levels.
1924	**Ultracentrifuge** (Theodor Svedberg): Svedberg's ultracentrifuge can separate isotopes, such as uranium 235 and uranium 238, from each other—a critical step in building the simplest kind of atomic bomb.
1926	**Automatic power loom** (Sakichi Toyoda): Toyoda's loom helps Japan catch up with the western Industrial Revolution.
1926	**Liquid-fueled rocket** (Robert H. Goddard): A solid-fueled rocket is either on or off, but a liquid-fueled rocket can be throttled up or back and can be shut off before all the fuel is expended.
1927	**Adiabatic demagnetization** (William Francis Giauque): Adiabatic demagnetization is part of a refrigeration cycle that, when used enough times, can chill a small sample to within a fraction of a kelvin above absolute zero.
1927	**All-electronic television** (Philo T. Farnsworth): Farnsworth transmits the first all-electronic television image using his newly developed camera vacuum tube, known as the image dissector. Previous systems combined electronics with mechanical scanners.
1928	**Sliced bread** (Otto F. Rohweddeer): Bread that came presliced was advertised as "the greatest forward step in the baking industry since bread was wrapped." Today the phrase "the greatest thing since sliced bread" is used to describe any innovation that has a broad, positive impact on daily life.
1928	**Link Trainer** (Edwin Albert Link): Link's flight simulator created realistic conditions in which to train pilots without the expense or risk of an actual airflight. Link also developed a submersible decompression chamber.
1929	**Iconoscope** (Vladimir Zworykin): Zworykin claims that he, not Philo Farnsworth. should be credited with the invention of television.
1929	**Dymaxion products** (R. Buckminster Fuller): Fuller's "Dymaxion" products feature an energy-efficient house using prefabricated, easily-shipped parts.

Date	Invention/Milestone
1929	**Strobe light** (Harold E. Edgerton): Edgerton's strobe is used as a flash bulb. He pioneers the development of high-speed photography.
1929-1936	**Cyclotron** (Ernest Orlando Lawrence and M. Stanley Livingston): Lawrence and Livingston are studying particle accelerators and develop the cyclotron, which consists of a vacuum tank between the poles of a large magnet. Alternating electric fields inside the tank can accelerate charged particles to high speeds. The cyclotron is used to probe the atomic nucleus or to make new isotopes of an element, including those used in medicine.
1930	**Schmidt telescope** (Bernhard Voldemar Schmidt): Schmidt's telescope uses a spherical main mirror and a correcting lens at the front of the scope. It can photograph large fields with little distortion.
1930	**Freon refrigeration and air-conditioning** (Charles F. Kettering): After inventing an electric starter in 1912 and the Kettering Aerial Torpedo in 1918 (the world's first cruise missile), he and Thomas Midgley, Jr., use Freon gas in their cooling technology. (Freon will later be banned because of the effects of chlorofluorocarbons on Earth's ozone layer.)
1930	**Scotch tape** (Richard G. Drew): After inventing masking tape, Drew invents the first waterproof, see-through, pressure-sensitive tape that also acted as a barrier to moisture.
1930	**Pluto discovered** (Clyde Tombaugh): Tombaugh observes a body one-fifth the mass of Earth's moon. Pluto comes to be regarded as the ninth planet of the solar system, but in 2006 it is reclassified as one of the largest known Kuiper Belt objects, a dwarf planet.
1930	**Synthetic rubber** (Wallace Hume Carothers): Carothers synthesizes rubber and goes on to develop nylon in 1935. His work professionalizes polymer chemistry as a scientific field.
1930	**Military and commercial aircraft** (Andrei Nikolayevich Tupolev): Tupolev emerges as one of the world's leading designers of military and civilian aircraft. His aircraft set nearly eighty world records.
1931	**Radio astronomy** (Karl G. Jansky): One of the founders of the field of radio astronomy, Janksy detects radio static coming from the Milky Way's center.
1931	**Electric razor** (Jacob Schick): Schick introduces his first electric razor, which allows dry shaving. It has a magazine of blades held in the handle.
1932	**Neutron discovered** (James Chadwick): Chadwick detects the neutron, an atomic particle with no charge and a mass only slightly greater than that of a proton. Except for hydrogen 1, the atomic nuclei of all elements consist of neutrons and protons.
1932	**Positron discovered** (Carl D. Anderson): Anderson discovers the positron, a positive electron and an element of antimatter.
1932	**Cockroft-Walton accelerator** (John Douglas Cockcroft and Ernest Thomas Sinton Walton): the Cockcroft-Walton accelerator is used to fling charged particles at atomic nuclei in order to investigate their properties.
1932	**Duplicating device for typewriters** (Beulah Louise Henry): Henry's invention uses three sheets of paper and three ribbons to produce copies of a document as it is typewritten. Henry also develops children's toys—for example, a doll whose eye color can be changed.
1932	**Richter scale** (Charles Francis Richter): Richter develops a scale to describe the magnitude of earthquakes, still used today.
1932	**Phillips-head screw** (Henry M. Phillips): The phillips-head screw has an X-shaped slot in the head and can withstand the torque of a machine-driven screwdriver, which is greater than the torque that can be withstood by the conventional screw.
1933	**Nuclear chain reaction** (Leo Szilard): Szilard conceives the idea of a nuclear chain reaction. He becomes a key figure in the Manhattan Project, which eventually builds the atomic bomb.
1933	**Magnetic tape recorder** (Semi Joseph Begun): Begun builds the first tape recorder, a dictating machine using wire for magnetic recording. He also develops the first steel tape recorder for mobile radio broadcasting and leads research into telecommunications and underwater acoustics.

DATE	INVENTION/MILESTONE
1933	**Electron microscope** (Ernst Ruska): Ruska makes use of the wavelengths of electrons—shorter than those of visible light—to build a microscope that can image details at the subatomic level.
1934	**Langmuir-Blodgett films** (Katharine Burr Blodgett): A thin Langmuir-Blodgett film deposited on glass can make it nearly nonreflective.
1935	**Diatometer** (Ruth Patrick): Patrick's diatometer is a device placed in the water to collect diatoms and allow them to grow. The number of diatoms is sensitive to water pollution.
1935	**Frequency modulation** (Edwin H. Armstrong): Armstrong exploits the fact that, since there are no natural souces of frequency modulation (FM), FM broadcasts are static-free.
1935	**Kodachrome color film** (Leopold Mannes and Leopold Godowsky, Jr.): Godowsky and Mannes invent Kodachrome, a color film that is easy to use and produces vibrant colors. (With the digital revolution of the late twentieth century, production of Kodachrome is finally retired in 2009.)
1935	**Mobile refrigeration** (Frederick McKinley Jones): Mobile refrigeration enables the shipping of heat-sensitive products and compounds, from blood to frozen food.
1935	**Physostigmine and cortisone** (Percy Lavon Julian): Julian synthesizes physostigmine, used to treat glaucoma, and cortisone, used for arthritis. He will hold more than 130 patents and will become the first African American chemist inducted into the National Academy of Sciences.
1935	**Fallingwater** (Frank Lloyd Wright): Wright designs and builds a showcase house blending its form with its surroundings. One of the greatest architects of the twentieth century, he will produce many architectural innovations in structure, materials, and design.
1935	**Radar-based air defense system** (Sir Robert Alexander Watson-Watt): Watson-Watt's technical developments and his efforts as an administrator will be so important to the development of radar that he will be called the "father of radar."
1936	**Pentothal** (Ernest Volwiler and Donalee Tabern): Pentothal is a fast-acting intravenous anesthetic.
1936	**Field-emission microscope** (Erwin Wilhelm Müller): Müller completes his dissertation, "The Dependence of Field Electron Emission on Work Function," and goes on to develop the field-emission microscope, which can resolve surface features as small as 2 nanometers.
1937	**Muon discovered** (Seth Neddermeyer): Neddermeyer, working with Carl Anderson, J. C. Street, and E. C. Stevenson, discovers the muon (a particle similar to a heavy electron) while examining cosmic-ray tracks in a cloud chamber.
1937	**Model K computer** (George Stibitz): The model K, an early electronic computer, employs Boolean logic.
1937	**X-ray crystallography** (Dorothy Crowfoot Hodgkin): Hodgkin uses X-ray crystallography to reveal the structure of molecules.
1937	**Concepts of digital circuits and information theory** (Claude Elwood Shannon): Shannon's most important contributions were electronic switching and using information theory to discover the basic requirements for data transmission.
1938	**Teflon** (Roy J. Plunkett): Plunkett accidentally synthesizes polytetrafluoroethylene (PTFE), now commmonly known as Teflon, while researching chlorofluorocarbon refrigerants.
1938	**Walkie-talkie** (Alfred J. Gross): Gross's portable, two-way radio allows the user to move around while sending messages without remaining tied to a bulky transmitter. Gross invents a pager in 1949 and a radio tuner in 1950 that automatically follows the drift in carrier frequency due to movement of a sender or receiver.
1938	**Xerography** (Chester F. Carlson): Xerography uses electrostatic charges to attract toner particles to make an image on plain paper. A hot wire then fuses the toner in place.
1938	**Electron microscope** (James Hillier and Albert Prebus): Adapting the work of German physicists, Hillier and Prebus develop a prototype of the electron microscope; and in 1940 Hillier produces the first commercial electron microscope available in the United States.

Date	Invention/Milestone
1939	**Helicopter** (Igor Sikorsky): Sikorsky, formerly the chief construction engineer and test pilot for the first four-engine aircraft, tests his helicopter, the Vought-Sikorsky 300, which after improvements will emerge as the world's first working helicopter.
1939	**Jet engine** (Hans Joachim Pabst von Ohain): The first jet-powered aircraft flies in 1939, while the first jet fighter will fly in 1941.
1939	**Atanasoff-Berry Computer** (Clifford Berry and John Vincent Atanasoff): The ABC, the world's first electronic digital computer, uses binary numbers and electronic switching, but it is not programmable.
1940	**Blood bank** (Charles Richard Drew): Drew establishes blood banks for World War II soldiers.
1940	**Audio oscillator** (William Redington Hewlett): Hewlett invents the audio oscillator, a device that creates one frequency (pure tone) at a time. It is the first successful product of his Hewlett-Packard Company.
1940	**Color television** (Peter Carl Goldmark): Goldmark produces a system for transmitting and receiving color-television images using synchronized rotating filter wheels on the camera and on the receiver set.
1940	**Thompson submachine gun** (John T. Thompson): Thompson works with Theodore Eickhoff and Oscar Payne to invent the American version of the submachine gun.
1940	**Paintball gun** (Charles and Evan Nelson): The gun and paint capsules, invented to mark hard-to-reach trees in the forest, are eventually used for the game of paintball (1981), in which people shoot each other with paint.
1940	**Antibiotics** (Selman Abraham Waksman): Waksman, through study of soil organisms, finds sources for the world's first antibiotics, including streptomycin and actinomycin.
1940	**Plutonium** (Glenn Theodore Seaborg): Seaborg synthesizes one of the first transuranium elements, plutonium. He becomes one of the leading figures in the Manhattan Project, which will build the atomic bomb. While he and others urged the demonstration of the bomb as a deterrent, rather than its use on the Japanese civilian population, the latter course was taken.
1940's	**Solar technology** (Maria Telkes): Telkes develops the solar oven and solar stills to produce drinking water from ocean water.
1941	**Jet engine** (Sir Frank Whittle): Whittle develops the jet engine independent of Hans Joachim Pabst von Ohain in Germany. After World War II, they meet and become good friends.
1941	**Solid-body electric guitar** (Les Paul): Paul's guitar lays the foundation for rock music. He also develops multitrack recording in 1948.
1941	**Velcro** (Georges de Mestral): Burrs sticking to his dog's fur give Mestral the idea for Velcro, which he perfects in 1948.
1941	**Z3 programmable computer** (Konrad Zuse): Zuse and his colleagues complete the first general-purpose, programmable computer, the Z3, in December. In 1950, Zuse will sell a Z4 computer—the only working computer in Europe.
1942	**Superglue** (Harry Coover and Fred Joyner): After developing superglue (cyanoacrylate), Coover rejects it as too sticky for a 1942 project. Coover and Joyner rediscover superglue in 1951, when Coover recognizes it as a marketable product.
1942	**Synthetic vitamins** (Max Tishler): After synthesizing several vitamins during the 1930's, Tischler and his team develop the antibiotic sulfaquinoxaline to treat coccidiosis. He also develops fermentation processes to produce streptomycin and penicillin.
1942	**Controlled nuclear chain reaction** (Enrico Fermi): In 1926, Fermi helped develop Fermi-Dirac statistics, which describe the quantum behavior of groups of electrons, protons, or neutrons. He now produces the first sustained nuclear chain reaction.

DATE	INVENTION/MILESTONE
1942	**Aqua-Lung** (Jacques-Yves Cousteau and Émile Gagnon): The Aqua-Lung delivers air at ambient pressure and vents used air to the surroundings.
1944	**V-2 rocket** (Wernher von Braun): Working for the German government during World War II, von Braun and other rocket scientists develop the V-2 rocket, the first long-range military missile and first suborbital missile. Arrested for making anti-Nazi comments, he later emigrates to the United States, where he leads the team that produces the Jupiter-C missile and launch vehicles such as the Saturn V, which help make the U.S. space program possible.
1944	**Phased array radar antennas** (Luis W. Alvarez): Alvarez's phased array sweeps a beam across the sky by turning hundreds of small antennas on and off and not by moving a radar dish.
1945	**Atomic bomb** (J. Robert Oppenheimer): Oppenheimer, the scientific leader of the Manhattan Project, heads the team that builds the atomic bomb. On the side of military use of the bomb to end World War II quickly, Oppenheimer saw this come to pass on August 6, 1945, when the bomb was dropped over Hiroshima, Japan, killing and maiming 150,000 people; a similar number of casualties ensued in Nagasaki on August 9, when the second bomb was dropped. Japan surrendered on August 14.
1945	**Automatic Computing Engine** (Alan Mathison Turing): While the ACE was never fully built, it was one of the first stored-program computers.
1945	**Dialysis machine** (Willem Johan Kolff): Kolff designs the first artificial kidney, a machine that cleans the blood of patients in renal failure, and refuses to patent it. He will construct the artificial lung in 1955.
1945	**Electronic Sackbut** (Hugh Le Caine): Caine builds the first music synthesizer, joined by the Special Purpose Tape Recorder in 1954, which could simultaneously change the playback speed of several recording tracks.
1945	**Radioimmunoassay** (Rosalyn Yalow): RIA required only a drop of blood (rather than the tens of milliliters previously required) to find trace amounts of substances.
1945	**Microwave oven** (Percy L. Spencer): The microwave oven grew out of the microwave generator, the magnetron tube, becoming more affordable.
1945	**ENIAC computer** (John William Mauchly and John Presper Eckert): The Electronic Numerical Integrator and Computer, ENIAC, is the first general-purpose, programmable, electronic computer. (The Z3, developed independently by Konrad Zuse independently from 1939 to 1941 in Nazi Germany, did not fully exploit electronic components.) Built to calculate artillery firing tables, ENIAC is used in calculations for the hydrogen bomb.
1946	**Tupperware** (Earl S. Tupper): Tupperware exploits plastics technology to develop a line of plastic containers that he markets at home parties starting in 1948.
1946	**Carbon-14 dating** (Willard F. Libby): Libby uses the half-life of carbon 14 to develop a reliable means of dating ancient remains. Radiocarbon dating has proven to be invaluable to archaeologists.
1946	**Magnetic tape recording** (Marvin Camras): Camras develops a magnetic tape recording process that will be adapted for use in electronic media, including music and motion-picture sound recording, audio and videocassettes, floppy disks, and credit card magnetic strips. For many years his method is the primary way to record and store sound, video, and digital data.
1946-1947	**Audiometer** (Georg von Békésy): Békésy invents a pure-tone audiometer that patients themselves can control to measure the sensitivity of their own hearing.
1947	**Transistor** (John Bardeen, Walter H. Brattain, and William Shockley): Hoping to build a solid-state amplifier, the team of Bardeen, Shockley, and Brattain discover the transistor, which replaces the vacuum tube in electronics. Bardeen is later part of the group that develops the theory of superconductivity.
1948	**Holography** (Dennis Gabor): Gabor publishes his initial results working with holograms in *Nature*. Holograms became much more spectacular after the invention of the laser.

Date	Invention/Milestone
1948	**Gamma-ray pinhole camera** (Roscoe Koontz): Working to make nuclear reactors safer, Koontz invents the gamma-ray pinhole camera. The pinhole should act like a lens and form an image of the gamma source.
1948	**Instant photography** (Edwin Herbert Land): Land develops the simple process to make sheets of polarizing material. He perfects the Polaroid camera in 1972.
1948	**Synthetic penicillin** (John C. Sheehan): Sheehan develops the first total synthesis of penicillin, making this important antibiotic widely available.
1948	**Long-playing record** (Peter Carl Goldmark): Goldmark demonstrates the LP playing the cello with CBS musicians. The musical *South Pacific* is recorded in LP format and boosts sales, making the LP the dominant form of recorded sound for the next four decades.
1949	**Magnetic core memory** (Jay Wright Forrester): Core memory is used from the early 1950's to the early 1970's.
1950	**Purinethol** (Gertrude Belle Elion): Elion develops the first effective treatment for childhood leukemia, 6-mercaptopurine (Purinethol). Elion later discovers azathioprine (Imuran), an immunosuppressive agent used for organ transplants.
1950	**Artificial pacemaker** (John Alexander Hopps): Hopps develops a device to regulate the beating of the heart to treat patients with erratic heartbeats. By 1957, the device is small enough to be implanted.
1950	**Planotron** (Pyotr Leonidovich Kapitsa): Kapitsa invents a magnetron tube for generating microwaves. He becomes a corecipient of the Nobel Prize for Physics in 1978 for discovering superfluidity in liquid helium.
1951	**Field-emission microscope** (Erwin Wilhelm Müller): Müller develops the field-ion microscope, followed by an atom-probe field-ion microscope in 1963, which can detect individual atoms.
1951	**The Pill** (Carl Djerassi): The birth-control pill, which becomes the world's most popular and is possibly the most widely used contraceptive, revolutionizes not only medicine but also gender relations and women's status in society. Its prolonged use is later revealed to have health consequences.
1951	**Maser** (Charles Hard Townes): The maser (microwave amplification by stimulated emission of radiation) is a "laser" for microwaves. Discovered later, the "laser" patterned its name on the acronym "maser."
1951	**Fiber-optic endoscope (fibroscope)** (Harold Hopkins): Hopkins fastened together a flexible bundle of optical fibers that could convey an image. One end of the bundle could be inserted into a patient's throat, and the physician could inspect the esophagus.
1952	**Improved electrical resistor** (Otis Boykin): Boykin's resistor had improved precision, and its high frequency characteristics were better than those of previous resistors.
1952	**Photovoltaic cell** (Gerald Pearson): The photovoltaic cell converts sunlight into electricity.
1952	**COBOL** (Grace Murray Hopper): Hopper invents the compiler, an intermediate program that translates English-language instructions into computer language, followed in 1959 by Common Business Oriented Language (COBOL), the first computer programming language to translate commands used by programmers into the machine language the computer understands.
1952	**Bubble chamber** (Donald A. Glaser): In a bubble chamber, bubbles form along paths taken by subatomic particles as they interact, and the bubble trails allow scientists to deduce what happened.
1953	**Medical ultrasonography** (Inge Edler and Carl H. Hertz): Edler and Hertz adapt an ultrasound probe used in materials testing in a shipyard for use on a patient. Their technology makes possible echograms of the heart and of the brain.
1953	**Inertial navigation systems** (Charles Stark Draper): Draper's INS system is designed to determine the current position of a ship or plane based on the initial location and acceleration.

DATE	INVENTION/MILESTONE
1954	**Geodesic dome** (R. Buckminster Fuller): After developing the geodesic dome, Fuller patents the structure, an energy-efficient house using prefabricated, easily-shipped parts.
1954	**Synthetic diamond** (H. Tracy Hall): Hall synthesizes diamonds using a high-pressure, high-temperature belt apparatus that can generate 120,000 atmospheres of pressure and sustain a temperature of 1,800° Celsius in a working volume of about 0.1 cubic centimeter.
1954	**Hydrogen bomb** (Edward Teller): The first hydrogen bomb, designed by Teller, is tested at the Bikini Atoll in the Pacific Ocean.
1954	**Silicon solar cells** (Calvin Fuller): Silicon solar cells have proven to be among the most efficient and least expensive solar cells.
1954	**Machine vision** (Jerome H. Lemelson): Machine vision allows a computer to move and measure products and to inspect them for quality control.
1954	**Atomic absorption spectroscopy** (Sir Alan Walsh): Atomic absorption spectroscopy is used to identify and quantify the presence of elements in a sample.
1955	**Color television's RGB system** (Ernst Alexanderson): The RGB system uses three image tubes to scan scenes through colored filters and three electron guns in the picture tube to reconstruct scenes.
1955	**Pulse transfer controlling device** (An Wang): The device allows magnetic core memory to be written or read without mechanical motion and is therefore very rapid.
1955	**Hovercraft** (Sir Christopher Cockerell): Cockerell files a patent for his hovercraft, an amphibious vehicle. He earlier invented several important electronic devices, including a radio direction finder for bombers in World War II.
1955	**Polio vaccine** (Jonas Salk): Salk's polio vaccine, which uses the killed virus, saves lives and improves the quality of life for millions afflicted by polio.
1955	**Floppy disk and floppy disk drive** (Alan Shugart): Working at the San Jose offices of International Business Machines (IBM), Shugart develops the disk drive, followed by "floppy" disks to provide a relatively fast way to permanently store programs and data.
1956	**Scotchgard** (Patsy O'Connell Sherman): Sherman develops a stain repellent for fabrics that is trademarked as Scotchgard.
1956	**Liquid Paper** (Bette Nesmith Graham): Graham markets her "Mistake Out" fluid for concealing typographical errors.
1956	**Videotape recorder** (Charles P. Ginsburg): The video recorder allows programs to be shown later, to provide instant replays in sports, and to make a permanent record of a program.
1956	**Dipstick blood sugar test** (Helen M. Free): Free and her husband Alfred coinvent a self-administered urinalysis test that allows diabetics to monitor their sugar levels and to adjust their medications accordingly.
1956	**Ovonic switch** (Stanford Ovshinsky): Ovshinsky invents a solid-state, thin film switch meant to mimic the actions of neurons.
1957	**Laser** (Gordon Gould, Charles Hard Townes, Arthur L. Schawlow, Theodore Harold Maiman): Having conducted research on using light to excite thallium atoms, Gould tries to get funds and approval to build the first laser, but he fails. Townes (inventor of the maser) and Schawlow of Bell Laboratories will first describe the laser, and Maiman will first succeed in building a small optical maser. Gould coins the term "laser," which stands for "light amplification by stimulated emission of radiation."
1957	**Wankel rotary engine** (Felix Wankel): Having fewer moving parts, the Wankel rotary engine ought to be sturdier and perhaps more efficient than the common reciprocating engine.
1958	**Integrated circuit** (Robert Norton Noyce and Jack St. Clair Kilby): The microchip, independently discovered by Noyce and Kilby, proves to be the breakthrough that allows the miniaturization of electronic circuits and paves the way for the digital revolution.

Date	Invention/Milestone
1960	**Echo satellite** (John R. Pierce): The first passive-relay telecommunications satellite, Echo, reflected signals. The signals, received from one point on Earth, "bounce" off the spherical satellite and are reflected back down to another, far distant, point on Earth.
1960	**Ruby laser** (Theodore Harold Maiman): Maiman produces a ruby laser, the world's first visible light laser.
1960	**Helium-neon gas laser** (Ali Javan): Javan produces the world's second visible light laser.
1960	**Automatic letter-sorting machine** (Jacob Rabinow): Rabinow's machine greatly increases the speed and efficiency of mail delivery in the United States. He also invented an optical character recognition scanner.
1961	**Audio-animatronics** (Walt Disney): Disney established WED, a research and development unit that developed the inventions he needed for his various enterprises. WED produced the audio-animatronic robotic figures that populated Disneyland, the 1964-1965 New York World's Fair, films, and other attractions. Audio-animatronics enabled robotic characters to speak or sing as well as move.
1962	**Quasar 3C 273** (Maarten Schmidt): Schmidt shows that this quasar is very distant and hence very bright. Further research shows quasars to be young galaxies with active, supermassive black holes at their centers.
1962	**Soft contact lenses** (Otto Wichterle): Wichterle's soft contacts can be worn longer with less discomfort than with hard contact lenses.
1962	**Continuously operating ruby laser** (Willard S. Boyle and Don Nelson): The invention relies on an arc lamp shining continuously (rather than the flash lamp used by Theodore Harold Maiman in 1960).
1962	**Light-emitting diode** (Nick Holonyak, Jr.): Holonyak makes the first visible-spectrum diode laser, which produces red laser light but also stops lasing yet remains a useful light source. Holonyak has invented the red light-emitting diode (LED), the first operating alloy device—the "ultimate lamp."
1962	**Telstar satellite** (John R. Pierce): The first satellite to rebroadcast signals goes into operation, revolutionizing telecommunications.
1963	**Learjet** (Bill Lear): The Learjet, a small eight-passenger jet with a top speed of 560 miles (900 kilometers) per hour, can shuttle VIPs to meetings and other engagements.
1963	**6600 computer** (Seymour Cray): The 6600 was the first of a long line of Cray "supercomputers."
1963	**Artificial heart** (Paul Winchell): Winchell receives a patent (later donated to the University of Utah's Institute for Biomedical Engineering) for an artifical heart that purportedly became the model for the successful Jarvik-7.
1964	**Moog synthesizer** (Robert Moog): The Moog synthesizer uses electronics to create and combine musical sounds.
1964	**Three-dimensional holography** (Emmett Leith): Leith and Juris Upatnieks present the first three-dimensional hologram at the Optical Society of America conference. The hologram must be viewed with a reference laser. The hologram of an object can then be viewed from different angles, as if the object were really present.
1964	**Cosmic background radiation** (Arno Penzias and Robert Wilson): Penzias and Wilson detect the cosmic background radiation, which corresponds to that that would be radiated by a body at 2.725 kelvins. It is thought that it is greatly redshifted primordial fireball radiation left over from the big bang.
1965	**Minicomputer** (Ken Olsen): Perhaps the first true minicomputer, the PDP-8, is released by Digital Equipment Corporation. Founder Olsen makes computers affordable for small businesses.
1966	**Gamma-electric cell** (Henry Thomas Sampson): Sampson works with George H. Miley to produce the gamma-electric cell, which converts the energy of gamma rays into electrical energy.

DATE	INVENTION/MILESTONE
1966	**Handheld calculator** (Jack St. Clair Kilby): Working for Texas Instruments, Kilby does for the adding machine what the transistor had done for the radio, inventing a handheld calculator that retails at $150 and becomes an instant commercial success.
1967	**Electrogasdynamic method and apparatus** (Meredith C. Gourdine): Gourdine develops electrogasdynamics, which involves the production of electricity from the conversion of kinetic energy in a moving, ionized gas.
1967	**Pulsars** (Jocelyn Bell and Antony Hewish): Pulsars, rapidly rotating neutron stars, are discovered.
1968	**Practical liquid crystal displays** (James Fergason): Fergason develops an LCD screen that has good visual contrast, is durable, and uses little electricity.
1969	**Charge-coupled device** (Willard S. Boyle and George E. Smith): Boyle and Smith develop the charge-coupled device, the basis for digital imaging.
1970	**Optical fiber** (Robert Maurer and others): Maurer, joined by Donald Keck, Peter Schultz, and Frank Zimar, produces an optical fiber that can be used for communication.
1970	**Compact disc** (James Russell): The CD revolutionizes the way digital media is stored.
1971	**Electronic switching system for telecommunications** (Erna Schneider Hoover): Hoover's system prioritizes telephone calls and fixes an efficient order to answer them.
1971	**Intel microprocessors** (Federico Faggin): Intel builds the world's first microprocessor chip.
1971	**Lithium-iodide battery** (Wilson Greatbatch): Greatbatch produces an artificial pacemaker. Although there are other pacemakers, Greatbatch's proves superior.
1971	**Touch screen** (Sam Hurst): Hurst's touch screen can detect if it has been touched and where it was touched.
1971	**Microprocessor** (Ted Hoff): The computer's central processing unit (CPU) is reduced to the size of a postage stamp.
1971	**Computerized axial tomography** (Godfrey Newbold Hounsfield): In London, doctors performed the first CAT scan of a living patient and detect a brain tumor. In a CAT (or CT) scan, X rays are taken of a body like slices in a loaf of bread. A computer then assembles these slices into a detail-laden three-dimensional image.
1972	**Cell encapsulation** (Taylor Gunjin Wang): Wang develops ways to encapsulate beneficial cells and introduce them into a body without triggering the immune system.
1972	***Pong* video game** (Nolan K. Bushnell and Ted Dabney): Bushnell and Dabney register the name of their new computer company, Atari, and issue *Pong* shortly thereafter, marking the rise of the video game industry.
1972	**Far-Ultraviolet Camera** (George R. Carruthers): The Carruthers-designed camera is used on the Apollo 16 mission.
1972	**First recombinant DNA organism** (Stanley Norman Cohen, Paul Berg, and Herbert Boyer): The methods to combine and transplant genes are discovered when this team successfully clones and expresses the human insulin gene in the *Escherichia coli*.
1973	**Automated teller machine** (Don Wetzel): Wetzel receives a patent for his ATM. To make it a success, he shows banks how to generate a group of clients who would use the ATM.
1973	**Automatic computerized transverse axial (ACTA) whole-body CT scanner** (Robert Steven Ledley): The first whole-body CT scanner is operational. Ledley goes on to spend much of his career promoting the use of electronics and computers in biomedical research.
1973	**Packet network interconnection protocols TCP/IP** (Vinton Gray Cerf and Bob Kahn): Cerf and Kahn develop Transmission Control Protocol/Internet Protocol (TCP/IP), protocols that enable computers to communicate with one another.
1974	**Kevlar** (Stephanie Kwolek): Kwolek receives a patent for the fiber Kevlar. Bullet-resistant Kevlar vests go on sale only one year later.

Date	Invention/Milestone
1975	**Ethernet** (Robert Metcalfe and David Boggs): Metcalfe and Boggs invent the Ethernet, a system of software, protocols, and hardware allowing instantaneous communication between computer terminals in a local area.
1976	**Kurzweil reading machine** (Ray Kurzweil): Kurzweil develops an optical character reader able to read most fonts.
1976	**Apple computer** (Steve Jobs): Jobs cofounds Apple Computer with Steve Wozniak.
1976	**Personal computer** (Steve Wozniak): Wozniak develops the Apple II, the best-selling computer of the 1970's and early 1980's.
1976	**Jarvik-7 artificial heart** (Robert Jarvik): The Jarvik-7 allows a calf to live 268 days with the artificial heart. Jarvik combined ideas from several other workers to produce the Jarvik-7.
1976	**Microsoft Corporation** (Bill Gates): Gates, along with Paul Allen, founds Microsoft, a software company. Gates will remain head of Microsoft for twenty-five years.
1977	**Gossamer Condor** (Paul MacCready): MacCready designs the Gossamer Condor, which enables human-powered flight.
1977	**Global Positioning System** (Ivan A. Getting): The first GPS satellite is launched, designed to support a navigational system that uses satellites to pinpoint the location of a radio receiver on Earth's surface.
1978	**Charon discovered** (James Christy): Charon is discovered as an apparent bulge on a fuzzy picture of Pluto. Its mass is about 12 percent that of Pluto.
1978	**Smart gels** (Toyoichi Tanaka): Tanaka discovers and works with "smart gels," polymer gels that can expand a thousandfold, change color, or contract when stimulated by minor changes in temperature, magnetism, light, or electricity. This capacity makes them useful in a broad range of applications.
1979	**In-line roller skates** (Scott Olson and Brennan Olson): After finding some antique in-line skates, the Olson brothers begin experimenting with modern materials, creating modern Rollerblades.
1980	**Alkaline battery** (Lewis Urry): Eveready markets alkaline batteries under the trade name Energizer. Urry's alkaline battery lasts longer than its predecessor, the carbon-zinc battery.
1981	**Scanning tunneling microscope** (Heinrich Rohrer and Gerd Binnig): The scanning tunneling microscope shows surfaces at the atomic level.
1981	**Ablative photodecomposition** (Rangaswamy Srinivasan): Srinivasan's research on ablative photodecomposition leads to multiple applications, including laser-assisted in situ keratomileusis (LASIK) surgery, which shapes the cornea to correct vision problems.
1981	**Improvements in laser spectroscopy** (Arthur L. Schawlow and Nicolaas Bloembergen): Schawlow shares the Nobel Prize in Physics with Bloembergen for their work on laser spectroscopy. While most of Schawlow's inventions involved lasers, he also did research in superconductivity and nuclear resonance.
1983	**Cell phone** (Martin Cooper): The first mobile (wireless) phone, the DynaTAC 8000X, receives approval by the Federal Communications Commission, heralding an age of wireless communication.
1983	**Polymerase chain reaction** (Kary B. Mullis): While driving to his cottage in Mendocino, California, Mullis develops the idea for the polymerase chain reaction (PCR). PCR will be used to amplify a DNA segment many times, leading to a revolution in recombinant DNA technology and a 1993 Nobel Prize in Chemistry for Mullis.
1984	**AIDS blood test** (Robert Charles Gallo): Gallo and his colleagues identify the virus HTLV-3/LAV (later renamed human immunodeficiency virus, or HIV) as the cause of acquired immunodeficiency syndrome, or AIDS. Gallo creates a blood test that can identify antibodies specific to HIV. This blood test to is essential to keeping the supply in blood banks pure.

DATE	INVENTION/MILESTONE
1984	**DNA profiling** (Alec Jeffreys): Noticing similarities and differences in DNA samples from his lab technician's family, Jeffreys discovers the principles that lead to DNA profiling, which has become an essential tool in forensics and the prosecution of criminal cases.
1984	**Imaging X-ray spectrometer** (George Edward Alcorn): Alcorn patents his device, which makes images of the source using X rays of specific energies, similar to making images with a specific wavelength (color) of light. It is used in acquiring data on the composition of distant planets and stars.
1985	**Industry Standard Architecture (ISA) bus** (Mark Dean and Dennis Moeller): Dean and Moeller design the standard way of organizing the central part of a computer and its peripherals, the ISA bus, which is patented in this year.
1985	**Windows operating system** (Bill Gates): The first version of Windows is released.
1986	**High-temperature superconductor** (J. Georg Bednorz and Karl Alexander Müller): Bednorz and Müller show that a ceramic compound of lanthanum, barium, copper, and oxygen becomes superconducting at 35 kelvins, a new high-temperature record.
1988	**Laserphaco probe** (Patricia Bath): Bath's probe is used to break up and remove cataracts.
1989	**World Wide Web** (Tim Berners-Lee and Robert Cailau): Lee finds a way to join the idea of hypertext and the young Internet, leading to the Web, coinvented with Cailau.
1989	**Method for tracking oil flow underground using a supercomputer** (Philip Emeagwali): Emeagwali receives the Gordon Bell Prize, considered the Nobel Prize for computing, for his method, which demonstrates the possibilities of computer networking.
1990	***BRCA1* gene discovered** (Mary-Claire King): King finds the cancer-associated gene on chromosome 17. She demonstrates that humans and chimpanzees are 99 percent genetically identical.
1991	**Carbon nanotubes** (Sumio Iijima): Although carbon nanotubes have been seen before, Iijima's 1991 paper establishes some basic properties and prompts other scientists' interest in studying them.
1991	**Nakao Snare** (Naomi L. Nakao): The Snare is a device that captures polyps that have been cut from the walls of the intestine, solving the problem of "lost polyp syndrome."
1993	**Flexible tailored elastic airfoil section** (Sheila Widnall): Widnall applies for a patent for this device, which addresses the problem of being able to measure fluctuations in pressure under unsteady conditions. She serves as secretary of the Air Force (the first woman to lead a branch of the military) and also serves on the board investigating the space shuttle *Columbia* accident of 1986.
1993	**Light-emitting diode (LED) blue and UV** (Shuji Nakamura): Nakamura's blue LED makes white LED light possible (a combination of red, blue, and green).
1993	**Mosaic** (Marc Andreessen): Andreessen launches Mosaic, followed by Netscape Navigator in 1995—the first Internet browsers. Both Mosaic and Netscape allow novices to browse the World Wide Web.
1995	**Global Positioning System** (Ivan A. Getting): The GPS system becomes fully operational.
1995	**51 Pegasi** (Michel Mayor and Didier Queloz): Mayor and Queloz detect a planet orbiting another normal star, the first extrasolar planet (exoplanet) to be found. As of June, 2009, 353 exoplanets were known.
1995	**iBot** (Dean Kamen): Kamen invents iBOT, a super wheelchair that climbs stairs and helps its passenger to stand.
1995	**Illusion transmitter** (Valerie L. Thomas): A concave mirror can produce a real image that appears to be three-dimensional. Thomas's system uses a concave mirror at the camera and another one at the television receiver.
1998	**UV Waterworks** (Ashok Gadgil): The device uses UV from a mercury lamp to kill waterborne pathogens.

DATE	INVENTION/MILESTONE
1998	**PageRank** (Larry Page): The cofounder of Google with Sergey Brin, Page devises PageRank, the count of Web pages linked to a given page and a measure of how valuable people find that page.
1999	**BlackBerry** (Research in Motion of Canada): A wireless handheld device that began as a two-way pager, the BlackBerry is also a cell phone that supports Web browsing, e-mail, text messaging, and faxing—the first "smart" phone.
2001	**Segway PT** (Dean Kamen): Kamen introduces his personal transport device, a self-balancing, electric-powered pedestrian scooter.
2001	**iPod** (Tony Fadell): Fadell introduces the iPod, a portable hard-drive-based MP3 player with an Internet-based electronic music catalog, for Apple, Inc.
2003	**Aqwon** (Josef Zeitler): The hydrogen-powered scooter Aqwon can reach 30 miles (50 kilometers) per hour. Its combustion product is water.
2004	***SpaceShipOne* and *SpaceShipTwo*** (Burt Rutan): Rutan receives the U.S. Department of Transportation's first license issued for suborbital flight for *SpaceShipOne*, which shortly thereafter reaches an altitude of 328,491 feet. Rutan's rockets are the first privately funded manned rockets to reach space (higher than 100 kilometers above Earth's surface).
2005	**Nix and Hydra discovered** (Pluto companion team): The Hubble research team—composed of Hal Weaver, S. Alan Stern, Max Mutchler, Andrew Steffl, Marc Buie, William Merline, John Spencer, Eliot Young, and Leslie Young—finds these small moons of Pluto.
2005	**Eris** (Mike Brown and others): Working with C. A. Trujillo and D. L. Rabinowitz, Brown discovers Eris, the largest known dwarf planet and a Kuiper Belt object. It is 27 percent more massive than Pluto, another large Kuiper Belt object.
2007	**iPhone** (Apple, Inc.): Apple introduces its "smart phone," a combined cell phone, portable media player (equal to a video iPod), camera phone, Internet client (supporting e-mail and Web browsing), and text messaging device, to an enthusiastic market.
2008	**Retail DNA test** (Anne Wojcicki): Wojcicki (wife of Google founder Sergey Brin) offers an affordable DNA saliva test, 23andMe, to determine one's genetic markers for ninety traits. The product heralds what *Time* magazine dubs a "personal-genomics revolution."
2009	**Hubble Space Telescope repairs** (NASA): STS-125 astronauts conducted five spacewalks from the space shuttle *Atlantis* to upgrade the Hubble Space Telescope, extending its life to at least 2014.

Biographical Directory of Inventors

*The following list of more than 1,000 inventors briefly summarizes the achievements of not only the 413 inventors covered in this publication (starred with an asterisk *) but 598 others as well. Birth and death dates are followed by the individual's nationality and a brief description of his or her major achievements.*

A

Abalakov, Vitaly Mikhaylovich (1906-1986): Russian. The Abalakov Cam, developed in the 1930's, is for rock climbing. Three of four wheels have a projecting hump pivot on a common axle so that the device can be wedged into fissures and used for support.

ʿAbbas ibn Firnas* (810-887): Spanish Arab. In 875, ibn Firnas built a glider and flew it successfully but was injured upon landing.

Abel, John Jacob (1857-1938): American. An experimental pharmacologist, Abel is best known for his invention of the vividiffusion apparatus in 1912. A form of renal dialysis machine, it removed waste products from blood.

Abū al-Qāsim al-Zahrāwī (Abulcasis) (939-1013): Spanish Arab. Al-Zahrāwī wrote an encyclopedic medical text that was the standard resource for surgical techniques and invented many surgical instruments.

Acheson, Edward Goodrich* (May 9, 1856-July 6, 1931): American. A former assistant to Thomas Alva Edison, in 1891 Acheson synthesized carborundum, an industrial abrasive. Later, by heating it further, he produced pure graphite, a substance useful in lubricants and electrodes.

Adamian, Hovannes (1879-1932): Armenian Russian. In 1908 in Germany, Adamian registered a patent for a color television, the first person to do so. In 1925, he demonstrated his device, "Eristavi," which successfully sent three-color patterns and figures from one laboratory to another.

Adams, Thomas (1818-1905): American. Adams used the tropical tree resin chicle to make a flavored chewing gum. In 1888, Adams's Tutti-Frutti gum became the first to be sold in vending machines.

Adler, Robert (December 4, 1913-February 15, 2007): Austrian American. Among Adler's 150 patents is one for a wireless remote control for television sets, the Space Command, which used high-frequency sound waves.

Affel, Herman A. (August 4, 1893-October 13, 1972): American. In 1929, Affel patented his conduction system, comprising two concentric cylinders of conducting material separated by air: the coaxial cable, which made possible high-volume transcontinental telephone and television transmission.

Aiken, Howard (March 9, 1900-March 14, 1973): American. With Grace Hopper, Aiken designed the first of the electromechanical Mark series of computers, built in 1944. The U.S. Navy used it to calculate trajectories for projectiles.

Airy, George Biddell* (July 27, 1801-January 2, 1892): British. Airy's inventions included the optical method for correcting astigmatism in eyes and a method for compensating a compass on a metal ship.

Alçelik, Turhan (b. 1958): Turkish. An ophthalmologist, Alçelik developed a vehicle headlight system, road tested in 2004, capable of illuminating roads sufficiently for night driving without producing harmful glare.

Alcorn, George Edward* (b. March 22, 1940): American. Alcorn invented remote sensing instruments for spacecraft. In 1984, he received the NASA/Goddard Space Flight Center Inventor of the Year Award for his imaging X-ray spectrometer.

Alexanderson, Ernst* (January 25, 1878-May 14, 1975): Swedish American. Alexanderson, a pioneering telecommunications engineer, received more than 345 patents. His fame rests on his 1906 invention of the high-frequency alternator for long-wave transmissions.

Alexeyev, Rostislav Evgenievich (December 18, 1916-February 9, 1980): Russian. Alexeyev headed secret research in Russia to build high-speed ships. His vessels had stubby wings that enabled them to ride on a cushion of air over the sea surface. The prototype was built in 1966.

Alford, Andrew (August 5, 1904-January 25, 1992): Russian American. Alford devised the localizer antenna system, a ground-based system of radio signals that guides aircraft as they approach airport runways.

Allen, Samuel Leeds (May 5, 1841-November 26, 1918): American. During his career, Allen received patents for more than three hundred inventions, among them the Flexible Flyer, introduced in 1918. It was the first sled to be steered by hand.

Altschul, Randice-Lisa (b. 1961): American. Altschul originally worked designing toys and games, but in 1999, with the help of engineer Lee Volte, she patented the first disposable cell phone, the Phone-Card-Phone.

Álvarez, Luis W.* (June 13, 1911-September 1, 1988): American. Álvarez developed the liquid-hydrogen bubble chamber, which permitted fellow physicists to identify previously unknown fundamental particles. He received the 1968 Nobel Prize in Physics for it.

Ames, Nathan (November 17, 1826-August 17, 1865): American. In 1859, Ames registered patents for Revolving Stairs, the first escalator. It comprised steps mounted on a continuous belt in a triangular loop. While feasible, the device was never constructed.

Ancker-Johnson, Betsy (b. April 29, 1927): American. In 1966, Ancker-Johnson invented a generator that emits signals in the gigacycle range when a low-density plasma is created in a semiconductor resting in a high-intensity electrical field and low-intensity parallel magnetic field.

Anderson, Mary (1866-June 27, 1953): American. Anderson invented a device to clean windshields from inside the vehicle by a hand crank, the first windshield wiper (patented in 1903).

Andreessen, Marc* (b. July 9, 1971): American. Andreessen, along with Eric Bina, created Mosaic (released in 1993), the first Internet browser to present graphics and text together. He also developed Netscape Navigator.

Anschütz-Kaempfe, Hermann (October 3, 1872-May 6, 1931): German. In 1904, Anschütz-Kaempfe patented his gyrocompass and made later modifications that compensated for the distortions caused by a ship's motion at sea. The invention grew from his obsession to reach the North Pole.

Appert, Nicolas François (October 23, 1749-June 3, 1841): French. Appert was a grocer who in 1809 won a 12,000-franc prize from Napoleon Bonaparte for inventing a safe way to store food in jars, used to feed Napoleon's troops as he waged war throughout the world.

Archimedes* (c. 287-212 B.C.E.): Greek. Legendary for his mathematics, Archimedes also devised a catapult to defend his home city, a system of mirrors for focusing burning light on enemy ships, pulleys and levers for hoisting large ships, and, most famously, Archimedes' screw, a pump for raising water from wells.

Argand, François-Pierre-Ami (July 5, 1750-October 13, 1803): Swiss. In 1784, Argand patented his improved oil lamp. His experiments revealed that an adjustable cylindrical wick in a cylindrical chimney produced light many times brighter and cleaner than existing light sources.

Aristotle* (384-322 B.C.E.): Greek. Among Aristotle's many foundational contributions to philosophy and literary criticism was categorical logic.

Arkwright, Sir Richard* (December 23, 1732-August 3, 1792): English. Working with John Kay, in 1768 Arkwright produced the water frame, or spinning frame. Powered by a water wheel, it had two rollers that pulled cotton fibers taut and twisted them into fine yarn whose thickness could be adjusted.

Armstrong, Edwin H.* (December 18, 1890-January 31, 1954): American. Armstrong's regenerative circuit enabled the same vacuum tube to amplify a signal many times. In 1933, he invented a means to convey signals by modulating radio wave frequencies—FM radio.

Arnot, Arthur James* (August 26, 1865-October 15, 1946): Australian. Arnot is credited with inventing the electric drill, which others modified for industrial or home use.

Arnott, Neil (May 15, 1788-March 2, 1874): Scottish. A physician, Arnott invented the Arnott waterbed in 1832, which he later modified into a water-filled chair intended to counteract a ship's motion and prevent seasickness.

Artsimovich, Lev Andreevich (February 25, 1909-March 1, 1973): Russian. A leading Soviet physicist, Artsimovich led the team of scientists that built the first tokamak in the 1950's, a device that creates a doughnut-shaped electromagnetic field in order to sustain a controlled fusion reaction.

Ashraf, al- (c. 1242-November 22, 1296): Yemeni. About 1282, Sultan al-Ashraf, Umar ibn Yusuf, wrote an astronomical treatise in which he described an early mariner's compass: a bowl of water in which a magnetized compass floats.

Aspdin, Joseph (1778-March 20, 1855): English. Aspdin coined "Portland cement" for his invention, because the end product resembled Portland stone, an English limestone frequently used for construction.

Aston, Francis William (September 1, 1877-November 20, 1945): English. In 1919, Aston discovered how to separate two isotopes of neon—in a focused electromagnetic field, which moved the small-mass isotope, achieving separation. Thus was born the mass spectrograph, which helped earn him the 1922 Nobel Prize in Chemistry.

Atanasoff, John Vincent* (October 4, 1903-June 15, 1995): American. A mathematics professor, Atanasoff conceived the idea for a digital computer with electronics as the medium, base-two numbers, condensers for memory, and direct logical action for computation. He built the first prototype in 1939.

Ayrton, Hertha Marks* (April 28, 1854-August 26, 1923): English. Ayrton made improvements to the electric arc, an important nineteenth century illumination source, and invented a drafting tool and a manually operated fan.

B

Babbage, Charles* (December 26, 1791-October 18, 1871): English. Babbage's difference engine (described in 1822) and analytical engine (1834) were programmable mechanical computers. The first was designed to produce mathematical tables; the second was for all arithmetic calculations.

Babcock, Alpheus (September 11, 1785-April 3, 1842): American. Babcock was a musical instrument maker best known for patenting in 1825 a single-piece iron piano frame. His design enhanced resistance to strain, volume, and tonal range.

Babcock, George Herman (June 17, 1832-December 16, 1893): American. With Stephen Wilcox, Babcock devised a safe high-pressure water-tube boiler to produce steam for electricity generation, patented in 1867.

Backus, John Warner (December 3, 1924-March 17, 2007): American. In the 1950's, Backus developed the computer programming language Fortran. An acronym for "formula translation," it allows direct entry of commands into computers with Englishlike words and algebraic symbols.

Bacon, Francis (December 21, 1904-May 24, 1992): English. Although fuel cells date from the mid-nineteenth century, Bacon developed the first practical hydrogen-oxygen cell. The Bacon Cell, introduced in 1959, could generate five kilowatts.

Bacon, Roger* (c. 1220-c. 1292): English. Franciscan friar Bacon, among the first people to rely on experimentation to study nature, improved the understanding of optics, astronomy, and chemistry, including the manufacture of gunpowder.

Baekeland, Leo Hendrik* (November 14, 1863-February 23, 1944): Belgian American. Baekeland's Bakelite, a hard, moldable plastic introduced in 1909, was the first plastic made from synthetic materials and inaugurated the modern plastics age.

Baer, Ralph (b. March 8, 1922): German American. Baer developed the "Brown Box" in the 1960's, the first console video game. Magnavox began marketing it as Magnavox Odyssey in 1972.

Bagley, Rodney D. (b. October 2, 1934): American. With Irwin Lachlan and Ronald L. Lewis, Bagley invented the honeycomb cellular ceramic substrate that made possible an efficient catalytic converter to reduce pollutants from car exhaust.

Bain, Alexander* (October 10, 1810-January 2, 1877): Scottish. Introduced in 1846, Bain's "chemical telegraph" used punch tape to send signals that could be decoded on a moving paper tape soaked in ammonium nitrate and potassium ferrocyanide. His invention was five times faster than Morse code telegraphy.

Baird, John Logie (August 13, 1888-June 14, 1946): Scottish. The best known of Baird's 178 patents were a mechanical scanning system for transmitting moving images and a cathode-ray color television.

Baitar, Ibn al- (c. 1188-1248): Spanish. One of the greatest botanists of the Middle Ages, Ibn al-Baitar is credited with creating the first herbal drug treatment for cancer, using hindiba (chicory).

Bakr of Isfahan, Abi (fl. thirteenth century): Persian. In 1235, Bakr invented an astrolabe (an instrument for finding stars) that had a mechanical calendar to calculate the date. The astrolabe survives and is the oldest complete mechanical geared machine in existence.

Baldwin, Matthias (November 10, 1795-September 7, 1866): American. In 1830, Baldwin, a New Jersey manufacturer, built *Old Ironsides*, a six-ton locomotive of improved design. It was the first of some fifteen hundred locomotives his company built during his lifetime.

Ball, Harvey (July 10, 1921-April 12, 2000): American. Ball invented the yellow smiley face symbol in 1963 to cheer up workers at the State Mutual Life Assurance Company. Never having trademarked it, he received only $45 for the now ubiquitous image.

Bánki, Donát (June 6, 1859-August 1, 1922): Hungarian. With János Csonka, in 1898 Bánki invented a high-compression gasoline engine with two carburetors, an important step for the nascent automobile industry.

Banks, Robert (November 24, 1921-January 3, 1989): American. In 1951, Banks and Paul Hogan found a way to produce crystalline polypropylene and high-density polyethylene (HDPE), marking the beginning of a multibillion-dollar industry producing such common items as milk jugs, baskets, and indoor-outdoor carpeting.

Banneker, Benjamin* (November 9, 1731-October 9, 1806): American. In 1791, Banneker, a self-taught African American mathematician and astronomer, published his first almanac, providing information about eclipses, star and lunar positions, and weather based on his calculations.

Banting, Frederick Grant (November 14, 1891-February 21, 1941): Canadian. In 1922, Banting and Charles Herbert Best developed a method to produce insulin for treating diabetes. For this work, he received the 1923 Nobel Prize in Physiology or Medicine.

Baran, Paul (b. April 29, 1926): American. With Donald Davies and Leonard Kleinrock, Baran introduced the concept of digital packet switching to speed up the operation of digital networks and give them greater flexibility and hardiness.

Barber, John (1734-1801): English. Barber patented a design for a gas turbine in 1791. It was the first design to use a compressor and combustion chamber to ignite gases in order to turn the paddles of the turbine.

Bardeen, John* (May 23, 1908-January 30, 1991): American. Bardeen is the only person to win two Nobel Prizes in Physics, one for his part in inventing the transistor (1956) and the other for his explanation of superconductivity (1972).

Barnard, Christiaan Neethling (November 8, 1922-September 2, 2001): South African. Barnard headed the surgical team that performed the first heart transplant. It took place on December 3, 1967, in Cape Town, South Africa. The patient lived for eighteen days.

Barringer, Anthony Rene (b. October 20, 1925): English Canadian. In the early 1960's, Barringer invented the Induced Pulse Transient (INPUT) airborne electromagnetic system, used to hunt for ore. With it, mining engineers discovered twenty-five major deposits.

Barton, Otis (June 5, 1899-April 15, 1992): American. Barton designed the bathysphere, which he and William Beebe used in 1930 to become the first humans to dive below one hundred meters in the ocean.

Bascom, Earl W. (June 19, 1906-August 28, 1995): American. Bascom was a cowboy artist who invented equipment for rodeos, such as the side-delivery bucking chute (1916) and the hornless bronco saddle (1922).

Basov, Nikolay Gennadiyevich (December 14, 1922-July 1, 2001): Russian. Basov shared the 1964 Nobel Prize in Physics for his role in devising the quantum electronics that led to the maser and laser.

Bassal, Ibn (c. 1038-c. 1075): Spanish. Bassal is credited with being the first to add a flywheel to the rotating shaft of a pump in order to moderate fluctuations and smooth out the flow of power.

Bateman, C. Donald (b. March 8, 1932): Canadian. Bateman devised the ground proximity warning system to detect airplane navigational errors. The number of crashes plummeted after the system became mandatory in 1974.

Bath, Patricia* (b. November 4, 1942): American. An ophthalmologist, Bath developed a procedure and equipment for removing cataracts by laser surgery.

Battānī, al- (858-929): Turkish Arabic. Among the most illustrious of early astronomers, al-Battānī introduced trigonometry to astronomical calculation, laying the groundwork for spherical trigonometry.

Baulieu, Étienne-Émile (b. December 12, 1926): French. Baulieu developed RU 486 (mifepristone), an oral medication that causes the human womb to reject a fertilized egg. It is sometimes called the "abortion pill."

Baumann, Eugen (December 12, 1846-November 3, 1896): German. Baumann, a chemist, formulated polyvinyl chloride (PVC) in 1872. It is a hardy, nonreactive plastic widely used in pipes, clothing, and electrical wiring.

Baylis, Trevor Graham (b. May 13, 1937): English. Inspired by a television program about acquired immunodeficiency syndrome (AIDS) in Africa, in 1991 Baylis invented the wind-up radio as an inexpensive means to convey information about the disease in rural areas.

Beard, Andrew Jackson* (March 29, 1849-May 10, 1921): American. Beard received a patent for the Jenny coupler 1897. It enabled railroad cars to latch automatically by bumping into each other.

Beaufort, Francis (May 7, 1774-December 17, 1857): Irish. An admiral in the Royal Navy, Beaufort invented the Beaufort scale, a widely used tool for estimating wind strength without instruments.

Beckman, Arnold O. (April 10, 1900-May 18, 2004): American. Wealthy from his invention of a reliable pH meter (to measure acidity) in 1934, Beckman became a major donor for science education and research.

Bednorz, J. Georg* (b. May 16, 1950): German. Bednorz, with Karl Alexander Müller, discovered high-temperature superconductivity in a new class of ceramic materials, starting a worldwide effort to develop superconductor technology.

Beg, Ulugh (March 22, 1394-October 27, 1449): Persian. Beg built the largest astronomical observatory of its day and stocked it with instruments of his own design, notably a large Fakhri sextant that enabled him to take highly accurate measurements.

Begun, Semi Joseph* (December 2, 1905-January 5, 1995): German American. Begun built the first tape recorder used for broadcasting in 1934 and later improved the quality of magnetic tape for sound recording.

Békésy, Georg von* (June 3, 1899-June 13, 1972): Hungarian American. Békésy's discovery of the mechanics and physiology of hearing brought him the 1961 Nobel Prize in Physiology or Medicine.

Bélidor, Bernard Forest de (1698-September 8, 1761): French. De Bélidor's four-volume *Architecture hydraulique* (1737-1753) was the first major work to apply integral calculus to practical engineering problems.

Bell, Alexander Graham* (March 3, 1847-August 2, 1922): Scottish American. Before inventing the telephone in 1876, Bell taught at a school for the deaf, where he became fascinated by the nature of sound. He later produced innovations in aviation and hydrofoils and was the first president of the National Geographic Society.

Bell, Chichester A. (1848-1924): American. With his cousin Alexander Graham Bell, Chichester A. Bell started Volta Laboratory Association in 1881, where he helped develop an improved phonograph.

Benedictus, Edouard (1878-1939): French. Benedictus developed safety glass after knocking over a flask in 1903 and discovering that it did not break because of a nitrocellulose film on it.

Benerito, Ruth (b. January 12, 1916): American. Benerito's invention of wrinkle-resistant cotton cloth in the 1950's reduced the drudgery of ironing. The wash-and-wear fabric is credited with revitalizing the cotton industry.

Bennett, Willard H. (June 13, 1903-September 28, 1987): American. Bennett developed the radio frequency mass spectrometer in 1950. The nonmagnetic instrument was light enough to be carried in satellites later in the decade.

Benz, Carl* (November 25, 1844-April 4, 1929): German. Benz built the first commercial automobile powered by an internal combustion engine, the three-wheel Motorwagen, patented in January, 1886.

Berger, Hans (May 21, 1873-June 1, 1941): German. Berger devised the electroencephalograph in 1924 to record electrical patterns in the brain. It provides direct evidence about how human brains function.

Bergius, Friedrich* (October 11, 1884-March 30, 1949): German Argentine. Bergius devised a method for converting coal to liquid fuel by high-pressure hydrogenation, a development key to the German war effort in World War II.

Berliner, Emile* (May 20, 1851-August 3, 1929): German American. A versatile inventor, Berliner developed the microphone (1877), gramophone player (1887), and flat recording disc (1888). In 1919, he produced an early version of the helicopter.

Berners-Lee, Tim* (b. June 8, 1955): English. In 1989 Berners-Lee propounded his conception of a global hypertext project and wrote the first server and client for what became known as the World Wide Web.

Berry, Clifford* (April 19, 1918-October 30, 1963): American. Berry's contributions to the Atanasoff-Berry Computer (ABC, 1942) were its design details and construction; thereby, he proved that an electronic digital computer would work.

Berry, Marcellus F. (1848-1915): American. An employee of American Express Company, in 1891 Berry copyrighted his idea for traveler's checks to make it easier for travelers to obtain money in foreign countries.

Berthelot, Marcellin (October 27, 1827-March 18, 1907): French. The first chemist to synthesize hydrocarbons, in 1866 Berthelot was also the first to prepare polystyrene from ethylene and benzene.

Bessemer, Sir Henry* (January 19, 1813-March 15, 1898): English. In 1855, Bessemer patented a process for mass-producing steel economically. The Bessemer process introduces oxygen into fluid iron to remove impurities.

Best, Charles Herbert (February 27, 1899-March 31, 1978): Canadian. With Frederick Grant Banting, Best isolated the pancreatic hormone insulin in 1921, a key discovery for the treatment of diabetes.

Bevis, Douglas Charles Aitchison (May 28, 1919-June 25, 1994): English. In 1952, Bevis published the results of his research using amniocentesis to assess the risk factors to a fetus during pregnancy, a landmark in prenatal health.

Bi Sheng (c. 990-c. 1051): Chinese. Bi Sheng, an engraver, invented movable, reusable type, producing three thousand wood blocks with individual Chinese characters. He later made the type fonts from porcelain.

Bigelow, Erastus Brigham (April 2, 1814-December 6, 1879): American. Bigelow devised power looms for weaving counterpanes, coach lace, carpets, silk brocatelle, and tapestry and founded Clinton, Massachusetts, to support his industrial works.

Binney, Edwin* (1866-December 18, 1934): American. In 1903, Binney and his partner C. Harold Smith marketed the first wax toy crayons in a box of eight colors.

Binnig, Gerd* (b. July 20, 1947): German. With Heinrich Rohrer, Binning developed the scanning tunneling microscope, capable of imaging a single atom. They shared the 1986 Nobel Prize in Physics for it.

Bird, Forrest M. (b. June 9, 1921): American. Besides devising respirators for crews in high-altitude aircraft, in 1958 Bird invented the Bird Universal Medical Respirator for cardiopulmonary care and later a pediatric respirator.

Birdseye, Clarence* (December 9, 1886-October 7, 1956): American. Birdseye perfected a quick-freeze method for frozen foods that preserved without causing extensive cellular damage. Wrapped in his coated cellophane, his products were first sold in 1930.

Bíró, László (September 19, 1899-November 24, 1985): Hungarian Argentine. Irritated by the difficulties of using a fountain pen and taking a cue from the rotary inker on printing presses, Bíró, a journalist, invented the ballpoint pen in 1943.

Bīrūnī, al- (September, 973-December 13, 1048): Persian. A scholar of vast learning, al-Bīrūnī championed the experimental method to increase knowledge. He invented several astronomical instruments, including a mechanical computer for calculating the date based on Moon phases and the solar year.

Bissell, Melville (September 24, 1843-March 15, 1889): American. Bissell built the first carpet sweeper machine (patented 1876) to make it easier for his wife, Anna, to clean up the clingy sawdust on the floor of their crockery shop.

Black, Harold Stephen (April 14, 1898-December 11, 1983): American. Black's 1927 invention of the negative feedback amplifier, which feeds a system's output back into the input, proved broadly important to electronics, increasing bandwidth and reducing distortion in telephone, radio, and telegraphy systems.

Blackton, J. Stuart (January 5, 1875-August 13, 1941): English American. Inspired by the motion pictures of Thomas Alva Edison, Blackton produced the first stop-frame animation, premiering *Humorous Phases of a Funny Face* in 1906.

Blanchard, Helen Augusta (1840-1922): American. In 1873, Blanchard patented a sewing machine capable of zigzag stitching and held twenty-eight patents in all, including ones for a pencil sharpener and elastic seams and gores.

Blanchard, Thomas (June 24, 1788-April 16, 1864): American. Blanchard advanced industrial production with several major inventions, especially the acentric lathe, which reproduces irregular forms from a pattern (patented 1819).

Bláthy, Ottó Titusz (August 11, 1860-September 26, 1939): Hungarian. Bláthy's close-core electrical transformer, developed in 1885 with Károly Zipernowsky and Miksa Déri, made it possible to transmit alternating current over long distances.

Blodgett, Katharine Burr* (January 10, 1898-October 12, 1979): American. The first woman to become a research scientist for General Electric, Blodgett invented nonreflecting glass in 1938 by coating regular glass with many layers of a fatty acid film, each one molecule thick.

Blum, Samuel (b. August 28, 1920): American. Blum first used the ultraviolet excimer laser for medical applications, notably laser-assisted in situ keratomileusis (LASIK) eye surgery to correct vision defects.

Blumberg, Baruch S. (b. July 28, 1925): American. In 1976, Blumberg was cowinner of the Nobel Prize in Physiology or Medicine with D. Carleton Gajdusek for developing a diagnostic test for hepatitis B and a vaccine.

Bobeck, Andrew H. (b. 1926): American. Bobeck and Robert F. Fischer invented bubble memory for data storage systems.

Bogardus, James (March 14, 1800-April 13, 1874): American. Bogardus pioneered the use of cast-iron frames as the load-bearing structure for buildings and erected the first entirely cast-iron building in 1847.

Bohlin, Nils Ivar (July 17, 1920-September 21, 2002): Swedish. An engineer for Volvo Car Corporation, Bohlin designed the three-point seat belt (side-fastened lap belt with a diagonal chest strap), introduced in 1959.

Boivin, Marie Anne Victoire* (April 9, 1773-May 16, 1841): French. A leading expert in midwifery, Boivin invented the Boivin bivalve vaginal speculum.

Bombardier, Joseph-Armand (April 16, 1907-February 18, 1964): Canadian. Bombardier built his first snowmobile in 1937, a boxy seven-passenger vehicle, but it was his agile, motorcyclelike Ski-Doo, marketed in 1959, that transformed winter sports.

Booth, Andrew Donald (b. February 11, 1918): English Canadian. In 1948, Booth devised the magnetic drum used in early computers, the equivalent of the modern hard drive.

Booth, H. Cecil* (July 4, 1871-January 18, 1955): English. Booth patented his vacuum cleaner in 1901. The "Puffing Billy," it is claimed, cleaned the carpets for the coronation of Edward VI a year later.

Borden, Gail, Jr. (November 9, 1801-January 11, 1874): American. Borden developed a process for condensing milk in 1856. During the Civil War, the Union army's demand for the spoilage-resistant milk made it a commercial success.

Bosch, Carl* (August 27, 1874-April 26, 1940): German. Bosch adapted the high-pressure synthesis of ammonia for large-scale commercial production, a key step in the creation of cheap nitrogen fertilizers. For this he shared the 1931 Nobel Prize in Chemistry.

Bose, Amar (b. November 2, 1929): American. Chairman of Bose Corporation, Bose innovated high-fidelity sound with the introduction of the 901 Direct/Reflecting speaker in 1968, the first capable of producing rich, panoramic sound.

Bose, Jagadish Chandra (November 30, 1858-November 23, 1937): Indian. Bose's wide-ranging intellect was directed toward plant physiology, science fiction, and mysticism, among other matters, but he is best known for broadcasting wireless microwave signals in 1895, a first.

Bothe, Walther* (January 8, 1891-February 8, 1957): German. Bothe designed the device and developed the procedures that made possible the coincidence method of particle detection, crucial to the development of nuclear physics.

Bower, Robert W. (b. June 12, 1936): American. In 1969, Bower patented his Self-Aligned Gate MOSFET (metal-oxide semiconductor field-effect transmitter), a basic component of integrated circuits.

Boyden, Seth (November 17, 1788-March 31, 1870): American. A versatile industrial inventor, Boyden produced innovations in patent leather, malleable iron castings, steam engines, hat and nail manufacturing, and strawberries.

Boyer, Herbert Wayne* (b. July 10, 1936): American. With Stanley Norman Cohen in 1973, Boyer created the first viable deoxyribonucleic acid (DNA) cloned from different types of bacteria—recombinant DNA, now a basic technique in genetic engineering.

Boykin, Otis* (August 29, 1920-March, 1982): American. Boykin's designs for electronic resistors and other devices enabled faster, cheaper manufacturing of basic electrical and electronic components.

Boyle, Willard S.* (b. August 19, 1924): Canadian. With George E. Smith, Boyle invented the charge-coupled device (CCD) in 1969, which enhances digital images. Boyle also built the first continuously pumped ruby laser.

Bradley, Milton (November 8, 1836-May 30, 1911): American. In 1864, Bradley launched Milton Bradley and Company to market his innovation, the printed board game.

Bragg, William Henry (July 2, 1862-March 10, 1942): English. With his son William Lawrence, Bragg shared the 1915 Nobel Prize in Physics for founding a new branch of science, the analysis of crystal structure by X-ray diffraction.

Bragg, William Lawrence (March 31, 1890-1971): English. Bragg became the youngest Nobel laureate when, at age twenty-five, he shared the physics prize with his father, William Henry, for inventing X-ray crystallography.

Braille, Louis* (January 4, 1809-January 6, 1852): French. Between the ages of twelve and fifteen, Braille developed the raised-dot writing system for the blind that still bears his name.

Branca, Giovanni* (April 22, 1571 [baptized]-January 24, 1645): Italian. In 1629, Branca published *Le machine*, containing innovative designs, including one for the first steam turbine.

Brandenberger, Jacques Edwin* (October 19, 1872-July 13, 1954): Swiss. In 1908, Brandenberger, a chemist, produced a thin sheet of cellulose that repelled liquids, greases, and bacteria, which made it ideal for packaging food. He named it cellophane.

Brannock, Charles F. (May 16, 1903-November 22, 1992): American. The Brannock device, invented in 1925 and still standard in the shoe industry, measures the dimensions of feet accurately enough to ensure proper fitting.

Brattain, Walter H.* (February 10, 1902-October 13, 1987): American. Brattain shared the 1956 Nobel Prize in Physics with John Bardeen and William Shockley for their invention of the transistor. His part was to test Shockley's arrangements of semiconductors.

Braun, Karl Ferdinand* (June 6, 1850-April 20, 1918): German. For his 1897 invention of the oscilloscope, a precursor to the television, and other electronics devices, Braun shared the 1909 Nobel Prize in Physics with Guglielmo Marconi.

Braun, Wernher von* (March 23, 1912-June 16, 1977): German American. Von Braun was a designer and motivating spirit for German rockets during World War II and the American space effort afterward.

Brearley, Harry (February 18, 1871-August 12, 1948): English. By adding chromium to steel, Brearley synthesized stainless steel in 1913, initially to keep rifle barrels from rusting.

Breed, Allen K. (July 27, 1927-December 13, 1999): American. Breed built the first electromechanical automotive air bag safety system in 1968 and founded Breed Corporation, which became the third-largest supplier of automotive safety devices in the world.

Brin, Sergey (b. August 21, 1973): Russian American. In 1998, with Larry Page, Brin unveiled Google, an Internet search engine based on his data mining system. Google, Inc., swiftly grew into the world's largest Internet company.

Brown, Rachel Fuller (November 23, 1898-January 14, 1980): American. Working with Elizabeth Lee Hazen, Brown synthesized nystatin, the first antifungal antibiotic, introduced as a medication for humans in 1954.

Browning, John Moses* (January 21, 1855-November 26, 1926): American. Browning designed many types of sports rifles, shotguns, and pistols but is best known for the Peacemaker (1890) and the Browning automatic rifle (BAR, 1917).

Brugnatelli, Luigi Gasparo (1761-1818): Italian. Brugnatelli developed electroplating in 1805, which he used to deposit a fine layer of gold over silver objects.

Brush, Charles Francis (March 17, 1849-June 15, 1929): American. Brush invented a direct-current generator, an electrical arc light, a method for manufacturing lead-acid batteries, and, in 1888, the first wind-powered electrical turbine.

Budding, Edwin Beard (1795-1846): English. Budding built the first mechanical lawn mower in 1830, conceiving of the invention while watching the bladed reel of a cutting machine in a cloth mill.

Bullock, William* (1813-April 12, 1867): American. Bullock revolutionized the newspaper business with his invention of the roll-fed rotary printing press, patented in 1863.

Bunsen, Robert Wilhelm* (March 31, 1811-August 16, 1899): German. Bunsen's burner, first described in 1860 and built by Peter Desaga, provides a high-temperature, nonluminous flame and quickly became a standard piece of laboratory equipment.

Burbank, Luther* (March 7, 1849-April 11, 1926): American. Through various hybridization techniques, Burbank created hundreds of varieties of fruits, vegetables, and flowers, most famously the Russet Burbank (Idaho) potato.

Burckhalter, Joseph H. (October 9, 1912-May 9, 2004): American. With Robert Seiwald, Burckhalter synthesized fluorescein isothiocyanate (FITC), an antibody labeling agent that proved valuable in identifying the causes of disease.

Burroughs, William Seward* (January 28, 1855-September 15, 1898): American. In 1888, Burroughs patented the first adding machine that was easy enough to use and reliable enough to be a commercial success.

Burton, William Meriam (November 17, 1865-December 29, 1954): American. In 1913, Burton worked out a method for cracking crude oil with high pressure and high temperature, which doubled gasoline production for the fledgling petroleum industry.

Bush, Vannevar (March 11, 1890-June 30, 1974): American. Bush pioneered the design and construction of electromechanical analog computers and was the first to describe the idea of hypertext.

Bushnell, David* (August 30, 1742-1824): American. Bushnell designed and built the first attack submarine, the *Turtle*, used unsuccessfully against a British ship during the Revolutionary War.

Bushnell, Nolan K.* (b. February 5, 1943): American. In 1972, Bushnell released *Pong*, the first commercially successful video game, through his start-up company, Atari.

Butts, Alfred (April 13, 1899-April 4, 1993): American. Butts invented Scrabble, released in 1948 and still among the most popular board games in the world.

C

Cai Lun* (c. 50-c. 121 C.E.): Chinese. About the year 105, Cai Lun invented the process for making paper by suspending felted fibers in water until they dried into thin sheets.

Cailliau, Robert* (b. January 26, 1947): Belgian. Cailliau helped Tim Berners-Lee develop the World Wide Web while they worked at the European Organization for Nuclear Research (CERN) in 1990.

Calahan, Edward (1838-1912): American. Calahan built the first stock ticker in 1863. Receiving data through the telegraph directly from the New York Stock Exchange, the machines could print out the values of stock, commodities, and bonds in offices nationwide.

Calmette, Albert (July 12, 1863-October 29, 1933): French. With Camille Guérin, Calmette synthesized a tuberculosis vaccine, and he later developed a diagnostic test for the disease, called Calmette's reaction.

Campbell, Donald L. (August 5, 1904-September 14, 2002): American. In 1942, Campbell contributed to the development of fluid catalytic cracking, a chemical process essential for high-yield refining of high-octane gasoline and heating oil from crude oil.

Campbell, John* (c. 1720-December 16, 1790): Scottish. Campbell helped develop the nautical sextant, an essential instrument for navigation.

Camras, Marvin* (January 1, 1916-June 23, 1995): American. Camras invented a recording device using magnetized piano wire to record the voice of his cousin, a singer. He later adapted the idea to magnetic tape and the multitrack tape recorder that transformed the recording industry.

Carlson, Chester F.* (February 8, 1906-September 19, 1968): American. Carlson first tested his process for electrophotography, or xerography, in 1938, making the first photocopy.

Carothers, Wallace Hume* (April 27, 1896-April 29, 1937): American. Working for Dupont, Carothers, a chemist, led a research team that synthesized nylon and neoprene, the first artificial polymer-based products that were comparable to natural materials.

Carpue, Joseph Constantine (May 4, 1764-January 30, 1846): English. An anatomist and surgeon, Carpue pioneered surgical techniques for rhinoplasty, re-creating a missing nose with skin and integuments from the patient's forehead.

Carrier, Willis* (November 26, 1876-October 9, 1950): American. Carrier provided relief from heat and humidity through his invention of the modern air conditioner in 1902.

Carruthers, George R.* (b. October 1, 1939): American. Carruthers invented ultraviolet imaging devices—a camera and a spectrograph—that detect pollutants in Earth's atmosphere. A camera of his design took photographs of the Moon during the Apollo 16 mission in 1972.

Carson, Benjamin S. (b. September 18, 1951): American. Carson led the Johns Hopkins University surgical team that in 1987 was the first to separate Siamese twins who were joined at the head, hailed as the most complex surgical feat in medical history.

Cartwright, Alexander J. (April 17, 1820-July 12, 1892): American. Cartwright established the first baseball club (the Knickerbocker Base Ball Club) in 1845 and published the first set of rules; accordingly, he is often cited as the game's inventor.

Cartwright, Edmund* (April 24, 1743-October 30, 1823): English. Cartwright's powered weaving machine, patented in 1785, revolutionized textile manufacture, a signal advance into the Industrial Revolution.

Carver, George Washington* (July 12, 1861?-January 5, 1943): American. Born a slave, Carver became a leading agricultural researcher, inventing a multitude of useful products from such plants as the peanut, sweet potato, and soybean while at the Tuskegee Institute in Alabama.

Caselli, Giovanni (1815-1891): Italian. In 1861, Caselli patented the pantelegraph, a precursor of the fax machine that transmitted images via telegraph lines.

Cayley, George* (December 27, 1773-December 15, 1857): English. In 1904, Cayley built the first successful model monoplane glider, which had a kite for lift attached to a pole with an adjustable cross-shaped tail for stability and control.

Cepollina, Frank J. (b. 1936): American. Having worked on the Hubble Space Telescope for the National Aeronautics and Space Administration (NASA) since the mid-1970's, Cepollina designed the servicing platforms and instrument carriers that led to the successful repair of the telescope in 1993.

Cerf, Vinton Gray* (b. June 23, 1943): American. Cerf codesigned the packet network interconnection protocols (TCP/IP) that became the groundwork for the Internet.

Chapin, Daryl (July 21, 1906-January 19, 1995): American. With Calvin Fuller and Gerald Pearson, in 1954 Chapin demonstrated their Bell Solar Battery, which directly converts sunlight into electricity.

Chappelle, Emmett W. (b. October 24, 1925): American. With Grace Picciolo, Chappelle developed a bioluminescent assay from the luciferase enzyme and luciferin found in fireflies. The assay, important to agriculture, detects the presence of adenosine triphosphate (ATP).

Chardonnet, Hilaire Bernigaud (May 1, 1839-March 11, 1924): French. In 1889, Chardonnet exhibited his artificial silk, made from cellulose nitrate, at the Paris Exhibition. This "Chardonnet silk" is a form of rayon.

Charnley, John (August 29, 1911-August 5, 1982): English. Charnley invented the low-friction artificial hip and developed the surgical techniques for emplacing it (total hip arthroplasty) to treat osteoarthritis of the hip joint.

Chernoff, Adrian (b. 1971): American. In addition to being a leading automobile engineer, Chernoff created Rubber Bandits, rubber bands with hardy attached labels used in bundling and organizing items.

Christensen, Niels (1865-1952): Danish American. Christensen devised the O-ring in 1933. It is widely used to form a hydraulic seal for a piston in a cylinder.

Christie, Samuel Hunter (May 22, 1784-January 24, 1865): English. In 1833, Christie described his method for comparing the resistances of wires of different thicknesses in a diamond-shaped circuit. The method later became known as the Wheatstone bridge.

Cierva, Juan de la (September 21, 1895-December 19, 1936): Spanish. De la Cierva built the first autogiro, a propeller-powered aircraft whose lift is provided by a rotor, like that of a helicopter. He tested it successfully in 1923.

Ciurcu, Alexandru (January 29, 1854-January 22, 1922): Romanian. With Just Buisson, in 1886 Ciurcu built a reaction engine that propelled a boat by combusting gases in a cylinder that had been introduced through a small hole.

Clarke, Arthur C. (December 16, 1917-March 18, 2008): English. In 1945, Clarke published a technical article in *Wireless World*, "Extra-terrestrial Relays," containing the first description of a system of communication satellites.

Claude, Georges* (September 24, 1870-May 23, 1960): French. In 1910, Claude succeeded in producing a bright red light by electrifying neon in a glass tube, the first neon lamp.

Coanda, Henri Marie (June 6, 1886-November 25, 1972): Romanian. In 1910, Coanda built his Turbine Aeroplane, a biplane propelled by an early jet engine that used a four-cylinder piston engine to compress air that was then ignited in two burner chambers.

Cochran, Josephine Garis* (March 8, 1839-August 3, 1913): American. Fed up with servants chipping her dinnerware, Cochran designed the first dishwashing machine, patented in 1886.

Cockerell, Sir Christopher* (June 4, 1910-June 1, 1999): English. Cockerell launched the first hovercraft in 1959. Capable of carrying four passengers, the seven-ton vessel rode over the water on a cushion of air at speeds up to 28 miles per hour.

Coffey, Aeneas (1780-1852): Irish. Although an excise agent who hunted illegal whiskey makers, in 1830 Coffey invented an improved column still capable of continuous production of high-grade alcohol.

Cohen, Adam (b. May 30, 1979): American. Cohen's anti-Brownian Electrokinetic trap (ABEL trap) isolates and manipulates individual fluorescent molecules in solution at room temperature. It is a tool for analyzing complex molecules.

Cohen, Stanley (b. November 17, 1922): American. Working with Rita Levi-Montalcini, Cohen isolated human growth factors, which led to improved understanding and treatment of many degenerative and developmental diseases.

Cohen, Stanley Norman* (b. February 17, 1935): American. Cohen, with Herbert Wayne Boyer, was the first scientist to synthesize a functional recombinant DNA molecule, a basic advance for genetic engineering.

Collip, James Bertram (November 20, 1892-June 19, 1965): Canadian. Part of Frederick Grant Banting's research team, Collip, a biochemist, produced the first purified insulin suitable for use in human beings.

Colt, Samuel* (July 19, 1814-January 10, 1862): American. In 1835, Colt obtained the first patent on a revolver, whose rotating cylinder automatically fed cartridges into the firing chamber.

Colton, Frank B. (March 3, 1923-November 25, 2003): Polish American. A research chemist, Colton invented Enovid. First used to treat menstrual disorders, it was introduced in 1960 as an oral contraceptive.

Congreve, William (May 20, 1772-May 16, 1828): English. Congreve invented a solid-fuel artillery rocket capable of traveling nine thousand feet. The "rockets' red glare" in "The Star-Spangled Banner" refers to Congreve rockets during the War of 1812.

Conover, Lloyd Hillyard (b. June 13, 1923): American. Conover developed the antibiotic tetracycline in 1952. Within three years, it was the most-prescribed broad-spectrum antibiotic in the United States.

Constantinescu, George (1881-1965): Romanian. Constantinescu invented an interrupter gear that permitted machine guns to fire between the blades of propellers on the fighter planes of World War I.

Conti, Piero Ginori (June 3, 1865-December 9, 1939): Italian. Conti built the first geothermal power plant in 1904, which powered a 10-kilowatt dynamo.

Cooke, William Fothergill* (May 4, 1806-June 25, 1879): English. Working with Charles Wheatstone, Cooke pioneered electric telegraphy in Great Britain.

Coolidge, William David* (October 23, 1873-February 3, 1975): American. Coolidge invented a vacuum tube for generating X rays, which he patented in 1913. He also developed a portable X-ray machine for medical use during World War I.

Cooper, Martin* (b. December 26, 1928): American. Working for Motorola, Cooper led the research effort to develop the first wireless mobile telephone.

Cooper, Peter* (February 12, 1791-April 4, 1883): American. Cooper invented a series of industrial processes and first demonstrated the capabilities of the steam locomotive on American railways.

Coover, Harry (b. March 6, 1919): American. While trying to develop transparent gun sights for use in World War II, Coover found that one class of substance, cyanoacrylates, are unusually sticky. At Eastman Kodak, he refined the discovery into a useful product, superglue, first marketed in 1958.

Copeman, Lloyd Groff (December 29, 1881-July 5, 1956): American. Copeman produced the first electric stove in 1909 and later established the Copeman Electric Stove Company to market it, as well as his automatic electric toaster.

Corliss, George (June 2, 1817-February 21, 1888): American. The Corliss steam engine, developed in the late 1840's, was much more efficient than previous designs because of its novel rotary valves and variable valve timing.

Corneliszoon, Cornelis (1550-1607): Dutch. In 1594, Corneliszoon converted the turning motion from a windmill via a crankshaft to move a blade up and down and saw wood: the first powered sawmill.

Coston, Martha J.* (April 10, 1828-January 12, 1904): American. Building on her deceased husband's idea, Coston devised and in 1871 patented a system of signal flares with which ships could communicate at night.

Cottrell, Frederick Gardner* (January 10, 1877-November 16, 1948): American. Cottrell invented the electrostatic precipitator, patented in 1907, which ionizes pollutants, such as dust and smoke, so that they can be removed by electrified plates.

Coulter, Wallace (February 17, 1913-August 7, 1998): American. The Coulter principle is a reference method for counting and sizing microscopic particles in a fluid. It proved a great improvement in assaying blood.

Cousteau, Jacques* (June 11, 1910-June 25, 1997): French. Cousteau opened underwater realm to adventurers and spectators, creating the Aqua-Lung with Emile Gagnan in 1943 and pioneering underwater photography.

Cowen, Joshua Lionel* (August 25, 1877-September 8, 1965): American. Cowen's Lionel electric toy trains set the standard for the market.

Coxe, Eckley Brinton (June 4, 1839-May 13, 1895): American. A mining engineer and mine operator, Coxe improved the safety and efficiency of coal mining through several inventions, including a coal-washing jig, corrugated rolls for breaking coal, and a mechanical stoker.

Crary, John Williamson (1814-1897): American. In 1858, Crary invented a brickmaking machine that produced bricks of uniform size and quality.

Cray, Seymour* (September 28, 1925-October 5, 1996): American. By densely packing together hundreds of thousands of computer chips, in 1963 Cray built the first supercomputer, the CDC 6600. The supercomputer proved invaluable to scientific research, weather forecasting, and engineering.

Cristofori, Bartolomeo* (May 4, 1655-January 27, 1732): Italian. Cristofori is credited with building the first piano (then known as the pianoforte) about 1709. Its key innovation lay in producing sound by hammering strings rather than plucking them, as does the harpsichord.

Crompton, George (March 23, 1829-December 29, 1886): English American. Crompton simplified power looms and made them more efficient and flexible through a series of improvements, taking his first patent in 1854.

Crookes, Sir William* (June 17, 1832-April 4, 1919): English. A great experimenter, Crookes discovered thallium and invented the radiometer, the spinthariscope for detecting alpha particles, and the Crookes tube, a vacuum tube that produces cathode rays (electrons).

Crosby, Caresse* (April 20, 1892-January 24, 1970): American. Born Mary Phelps Jacob, Crosby received a patent for a wireless brassiere in 1914, the first design to be thus protected. She later became a celebrated poet and publisher.

Cruikshank, William Cumberland (1745-1800): English. Cruikshank introduced chlorination to make water safe to drink.

Crum, George (1822-1914): American. Crum is credited with inventing the potato chip in 1853, which he served but never patented.

Csonka, János (January 22, 1852-October 27, 1939): Hungarian. With Donát Bánki, Csonka invented the carburetor in 1893. They also produced the first motor tricycle and a gas engine.

Ctesibius of Alexandria* (c. 290-probably after 250 B.C.E.): Greek. Ctesibius, the "father of pneumatics," invented the force pump and water organ and refined the water clock.

Cugnot, Nicolas-Joseph* (February 26, 1725-October 2, 1804): French. In 1769, Cugnot built a steam-powered cart to haul artillery for the French army, and a year later he devised a vehicle that could carry four people.

Cullen, William (April 15, 1710-February 5, 1790): English. A medical chemist, Cullen is credited with creating the first workable design for a refrigerator (1748). His was a proof-of-concept device and never saw practical use.

Curtiss, Glenn H.* (May 21, 1878-July 23, 1930): American. A pioneering aviator, Curtiss introduced the aileron to provide airplanes with lateral stability. He also built the first successful seaplane.

Cushman, David Wayne (November 15, 1939-August 14, 2000): American. In the 1970's with Miguel Ondetti, Cushman developed captopril, the first angiotensin-converting enzyme (ACE) inhibitor, as an oral medication to control hypertension.

D

Daguerre, Louis Jacques* (November 18, 1787-July 10, 1851): French. In 1837, Daguerre, a painter and printmaker, perfected a process for chemically developing latent photographic images, which became known as daguerreotypes.

Daimler, Gottlieb* (March 17, 1834-March 6, 1900): German. With Wilhelm Maybach, Daimler built the first modern internal combustion engine with a gasoline-injecting carburetor in 1882, using various models to power a boat, bicycle, and carriage.

Dalén, Nils Gustaf* (November 30, 1869-December 9, 1937): Swedish. Dalén invented a fuel-saving, reliable acetylene gas lighting system for lighthouses and buoys, a boon to seafarers. He received the 1912 Nobel Prize in Physics for this invention.

Damadian, Raymond* (b. March 16, 1936): American. In 1974, Damadian patented the design for a nuclear magnetic resonance device to detect cancer and in 1977 produced the first magnetic resonance imaging (MRI) scan of the human body.

Darby, Abraham* (c. 1678-May 8, 1717): English. In 1709, Darby devised a coke-fueled blast furnace capable of producing high-grade iron, a significant step toward the Industrial Revolution.

Darby, Newman (b. 1928): American. Darby attached a movable sail to a pontoon catamaran in 1948, creating the first sailboard and inventing windsurfing.

D'Armate, Salvino (c. 1258-c. 1317): Italian. D'Armate is credited with inventing eyeglasses sometime in the late thirteenth century. He did so in hopes of achieving a direct view of God.

Darrow, Charles (1889-August 29, 1967): American. An engineer, in 1933 Darrow created Monopoly, which became the most popular board game ever.

Davies, Donald Watts (June 7, 1924-May 28, 2000): English. The Internet depends upon packet switching, a means of communication between computers that Davies conceived in 1965.

Davis, Jacob (1834-1908): Latvian American. Using Levi Strauss's denim cloth, Davis invented blue jeans with riveted pockets for extra strength, which he patented with Strauss in 1873.

Davy, Edmund (1785-November 5, 1857): English. In 1836, Davy created acetylene by heating potassium carbonate to high temperatures and letting it react with water.

Davy, Sir Humphry* (December 17, 1778-May 29, 1829): English. A renowned chemist, Davy also invented the miner's safety lamp, which made it possible for coal miners to work in methane-laden air.

Day, Joseph (1855-1946): English. In 1891, Day built the valveless two-stroke engine, a lightweight design that later was widely used in small vehicles and machines.

Dean, Mark* (b. March 2, 1957): American. With Dennis Moeller, Dean designed the Industry Standard Architecture (ISA) bus that enables users to hook up peripheral devices to their personal computers.

DeBakey, Michael Ellis (September 7, 1908-July 11, 2008): American. In 1966, DeBakey performed the first implantation of a left ventricle assist device (LVAD), a type of artificial heart.

Deere, John* (February 7, 1804-May 17, 1886): American. In 1837, Deere produced the first self-scouring steel plow, widely used by homesteaders in midwestern America.

De Forest, Lee* (August 26, 1873-June 30, 1961): American. In 1906, De Forest built the first three-element electron vacuum tube—the triode—which he called the audion. It could amplify signals and generate oscillations for transmitting sound via radio.

De Groote, Melvin (1896-February, 1963): American. An industrial chemist, De Groote synthesized demulsifiers for purifying crude oil of salt, sulfur, and water.

Dennard, Robert (b. September 5, 1932): American. In 1967, Dennard invented the one-transistor dynamic random access memory (DRAM), a crucial advance in computer technology.

Devol, George (b. February 20, 1912): American. A pioneer in robotics, Devol obtained more than forty patents, including one for Unimate (1954), the first industrial robot.

Dewar, Sir James* (September 20, 1842-March 27, 1923): English. Among Dewar's wide-ranging achievements as a chemist was his invention of the double-walled flask in 1872, later marketed to the public as the Thermos.

Dham, Vinod K. (b. 1950): Indian American. In 1990, Dham led the team at Intel Corporation to create the Pentium (586) processor chip, and in 1996 he oversaw the development of Advanced Micro Device's K6 processor.

Dickson, Earle (October 10, 1892-September 21, 1961): American. Because his wife was accident-prone, Dickson kept handy a supply of gauze pads on surgical tape. Johnson and Johnson learned of his invention and in 1924 began manufacturing it as the Band-Aid adhesive bandage.

Dickson, William Kennedy Laurie (August 3, 1860-September 28, 1935): English. In 1890, while an engineer in the laboratory of Thomas Alva Edison, Dickson built a motion-picture camera, the kinetograph, and made a short film called *Monkeyshines*.

Diehl, Philip (January 29, 1847-April 7, 1913): German American. Diehl attached a fan blade to a sewing machine motor and hung it on the ceiling. He patented his ceiling fan in 1887, later incorporating a light in the design.

Diesel, Rudolf* (March 18, 1858-September 29, 1913): German. The diesel engine, which Diesel successfully built in 1893, was an internal combustion engine that used pressure rather than a spark to ignite fuel.

Din, Taqi al- (June 14, 1526-1585): Turkish. One of al-Din's many books, *The Sublime Methods of Spiritual Machines* (1551), outlines the design of a rudimentary steam turbine, which he proposed be used for turning meat on a spit.

Disney, Walt* (December 5, 1901-December 15, 1966): American. Disney's studio produced the first cartoon with a synchronized sound track, *Steamboat Willie* (1928), and the first short feature to use the multiplane camera technique, *The Old Mill* (1937).

Djerassi, Carl* (b. October 29, 1923): Austrian American. With Luis Miramontes and George Rosenkranz, in 1951 Djerassi produced an oral contraceptive pill containing norethisterone synthesized from progesterone, which inhibits ovulation.

Dobelle, William H. (October 24, 1941-October 5, 2004): American. Dobelle invented an artificial vision system for the blind in which a minicamera mounted on sunglasses feeds images though sixty-eight electrodes to the visual cortex after processing in a small computer.

Dolby, Ray Milton (b. January 18, 1933): American. In 1966, Dolby invented the Dolby A-type noise reduction, a system that suppresses background noise.

Dollond, John (1706-1761): English. An optician, Dollond eliminated the color fringe in refracting telescopes with his invention of the achromatic lens, patented in 1758.

Donkin, Bryan (1768-1855): English. In 1813, Donkin patented a rotary press whose composition ink rollers, made of glue and molasses, were an influential innovation.

Donovan, Marion (October 15, 1917-November 4, 1998): American. Donovan simplified laundry chores by inventing a waterproof diaper, the Boater, patented in 1951, and disposable version soon after.

Dow, Herbert Henry* (February 26, 1866-October 15, 1930): American. Dow's method for extracting bromine cheaply from brine by electrolysis set the stage for a great expansion in the American chemical industry, particularly through Dow Chemical Company, founded in 1895.

Dragomir, Anastase (1896-1966): Romanian. Dragomir's "parachute cell," tested in 1929, was a prototype of the aircraft ejection seat.

Drais, Karl (April 29, 1785-December 10, 1851): German. In 1813, Drais built a four-wheel carriage powered by human pedalers, and in 1817 he tested his two-wheel velocipede (also known as a hobby horse), the ancestor of the modern bicycle.

Draper, Charles Stark* (October 2, 1901-July 25, 1987): American. Draper is widely known as the "father of inertial navigation" because his system, based upon gyroscopes and accelerometers, senses directional change on its own and has been used in submarines, missiles, aircraft, and spacecraft.

Drebbel, Cornelius (1572-November 7, 1633): Dutch. Drebbel is credited with constructing the first navigable submarine about 1621. Oar-powered, it operated at about four meters depth.

Drew, Charles Richard* (June 3, 1904-April 1, 1950): American. Drew revolutionized the storage of blood through his method of separating plasma from whole blood and dehydrating it. The technique produced large quantities of transfusible blood for the wounded during World War II.

Drew, Richard G.* (June 22, 1899-December 14, 1980): American. Drew invented the first paper-backed masking tape in 1925 and five years later the first transparent cellophane Scotch tape.

Drinker, Philip (December 12, 1894-October 19, 1972): American. With Louis Agassiz Shaw, Drinker invented the iron lung to make it easier for people with forms of paralysis, such as polio, to breathe. It was successfully tested on a patient in 1928.

Duggar, Benjamin Minge (September 1, 1872-September 10, 1956): American. In 1948, Duggar isolated the commercially viable broad-spectrum antibiotic aureomycin from fungus.

Dunlop, John Boyd* (February 5, 1840-October 23, 1921): Scottish. In 1888, Dunlop invented the pneumatic tire in an attempt to make his son's tricycle more comfortable to ride.

Dunwoody, Henry Harrison Chase (October 23, 1842-January 1, 1933): American. A brigadier general in the U.S. Army Signal Corps, Dunwoody received a patent for the carborundum crystal detector, an early form of the radio, in 1906, developing it with Greenleaf W. Pickard.

Durant, Graham John (b. March 14, 1934): English. With John Emmett and Charon Ganellin, Durant discovered the H2 receptor class of drugs, including the acid-inhibitor cimetidine (Tagamet, patented in 1976).

Duryea, Charles Edgar (December 15, 1861-September 28, 1938): American. Assisted by his younger brother James Frank, Duryea built the first successful American automobile with a gasoline engine in 1893.

Dyson, James (b. May 2, 1947): English. Dyson's G-Force, the first bagless vacuum cleaner, went on sale in Japan in 1986, and his better-known Dual Cyclone entered the market in England in 1993.

E

Eames, Charles and Ray (June 17, 1907-August 21, 1978 [Charles]; December 15, 1912-August 21, 1988 [Ray]): American. Both architects, this married couple built Eames House in 1949, a prototype of the modern, space-efficient prefabricated house.

Eastman, George* (July 12, 1854-March 14, 1932): American. Eastman greatly simplified photography, first with mass-produced dry glass photographic plates in 1880 and then with celluloid roll film in 1889.

Eckert, John Presper* (April 9, 1919-June 3, 1995): American. Working with John William Mauchly, Eckert built the first general-purpose electronic digital computer, ENIAC, in 1946 and the first commercial model, UNIVAC, in 1951.

Edgerton, Harold E.* (April 6, 1903-January 4, 1990): American. "Doc" Edgerton invented the gas flash bulb in 1928 and in 1931 synchronized a stroboscope with a camera, which permitted ultra-high-speed and stop-action photography.

Edison, Thomas Alva* (February 11, 1847-October 18, 1931): American. America's most famous inventor opened his Menlo Park laboratory in 1876 and produced the light bulb, improved stock ticker, motion-picture projector, and phonograph, among many other innovations.

Ehrlich, Paul (March 14, 1854-August 14, 1915): German. Ehrlich received the 1908 Nobel Prize in Physiology or Medicine for inventing Salvarsan (arsphenamine), the "magic bullet" that cured syphilis.

Eich, Brendan (b. July 4, 1964): American. In 1995, Eich created the scripting language JavaScript for World Wide Web applications.

Einhorn, Alfred (1856-1917): German. Einhorn synthesized Novocain in 1905 to replace cocaine as an anesthetic.

Einstein, Albert* (March 14, 1879-April 18, 1955): German American. With Leo Szilard in 1930, Einstein patented an electric refrigerator using ammonia, butane, and water in the heat-exchange process. Never marketed, the design attracted renewed attention in the twenty-first century as less harmful to the environment than existing machines.

Einthoven, Willem* (May 21, 1860-September 28, 1927): Dutch. In 1903, Einthoven developed the string galvanometer (forerunner of the electrocardiogram), which affords a sensitive, visual record of the heart's action. He received the 1924 Nobel Prize in Physiology or Medicine for it.

Elion, Gertrude Belle* (January 23, 1918-February 21, 1999): American. Elion synthesized a purine-based compound that checks the growth of leukemia cells, for which she shared the 1988 Nobel Prize in Physiology or Medicine.

Elmqvist, Rune (December 1, 1906-December 15, 1996): Swedish. Elmqvist devised a rechargeable, implantable cardiac pacemaker in 1958.

Elster, Julius (1854-1920): German. With Hans Friedrich Geitel, in 1904 Elster built a photoelectric cell consisting of a vacuum tube with a cathode and anode.

Emeagwali, Philip* (b. August 23, 1954): Nigerian American. In addition to helping launch the Internet, Emeagwali invented a method to track oil flow underground using a supercomputer.

Engelbart, Douglas C. (b. January 30, 1925): American. Engelbart revolutionized the human-computer interface with his invention of the computer mouse, hypertext, and groupware.

Ericsson, John* (July 31, 1803-March 8, 1889): Swedish American. Among Ericsson's many nautical innovations were the screw propeller and the *Monitor*, the first ironclad warship.

Ericsson, Lars Magnus (May 5, 1846-December 17, 1926): Swedish. Ericsson's designs for telephones and telephone exchanges, including the first multideck unit in the 1880's, were imitated by companies worldwide.

Espenschied, Lloyd (April 27, 1889-June 1, 1986): American. As well as developing the coaxial cable with Herman Affel, Espenschied patented a collision-avoidance system for trains and a radio altimeter for airplanes.

Evans, Oliver* (September 13, 1755-April 15, 1819): American. Evans refined the high-pressure steam engine, applied his design to power a flour mill, and received the first American patent for a steam-powered vehicle.

Evinrude, Ole (April 19, 1877-July 12, 1934): Norwegian American. Evinrude introduced the first commercially practical outboard motor in 1909. It had a single cylinder and produced 1.5 horsepower.

F

Face, Samuel (1923-2001): American. Face developed concrete leveling technology that became the industry standard and invented the Lightning Switch, a wireless light switch.

Factor, Max (1877-August 30, 1938): Polish American. World renowned for his cosmetic company, Factor adapted makeup for the movies and invented lip gloss in 1930 and Pan-Cake makeup in 1937.

Fadell, Tony* (b. 1969): American. Fadell conceived of the iPod music and video player as an independent businessman, and in 2001 Apple Computer hired him to lead the team developing it.

Faget, Maxime (August 26, 1921-October 9, 2004): American. Faget designed the Mercury space capsule for the National Aeronautics and Space Administration (NASA), first launched in 1961, and contributed to the design of the Gemini and Apollo capsules and the space shuttle.

Faggin, Federico* (b. December 1, 1941): Italian American. Faggin invented the metal-oxide-semiconductor (MOS) silicon gate technology, which became the basis for most computer chip designs, and later helped develop the first microprocessor, the Intel 4004.

Fahrenheit, Daniel Gabriel* (May 24, 1686-September 16, 1736): German. Fahrenheit invented the mercury thermometer in 1714 and the temperature scale that bears his name.

Faraday, Michael* (September 22, 1791-August 25, 1867): English. Besides contributing to the fundamental understanding of electromagnetism, Faraday invented the electric transformer, generator, and motor.

Farina, Johann Maria (December 8, 1685-November 25, 1766): Italian German. In 1709, Farina invented Eau de Cologne, whose citrus-based fragrance marked a departure from earlier, sweeter perfumes.

Farmer, Moses G. (February 9, 1820-May 25, 1893): American. With William F. Channing, in 1851 Farmer installed the first electric fire alarm system in Boston.

Farnsworth, Philo T.* (August 19, 1906-March 11, 1971): American. In 1927, Farnsworth was the first to achieve an all-electronic transmission of images with his image dissector.

Feinbloom, William (1903-1985): American. An optometrist, in 1937 Feinbloom patented a lightweight glass-plastic contact lens.

Fergason, James* (January 12, 1934-December 9, 2008): American. Fergason built the first operating liquid crystal display (LCD), demonstrated in 1971, and led the development of the technology.

Fermi, Enrico* (September 29, 1901-November 28, 1954): Italian American. As well as his foundational work in radiation physics, for which he received the 1938 Nobel Prize in Physics, Fermi designed and oversaw the construction of the first nuclear reactor in 1942.

Fernández-Morán, Humberto (February 18, 1924-March 17, 1999): Venezuelan. Fernández-Morán invented the diamond scalpel and pioneered cryoultramicrotomy, both means to slice tissue for examination by electron microscope.

Fessenden, Reginald Aubrey* (October 6, 1866-July 22, 1932): Canadian. Fessenden made the first two-way transatlantic radio transmission in 1906 and invented the heterodyne circuit and the radio compass.

Fick, Adolf Eugen (September 3, 1829-August 21, 1901): German. In 1887, Fick produced the first successful contact lens, made of heavy brown glass.

Fihri, Fatima al- (fl. mid-ninth century): Moroccan. Al-Fihri founded the University of Al-Qarawiyin in 859 said to be the first degree-granting university and still in operation.

Firestone, Harvey Samuel (December 20, 1868-February 7, 1938): American. The Firestone Tire and Rubber Company, established in 1900, was the first to cater to the automobile industry, first with solid rubber tires and then with Firestone's specially developed pneumatic rubber tires.

Fischer, Artur (b. December 31, 1919): German. Among Fischer's more than one thousand patents are the Photo Flash Light, a threaded plug for inserting a screw into a wall, and the construction toy fischertechnik.

Fischer, Rudolph (1881-1957): German. In 1911, Fischer patented a photographic film of three layers, each producing a different color when developed. It was later sold as Agfacolor.

Fisher, Alva J. (1862-1947): American. Fisher invented Thor, an early electric-powered washing machine, first marketed in 1908.

Fitch, John* (January 21, 1743-July 2, 1798): American. Fitch is credited with building the first successful steamboat, launched in August, 1787. It had six paddles on each side, propelling it like a canoe.

Flanigen, Edith (b. January 28, 1929): American. Beginning in 1956, Flanigen developed numerous synthetic molecular sieves from zeolites. They are used in the chemical and petroleum industries for producing products such as gasoline and oxygen and cleaning up nuclear waste.

Fleming, Alexander (August 6, 1881-March 11, 1955): Scottish. Fleming received the 1945 Nobel Prize in Physiology or Medicine for discovering in 1928 that penicillin prevented the growth of staphylococci, a discovery that led to a revolution in medical treatment with antibacterial drugs.

Fleming, John Ambrose (November 29, 1849-April 18, 1945): English. In 1904, Fleming patented his thermionic tube, later known as the two-electrode radio rectifier, or vacuum diode. Capable of detecting high-frequency signals, it was an important step in the development of radio.

Fleming, Sandford (January 7, 1827-July 22, 1915): Scottish Canadian. A civil engineer, Fleming first proposed standard time with time zones and designed Canada's first postage stamp.

Flowers, Tommy (December 22, 1905-October 28, 1998): English. Flowers designed Colossus, an early electronic computer. The one-ton, room-sized machine was completed in 1943.

Focke, Heinrich (October 8, 1890-February 25, 1979): German. A pioneer in fighter plane design, Focke also invented the twin-rotor helicopter, which first flew in 1936.

Fogarty, Thomas J. (b. February 25, 1934): American. In 1969, Fogarty, a cardiovascular surgeon, patented his balloon catheter, used to clear clogged blood vessels.

Fokker, Anthony Herman Gerard (April 6, 1890-December 23, 1939): Dutch American. A designer of fighter planes in World War I, Fokker invented an interrupter gear, which enabled a machine gun to fire past a plane's spinning propeller.

Ford, Henry* (July 30, 1863-April 7, 1947): American. The most famous name in the American automobile industry, Ford completed the Quadricycle, his first self-propelled vehicle, in 1896, and founded Ford Motor Company in 1903. His Model T, introduced in 1908, quickly dominated the market.

Forrester, Jay Wright* (b. July 14, 1918): American. Forrester built Whirlwind, a high-speed general-purpose digital computer that became operational in 1951. It was the first to use magnetic core memory.

Foucault, Léon* (September 18, 1819-February 11, 1868): French. A brilliant experimental physicist, Foucault fabricated the first gyroscope in 1852 in order to demonstrate that Earth rotates.

Fourneyron, Benoît (October 31, 1802-July 31, 1867): French. Fourneyron constructed the first water turbine in 1827, which had six horsepower. His larger, more efficient turbines powered many factories in the early Industrial Revolution.

Fowler, John (July 11, 1826-December 4, 1864): English. Fowler constructed the first steam-powered plow in 1852. It was dragged across a field as the engine turned a winch that pulled on an anchored cable.

Franklin, Benjamin* (January 17, 1706-April 17, 1790): American. Besides helping to establish the United States, Franklin is well known for inventing the Franklin stove, bifocals, the lightning rod, and the odometer.

Franz, John E. (b. December 21, 1929): American. Franz synthesized glyphosate in 1970. This broad-spectrum herbicide kills weeds after they grow, and so its use does not entail topsoil loss and the expense of tillage.

Fraunhofer, Joseph von* (March 6, 1787-June 7, 1826): German. Fraunhofer's method for measuring the index of refraction in glass improved optical quality; he also invented diffraction grating, which scatters white light into various wavelengths.

Free, Helen M.* (b. February 20, 1923): American. With her husband, Alfred H. Free, Free developed the swift "dip-and-read" urine test for glucose, used to monitor diabetes.

Frenkiel, Richard Henry (b. March 4, 1943): American. With Joe S. Engel, Frenkiel led the team at Bell Labs that during the 1960's devised basic cellular phone system architecture.

Fresnel, Augustin-Jean (May 10, 1788-July 14, 1827): French. Drawing from his wave theory of light, Fresnel invented the Fresnel lens, a lightweight design with large aperture and short focal length that became widely used in lighthouses.

Fry, Art (b. August 19, 1931): American. Fry's Post-it notes, developed with Spencer Silver and first marketed by the Minnesota Mining and Manufacturing Company (3M) in 1977, soon became as ubiquitous in office work as the stapler and the paper clip.

Fry, Joseph (1795-1879): English. Fry is credited with producing the first commercial candy bar in 1847.

Fuller, Calvin* (May 25, 1902-October 28, 1994): American. Fuller was among the coinventors of the first efficient silicon solar cell.

Fuller, R. Buckminster* (July 12, 1895-July 1, 1983): American. The epitome of the modern Renaissance man, Fuller was above all things as a visionary inventor, and his best-known innovations were the Dymaxion omnidirectional car (1932) and the geodesic dome (1947).

Fulton, Robert* (November 14, 1765-February 24, 1815): American. Fulton demonstrated the reliability of steam navigation when he and Robert R. Livingston sailed the steamboat *Clermont* from New York City to Albany on the Hudson River in 1807.

Funk, Casimir (February 23, 1884-November 20, 1967): Polish American. Funk discovered that a deficiency of amines led to certain diseases, such as scurvy and rickets. He called these vital amines "vitamines," later shortened to vitamins.

Fyodorov, Svyatoslav (August 8, 1927-June 2, 2000): Russian. Fyodorov originated radial keratotomy in 1974, a surgical procedure to correct myopia with incisions near the cornea of the eye.

G

Gabe, Frances (b. 1915): American. Gabe built the self-cleaning house, whose rooms, sink, shower, toilet, and bathtub are washed with jets of soapy water, drained, and dried with a blower, all operated with push-button controls.

Gabor, Dennis* (June 5, 1900-February 8, 1979): Hungarian British. Gabor received the 1971 Nobel Prize in Physics for his invention of holography—three-dimensional, lensless imaging.

Gadgil, Ashok* (b. 1950): Indian. In 1996, Gadgil produced his UV Waterworks, a technology that disinfects drinking water and is inexpensive and effective enough to use widely in developing countries.

Galileo* (February 15, 1564-January 8, 1642): Italian. Many scholars believe that Galileo established the modern form of scientific experimentation, but he also invented practical devices, such as the water thermometer in 1593 and a horse-powered pump in 1594.

Galitzine, Boris Borisovich (March 2, 1862-May 17, 1916): Russian. Galitzine built the first electromagnetic seismograph in 1906 and was a founder of the scientific discipline seismology.

Gallo, Robert Charles* (b. March 23, 1937): American. Besides codiscovering the human immunodeficiency virus (HIV) with Luc Montagnier, Gallo developed a blood test to detect it.

Galvani, Luigi (September 9, 1737-December 4, 1798): Italian. An anatomist studying frogs, Galvani discovered that a muscle contracts when its associated nerves touch certain metals. This galvanism (current electricity) inspired Alessandro Volta to invent the battery.

Garand, John (January 1, 1888-February 16, 1974): Canadian American. Garand designed the M1 semiautomatic rifle, the mainstay of American ground forces during World War II.

Gates, Bill* (b. October 28, 1955): American. Gates was one of the inventors of the basic operating system that underlies personal computer software and cofounded Microsoft Corporation.

Gates, Elmer R. (1859-1923): American. A versatile inventor for both home and industry, Gates is best known for his foam fire extinguisher.

Gatling, Richard* (September 12, 1818-February 26, 1903): American. Gatling designed the hand-cranked Gatling gun, capable of firing 350 bullets per minute, during the Civil War, although the U.S. Army did not use it until later.

Gay-Lussac, Joseph-Louis* (December 6, 1778-May 9, 1850): French. Gay-Lussac made significant advances in industrial and analytic chemistry and invented techniques and apparatuses for the production and study of chemicals.

Geiger, Hans* (September 30, 1882-September 24, 1945): German. The Geiger counter (1908) detects the alpha particles (positive ions) emitted during radioactive decay. It was widely used by prospectors searching for uranium ore.

Geissler, Heinrich (May 26, 1815-January 24, 1879): German. The Geissler tube, invented in 1857, contains low-pressure gas that glows when high voltage is applied to the electrodes on either end.

Germer, Edmund (August 24, 1901-August 10, 1987): German American. Germer improved the efficiency of lighting with his inventions of the fluorescent lamp (patented in 1926 with Friedrich Meyer and Hans Spanner) and the high-pressure mercury-vapor lamp.

Getting, Ivan A.* (January 18, 1912-October 11, 2003): American. Getting originated and advocated the development of the Global Positioning System (GPS), used by the military and civilians for pinpointing location.

Giannini, Amadeo Peter (May 6, 1870-June 3, 1949): American. Following the 1906 San Francisco earthquake, Giannini launched a shoestring bank that extended loans to small businesses and individuals from branch banks. His innovation in consumer banking grew into Bank of America, the nation's largest.

Giauque, William Francis* (May 12, 1895-March 28, 1982): Canadian American. Giauque received the 1949

Nobel Prize in Chemistry for his experiments in ultra-low temperatures using adiabatic demagnetization refrigeration.

Gibbon, John Heysham (September 29, 1903-February 5, 1973): American. In 1935, Gibbon, a surgeon, kept a cat alive with an external pump acting as an artificial heart, and in 1953 he successfully used his heart-lung machine during open-heart surgery on a person.

Giffard, Henri (1825-1882): French. Giffard built the first powered, steerable airship in 1852: a 144-foot long, hydrogen-filled balloon propelled by a propeller and three-horsepower steam engine.

Gilbreth, Lillian Evelyn* (May 24, 1878-January 2, 1972): American. Gilbreth was among the first organizational psychologists and a pioneer in industrial engineering.

Gillette, King Camp* (January 5, 1855-July 9, 1932): American. With William Nickerson, Gillette developed his safety razor in 1903 with a blade intended to be used and thrown away, thus supporting steady sales.

Ginsburg, Charles P.* (July 27, 1920-April 9, 1992): American. With Ray Dolby, Ginsburg constructed the first practical magnetic videotape recorder in 1956.

Glaser, Donald A.* (b. September 21, 1926): American. Glaser's ether-filled bubble chamber, for which he received the 1960 Nobel Prize in Physics, revolutionized nuclear physics, enabling scientists to detect short-lived subatomic particles.

Glidden, Joseph* (January 18, 1813-October 9, 1906): American. Glidden patented his invention, two-stranded barbed wire, in 1874. It became the most popular fencing for Western farms and ranchland.

Gobyato, Leonid (1875-1915): Russian. With Roman Kondratenko, Gobyato built and used the first portable mortar during the defense of Port Arthur in the 1904 Russo-Japanese War.

Goddard, Robert H.* (October 5, 1882-August 10, 1945): American. Widely held to be the father of rocket science, Goddard launched the first liquid-fuel rocket in 1923.

Goddard, William A. (July 10, 1913-September 29, 1997): American. In 1955, Goddard, John Lynott, and Louis Stevens developed a computer memory system of stacked magnetized disks on a rotating shaft with detached read-write heads: a magnetic disk drive.

Godowsky, Leopold, Jr.* (May 27, 1900-February 18, 1983): American. A professional violinist and amateur photographer, Godowsky and Leopold Mannes, another musician, invented the process for producing Kodachrome color transparency film, patented in 1935.

Goldman, Sylvan (November 15, 1898-November 25, 1984): American. A grocer, Goldman conceived of the shopping cart in 1936 and introduced it a year later for the convenience of shoppers at his Standard-Humpty Dumpty supermarkets.

Goldmark, Peter Carl* (December 2, 1906-December 7, 1977): Hungarian American. Goldmark invented the 33⅓ revolutions-per-minute long-playing (LP) phonograph record, introduced in 1948.

Goodyear, Charles* (December 29, 1800-July 1, 1860): American. In 1844, Goodyear patented his process for the vulcanization of rubber: curing by heating natural rubber mixed with sulfur.

Gore, Robert W. (b. 1939): American. Gore synthesized a new form of polytetrafluorethylene (PTFE) and found it was perfect for making a sturdy fabric. It was marketed as GORE-TEX in 1976.

Gould, Gordon* (July 17, 1920-September 16, 2005): American. Gould coined "laser" as an acronym for "light amplification by stimulated emission of radiation," a process he formulated independently of Theodore Harold Maiman, who built the first device.

Gourdine, Meredith C.* (September 26, 1929-November 20, 1998): American. Gourdine was a pioneer in electrogasdynamics—the action of charged particles through a gas—and applied it in practical inventions for energy conversion, spraying systems, and pollution control.

Gower, Richard Hall (1768-1833): English. Gower was a naval architect who invented a novel concave design for a ship's prow, an instrument for measuring a ship's speed, a speaking tube to lower decks, and a floating anchor.

Graham, Bette Nesmith* (March 23, 1924-May 12, 1980): American. A secretary, in 1951 Graham began painting white tempera over typewriter mistakes in order to make corrections. She began bottling her Mistake Out in 1956 and patented it as Liquid Paper a year later.

Gramme, Zénobe (April 4, 1826-January 20, 1901): Belgian. Gramme introduced the Gramme dynamo in 1869, a continuous-current electrical generator that was the first generator powerful enough to be used in industry.

Gray, Elisha* (August 2, 1835-January 21, 1901): American. Gray was among the developers of telegraphy and filed for a patent for the telephone on the same day as Alexander Graham Bell.

Greatbatch, Wilson* (b. September 6, 1919): American. Greatbatch developed an implantable heart pacemaker and a corrosion-free lithium-iodide battery to power it.

Greene, Leonard Michael (June 8, 1918-November 30, 2006): American. Greene invented a device to warn pilots that their planes were about to stall and another to detect wind shear; both saved many lives.

Greenwood, Chester (December 4, 1858-July 5, 1937): American. To protect his ears while he was testing new ice skates in 1873, Greenwood invented thermal earmuffs.

Gregory, James* (November, 1638-October, 1675): Scottish. Gregory designed the first practical reflecting telescope.

Gross, Alfred J.* (February 22, 1918-December 21, 2000): Canadian American. A visionary in mass communications, Gross developed many modern electronic devices, such as the walkie-talkie and the pager.

Grove, Sir William Robert* (July 11, 1811-August 1, 1896): English. Grove devised two new kinds of electrical batteries: the nitric acid battery and the gas battery.

Grumman, Leroy (January 4, 1895-October 4, 1982): American. Grumman cofounded Grumman Aerospace Corporation and patented a retractable landing gear for airplanes in 1932.

Guérin, Camille (December 22, 1872-June 9, 1961): French. With Albert Calmette, in 1921 Guérin developed bacillus Calmette-Guérin (BCG), a vaccine against tuberculosis.

Guericke, Otto von* (November 20, 1602-May 11, 1686): German. Von Guericke investigated the nature of atmospheric pressure and invented a vacuum pump.

Gundlach, Robert (b. September 7, 1926): American. As a research scientist for the Haloid Company (later Xerox Corporation), Gundlach made innovations to the photocopier that made it more versatile and easier and cheaper to use.

Gürsu, Hakan (b. 1959): Turkish. Gürsu designed the *Volitan*, a boat powered by both wind and solar energy.

Gutenberg, Johann* (1394-1399-Probably February 3, 1468): German. Gutenberg invented a printing press with metal movable type, reducing the cost of books and fostering a burgeoning of literacy.

Guthrie, Samuel (1782-October 19, 1848): American. Guthrie was the first American to synthesize chloroform, which he did in 1831 independently of European researchers.

H

Haber, Fritz* (December 9, 1868-January 29, 1934): German. Haber received the 1918 Nobel Prize in Chemistry for developing artificial nitrogen-bearing fertilizers, which expanded global agricultural production.

Hadley, John (April 16, 1682-February 14, 1744): English. In 1731, Hadley, a mathematician, published a description of his octant, which could be used to measure the height of the Sun above the horizon at sea in order to calculate a ship's latitude.

Haffkine, Waldemar (March 15, 1860-October 25, 1930): Russian Swiss. Haffkine discovered the principle of inoculation with a weakened form of a pathogen, with which he developed anticholera (1892) and antiplague (1896) vaccines.

Haldane, T. G. N. (December 14, 1897-June 24, 1981): English. In 1927, Haldane became the first person to patent a heat pump, which cools by transferring heat, usually by means of a cold fluid.

Hall, Charles Martin* (December 6, 1863-December 27, 1914): American. Large-scale aluminum production became possible after Hall found a way to produce pure metallic aluminum from ore by electrolysis.

Hall, H. Tracy* (October 20, 1919-July 25, 2008): American. Hall invented the method for producing synthetic diamond, which has many applications in industry, electronics, and jewelry.

Hall, Joyce C. (August 29, 1891-October 29, 1982): American. Hall founded Hall Brothers (later Hallmark) in 1910, commercializing greeting cards and helping make them a major form of personal communication.

Hall, Lloyd Augustus (June 20, 1894-January 2, 1971): American. Hall developed an improved process for curing and preserving foods with salts in 1925 and later a way to sterilize foods with ethylene oxide gas.

Hall, Robert N. (b. December 25, 1919): American. Hall built the first semiconductor injection laser in 1962, now widely used in compact disc (CD) players, printers, and optical fiber communications.

Hall, Thomas Seavey (April 1, 1827-December 1, 1880): American. In 1869, Hall invented the banjo signal, which warns when more than one train is on the same track, and other railroad safety devices during the 1860's and 1870's.

Hallidie, Andrew (March 16, 1836-April 24, 1900): English American. In 1873, Hallidie built the world's first cable car system in San Francisco, California.

Hamilton, William (August 4, 1805-September 2, 1865): Irish. A leading mathematical physicist of the nineteenth century, Hamilton is best known for introducing quaternions in 1843, a number system used in calculations involving three-dimensional rotations.

Hammond, John Hays, Jr. (April 13, 1888-February 12, 1965): American. Of his more than one hundred patents, Hammond's best known is a radio-operated remote-control system (1914).

Hancock, Thomas (May 8, 1786-March 26, 1865): English. With his "masticator" (1821), Hancock could produce shredded rubber for forming into blocks or sheets. He is credited with founding the British rubber industry.

Hanford, William Edward (December 9, 1908-January 27, 1996): American. Hanford and Donald Fletcher Holmes developed the process of synthesizing polyurethane, patented in 1942.

Hargreaves, James* (January 8, 1720 [baptized]-April 22, 1778): English. Hargreaves's spinning jenny was among the first devices in the industrialization of the textile industry.

Harington, Sir John* (1561-November 20, 1612): English. A member of the Elizabethan literati, Harington was the first person to describe a workable flush toilet (1596).

Harrison, John* (March, 1693-March 24, 1776): English. Harrison constructed the first marine chronometer that could keep time accurately at sea, a development crucial to finding the longitude for navigation.

Hasselblad, Victor (March 8, 1906-August 5, 1978): Swedish. Hasselblad released the civilian version of a 6-by-6-centimeter single-lens reflex camera in 1948; one of its descendants went to the Moon with Apollo 11.

Hayes, Dennis (b. 1950): American. In 1977, Hayes and Dale Heatherington produced the modulator-demodulator for personal computers (PC modem) for converting data to a form transmissible by telephone line.

Heaviside, Oliver* (May 18, 1850-February 3, 1925): English. An innovative mathematical physicist, Heaviside also invented the distortionless transmission line for telegraph and telephone cables.

Heilman, M. Stephen (b. December 25, 1933): American. Heilman coinvented the implantable heart defibrillator, which detects and corrects deadly errant heart rhythms.

Hell, Jozef Karol (1713-1789): Hungarian. Hell's water pillar, invented in 1749, could pump water up from depths of more than two hundred meters.

Helmholtz, Hermann von* (August 31, 1821-September 8, 1894): German. Helmholtz invented the ophthalmoscope for seeing into the eye and the ophthalmometer for measuring its curvature.

Henry, Beulah Louise* (September 28, 1887-February, 1973): American. Among Henry's numerous inventions are the vacuum ice cream freezer, children's toys, and improvements to typewriters and sewing machines.

Henry, Joseph* (December 17, 1797-May 13, 1878): American. An early master of electrical experiments, Henry invented an electric motor and the electromagnetic relay used in telegraphy.

Hero of Alexandria* (Before 62-c. 100 C.E.): Greek. Hero produced a novel surveying instrument, catapult, and coin-operated water dispenser but is best known for inventing the aeolipile, a precursor of the steam engine.

Hertz, Heinrich* (February 22, 1857-January 1, 1894): German. Hertz constructed the first radio transmitter and receiver and investigated the wave properties of electromagnetic radiation and the photoelectric effect.

Hevesy, George de (August 1, 1885-July 5, 1966): Hungarian. As well as codiscovering the element hafnium, von Hevesy received the 1943 Nobel Prize in Chemistry for developing radioactive tracer analysis, used in chemistry and medicine.

Hewitt, Peter Cooper* (May 5, 1861-August 25, 1921): American. Hewitt devised a bright, energy-efficient mercury-vapor lamp, which became a common source of industrial lighting.

Hewlett, William Redington* (May 20, 1913-January 12, 2001): American. Cofounder of the Hewlett-Packard Company, Hewlett invented the audio oscillator, which was the company's first successful product.

Higinbotham, William A. (October 25, 1910-November 10, 1994): American. In 1958, Higinbotham invented one of the first computer games, Tennis for Two.

Highs, Thomas (1718-1803): English. Highs produced an early version of the spinning jenny in 1764.

Higonnet, Rene Alphonse (April 5, 1902-October 13, 1984): French. With Louis Marius Moyroud, Higonnet built the first practical phototypesetting machine in 1946.

Hill, Rowland (December 3, 1795-August 27, 1879): English. In his *Post Office Reform* (1837), Hill argued for adhesive postage stamps to demonstrate prepayment of postage by the sender. England's Post Office brought out the first stamps four years later.

Hilleman, Maurice Ralph (August 30, 1919-April 11, 2005): American. Hilleman created dozens of vaccines for some of the deadliest human diseases, including influenza, hepatitis A and B, measles, and meningitis.

Hillier, James* (August 22, 1915-January 15, 2007): Canadian. With Albert Prebus, Hillier built a successful high-resolution electron microscope in 1938, the first in the United States.

Hodgkin, Dorothy Crowfoot* (May 12, 1910-July 29, 1994): English. An expert in X-ray crystallography, Hodgkin received the 1964 Nobel Prize in Chemistry for defining the structure of cholesterol, penicillin, vitamin B_{12}, and insulin.

Hoe, Richard March* (September 12, 1812-June 7, 1886): American. Hoe's rotary printing presses produced newspapers so quickly that they facilitated modern mass-produced journalism.

Hoff, Ted* (b. October 28, 1937): American. Hoff developed the microprocessor: the entire circuitry for a computer's central processing unit (CPU) on a single chip.

Hoffmann, Felix (January 21,1868-February 8, 1946): German. In 1897, Hoffman synthesized acetyl salicylic acid (aspirin), which Bayer first distributed to doctors as a pain reliever two years later.

Hogan, Paul (b. August 7, 1919): American. In 1951, Hogan and Robert Banks invented crystalline and high-density polyethylene (HDPE), plastics since used in common products such as milk jugs and indoor-outdoor carpeting.

Holland, John Philip* (February 29, 1840-August 12, 1914): Irish American. Holland designed and oversaw construction of the USS *Holland*, the first submarine commissioned by the U.S. Navy.

Hollerith, Herman* (February 29, 1860-November 17, 1929): American. Hollerith's punch-card tabulating machine, and associated sorting and counting devices, proved invaluable to governments and businesses after their successful use in the 1890 census.

Holley, Alexander (July 20, 1832-January 29, 1882): American. Holley made improvements in Sir Henry Bessemer's steelmaking process, opening the first of many steel factories in 1865.

Holly, Birdsill, Jr. (November 8, 1820-April 27, 1894): American. A holder of some 150 patents, Holly is best known for his fire protection system, which included a steam engine, a rotary water pump, and the fire hydrant.

Holonyak, Nick, Jr.* (b. November 3, 1928): American. Holonyak invented the first practical light-emitting diode, the first visible-spectrum laser, and the light-dimmer switch, also coinventing the transistor laser.

Holt, Benjamin (January 1, 1849-December 5, 1920): American. In 1890, Holt successfully tested a steam-powered tractor, naming a later model the Caterpillar.

Hood, Leroy E. (b. October 10, 1938): American. Hood is renowned for the automatic DNA sequencer, with which the entire genome of a human being was decoded in 2003.

Hooke, Robert* (July 18, 1635-March 3, 1703): English. In charge of devising demonstration experiments for England's Royal Society, Hooke innovated broadly in science theory and equipment. Among his many inventions were a balance wheel, universal joint, iris diaphragm, and air pump.

Hoover, Erna Schneider* (b. June 19, 1926): American. Hoover made possible modern telecommunications with her computerized switching system that can process a high volume of calls.

Hopkins, Samuel (1743-1818): American. Hopkins patented an improved method for making potash, for which he acquired the first patent granted under the United States' Patent Act of 1790.

Hopper, Grace Murray* (December 9, 1906-January 1, 1992): American. A U.S. naval officer, Hopper developed the COBOL computer programming language and a variety of innovative software.

Hopps, John Alexander* (1919-November 24, 1998): Canadian. Hopps laid the foundation for the cardiac pacemaker when he became the first person to stimulate a failing heart with electric current.

Hornby, Frank (1863-1936): English. A pioneering toy manufacturer, Hornby introduced a construction toy (Meccano), chemistry set (Kemex), electrical kit (Elektron), and model vehicles.

Houdry, Eugene (April 18, 1892-July 18, 1962): French American. In 1927, Houdry discovered a process for catalytically cracking low-grade crude oil into high-test gasoline.

Hounsfield, Godfrey Newbold* (August 28, 1919-August 12, 2004): English. Hounsfield shared the 1979 Nobel Prize in Physiology or Medicine for designing and building the first computerized axial tomography (CAT) scanner.

Howe, Elias* (July 9, 1819-October 3, 1867): American. Howe was the first American to build and patent a workable sewing machine.

Huangdi* (c. 2704-c. 2600 B.C.E.): Chinese. A figure of legendary stature, Huangdi is credited with introducing the horse-drawn chariot, ceramics, military armor, and agricultural calendar.

Hubert, Conrad (1855-March 14, 1928): Russian American. In the late 1890's, Hubert and David Misell developed a small electric lamp and a battery to power it, the genesis of the tubular flashlight. Their company later became Eveready.

Hughes, David Edward* (May 16, 1831-January 22, 1900): English. Hughes's carbon microphone was important to the development of the telephone, and he invented a telegraph printer.

Hughes, Howard R. (September 9, 1869-January 14, 1924): American. In 1909, Hughes, father of the famed aviator and movie director, obtained patents for the two-cone rock drill bit that became standard on rotary drills.

Hulett, George (September 26, 1846-January 17, 1923): American. The Hulett unloader featured a bucket with a cantilevered arm for unloading ore and coal from vessels, greatly speeding the process.

Hülsmeyer, Christian (December 25, 1881-January 31, 1957): German. In 1904, Hülsmeyer demonstrated his telemobiloscope, a precursor to radar, which served as a collision-warning device aboard ships.

Hunt, Walter (July 29, 1796-June 8, 1859): American. Hunt invented many practical gadgets, such as a knife sharpener and a sewing machine, but he is best known for his safety pin, patented in 1849.

Hutchison, Miller Reese* (August 6, 1876-February 16, 1944): American. A chief engineer in Thomas Alva Edison's laboratory, Hutchison influenced numerous inventions and created others in communications, transportation, and military technology.

Huygens, Christiaan* (April 14, 1629-July 8, 1695): Dutch. Huygens developed an improved method for grinding telescope lenses, invented the pendulum clock, and proposed a wave theory of light.

Hyatt, John Wesley (November 28, 1837-May 10, 1920): American. Hyatt launched large-scale celluloid manufacturing with his discovery of a simplified production process in 1869 and his mastery of industrial management.

Hyde, Ida H.* (September 8, 1857-August 22, 1945): American. Hyde invented a microelectrode thin enough to be inserted into a single cell.

Hyde, J. Franklin (March 11, 1903-October 11, 1999): American. In 1934, Hyde created a way to make ultrapure glass from fused silica, which found applications in spacecraft windows, telescopes, precision lenses, and optical fiber.

I

Ibuka, Masaru (April 11, 1908-December 19, 1997): Japanese. A cofounder of Sony Corporation, Ibuka led the team that produced the first transistor radio in 1955.

Iijima, Sumio* (b. May 2, 1939): Japanese. Iijima synthesized the first nanotubes in 1991, a basic advance in the development of nanotechnology.

Ilizarov, Gavril A. (June 15, 1921-July 24, 1992): Russian. The Ilizarov apparatus, patented in 1952, holds together a severed bone so that material can grow between the pieces, correcting deformities, a process called distraction osteogenesis.

Immink, Kees A. Schouhamer (b. December 18, 1946): Dutch. Schouhamer developed coding technologies for many modern consumer goods, such as the compact disc (CD), CD-ROM, digital video disc (DVD), and Blu-ray disc.

Ingersoll, Simon (March 3, 1818-July 24, 1894): American. Ingersoll's steam-powered rock drill, patented in 1871, was widely used in excavation, mining, and tunneling.

Inoue, Daisuke (b. May 10, 1940): Japanese. Inoue invented the karaoke machine in 1971, beloved by bar owners and amateur singers the world over.

J

Jābir ibn Ḥayyān, Abū Mūsā (Geber) (c. 721-c. 815): Arab. Geber is credited with urging the conversion of alchemy to an experimental science.

Jackson, Augustus (1808-unknown): American. Jackson improved the way to make ice cream in 1832 and developed new flavors, possibly during his tenure as a chef in the White House.

Jacobsen, Clayton II (b. 1932 or 1933): American. Jacobsen invented the Sea-Doo, a personal watercraft first sold in 1968 and then as the Jet Ski in 1973.

Jacquard, Joseph Marie (July 7, 1752-August 7, 1834): French. The Jacquard loom (1801) was the first to be programmable with punch cards.

Janney, Eli H. (November 12, 1831-June 16, 1912): American. Janney patented his knuckle-style automatic coupler for railroad cars in 1873.

Jansky, Karl G.* (October 22, 1905-February 14, 1950): American. While trying to rid an antenna of radio interference, Jansky discovered astronomical radio emissions, thus founding radio astronomy.

Janssen, Zacharias* (c. 1580-c. 1638): Dutch. An optician, Janssen developed a compound microscope and a telescope.

Jarvik, Robert* (b. May 11, 1946): American. Implanted in 1982, the Jarvik-7 became the first artificial heart to keep a terminally ill patient alive.

Javan, Ali* (b. December 26, 1926): Iranian American. Javan led a Bell Labs team that in 1960 built the helium-neon laser, the first gas laser and first continuous-light laser.

Jazarī, al-* (c. 1150-c. 1220): Arab. Al-Jazarī invented a suction pump and gears, levels, and values for water clocks and irrigation devices.

Jefferson, Thomas* (April 13, 1743-July 4, 1826): American. A versatile, practical scientist, the third U.S. president produced an improved ox plow, lap desk, and mechanical copier, as well as innovations in agriculture.

Jeffreys, Alec* (b. January 9, 1950): English. Jeffreys gave a powerful new tool to forensic science with his development of DNA profiling, also known as DNA fingerprinting, in 1984.

Jendrassik, György (May 13, 1898-February 8, 1954): Hungarian. In 1937, Jendrassik designed the Jendrassik Cs-1 turboprop, the prototype of engines used on many long-distance aircraft.

Jenkins, Charles Francis (August 22, 1867-June 6, 1934): American. Jenkins invented a mechanical scanning television and gave the first public television demonstration in the United States in 1925.

Jenner, Edward* (May 17, 1749-January 26, 1823): English. Jenner's great discovery, vaccination against disease, helped eradicate smallpox and started a revolution in public health.

Jennings, Thomas L.* (1791-February 11, 1859): American. Jennings's 1821 patent for a dry-cleaning technique to remove clothing stains was the first issued to an African American.

Jobs, Steve* (b. February 24, 1955): American. Jobs exerted a pervasive influence upon personal computing and consumer electronics as the cofounder and guiding spirit of Apple Computer from 1976 to 2009.

Joel, Amos Edward, Jr. (b. March 12, 1918): American. Developed in the 1960's, Joel's systems for switching cell phone service as the caller moves is the basis for modern telephone communications.

Johansson, Carl Edvard (March 15, 1864-September 30, 1943): Swedish. Johansson produced lengths of steel, called a gauge block set (patented in 1901), that provided exact standards of measurement and are widely used in machine shops and industry.

Johansson, Johan Petter (December 12, 1853-August 25, 1943): Swedish. In 1888, Johansson patented the pipe wrench and in 1892 the adjustable wrench.

Johnson, Clarence (February 27, 1910-December 21, 1990): American. As a leader in Lockheed's famous

Skunk Works, Johnson helped design some of the most advanced aircraft of his era, such as the U-2 and SR-71 spy planes.

Johnson, Edward H. (1846-1917): American. A business associate of Thomas Alva Edison, in 1882 Johnson became the first person to decorate a Christmas tree with electric lights.

Johnson, Eldridge R.* (February 18, 1867-November 14, 1945): American. With Emile Berliner, Johnson founded the Victor Talking Machine Company, the pioneering producer of phonographs and phonograph records.

Johnson, Herbert (fl. early twentieth century): American. In 1908, Johnson invented the standing electric mixer, originally intended for mixing bread dough.

Johnson, Lonnie G. (b. October 6, 1949): American. An engineer for the Air Force and Jet Propulsion Laboratory, Johnson invented the Super Soaker squirt gun in 1982.

Johnson, Nancy (c. 1795-1890): American. Credit for invention of the hand-cranked ice cream maker goes to Johnson, who patented one in 1843.

Jones, Amanda Theodosia (1835-1914): American. The Jones process, patented in 1873, is a method for preserving food by vacuum packing glass jars.

Jones, Frederick McKinley* (May 17, 1892-February 21, 1961): American. Jones created a ticket-dispensing machine, self-starting gas engine, starter generator, and vehicle air conditioner, among many other inventions.

Jones, Scott A. (b. 1960): American. Jones created voice mail in 1986 and founded the search engine ChaCha in 2006.

Judson, Whitcomb (1836-1909): American. Judson's "clasp locker" fastener, first exhibited in 1893, had hooks and eyes that were joined by a slide clasp: a precursor of the zipper.

Julian, Percy Lavon* (April 11, 1899-April 19, 1975): American. Julian, a chemist, produced several therapeutic drugs from plants, including the arthritis-relieving cortisone and the glaucoma medicine physostigmine.

K

Kahn, Bob* (b. December 23, 1938): American. Kahn and Vinton Gray Cerf developed the packet network interconnection protocols (TCP/IP), the system of technical rules used to transfer information though the Internet.

Kalashnikov, Mikhail (b. November 10, 1919): Russian. In 1947, Kalashnikov designed the AK-47, the most famous and widely used assault rifle.

Kallmann, Hartmut (February 5, 1896-June 11, 1978): German. Kallmann invented the scintillation counter, which measures ionizing radiation.

Kamen, Dean* (b. April 5, 1951): American. Kamen introduced his Segway PT (personal transporter), a self-balancing, electric-powered, two-wheeled platform, in 2001.

Kamerlingh Onnes, Heike* (September 21, 1853-February 21, 1926): Dutch. A pioneer in ultra-low-temperature physics, Kamerlingh Onnes liquefied helium and discovered superconductivity, for which he was honored with the 1913 Nobel Prize in Physics.

Kane, Nathan (b. 1968): American. Based on mathematical analysis, Kane built low-distortion bellows of maximum efficiency.

Kapitsa, Pyotr Leonidovich* (July 8, 1894-April 8, 1984): Russian. Kapitsa received the 1978 Nobel Prize in Physics for his investigations into the superfluidity of liquid helium and basic inventions in low-temperature physics.

Kármán, Theodore von (May 11, 1881-May 7, 1963): Hungarian American. An engineer in the early U.S. space program, von Kármán developed the mathematical analysis of fluid dynamics, especially turbulence, and its application to jet aircraft and rockets.

Kay, John* (July 16, 1704-1780 or 1781): English. Kay introduced the flying shuttle in weaving, which sped up the process of making cloth.

Keck, Donald (b. January 2, 1941): American. In 1970, Keck, Robert Maurer, and Peter Schultz produced the first optical fiber, which transmitted 65,000 times more information than copper wire.

Keichline, Anna Wagner (1889-1943): American. Keichline patented the K Brick, a precursor of the cement block, in 1927.

Kellogg, John Harvey* (February 26, 1852-December 14, 1943): American. An advocate of a healthy diet and exercise, Kellogg developed the ready-to-eat breakfast cereal of flaked whole grain.

Kelman, Charles (May 23, 1930-June 1, 2004): American. In 1967, Kelman introduced the phacoemulsification procedure, a form of cataract surgery that greatly shortened the recovery period.

Kelvin, Lord* (June 26, 1824-December 17, 1907): Irish. Lord Kelvin (William Thomson) was a master inventor of measuring devices and metrics, most famously the Kelvin temperature scale, which begins at absolute zero (0 kelvin).

Kemeny, John George (May 31, 1926-December 26, 1992): Hungarian American. With Thomas Kurtz, Kemeny created Beginners All-Purpose Symbolic Instruction Code (BASIC), a computer language first tested in 1964.

Kemurdzhian, Alexander (October 4, 1921-February 25, 2003): Russian. Kemurdzhian designed Lunokhod 1, the first space-exploration rover, which roamed on the Moon in 1970.

Kendall, Edward Calvin (March 8, 1886-May 4, 1972): American. Kendall shared the 1950 Nobel Prize in Physiology or Medicine for his work in isolating and analyzing hormones of the adrenal cortex, especially cortisone.

Kepler, Johannes (December 27, 1571-November 15, 1630): German. Kepler invented modern astronomy with his discovery of the three laws of planetary motion, which prove that the universe does not operate by caprice.

Kerst, Donald William (November 1, 1911-August 19, 1993): American. Kerst designed the betatron (1940), the first particle accelerator based on magnetic induction.

Kettering, Charles F.* (August 29, 1876-November 25, 1958): American. Kettering invented widely, producing, for instance, an improved railroad engine, refrigerators, a torpedo, automobiles, and unmanned aircraft.

Khalid (fl. ninth century): Ethiopian. Khalid is credited with discovering the stimulating effects of coffee, c. 850 C.E., and ground and boiled the beans for consumption.

Khan, Fazlur Rahman (April 3, 1929-March 27, 1982): Indian American. Kahn developed the shear wall frame interaction system, framed-tube structure, and tube-in-tube structure that made modern skyscrapers possible.

Khorana, Har Gobind (b. January 9, 1922): Indian American. Khorana shared the 1968 Nobel Prize in Physiology or Medicine for his work in protein synthesis and in 1970 was the first to synthesize a gene.

Khwārizmī, al-* (c. 780-c. 850): Persian. Al-Khwārizmī was among the scholars who gathered scientific knowledge and mathematics from Indian, Greek, and Roman sources and developed it further. Afterward, this learning passed into Europe.

Kies, Mary Dixon (1752-1837): American. In 1809, Kies became the first woman to be granted a patent in the United States. Her invention was a process to weave straw with silk or thread for the hatmaking industry.

Kilby, Jack St. Clair* (November 8, 1923-June 20, 2005): American. Kilby received the 2000 Nobel Prize in Physics as the inventor of the integrated circuit; he also developed a hand calculator and thermal printer.

Kindī, al- (Alkindus) (c. 801-873): Yemeni. The first philosopher in the Arab tradition to draw from Greek thought, al-Kindī was also the first to describe the distillation of pure alcohol.

King, Mary-Claire* (b. February 27, 1946): American. King established that a genetic mechanism can exist for cancer when she identified the gene responsible for some breast and ovarian cancers.

Kingsbury, Albert (December 23, 1863-July 28, 1943): American. Kingsbury invented the durable tilting-pad thrust bearing in 1912; his bearings could withstand high pressure and increased the performance and life of many machines.

Kirchhoff, Gustav (March 12, 1824-October 17, 1887): German. With Robert Wilhelm Bunsen, Kirchhoff promulgated the theory of spectrum analysis and coinvented the recording spectroscope.

Klatte, Fritz (March 28, 1880-February 11, 1934): German. Klatte patented his process for synthesizing vinyl acetate in 1913, also known as polyvinyl chloride (PVC).

Kleist, Dale (1909-1998): American. In 1932, Kleist developed the steam-blown process for making fiberglass.

Kleist, Ewald Georg von* (June 10, 1700-December 11, 1748): German. Independently of Pieter van Musschenbroek, von Kleist invented the Leiden jar, an early capacitor that stored electricity produced by friction.

Knight, Margaret E.* (February 14, 1838-October 12, 1914): American. A versatile mechanical engineer, Knight is best known for designing a machine that manufactured square-bottom paper grocery bags.

Knunyants, Ivan Ludvigovich (June 4, 1906-December 21, 1990): Armenian Russian. Knunyants invented polycaprolactam (nylon-6) and was a central figure in the Soviet chemical weapons program.

Koch, Robert (December 11, 1843-May 27, 1910): German. A founder of bacteriology and public health, Koch received the 1905 Nobel Prize in Physiology or Medicine for discovering several human pathogens, and he developed a method for culturing bacteria on a solid medium.

Kolff, Willem Johan* (February 14, 1911-February 11, 2009): Dutch American. Kolff designed the first dialysis machine, which cleansed the blood of people with kidney failure.

Kollsman, Paul (February 22, 1900-September 26, 1982): German American. Kollsman made it possible for pilots to fly by instruments with his invention of the barometric altimeter in 1928.

Kompfner, Rudolf (May 16, 1909-December 3, 1977): Austrian American. In 1943, Kompfner invented the traveling wave tube, which amplifies radio signals to high power.

Koontz, Roscoe* (December 16, 1922-May 17, 1997): American. Koontz was a pioneer in creating safety procedures to protect workers from radiation at nuclear reactors, thereby helping to establish the field of health physics.

Kornberg, Arthur (March 3, 1918-October 26, 2007): American. Kornberg isolated the enzyme DNA polymerase, with which he made copies of DNA. He shared the 1959 Nobel Prize in Physiology or Medicine for his work.

Korolyov, Sergey (January 12, 1907-January 14, 1966): Russian. Korolyov led the team that developed the first intercontinental ballistic missile (ICBM) and was chief designer of the rockets in the Soviet space program from 1953 until his death.

Kotelnikov, Gleb (1872-November 22, 1944): Russian. Kotelnikov invented the knapsack parachute, which was first tested in 1912.

Kroll, William (November 24, 1889-March 30, 1973): Luxembourger American. In 1932, Kroll developed a process for mass producing ductile metallic titanium, later a key material in aircraft.

Kulibin, Ivan (April 21, 1735-August 11, 1818): Russian. As well as many optical, acoustic, and measuring instruments, Kulibin invented a searchlight in 1779 and a mechanical elevator in 1794.

Kurchatov, Igor (January 12, 1903-February 7, 1960): Russian. Kurchatov led the Soviet program to develop nuclear weapons, beginning in 1943. He also oversaw construction of a Russian cyclotron (1949) and its first nuclear power plant (1954).

Kurzweil, Ray* (b. February 12, 1948): American. Kurzweil invented several advanced computer-based pattern-recognition (expert systems) technologies for use in finance, music composition and instrumentation, and other fields.

Kwolek, Stephanie* (b. July 31, 1923): American. Kwolek discovered liquid crystalline polymers, which made possible the development of the high-performance fiber Kevlar.

Kyan, John Howard (1774-1850): Irish. Kyanising, which Kyan patented in 1832, was a method of preserving wood by soaking it in mercuric chloride.

L

Laënnec, René-Théophile-Hyacinthe* (February 17, 1781-August 13, 1826): French. Laënnec's invention of the stethoscope in 1816 improved the accuracy of diagnoses for heart and chest problems.

Lakhovsky, Georges (1869-1942): Russian French. Working with Nikola Tesla, Lakhovsky developed the multiple-wave oscillator, used in alternative medicine for electromagnetic therapy.

Lamarr, Hedy (November 9, 1913-January 19, 2000): Austrian American. A leading Hollywood actress, in 1941 Lamarr invented the spread-spectrum radio system with composer George Antheil. It could foil jamming and was intended for a radio-guided torpedo system.

Lambert, John William (January 29, 1860-May 20, 1952): American. In 1890, Lambert constructed a car powered by a single-cylinder gasoline engine. He later patented a friction transmission.

Lanchester, Frederick William (October 23, 1868-March 8, 1946): English. Lanchester built the first automobile in England in 1896 and was a pioneer aeronautics engineer.

Land, Edwin Herbert* (May 7, 1909-March 1, 1991): American. Land introduced instant photography in sepia (1947), black and white (1950), and color (1963).

Langer, Alois A. (b. February 24, 1945): American. Langer engineered the first implantable cardioverter-defibrillator (ICD), which automatically corrects irregular heartbeats to avoid heart failure.

Langer, Robert S. (b. August 29. 1948): American. A leader in biomedical engineering, Langer developed controlled drug delivery in 1986 and pioneered remotely controlled drug delivery and tissue engineering.

Langevin, Paul (January 23, 1872-December 19, 1946): French. Langevin was a central figure in the development of submarine detection by echolocation during World War I, a technology later called sonar.

Langley, Samuel Pierpont* (August 22, 1834-February 27, 1906): American. A pioneer in aviation and an astronomer, Langley was also the inventor of the bolometer, which measures radiant electromagnetic energy.

Langmuir, Irving* (January 31, 1881-August 16, 1959): American. Langmuir developed a successful type of incandescent bulb, and his work in surface chemistry brought him the 1932 Nobel Prize in Chemistry.

Langstroth, Lorenzo Lorraine (December 25, 1810-October 6, 1895): American. Langstroth invented a beehive for domesticated bees in 1851, multiplying honey production.

Lanston, Tolbert (February 3, 1844-February 18, 1913): American. Lanston invented the monotype typesetting machine in 1885, the first to cast individual type and justify the margins line by line.

Latimer, Lewis Howard* (September 4, 1848-December 11, 1928): American. Among Latimer's inventions were a "Water Closet for Railroad Cars," patented in 1874, and improvements in the manufacture of light bulbs.

Lauks, Imants (fl. late twentieth century): Canadian. In 1986, Lauks and Jan Van der Spiegel developed the silicon chip blood analyzer.

Lauterbur, Paul Christian (May 6, 1929-March 27, 2007): American. Lauterbur conceived the nuclear magnetic resonance in magnetic resonance imaging (MRI), for which he shared the 2003 Nobel Prize in Physiology or Medicine.

Laval, Gustaf de (May 9, 1845-February 2, 1913): Swedish. A prolific inventor, de Laval is particularly known for his continuously operating centrifugal cream separator and the de Laval nozzle, a component in steam engines.

Lawes, John Bennet (December 28, 1814-August 31, 1900): English. In 1842, Lawes perfected his process for making the chemical fertilizer superphospate and launched the artificial fertilizer industry.

Lawrence, Ernest Orlando* (August 8, 1901-August 27, 1958): American. Lawrence invented the cyclotron, a circular particle accelerator that made possible the direct investigation of the atomic nucleus and produced new radioactive isotopes.

Lear, Bill* (June 26, 1902-May 14, 1978): American. Lear invented the eight-track tape recorder, an autopilot system for aircraft, and the two-engine commercial Learjet.

Lebedev, Sergei Vasilyevich (July 25, 1874-May 2, 1934): Russian. In 1910, Lebedev produced a synthetic elastic rubber from polybutadiene.

Le Caine, Hugh* (May 27, 1914-July 3, 1977): Canadian. A founder of electronic music, Le Caine introduced the Electronic Sackbut and the Special Purpose Tape Recorder.

Ledley, Robert Steven* (b. June 28, 1926): American. Ledley's automatic computerized transverse axial (ACTA) X-ray scanner, introduced in 1973, first afforded physicians three-dimensional, whole-body images.

Leduc, René (1898-1968): French. In 1949, Leduc built the first aircraft to be powered by ramjet engines, which he patented in 1935.

Leeuwenhoek, Antoni van* (October 24, 1632-August 26, 1723): Dutch. Leeuwenhoek pioneered the design, construction, and use of microscopes. His discovery of microorganisms opened a new world to science.

Leibniz, Gottfried Wilhelm* (July 1, 1646-November 14, 1716): German. As well as coinventing calculus, Leibniz constructed a calculating machine and a binary system of numeration.

Leith, Emmett* (March 12, 1927-December 23, 2005): American. With Juris Upatnieks, Leith displayed the first hologram, a three-dimensional image, in 1964.

Leland, Henry Martin (February 16, 1843-March 26, 1932): American. A founder of Lincoln Motor Company and Cadillac, Leland introduced interchangeable parts in automotive construction and contributed to the V-8 engine and electric starter.

Lemelson, Jerome H.* (July 18, 1923-October 1, 1997): American. Second only to Thomas Alva Edison as America's most prolific inventor, Lemelson innovated such technology as machine vision, automated teller machines (ATMs), and videocassette recorders.

Lenoir, Étienne* (January 12, 1822-August 4, 1900): Belgian French. Lenoir invented a two-stroke internal combustion engine fired by a mixture of coal gas and air; it contained the first spark plug, patented in 1860.

Lenormand, Louis-Sébastien* (1757-1837): French. As well as coining the word "parachute," Lenormand is credited with making the first successful parachute descent.

Leonardo da Vinci* (April 15, 1452-May 2, 1519): Italian. Of the myriad inventions by this great Renaissance painter, the most renowned involved flying. His design for a glider was tested successfully in the twenty-first century.

LeTourneau, Robert Gilmore (November 30, 1888-June 1, 1969): American. With some three hundred patents, LeTourneau introduced many innovations in earthmoving equipment, such as the heavy-duty rubber tire and electric wheel drive.

Libby, Willard F.* (December 17, 1908-September 8, 1980): American. Libby received the 1960 Nobel Prize in Chemistry for inventing radiocarbon dating. It traces the decay of carbon-14 in order to determine the age of materials.

Liebig, Justus von (May 12, 1803-April 18, 1873): German. The founder of agricultural chemistry, Liebig discovered that nitrogen was a basic plant nutrient-based fertilizer and developed the first inorganic fertilizers.

Lilienthal, Otto (May 23, 1848-April 10, 1896): German. In 1891, Lilienthal built the first human-carrying hang glider.

Linde, Carl von* (June 11, 1842-November 16, 1934): German. Linde developed modern refrigeration technology and a technique for extracting pure oxygen and nitrogen from air.

Lindqvist, Frans Wilhelm (1862-1931): Swedish. In 1892, Lindqvist invented the sootless kerosene stove and started a company, Primus, to market it.

Link, Edwin Albert* (July 26, 1904-September 7, 1981): American. Link's invention of the flight simulator allowed pilots to develop flying skills without leaving the ground.

Lippershey, Hans* (c. 1570-September, 1619): Dutch. A maker of eyeglasses, Lippershey also made an early refracting telescope, which many scholars believe was the first.

Lippmann, Gabriel* (August 16, 1845-July 13, 1921): French. Lippmann's color photography process based on the interference phenomenon brought him the 1908 Nobel Prize in Physics.

Littleton, Jesse T. (1888-1966): American. Littleton is credited with recognizing the potential of Nonex, the precursor of Pyrex glass, in cooking vessels and testing it in 1913.

Livens, William Howard (1889-1964): English. Livens invented chemical and incendiary weapons, notably the Livens Projector, which could hurl containers of toxic chemicals.

Livingston, M. Stanley* (May 25, 1905-August 25, 1986): American. Livingston worked with Ernest Orlando Lawrence to build the first cyclotron and later designed other particle accelerators used in nuclear research.

Lodge, Oliver Joseph (June 12, 1851-August 22, 1940): English. Lodge invented the coherer—the radio-wave detector in early radiotelegraph receivers—in 1894.

Lodygin, Alexander (1847-1923): Russian. Lodygin demonstrated his lamp with a carbon-filament incandescent light bulb in 1873.

Long, Crawford Williamson (November 1, 1815-July 16, 1878): American. In 1842, Long used ether as an anesthetic during surgery to remove a neck tumor, the first physician to do so.

Losev, Oleg (1903-1942): Russian. In the early 1920's, Oleg independently discovered the principle of the light-emitting diode.

Lovelace, Ada (December 10, 1815-November 27, 1852): English. Lovelace introduced the basis for computer programming in a 1843 commentary describing how to operate Charles Babbage's difference engine.

Low, Archibald Montgomery (1888-September, 1956): English. Low invented a forerunner of the television and guidance systems for torpedoes, airplanes, and rockets.

Lumière, Auguste and Louis* (October 19, 1862-April 10, 1954 [Auguste]; October 5, 1864-June 6, 1948 [Louis]): French. Auguste and Louis Lumière invented the cinématographe, a motion-picture system, and started the movie theater business.

Lundström, John Edvard (1815-1888): Swedish. In 1855, Lundström invented a safety match that lit when the fire-starting chemicals on its head were scraped across a red phosphorous strip on the matchbox.

Luppis, Giovanni (1813-1875): Austrian. A commander in the Austrian navy, in 1866 Luppis devised a self-propelled, steerable torpedo with Robert Whitehead's help.

Lyons, Harold (February 16, 1913-March 23, 1998): American. Lyons oversaw the construction of the first atomic clock in 1948. It was accurate to one second in 231 days.

M

Ma Jun (c. 200-c. 260): Chinese. Ma Jun developed the compass vehicle, a nonmagnetic mechanical device that served as a directional compass.

McAdam, John Loudon* (September 21, 1756-November 26, 1836): Scottish. McAdam's method of paving road surfaces with three layers of broken stone, called macadam, and lining them with drainage ditches made roads hardier and easier to maintain.

McCormick, Cyrus Hall* (February 15, 1809-May 13, 1884): American. The McCormick reaper, patented in 1834, increased the efficiency and lowered the cost of harvesting, fostering the development of agriculture in the American West.

McCoy, Elijah* (March 27, 1843, or May 2, 1844-October 10, 1929): Canadian American. McCoy concentrated his inventive genius on locomotives, producing more than fifty devices, including an automatic lubricator.

MacCready, Paul B.* (September 29, 1925-August 28, 2007): American. MacCready built the Gossamer Condor, which won the Kremer Prize in 1977 as the first human-powered aircraft.

McIntire, Otis Ray (August 24, 1918-February 2, 1996): American. In 1944, McIntire patented extruded polystyrene foam, better known by its brand name, Styrofoam.

Macintosh, Charles* (December 29, 1766-July 25, 1843): Scottish. In 1823, Macintosh patented the first raincoat, waterproofed by sandwiching soluble rubber between layers of cloth.

McLean, Malcolm Purcell (November 14, 1914-May 25, 2001): American. McLean founded Sea-Land and started the first containerized shipping system in 1956, transforming the trucking industry.

McMaster, Harold (July 20, 1916-August 25, 2003): American. McMaster invented tempered glass by pressing glass to increase tensile strength.

MacMillan, Kirpatrick (1812-January 26, 1878): Scottish. In 1839 MacMillan invented the first bicycle to be propelled by pedaling.

MacPherson, Cluny (1879-1966): Canadian. MacPherson devised the MacPherson respirator, a type of gas mask, in 1915, the first generally used protection from chemical weapons.

Madhani, Akhil J. (b. 1968): Kenyan American. Madhani produced the Black Falcon telerobotic surgical system in 1997, designed to improve the surgeon's control and minimize trauma to the patient.

Maiman, Theodore Harold* (July 11, 1927-May 5, 2007): American. Maiman designed and built the first operable laser, using a synthetic ruby as the amplifier, and he foresaw many applications for the laser.

Maksutov, Dmitri Dmitrievich (1896-1964): Russian. The Maksutov telescope, invented in 1941, uses a corrector plate to eliminate spherical aberrations that distort images.

Manby, George William (November 28, 1765-November 18, 1854): English. Manby invented the first fire extinguisher, patented in 1813. It involved a nozzled copper cylinder with water and compressed air.

Mannes, Leopold* (December 26, 1899-August 11, 1964): American. Mannes worked out the process to produce Kodachrome color film with fellow musician Leopold Godowsky, Jr.

Mansfield, Peter (b. October 9, 1933): English. Mansfield shared the 2003 Nobel Prize in Physiology or Medicine for providing the mathematical analysis necessary to produce images in magnetic resonance imaging (MRI).

Marconi, Guglielmo* (April 25, 1874-July 20, 1937): Italian. Marconi shared the 1909 Nobel Prize in Physics for his improvements in wireless telegraphy and his long-distance wireless transmission across the Atlantic Ocean.

Marrison, Warren Alvin (May 21, 1896-March 27, 1980): Canadian American. With J. W. Horton, in 1927 Marrison built the first clock that monitored time with a quartz oscillator.

Mars, Forrest (March 21, 1904-July 1, 1999): American. The heir to Mars, Inc., the family candy company, Mars invented the Mars Bar in 1932 and M&M's in 1940.

Mason, John Landis (1832-February 26, 1902): American. In 1858, Mason patented a square-shouldered glass jar for preserving food. The Mason jar produced a seal with a zinc screw cap.

Mason, Stanley (August 18, 1921-December 6, 2006): American. Mason invented a wide variety of common goods, such as the squeezable ketchup bottle, the baby-shaped disposable diaper, the granola bar, and microwave cookware.

Massie, Thomas (b. 1971): American. In 1993, with Kenneth Salisbury, Massie invented the Phantom haptic interface, a device that helps computer users "feel" images of three-dimensional objects on the computer screen, part of a virtual reality system.

Matzeliger, Jan Ernst* (September 15, 1852-August 24, 1889): American. American shoe manufacturing increased dramatically following the introduction of Matzeliger's shoe-lasting machine, patented in 1883.

Mauchly, John William* (August 30, 1907-January 8, 1980): American. Mauchly worked with John Presper Eckert in designing and building ENIAC, the first general-purpose electronic digital computer.

Maudslay, Henry (August 22, 1771-February 14, 1831): English. Maudslay introduced the metal lathe and bench micrometer, both crucial to manufacturing in the Industrial Revolution.

Maxim, Hiram Percy* (September 2, 1869-February 17, 1936): American. More than his various automotive inventions, Maxim is known for creating the firearm silencer, patented in 1909.

Maxim, Hiram Stevens* (February 5, 1840-November 24, 1916): American. The Maxim gun, patented in 1885, was the first recoil-driven machine gun.

Maxim, Hudson* (February 3, 1853-May 6, 1927): American. A chemist, Maxim produced a smokeless gunpowder and maximite (mono-nitro-naphthalene), which is 50 percent more powerful than dynamite.

Maxwell, James Clerk (June 13, 1831-November 5, 1879): Scottish. Maxwell's electromagnetic theory and attendant equations (published 1873) constituted a fundamental advance in physics.

Maybach, Wilhelm (February 9, 1846-December 29, 1929): German. Maybach led the team that designed the Mercedes automobile in 1901.

Maynard, Edward (1813-1891): American. In 1845, Maynard patented a percussion-cap primer for rifles and in 1851 a lightweight breech-loading rifle that used a metallic cartridge of his design.

Mazor, Stanley (b. October 22, 1941): American. With Ted Hoff and Federico Faggin, Mazor helped design the first microprocessor chip in 1971.

Mead, Carver Andress (b. May 1, 1934): American. A pioneer in computer chip design, Mead configured the first gallium-arsenide metal epitaxial semiconductor field effect transistor (MESFET), used in modern wireless electronics.

Mège-Mouriés, Hippolyte (October 24, 1817-May 31, 1880): French. In 1869, Mège-Mouriés patented his process for producing margarine from animal fat and skim milk, which won a government award as a substitute for butter.

Meikle, Andrew (1719-November 27, 1811): Scottish. In 1788, Meikle patented a threshing machine that removed the outer husks from grains of wheat.

Mendeleyev, Dimitry Ivanovich* (February 8, 1834-February 2, 1907): Russian. Mendeleyev's periodic table of elements is among the greatest achievements of modern chemistry.

Mercator, Gerardus* (March 5, 1518-December 2, 1594): Flemish. Widely considered to be the first modern cartographer, Mercator created a method for projecting a map of the globe onto a flat surface.

Mergenthaler, Ottmar* (May 11, 1854-October 28, 1899): German American. Mergenthaler's key-operated typesetting machine, the Linotype (introduced in 1884), multiplied the speed and accuracy of printing.

Merryman, Jerry D. (b. 1932): American. With Jack St. Clair Kilby and James H. Van Tassel, Merryman invented the handheld electronic calculator in 1967.

Mestral, Georges de* (June 19, 1907-February 8, 1990): Swiss. In 1955, Mestral patented Velcro, the hook-and-loop fastener. The idea came to him while examining how the hooked barbs of burrs stuck to his clothing.

Metcalfe, Robert* (b. April 7, 1946): American. With David Boggs, Metcalfe coinvented the Ethernet, a system linking computer terminals in a local network.

Meucci, Antonio (April 13, 1808-October 18, 1889): Italian. Meucci built a prototype telephone sometime after conceiving the underlying principle in 1849.

Michelin, André and Édouard* (January 16, 1853-April 4, 1931 [André]; June 23, 1859-August 25, 1940 [Édouard]): French. The Michelin brothers ran Michelin Tire Company, incorporated in 1888, a pioneer manufacturer of pneumatic tires.

Midgley, Thomas, Jr. (May 18, 1889-November 2, 1944): American. Midgley discovered in 1921 that adding tetraethyl lead to gasoline eliminated preignition "knocking."

Miles, Alexander (1838-unknown): American. In 1887, Miles patented his automatically shutting and opening elevator doors, an improvement in safety.

Miller, Lewis (July 24, 1829-February 17, 1899): American. A founder of the Chautauqua Institution for popular education, Miller also invented the combine harvester with the blade mounted in front of the driver.

Miller, Stanley Lloyd (March 7, 1930-May 20, 2007): American. With Harold Urey, Miller designed an experiment that synthesized amino acids from a mixture of gases thought to mimic Earth's early atmosphere—theoretically, a step in the generation of life.

Millman, Irving (b. May 23, 1923): American. In 1963, Millman and Baruch S. Blumberg developed a test to detect the hepatitis B virus in blood samples and then created a vaccine to protect people from it.

Milne, John* (December 30, 1850-July 31, 1913): English. Milne devised a seismograph and established the first international seismological network for detecting and measuring earthquakes.

Mirowski, Michel (October 14, 1924-March 26, 1990): Polish American. Mirowsky oversaw development of the automatic implantable cardioverter-defibrillator (ICD), which corrects potentially fatal irregular heartbeats.

Moeller, Dennis (b. 1950): American. While working for International Business Machines (IBM), Moeller helped design the Industry Standard Architecture (ISA) computer architecture, introduced in 1984, that connects peripheral devices to personal computers.

Molchanov, Pavel (1893-1941): Russian. A meteorologist, Molchanov built and in 1930 launched the radiosonde, a package of atmospheric instruments and a radio transmitter attached to a balloon.

Molloy, Bryan B. (March 30, 1939-May 8, 2004): Scottish American. Molloy and Klaus Schmiegel developed the active agent in the widely used antidepressant Prozac, introduced in 1988.

Monier, Joseph* (November 8, 1823-March 13, 1906): French. Monier's invention of concrete reinforced with iron mesh, patented in 1867, became a standard material in the construction of buildings and bridges.

Montagnier, Luc (b. August 18, 1932): French. A leading virus researcher, Montagnier discovered the human immunodeficiency virus (HIV) virus in 1983 with Françoise Barré-Sinoussi and Jean-Claude Chermann, and HIV-2 in 1986.

Montgolfier, Joseph-Michel and Jacques-Étienne* (August 26, 1740-June 26, 1810 [Joseph-Michel]; January 6, 1745-August 2, 1799 [Jacques-Étienne]): French. The Montgolfier brothers built the first hot-air balloon, launched in 1782.

Montgomery, John J. (February 15, 1858-October 31, 1911): American. Montgomery built the first successful American monoplane glider in 1884 and may have discovered how air circulation past the wings provides lift.

Monturiol i Estarriol, Narcís (September 28, 1819-September 6, 1885): Spanish. In 1862, Monturiol i Estarriol built the first steam-powered submarine.

Moog, Robert* (May 23, 1934-August 21, 2005): American. The keyboard-played Moog synthesizer, first demonstrated in 1964, introduced a new range of sound to popular music.

Moore, Hugh (April 27, 1887-November 25, 1972): American. With his brother-in-law, Lawrence Luellen, Moore invented disposal drinking cups, first called Health Kups and later Dixie Cups.

Morey, Samuel (October 23, 1762-April 17, 1843): American. Morey received several patents on improvements to steam engines and in 1826 a patent on a two-cylinder internal combustion engine that ran on turpentine.

Morgan, Garrett Augustus* (March 4, 1877-July 27, 1963): American. Morgan invented the safety hood, a precursor to the gas mask, and the three-armed traffic signal, which later morphed into the three-color traffic light.

Morlan, Krysta (b. 1983): American. When she was a tenth grader, Morlan invented the cast cooler, a battery-powered device that relieves irritation for those wearing casts by funneling in cool air.

Morse, Samuel F. B.* (April 27, 1791-April 2, 1872): American. Initially a portrait painter, Morse invented the code of dots and dashes for telegraphy and, in 1844, sent the first long-distance message over his own telegraph system.

Mower, Morton (b. January 31, 1933): American. Mower coinvented the automatic implantable cardioverter-defibrillator (ICD) with Stephen Heilman, Alois A. Langer, and Michel Mirowsky. The first was implanted in 1980.

Müller, Erwin Wilhelm* (June 13, 1911-May 17, 1977): German American. Müller invented the field-emission microscope, field-ion microscope, and atom-probe microscope.

Müller, Karl Alexander* (b. April 20, 1927): Swiss. With J. Georg Bednorz, Müller discovered high-temperature superconductivity in novel ceramic materials, receiving the 1987 Nobel Prize in Physics for their work.

Müller, Paul (January 12, 1889-October 12, 1965): Swiss. Müller discovered that dichlorodiphenyltrichloroethane (DDT) was a powerful insecticide, for which he received the 1948 Nobel Prize in Physiology or Medicine.

Mullis, Kary B.* (b. December 28, 1944): American. Mullis's invention of the polymerase chain reaction (PCR) in 1983 made it possible to replicate deoxyribonucleic acid (DNA) rapidly in order to study genetic variation, with applications in medicine and forensic science.

Murdock, William* (August 21, 1754-November 15, 1839): Scottish. Murdock pioneered the use of coal gas for commercial and domestic lighting.

Murgaš, Jozef (February 17, 1864-May 11 or 23, 1929): Slovak. A Catholic priest, Murgaš built an early radiotelegraph station and put on public demonstrations in 1905.

Murphy, William, Jr. (b. November 11, 1923): American. Murphy invented the disposable medical tray in 1961, which reduced bacterial contamination in surgeries.

Musschenbroek, Pieter van* (March 14, 1692-September 19, 1761): Dutch. Musschenbroek is credited with the invention of the Leiden jar in 1746, a precursor of the capacitor that stored static electricity.

N

Naismith, James (November 6, 1861-November 28, 1939): Canadian American. Naismith invented basketball in 1891 and may have introduced the football helmet as well.

Naito, Ryoichi (1906-July, 1982): Japanese. Naito developed Fluosol-DA, an artificial blood that keeps tissue healthy during surgical procedures, first tested in 1978.

Nakamatsu, Yoshiro (b. 1928): Japanese. Holder of thousands of patents, Nakamatsu developed technology behind the floppy disk, compact disc (CD), digital video disc (DVD), digital watch, and taxicab meter.

Nakamura, Shuji* (b. May 22, 1954): Japanese American. Nakamura's invention of the blue light-emitting diode and blue laser diode fostered advances in energy-efficient lighting and optical data storage.

Nakao, Naomi L.* (b. January 13, 1948): Israeli American. Nakao made several important improvements to the equipment used in gastroenterological procedures, including an endoscopic/laparoscopic stapler, the Nakao Snare line, and the Nakao EndoRetractor.

Napier, John* (1550-April 4, 1617): Scottish. Napier greatly simplified calculations necessary in navigation and astronomy with his development of logarithmic tables.

Nasmyth, James* (August 19, 1808-May 7, 1890): Scottish. Nasmyth's steam hammer became a significant tool in the early Industrial Revolution, capable of a wide range of jobs in metalworking.

Natta, Giulio (February 26, 1903-May 2, 1979): Italian. Natta shared the 1963 Nobel Prize in Chemistry for research on high polymers, including production of polypropylene.

Nestlé, Henri* (August 10, 1814-July 7, 1890): German Swiss. Nestlé produced many innovative foods and beverages, most notably an infant formula for bottle-fed babies. He hoped that it would reduce the mortality rate.

Neumann, Gerhard (October 8, 1917-November 2, 1997): German American. Neumann developed the variable-stator jet engine in 1952, which was the first to power an aircraft past Mach 2.

Neustadter, Alfred (1911-1996): American. In 1950, Neustadter marketed the Rolodex, a rotary filing system for note cards, which his employee Hildaur Neilsen had invented and later patented.

Newcomen, Thomas* (January or February, 1663-August 5, 1729): English. Newcomen's steam engine, the first to do practical work reliably, made possible the age of industry.

Newton, Sir Isaac* (December 25, 1642-March 20, 1727): English. Newton's contributions to science were varied and profound, among them the nature of optics, celestial mechanics, and the calculus, arrived at independently of Gottfried Wilhelm Leibniz.

Niépce, Nicéphore* (March 7, 1765-July 5, 1833): French. Niépce made the first lasting photographic images, which he called "heliography" (sun drawing), in 1818, after some twenty years of experimentation.

Nieuwland, Julius (February 14, 1878-June 11, 1936): Belgian American. Nieuwland invented the first synthetic rubber, neoprene, marketed in 1932.

Nipkow, Paul (August 22, 1860-August 24, 1940): German. Nipkow patented a mechanical, rotating disk television system in 1884, thought to be the first such system.

Nishizawa, Jun-ichi (b. September 12, 1926): Japanese. Known as the "father of Japanese microelectronics," Nishizawa developed fundamental semiconductor materials, the pin diode, and the static induction transistor.

Nobel, Alfred* (October 21, 1833-December 10, 1896): Swedish. Nobel's invention of dynamite was important to heavy construction and warfare. The international prizes given in his name for chemistry, economics, medicine, physics, literature, and peace became the modern emblems of genius.

Nobile, Arthur (May 6, 1920-January 13, 2004): American. Nobile invented the steroids prednisone and prednisolone in 1950, which became widely used anti-inflammatory drugs.

Northrop, John Howard (July 5, 1891-May 27, 1987): American. Northrop received the 1946 Nobel Prize in Chemistry for his research on enzymes, proteins, and viruses. He also invented a fermentation process for acetone.

Noyce, Robert Norton* (December 12, 1927-June 30, 1990): American. The digital revolution of mass-produced computer circuitry proceeded from Noyce's development of the integrated circuit.

Nyberg, Carl Richard (May 28, 1858-1939): Swedish. Nyberg invented the blowtorch and began manufacturing it in 1882.

O

Ochoa, Ellen (b. May 10, 1958): American. The first Hispanic female astronaut, Ochoa patented an optical inspection system, an optical recognition system, and a method for noise removal in images.

Ochoa, Severo (September 24, 1905-November 1, 1993): Spanish American. Ochoa shared the 1959 Nobel Prize in Physiology or Medicine for being the first to assemble synthetic ribonucleic acid (RNA).

Ochoa, Victor Leaton* (1850-c. 1945): Mexican American. The Ochoaplane was an airplane with collapsible wings. Ochoa also invented an adjustable wrench, windmill, and streetcar brake.

Odhner, Theophil Wilgodt (1845-1905): Swedish. The Odhner arithmometer, first built in 1874, was a mechanical adding machine.

Ohain, Hans Joachim Pabst von* (December 14, 1911-March 13, 1998): German American. Von Ohain developed the first working self-contained jet engine, and his engines were the first to power an all-jet aircraft, the Heinkel 178, in 1939.

Olds, Ransom Eli* (June 3, 1864-August 26, 1950): American. As well as building early steam- and gasoline-powered vehicles, Olds innovated the automobile production process.

Oliver, Bernard M. (May 27, 1916-November 23, 1995): American. Oliver invented pulse-code modulation, which enables information to be transmitted in binary code.

Olsen, Ken* (b. February 20, 1926): American. Under Olsen's leadership, Digital Equipment Corporation (DEC) made small computers affordable to businesses, beginning in 1960 with the PDP-1 Minicomputer.

Ondetti, Miguel Angel (May 14, 1930-August 23, 2004): Argentine American. Ondetti invented captopril in 1974, a type of angiotensin-converting enzyme (ACE) inhibitor, which reduces hypertension effectively without burdensome side effects.

Oppenheimer, J. Robert* (April 22, 1904-February 18, 1967): American. A particle physicist and astrophysicist, Oppenheimer led the top-secret Manhattan Project, which detonated the first atomic bomb in 1945.

O'Rear, Dennis (b. November 21, 1950): American. A chemical engineer, O'Rear holds some seventy patents, many involving oil-processing techniques, such as processes to produce lubricating oils.

O'Reilly, Samuel (d. 1908): English American. O'Reilly is the inventor of the electric tattoo machine, patented in 1891.

Ørsted, Hans Christian (August 14, 1777-March 9, 1851): Danish. Ørsted discovered that a magnetized needle is deflected in the presence of an electric current—that is, electromagnetism. He was also the first to produce metallic aluminum.

Otis, Elisha Graves* (August 3, 1811-April 8, 1861): American. Otis invented the first elevator with a safety brake in 1852 and soon after founded the Otis Elevator Company, the leading manufacturer and installer.

Ott, John Nash (October 23, 1909-April 6, 2000): American. Ott pioneered time-lapse photography and discovered health benefits from full-spectrum lighting.

Otto, Nikolaus August* (June 10, 1832-January 26, 1891): German. Otto's four-stroke engine, patented in 1876, marked an important milestone for the development of the internal combustion engine.

Oughtred, William (March 5, 1575-June 20, 1660): English. Oughtred introduced the symbol × for use in multiplication and invented the linear slide rule, which he described in 1621, and probably the circular version as well.

Ovshinsky, Stanford* (b. November 24, 1922): American. Ovshinsky pioneered ovonics, the study of disordered materials, and developed the ovonic switch in 1957, which rendered amorphous materials suitable to a variety of technologies.

Owens, Michael Joseph (January 1, 1859-December 27, 1923): American. Owens's automatic bottle-blowing machine, patented in 1895, could produce four completed bottles per second, reducing labor costs and increasing production for the industry.

P

Page, Charles G. (January 25, 1812-May 5, 1868): American. In 1836, Page invented the high-voltage induction coil, precursor of the modern transformer.

Page, Larry* (b. March 26, 1973): American. Page's development of the PageRank algorithm improved the accuracy with which Internet search engines evaluate the content of a given page on the World Wide Web.

Paige, James W. (1842-1917): American. Paige invented a typesetting machine whose chief virtue was that it attracted the financial support of Mark Twain.

Painter, William (November 20, 1838-July 15, 1906): American. In 1892, Painter created the crown bottle cap, a great improvement for sealing bottles containing a carbonated fluid.

Pall, David Boris (April 2, 1914-September 21, 2004): American. An innovator in filtration systems, Pall invented filters that remove oil impurities from engines and hydraulics and a filter that reduces the number of white blood cells in blood transfusion.

Palmaz, Julio C. (b. 1945): Argentine American. A physician, in 1988 Palmaz patented the first commercially successful intravascular stent, used to open clogged blood vessels.

Palmcrantz, Helge (July 7, 1842-November 22, 1880): Swedish. Palmcrantz invented the multibarrel, lever-actuated machine gun, patented in 1873 and marketed as the Nordenfelt machine gun.

Palmer, Daniel David (March 7, 1845-October 20, 1913): Canadian American. Palmer invented chiropractic, beginning his practice in 1895.

Palmieri, Luigi (April 22, 1807-September 9, 1896): Italian. Palmieri invented a mercury seismometer in 1855 that detected and measured ground movement with great sensitivity. With it, he was able to predict volcanic eruptions.

Papanicolaou, George N. (May 13, 1883-February 19, 1962): Greek American. Papanicolaou developed the pap smear, patented in 1928, a diagnostic test for uterine cancer in women.

Parker, Louis W. (January 1, 1906-June 21, 1993): Hungarian American. Parker invented the intercarrier sound system, patented in 1948, that coordinates sound and images on television and the vertical-line color television system.

Parkes, Alexander (December 29, 1813-June 29, 1890): English. Parkes invented Parkesine, a form of cellulose nitrate, in 1862; it was an early artificial plastic.

Parkhouse, Albert J. (1879-1927): Canadian. Parkhouse invented the coat hanger in 1903.

Parkinson, Bradford (b. 1935): American. Under Parkinson's supervision, the first test version of the Global Positioning System (GPS) was produced by the U.S. Air Force in 1978.

Parsons, Charles* (June 13, 1854-February 11, 1931): English. Parsons built the *Turbinia* and powered it with his invention, the steam turbine. In 1897, it was the world's fastest ship.

Parsons, John T. (October 11, 1913-April 18, 2007): American. An innovator in machining and tooling, Parsons introduced computers to design work and manufacturing and in 1948 developed the numerical control of machines with binary punch cards.

Pascal, Blaise* (June 19, 1623-August 19, 1662): French. Pascal's investigations in physics improved knowledge of hydraulics and led to the invention of the hydraulic press and the syringe.

Pasch, Gustaf Erik (1788-1862): Swedish. A professor of chemistry, Pasch invented a safety match, patented in 1844, which proved too expensive to manufacture for profit.

Pasteur, Louis* (December 27, 1822-September 28, 1895): French. Pasteur's work in microbiology established the germ theory of disease, which afforded new medical treatments, such as vaccines, and he made dairy products safer through his pasteurization process.

Patrick, Ruth* (b. November 26, 1907): American. A pioneer in freshwater biology, Patrick developed tests for assessing the pollution levels in lakes and rivers.

Paul, Les* (June 9, 1915-August 13, 2009): American. Paul provided many of the tools for modern popular music with his invention of the solid-body electric guitar and development of novel recording techniques.

Paulescu, Nicolae (1869-1931): Romanian. Paulescu isolated the hormone insulin and discovered its relation to diabetes, publishing his findings in 1921.

Pearson, Gerald* (March 31, 1905-October 25, 1987): American. Pearson coinvented the silicon photovoltaic (solar) cell at Bell Telephone Laboratories in 1954.

Pelton, Lester (September 5, 1829-March 14, 1918): American. Patented in 1889, the Pelton water turbine involved a rotor driven by a water jet and was important to the commercial development of hydroelectric power.

Pemberton, John Stith* (July 8, 1831-August 16, 1888): American. First marketed as a pain reliever, Colonel Pemberton's invention, Coca-Cola (patented in 1887), was more successful as a thirst-quencher.

Penkala, Slavoljub Eduard (April 20, 1871-February 5, 1922): Croatian. In 1906, Penkala patented his "automatic pencil," the first mechanical pencil.

Perkin, William Henry (March 12, 1838-July 14, 1907): English. Perkin produced the first synthetic dye, patented in 1856. It was aniline purple, better known as mauve.

Perky, Henry (December 7, 1843-June 29, 1906): American. In 1895, Perky received a patent for a machine to produce his invention, shredded wheat.

Perry, Stephen (fl. mid-nineteenth century): English. Perry patented the rubber band in 1845.

Petroff, Peter (October 21, 1919-February 27, 2003): Bulgarian American. Petroff invented the digital wristwatch, first marketed in 1971.

Pfleumer, Fritz (March 20, 1881-August 29, 1945): German. In 1928, Pfleumer patented magnetic tape for sound recording, developed with Heinz Thiele and Wilhelm Gaus.

Piccard, Auguste (January 28, 1884-March 24, 1962): Swiss. Piccard built the first bathyscaphe in 1948, a submersible for deep sea exploration.

Pickering, Thomas R. (1831-February 21, 1895): English American. In 1868, Pickering produced an improved velocipede, a precursor to the bicycle.

Pierce, John R.* (March 27, 1910-April 2, 2002): American. In addition to inventions in the electronics of particle accelerators, Pierce designed the Echo (launched 1960) and Telstar (launched 1962) communication satellites.

Pincus, Gregory (April 9, 1903-August 22, 1967): American. Pincus invented an oral contraceptive; the Pill, as it became known, was approved for use in 1960.

Pitney, Arthur (1871-1933): American. A wallpaper store clerk, in 1902 Pitney patented the postage meter that franked envelopes mechanically.

Plateau, Joseph Antoine Ferdinand (October 14, 1801-September 15, 1883): Belgian. Plateau and his sons invented the phenakistoscope, otherwise known as the stroboscope, in 1832.

Platen, Baltzar von (1898-1984): Swedish. Von Platen and Carl Munters invented gas absorption refrigeration in 1922.

Plimpton, James Leonard (April 14, 1828-1911): American. In 1863, Plimpton patented the "rocker skate," a skate with two axles of two wheels and tilt steering.

Plunkett, Roy J.* (June 26, 1910-May 12, 1994): American. Plunkett synthesized Teflon, patented in 1941. Its nonstick, nonreactive properties transformed the plastics industry.

Poenaru, Petrache (1799-1875): Romanian. In 1827, Poenaru patented a fountain pen and later designed the national flag of Romania.

Polhem, Christopher (December 18, 1661-August 30, 1751): Swedish. A mining engineer, Polhem built an automated factory powered by a water wheel in 1699 and later invented a padlock and inside-mounted door lock.

Polzunov, Ivan (1728-1766): Russian. Polzunov built the first two-cylinder steam engine in 1766 in order to power air pumps in a steel factory.

Poplawski, Stephen (August 14, 1885-December 9, 1956): Polish American. In 1922, Poplawski filed the first of several patents for electric blenders, including one intended for home use in 1940.

Popov, Aleksandr Stepanovich (March 16, 1859-January 13, 1906): Russian. Popov has a claim as the inventor of radio, since he demonstrated radio reception with a coherer in 1895. He also used his device as a lightning detector.

Potts, William L. (1883-1947?): American. A police officer, Potts introduced the three-color traffic light in 1920.

Poulsen, Valdemar (November 23, 1869-July 23, 1942): Danish. In 1898, Poulsen filed a patent for his telegraphone, an all-electric machine that could record thirty minutes of sound on a magnetized wire.

Priestley, Joseph* (March 13, 1733-February 6, 1804): English. A master chemist, Priestley devised lab equipment, discovered oxygen, and invented soda water and an eraser.

Ptolemy* (c. 100-c. 178 C.E.): Egyptian. Ptolemy defined the universe for more than a millennium with his Earth-centered cosmology, but he also wrote about geography and optics.

Pullman, George Mortimer* (March 3, 1831-October 19, 1897): American. After founding the Pullman Palace Car Company in 1867, Pullman brought luxury to train passengers with his plush designs for sleeping, dining, and parlor cars.

Pupin, Michael I. (October 4, 1858-March 12, 1935): Serbian American. In 1893, Pupin invented the resonator, which was subsequently used to tune radios, and in 1894 the Pupin coil, which facilitated long-distance telephone calling.

Pusey, Joshua (1842-1906): American. Pusey invented the paper matchbook in 1889.

Puskás, Tivadar (September 17, 1844-March 16, 1893): Hungarian. With Thomas Alva Edison's help, Puskás invented the telephone exchange in 1877 and ten years later introduced the multiplex switchboard.

Q

Quackenbush, Henry M. (April 27, 1847-September 8, 1933): American. Credited with developing the air rifle, Quackenbush was also the first to patent a nutcracker (1909).

R

Rabinow, Jacob* (January 8, 1910-September 11, 1999): Russian American. Rabinow invented prolifically, producing, for instance, automatic regulating clocks, letter-sorting machines, magnetic computer disk files, and bomb safety mechanisms.

Ramsden, Jesse* (October 6, 1735-November 5, 1800): English. Ramsden's innovations in calibrating measurement instruments enabled him to construct large optical instruments, such as astronomical telescopes.

Reard, Louis (1898-1984): French. Reard invented the bikini in 1946; the name was inspired by the nuclear bomb test at Bikini Atoll in the South Pacific.

Reichenbach, Karl von (1788-1869): German. Von Reichenbach produced several commercially valuable substances from coal and wood tar, including creosote, paraffin, and phenol.

Remsen, Ira* (February 10, 1846-March 4, 1927): American. With Constantin Fahlberg, Remsen synthesized the artificial sweetener saccharin in 1879.

Renault, Louis (February 15, 1877-October 24, 1944): French. Renault invented the direct-drive gearbox for his two-seater car in 1898; it had three speeds and reverse.

Reno, Jesse W.* (August 4, 1861-June 2, 1947): American. Reno patented his moving stairs (or escalator) in 1892. At first a curiosity in the Coney Island amusement park near New York City, the escalator eventually became a fixture in stores throughout the United States and Europe.

Ressel, Josef (June 29, 1793-October 9, 1857): Czech. Ressel developed the first practical ship propeller in 1829.

Richardson, Ken (b. November 26, 1939): English. Richardson led the team that discovered fluconazole in 1981, an antifungal medication that can be given to people with weak immune systems.

Richter, Charles Francis* (April 26, 1900-September 30, 1985): American. A pioneering seismologist, Richter invented the scale for measuring the intensity of earthquakes.

Rickover, Hyman George (January 27, 1900-July 8, 1986): Polish American. Considered the father of the U.S. nuclear submarine service, Rickover oversaw construction of its first vessel, the USS *Nautilus*, launched in 1954.

Rillieux, Norbert* (March 17, 1806-October 8, 1894): American. Rillieux's invention, the vacuum evaporator (patented 1843), allowed sugar refineries to produce sugar more efficiently and with less labor.

Rines, Robert H. (b. August 30, 1922): American. Rines's technical innovations made possible high-resolution image-scanning radar, used in military weapons systems and by explorers seeking sunken ships, such as the *Titanic*.

Rittenhouse, David R. (April 8, 1732-June 26, 1796): American. A celebrated astronomer, Rittenhouse also was an inventor, producing an accurate orrery about 1767 and improving Benjamin Franklin's stove in 1790 by adding an L-shaped chimney.

Ritty, James (1837-1918): American. In 1879, Ritty patented "Ritty's Incorruptible Cashier," the first cash register.

Rochow, Eugene G. (October 4, 1909-March 21, 2002): American. Rochow developed a method to produce silicone polymers in 1940.

Roebling, John Augustus* (June 12, 1806-July 22, 1869): German American. The designer of the Brooklyn Bridge in New York City, Roebling made such suspension bridges possible with his invention of the stranded wire cable in 1841.

Roebuck, John (1718-July 17, 1794): English. In 1746, Roebuck improved the processing of sulfuric acid by replacing glass jars with "lead cathedrals" (condensing chambers).

Rogers, John Raphael (December 11, 1856-February 18, 1934): American. Rogers invented a device that automatically justified type as each line was set for printing.

Rohrer, Heinrich* (b. June 6, 1933): Swiss. The scanning tunneling microscope, which Rohrer developed with Gerd Binnig, gives scientists three-dimensional images of objects as small as a single atom.

Röntgen, Wilhelm Conrad* (March 27, 1845-February 10, 1923): German. Röntgen discovered X rays in 1895 and then put them to use in making images of structures inside the human body, fostering a revolution in medical diagnosis. These achievements brought him the first Nobel Prize in Physics (1901).

Roper, Sylvester* (November 24, 1823-June 1, 1896): American. Roper invented a wide variety of mechanisms but particularly is known for his steam-powered bicycle (1867), the precursor of the gasoline-engine motorcycle.

Rosen, Harold (b. March 20, 1926): American. With patents in skiing, diving, and windsurfing, Rosen is best known for introducing the spin-stabilized satellite in 1957 and directed the team that built the first synchronous (geostationary) communication satellite, in service in 1963.

Rubin, Benjamin A. (b. September 27, 1917): American. Rubin patented his "Pronged Vaccinating and Testing Needle" in 1965. Its forked design makes inoculation against smallpox much faster.

Ruska, Ernst* (December 25, 1906-May 30, 1988): German. Ruska received the 1986 Nobel Prize in Physics for his investigations into electron optics and in particular his design for the electron microscope in 1933.

Russell, James* (b. February 23, 1931): American. Russell invented optical digital recording, patented in 1970, which led to the development of the digital compact disc.

Rutan, Burt* (b. June 17, 1943): American. Rutan designed and built the first private suborbital rocket plane, *SpaceShipOne*. It flew successfully in 2004 in preparation for tourism flights.

S

Sabin, Albert (August 26, 1906-March 3, 1993): Polish American. Sabin developed several vaccines, most famously the oral polio vaccine. Approved for use in 1960, it helped stem an epidemic of polio.

Sakharov, Andrei (May 21, 1921-December 14, 1989): Russian. As well as a Nobel Peace Prize (1975) laureate, Sakharov was a central figure in the Soviet program that developed the hydrogen bomb and conceived of the tokamak nuclear fusion reactor in 1950.

Salk, Jonas* (October 28, 1914-June 23, 1995): American. The Salk vaccine was the first safe, effective killed-virus polio vaccine and contributed to the near elimination of the disease in the United States and many other countries.

Sampson, Henry Thomas* (b. April 22, 1934): American. Sampson's innovations for aerospace, the military, and industry include methods for preparing rocket propellants and a generator that produces electricity from nuclear radiation.

Samuelson, Ralph (July 3, 1904-August 1977): American. Samuelson is credited with inventing water skiing during the summer of 1922.

Santorio, Santorio* (March 26 or 29, 1561-February 22 or March 6, 1636): Italian. A pioneering physician who studied factors affecting metabolism, Santorio invented a clinical thermometer and other instruments.

Santos-Dumont, Alberto (July 20, 1873-July 23, 1932): Brazilian. In 1898, Santos-Dumont was the first person to build and fly a balloon propelled by a gasoline engine.

Sarett, Lewis Hastings (December 22, 1917-November 28, 1999): American. In 1944, Sarett synthesized the steroid cortisone, a powerful anti-inflammatory agent.

Savery, Thomas* (c. 1650-May, 1715): English. Savery built an early steam engine intended to power drainage pipes, especially for use in mines.

Sax, Adolphe (November 6, 1814-February 4, 1894): Belgian. Sax invented the saxophone in 1841 but also introduced valved bugles and an early version of the contrabass clarinet.

Saxton, Joseph (March 22, 1799-October 26, 1873): American. A versatile inventor, Saxton is best known for producing balances and weights used at the United States Mint in Philadelphia and for measuring instruments, such as a reflecting pyrometer (for measuring the thermal expansion of metal).

Schauberger, Viktor (June 30, 1885-September 25, 1958): Austrian. A naturalist and hydrologist, Schauberger invented efficient flumes for conveying logs, silent turbines, and self-cleaning pipes.

Schawlow, Arthur L.* (May 5, 1921-April 28, 1999): American. Schawlow received a share of the 1981 Nobel Prize in Physics for his work in laser spectroscopy.

Schick, Bela (July 16, 1877-December 6, 1967): Hungarian American. As well as conducting foundational research on allergies, Schick invented a test for diphtheria in 1913, which proved important to public health.

Schick, Jacob* (September 16, 1877-July 3, 1937): American. Schick simplified the chore of shaving with his invention of the electric razor, introduced in 1931.

Schilling, Pavel (1786-1837): Estonian Russian. Schilling produced an electronically detonated mine in 1812 and an early form of electromagnetic telegraphy in 1832.

Schmidt, Bernhard Voldemar* (March 30, 1879-December 1, 1935): Estonian German. Schmidt's telescope, invented in 1930, allowed a large field of view without the distortion of traditional Newtonian telescopes.

Schönbein, Christian Friedrich (October 18, 1799-August 29, 1868): German. Schönbein discovered ozone in 1840 and synthesized guncotton (nitrocellulose), which is used in explosives, in 1845.

Schweigger, Johann Salomo Christoph (April 8, 1779-September 6, 1857): German. Schweigger invented the needle galvanometer in 1820 to measure the force and direction of electric current.

Schwinn, Ignaz* (April 1, 1860-1948): German American. An innovative manufacturer, Schwinn became the leading maker of bicycles in the United States and the first to sell balloon-tire models, starting with the Aerocycle in 1934, and European-style racing models in the 1960's.

Scott, Arthur Hoyt (March 16, 1875-February 25, 1927): American. In 1907, the Scott Paper Company, under the leadership of Scott, the founder's son, introduced paper towels to the American public.

Seaborg, Glenn Theodore* (April 19, 1912-February 25, 1999): American. Seaborg shared the 1951 Nobel Prize in Chemistry for synthesizing transuranic elements and was the first scientist to chair the Atomic Energy Commission.

Seeberger, Charles (1857-September 12, 1931): American. Seeberger oversaw construction of his design for an escalator at the Otis Elevator Company in 1899.

Seguin, Marc (April 2, 1786-February 24, 1875): French. In the mid-1820's, Seguin built the first European wire-cable suspension bridge, which crossed the Rhone River at Tournon, France.

Seiwald, Robert J. (b. March 26, 1925): American. Seiwald and Joseph Burkhalter synthesized isothiocyanate compounds, the first labeling agents for human antibodies, which made possible rapid, accurate identification of infectious diseases.

Sellers, Coleman (January 28, 1827-December 28, 1907): American. A pioneer in using artificial light for photography, Sellers also designed the first large electrical dynamos for the Niagara Falls power plant.

Sellers, William (September 19, 1824-January 24, 1905): American. The inventor of a variety of machinery and machining tools, Sellers is best known for his spiral-geared planer, patented in 1862, and the American standard screw thread (1864).

Semmelweis, Ignaz (July 1, 1818-August 13, 1865): Hungarian. Semmelweis was a pioneer of antiseptic policy; in 1847, he established that puerperal (childbed) fever was contagious but that infections could be reduced by hand washing.

Semon, Waldo L. (September 10, 1898-May 26, 1999): American. Semon invented a method to plasticize polyvinyl chloride in 1930, making it commercially more useful as vinyl, as well as creating other synthetic rubber compounds.

Senefelder, Aloys (November 6, 1771-February 26, 1834): German. Senefelder invented lithography (flat-surface printing) in 1796 and a process for color lithography in 1826.

Serrurier, Iwan (fl. early twentieth century): Dutch American. In 1924, Serrurier invented the Moviola, a film-editing machine that became basic equipment in the movie industry.

Sessler, Gerhard (b. February 15, 1931): German American. In 1962, Sessler and James E. West invented the foil electret microphone with high sensitivity and broad frequency range, and Sessler invented the silicon microphone in 1983.

Seversky, Alexander Procofieff de (June 7, 1894-August 24, 1974): Russian American. A designer of fighter planes and an air war theorist, de Seversky was granted a patent for the concept of air-to-air refueling in 1921.

Shannon, Claude Elwood* (April 30, 1916-February 24, 2001): American. Shannon contributed fundamentally to modern digital computing with his method of electronic switching and his work on information theory.

Sharp, Walter B. (December 12, 1870-November 28, 1912): American. With Howard Hughes, Sr., his business partner, Sharp designed the Sharp-Hughes Tool Company's Rock Bit for drilling oil wells.

Sheehan, John C.* (September 23, 1915-March 21, 1992): American. Sheehan facilitated the manufacture of pure penicillin and derivatives of it with his process for synthesizing the antibiotics.

Shen Kuo (1031-1095): Chinese. Shen described the magnetic needle compass in 1088 and discovered that magnetic north differs from true north (the north pole).

Shen Nung (fl. twenty-eighth century B.C.E.): Chinese. According to legend, Emperor Shen Nung invented tea in 2737 B.C.E.

Sherman, Patsy O'Connell* (September 15, 1930-February 11, 2008): American. Working for Minnesota Mining and Manufacturing Company (3M), Sherman helped develop such successful products as the Scotchgard textile protector, first marketed in 1956.

Shockley, William* (February 13, 1910-August 12, 1989): American. Shockley shared the 1956 Nobel Prize in Physics for the invention of the junction transistor, which transformed the electronics industry and hastened the trend of miniaturization.

Sholes, Christopher Latham* (February 14, 1819-February 17, 1890): American. Sholes produced the first commercially successful typewriter, patented in 1868, and designed the keyboard, still in use, known by the letters on the left side of the top row, QWERTY.

Shrapnel, Henry (June 3, 1761-March 3, 1842): English. Shrapnel, an artillery officer, invented the exploding case shell, adopted by the British military in 1803.

Shugart, Alan* (September 27, 1930-December 12, 2006): American. Shugart helped develop the first disk drive while working for International Business Machines (IBM) in 1955, a key advance on the way to personal computers.

Shukhov, Vladimir (August 28, 1853-February 2, 1939): Russian. Shukhov introduced hyperboloids, double-curve structures, to architecture for use in towers and roofs as well as the mathematical analysis to calculate their strength.

Shuman, Frank (1862-1918): American. In 1897, Shuman demonstrated a device that powered a small steam engine by heating ether vapor with reflected sunlight and using the vapor to drive a water pump.

Sickels, Frederick Ellsworth (September 20, 1819-March 8, 1895): American. Sickels's cutoff valve for steam engines, patented in 1842, improved their efficiency and usefulness to American industry.

Siebe, Augustus (1788-1872): German English. Siebe produced the closed diving suit, comprising a rubberized canvas suit and a helmet with a built-in valve, tested in 1840.

Siemens, Werner* (December 13, 1816-December 6, 1892): German. Siemens engineered early applications of electricity to telegraphy and participated in establishing international, underwater cable lines.

Siemens, William (April 4, 1823-November 10, 1883): German English. Siemens and his brother Friedrich patented their regenerative (open hearth) furnace in 1856. Heated by waste gas from coal, it was widely used in the steelmaking and glass industries.

Sikorsky, Igor* (May 25, 1889-October 26, 1972): Russian American. An aviation pioneer, Sikorsky designed and flew the first multiengine airplane in 1913 and was a principal developer of the helicopter industry.

Simjian, Luther-George (January 28, 1905-October 23, 1997): Armenian American. Simjian invented an early version of the automated teller machine (ATM) in the late 1930's but also produced a self-focusing camera, postage metering machine, and teleprompter, among others.

Simon, Juanito A. (b. 1948): Filipino. In 1995, Simon developed lubrication technology that greatly reduced friction in engines and increased efficiency.

Sīnā, Ibn (Avicenna) (c. 980-1037): Persian. Among the most illustrious natural philosophers of the Middle Ages, Ibn Sīnā published influential medical treatises that describe contagious and sexually transmitted diseases, advocate the use of quarantine, and insist upon quantifiable trials for new medications.

Singer, Isaac Merrit* (October 27, 1811-July 23, 1875): American. Singer's improvements to the sewing machine and his brilliant marketing plan made him a leading manufacturer.

Slagle, James R. (b. 1934): American. Slagle wrote the first computer symbolic integration program, SAINT, in 1961. It demonstrated that computers can solve the kinds of analogy problems given on IQ tests.

Slater, Samuel (June 9, 1768-April 21, 1835): English American. Slater built the first successful water-powered textile mill in 1793 and conceived the company-owned mill village to house its workers.

Slayter, Russell Games (December 9, 1896-October 15, 1964): American. Slayter, Dale Kleist, and Jack Thomas created the methods of mass producing affordable glass wool (fiberglass) during the 1930's.

Smith, George Albert (January 4, 1864-May 17, 1959): English. A magician and psychic, Smith was also a filmmaker and inventor. He built on the work of Edward Turner to produce a two-color motion-picture camera, patented in 1906.

Spaeth, Mary (b. December 17, 1938): American. Spaeth and D. P. Bortfield developed the tunable dye laser in 1966, which became important to the production of atomic isotopes.

Spallazani, Lazzaro (January 12, 1729-February 11 or 12, 1799): Italian. A founder of experimental biology, Spallazani achieved successful artificial insemination in dogs, demonstrating that spermatozoa and ovules must have contact.

Spangler, James Murray* (November 20, 1848-January 22, 1915): American. Spangler invented the electric suction sweeper, patented in 1908, and started a company that became the Hoover Company.

Spencer, Percy L.* (July 9, 1894-September 8, 1970): American. In 1945, while testing a high-powered magnetron, Spencer noticed that a nearby candy bar melted. This gave him the idea for the microwave oven, introduced two years later.

Sperry, Elmer Ambrose* (October 12, 1860 [baptized]-June 16, 1930): American. A versatile inventor, Sperry is best known for his improved gyrocompass and contributions to military programs before World War I.

Spikes, Richard B. (1882-1962 or 1963): American. Spikes invented a beer keg tap and automobile directional signal, but he is perhaps best known for his automatic gearshift (1932) and automatic safety brake system (1962).

Sprague, Frank J.* (July 25, 1857-October 25, 1934): American. Sprague developed the first commercially successful electric railway system and contributed innovations to the electric elevator.

Srinivasan, Rangaswamy* (b. February 28, 1929): Indian. Srinivasan's development of ablative photodecomposition (APD) of organic materials with ultraviolet radiation found applications in the manufacture of microcircuits and in laser eye surgery.

Stanley, William, Jr. (November 22, 1858-May 14. 1916): American. In 1886, Stanley invented an induction coil system for producing alternating current (AC). It became the basis for later transformers.

Steinmetz, Charles Proteus* (April 6, 1865-October 26, 1923): German. Steinmetz developed the mathematical basis for practical alternating current and the techniques of long-distance transmission of electricity.

Stephenson, George* (June 9, 1781-August 12, 1848): English. Stephenson built the first railway line for steam locomotives, of which his *Rocket* was a successful model. The gauge of his railroad track became the world's standard.

Sternbach, Leo H. (May 7, 1908-September 28, 2005): American. Sternbach synthesized a novel class of tranquilizers called benzodiazeprines, among them valium, introduced in 1963.

Stevens, John* (1749-March 6, 1838): American. Stevens built the first oceangoing steamboat in 1809 and the first American steam locomotive in 1825.

Stevens, Louis (b. April 15, 1925): American. With William A. Goddard and John Lynott, Stevens produced a magnetic disk drive in 1955.

Stevin, Simon (1548-1620): Dutch. Stevin formulated the law of inclined planes and laws of hydraulics, and in 1599 he described a twenty-six-seat, self-propelled land yacht—a carriage with sails for use on beaches.

Stibitz, George* (April 20, 1904-January 31, 1995): American. A visionary in uses for computers, Stibitz performed the first long-distance transfer of computer data in 1940.

Stirling, Robert* (October 25, 1790-June 6, 1878): Scottish. A minister and classical scholar, Stirling invented the Stirling hot-air engine with his brother James, patented in 1827.

Stodola, Aurel (May 10, 1859-December 25, 1942): Slovak. In 1915, Stodola and surgeon Ferdinand Sauerbruch created the first artificial hand, but Stodola is better known as an expert in thermodynamics and its application in designing steam and gas turbines.

Stokes, Rufus (1922 or 1924-1986): American. In 1968, Stokes patented an air-purification system for cutting gas and ash emissions from furnaces.

Strauss, Levi* (February 26, 1829-September 26, 1902): German American. Strauss created the quintessential Western wear with his "waist overalls" (blue jeans), patented in 1873.

Strite, Charles P. (fl. early twentieth century): American. Strite received a patent for the automatic toaster in 1921.

Sturgeon, William* (May 22, 1783-December 4, 1850): English. Sturgeon is credited with building the first electromagnet, and he invented an electric motor, galvanometer, and long-lasting battery cell.

Su Song (1020-1101): Chinese. Su built a water-powered astronomical clock tower that was the first device to use a continuous chain drive.

Sunatori, Simon (b. January 10, 1959): Canadian. Sunatori invented the MagneScribe three-in-one, auto-retractable pen and Magic Spicer, a self-sealing hanging dispenser.

Sundback, Gideon (1880-1954): Swedish Canadian. In 1913, Sundback invented the modern zipper of two facing rows of teeth joined by a slider.

Sutherland, Ivan (b. May 16, 1938): American. Sutherland pioneered computer graphics with the program Sketchpad in 1960 and contributed to three-dimensional computer modeling, visual simulations, and virtual reality.

Sveda, Michael (February 3, 1912-August 10, 1999): American. Sveda invented the noncaloric artificial sweetener cyclamate in 1937, widely used until 1969, when the U.S. government banned it on suspicion that it was a carcinogen.

Svedberg, Theodor* (August 30, 1884-February 25, 1971): Swedish. The 1926 Nobel laureate in chemistry, Svedberg invented the ultracentrifuge in 1924, which is capable of separating out very small particles, and a device for measuring low osmotic pressure.

Swan, Joseph Wilson* (October 31, 1828-May 27, 1914): English. Swan was the first to patent an incandescent lamp, which he demonstrated in 1878, and contributed to the development of photographic printing.

Szilard, Leo* (February 11, 1898-May 30, 1964): Hungarian American. Szilard conceived the chain reaction necessary for nuclear reactors and bombs. He also developed a refrigerator in collaboration with Albert Einstein.

T

Tabern, Donalee L. (January 27, 1900-December 31, 1974): American. In 1936, Tabern and Ernest Volwiler synthesized pentothal, a general anesthetic widely used in surgery.

Tainter, Charles (April 25, 1854-April 20, 1940): American. With Alexander Graham Bell and Chichester A. Bell, Tainter produced an improved phonograph, the graphophone, patented in 1886. Later, Tainter modified it to take dictation: the Dictaphone.

Talbot, William Fox (February 11, 1800-September 17, 1877): English. In 1834 and 1835, Talbot experimented with paper coated with salt and silver nitrate until he had created a negative photographic image, from which many positive prints could be made, known as the collotype process.

Tamm, Igor (July 8, 1895-April 12, 1971): Russian. A 1956 Nobel laureate in physics, Tamm was also a central theoretician behind the first Soviet thermonuclear bomb and attempts to use fusion peacefully with the tokamak system.

Tanaka, Toyoichi* (January 4, 1946-May 20, 2000): Japanese American. Following Tanaka's discovery of "smart gels," scientists were able to track microscopic changes in a macroscopic way; the polymer gels also had a wide range of practical applications.

Taylor, Charles E.* (May 24, 1868-June 30, 1956): American. Taylor built the engines that Orville and Wilbur Wright used in their first few airplanes.

Taylor, Frederick W. (March 20, 1856-March 21, 1915): American. Taylor developed a business structure strategy, known as scientific management, that emphasized precise production procedures based upon analysis of workflows and thorough managerial control.

Teetor, Ralph (1891-1982): American. Teeter was granted the first patent for a cruise-control device for automobiles, Speedostat.

Telford, Thomas (August 9, 1757-September 2, 1834): Scottish. Telford was a civil engineer who built aqueducts, canals, roads, and bridges, including the Menai Bridge (completed 1826), then the longest suspension bridge in the world.

Telkes, Maria* (December 12, 1900-December 2, 1995): Hungarian American. Telkes is noted for developing diverse applications of solar energy, including a solar still, a solar oven, and even a completely solar home.

Tellegen, Bernard D. H. (June 24, 1900-August 30, 1990): Dutch. In 1926, Tellegen invented the pentode valve, an electronics component containing five electrodes, used in radios.

Teller, Edward* (January 15, 1908-September 9, 2003): Hungarian American. Teller played a leading role in the design and development of the fusion bomb and vigorously argued that it should be part of the United States' arsenal of weapons.

Temple, Lewis (1800-May, 1854): American. Temple's Toggle, which he invented in 1848, was a harpoon with a pivoting head that did not come dislodged when whales spun or thrashed after being speared.

Terry, Eli (April 13, 1772-February 26, 1852): American. Terry held several patents for clocks, including the first that the U.S. Patent Office granted for a clock (1797), and he pioneered their mass production.

Tesla, Nikola* (July 9/10, 1856-January 7, 1943): Serbian American. Tesla brought many theoretical and applied innovations to electromagnetism, notably his brushless alternating current induction motor (1888).

Theiler, Max (January 30, 1899-August 11, 1972): South African. Theiler received the 1951 Nobel Prize in Physiology or Medicine for creating a vaccine against yellow fever.

Thomas, Valerie L.* (b. February 1, 1943): American. A mathematician working for the National Aeronautics and Space Administration (NASA), Thomas invented the illusion transmitter, patented in 1980, which conveys three-dimensional images.

Thompson, Benjamin* (March 26, 1753-August 21, 1814): English. Thompson (Count Rumford) was a leading scientific investigator of his day and invented an improved oven, lamp, and fireplace and a drip coffee maker.

Thompson, John T.* (December 31, 1860-June 21, 1940): American. With Theodore Eickhoff and Oscar Payne, Thompson created the Thompson submachine gun in 1919.

Thompson, Robert (1822-1873): Scottish. In 1845, Thompson devised a pneumatic tire—a hollow band of rubber, inflated, around a steel wheel—in order to reduce shocks and vibrations for carriages.

Thomson, Elihu* (March 29, 1853-March 13, 1937): American. Thomson was a leading electrical engineer of his era, developing light and power systems in the United States, the United Kingdom, and France.

Tiffany, Louis Comfort (February 18, 1848-January 17, 1933): American. Tiffany created Favrile stained glass following experiments that began in 1875. It was among the first innovations of the Art Nouveau style.

Tigerstedt, Eric (1887-1925): Finnish. Tigerstedt developed the first sound-on-film technology for "talking pictures" in 1914.

Tihanyi, Kálmán (April 28, 1897-February 26, 1947): Hungarian. Tihanyi was a coinventor of the cathode-ray tube and iconoscope and developed remote-controlled mines and aircraft.

Tilghman, Benjamin Chew (October 26, 1821-July 3, 1901): American. In 1866, Tilghman developed a sulfite process to pulp wood for papermaking; in 1870, he invented sandblasting.

Tipu Sultan (November 20, 1750-May 4, 1799): Indian. A leader in the resistance to British occupation of India, Tipu Sultan, the "Tiger of Mysore," invented the tactic of mass rocket attacks on enemy infantry.

Tishler, Max* (October 30, 1906-March 18, 1989): American. Tishler led research into the synthesis of ascorbic acid (vitamin C), cortisone, riboflavin, vitamin B_{12}, streptomycin, and other compounds valuable to medicine.

Torricelli, Evangelista* (October 15, 1608-October 25, 1647): Italian. A mathematician and physicist, Torricelli invented the barometer in 1644.

Townes, Charles Hard* (b. July 28, 1915): American. Townes invented microwave amplification by stimulated emission of radiation (maser), a precursor of the laser. For it he shared the 1964 Nobel Prize in Physics.

Toyoda, Sakichi* (February 14, 1867-October 30, 1930): Japanese. From 1890 to 1925, Toyoda revolutionized Japanese industry with his power looms, and he provided the seed money for his son to start Toyota Motor Company.

Traeger, Alfred (August 2, 1895-July 31, 1980): Australian. Traeger invented a radio whose generator was run by pedal power, introduced in 1929 for medical communications in Australia's remote communities.

Trevithick, Richard* (April 13, 1771-April 22, 1833): English. Trevithick developed a steam locomotive whose power plant, when used for stationary applications, was known as the Cornish engine.

Trkman, Franc (1903-1978): Slovenian. Among Trkman's inventions were an electrical switch for hot plates, a key-making process, and watertight windows.

Tsiolkovsky, Konstantin* (September 17, 1857-September 19, 1935): Russian. A visionary advocate of space travel, Tsiolkovsky designed space stations and rocket-powered vehicles with life-support systems.

Tsvet, Mikhail (May 14, 1872-June 26, 1919): Italian Russian. In 1901, Tsvet pioneered chromatography, a technique for separating chemical mixtures and analyzing them.

Tull, Jethro* (March 30, 1674 [baptized]-February 21, 1741): English. Tull's invention of the seed drill multiplied crop yields and improved weed control, inaugurating the late eighteenth century agricultural revolution in England.

Tupolev, Andrei Nikolayevich* (November 10, 1888-December 23, 1972): Russian. Tupolev designed more than one hundred military and civilian aircraft.

Tupper, Earl S.* (July 28, 1907-October 5, 1983): American. Thanks to Tupper's innovative marketing strategy based upon home sales parties, his Tupperware plastic containers became the standard for household food storage beginning in the 1950's.

Turing, Alan Mathison* (June 23, 1912-June 7, 1954): English. Turing conceived the basic ideas behind the design of early computers and created the Turing test to distinguish computing from human intelligence.

Twain, Mark* (November 30, 1835-April 21, 1910): American. Born Samuel Langhorne Clemens, Twain was an inventor as well as a writer. The most successful of his three patented inventions was the self-pasting scrapbook, which had adhesive on the pages so items could be directly attached.

Tyndall, John* (August 2, 1820-December 4, 1893): Irish. An early atmospheric scientist, Tyndall conceived the idea of the "atmospheric envelope," which implied that sunlight could be trapped in Earth's atmosphere (the greenhouse effect). He also developed a respirator for firefighters in 1871.

U

Upjohn, William Erastus (June 5, 1853-October 18, 1932): American. A founder of the American pharmaceutical industry, Upjohn invented dissolvable pills and in 1884 a machine to mass-produce them.

Urry, Lewis* (January 29, 1927-October 19, 2004): Canadian. Urry's invention of the long-lasting alkaline battery significantly extended the operational lifetime and reliability of innumerable electrical devices.

V

Vallino, Lisa (b. 1916): American. In 1993 Vallino and her mother, Betty Rozier, patented the "IV House," a plastic shield that protects the site of an intravenous line during medical care.

Van de Graaff, Robert Jemison (December 20, 1901-January 16, 1967): American. The Van de Graaff generator (1929), standard equipment in school physics labs, accumulates electrical charge on a moving belt and deposits it in a hollow glass sphere at the top.

Van Doorne, Hub (1900-1979): Dutch. Van Doorne developed the continuously variable truck transmission, introduced in 1959.

Van Houten, Coenraad Johannes (1801-1887): Dutch. In 1822, Van Houten invented a press to remove cocoa oil, leaving cocoa powder, soon to spread through the Western world in everything from chocolate bars to chocolate milk.

Van Kannel, Theophilus (1841-December 24, 1919): American. Van Kannel invented the revolving door in 1888.

Vaucanson, Jacques de* (February 24, 1709-November 21, 1782): French. Vaucanson invented machine tools, such as the punch card, and tool-making machinery, which significantly contributed to the automation of manufacturing.

Vitullo, Louis R. (1924-January 3, 2006): American. A police detective, in the 1970's Vitullo developed the standard evidence kit to detect sexual assault.

Vo-Dinh, Tuan (b. 1948): Vietnamese American. Vo-Dinh invented several medical sensors based on synchronous luminescence technology that can identify toxins, gene mutations, or disease by optical scanning.

Vogel, Orville (May 19, 1908-April 12, 1991): American. Vogel developed semidwarf wheat varieties. First released to farmers in the 1960's, they were part of the Green Revolution in agriculture.

Volta, Alessandro* (February 18, 1745-March 5, 1827): Italian. Volta is best known for inventing the voltaic pile, an electric battery, in 1799, but he also produced several instruments, such as a eudiometer for measuring the purity of air.

Von Neumann, John (December 28, 1903-February 8, 1957): Hungarian American. A leading mathematician of the twentieth century, von Neumann invented game theory and worked out the basis for computer architecture, among many other diverse achievements.

Vrančić, Faust* (1551-January 17, 1617): Croatian. A man of wide-ranging interests, Vrančić published *Machinae novae* (new machines) in 1595; it contained the first printed design of a parachute.

W

Waksman, Selman Abraham* (July 22, 1888-August 16, 1973): Russian American. From his studies of soil microorganisms, Waksman developed numerous antibiotics, most notably streptomycin (1943), which greatly enhanced public health worldwide. He received the 1952 Nobel Prize in Physiology or Medicine for his work.

Walker, Madam C. J.* (December 23, 1867-May 25, 1919): American. Born Sarah Breedlove, Walker reinvented herself. Her business and marketing strategies for selling her hair care products enabled women, African Americans in particular, to become financially independent.

Walker, Hildreth, Jr. (b. 1933): American. Walker developed laser systems for the military and civilian use, for instance leading the team that used a laser to measure the distance to the Moon during the Apollo 11 mission.

Wallis, Barnes (September 26, 1887-October 20, 1979): English. Wallis was the first to use the geodesic design in aircraft but is better known for inventing the bouncing bomb in 1943, used for dam busting in World War II.

Walsh, Sir Alan* (December 19, 1916-August 3, 1998): English. Walsh invented atomic absorption spectroscopy, enabling scientists to identify quickly the chemical elements present in a sample.

Walton, Ernest Thomas Sinton* (October 6, 1903-June 25, 1995): Irish. Working with John Cockroft, Walton built the first high-energy particle accelerator in 1932 and produced the first human-made nuclear reaction. They shared the 1951 Nobel Prize in Physics for their work.

Walton, Mary (fl. late nineteenth century): American. In 1879, Walton invented a device to reduce emissions from smokestacks by running the smoke through water tanks, and in 1881 she developed a sound-dampening system for elevated commuter trains.

Wang, An* (February 7, 1920-March 24, 1990): Chinese American. A leading entrepreneur in the computer industry, in 1955 Wang patented a device that made magnetic core memory possible.

Wang, Taylor Gunjin* (b. June 16, 1940): Chinese American. Wang became the first Chinese American astronaut when he flew on the space shuttle *Challenger* in 1985, before which he invented novel methods of acoustic manipulation of matter and designed drop dynamics experiments in zero gravity.

Wankel, Felix* (August 13, 1902-October 9, 1988): German. The Wankel rotary engine, designed in 1954, operates by using orbiting triangular rotors that perform the function of pistons in conventional gasoline engines.

Warner, Ezra J. (1841?-1910?): American. Warner patented the can opener in 1858. It was first widely used during the Civil War.

Waterman, Lewis* (November 20, 1837-May 1, 1901): American. Waterman patented his fountain pen, the first to be leakproof and to operate reliably, in 1884.

Watson-Watt, Sir Robert Alexander* (April 13, 1892-December 5, 1973): Scottish. Watson-Watt developed the physics of radar, and his administrative efforts helped in producing a radar-based air defense system during World War II.

Watt, James* (January 19, 1736-August 25, 1819): Scottish. Watt's innovations in the steam engine, such as a separate condenser allowing faster, more efficient operation, fostered the Industrial Revolution.

Wedgwood, Thomas (May 14, 1771-July 11, 1805): English. With Sir Humphry Davy, Wedgwood invented a method for temporarily fixing images on glass coated with silver nitrate, described in 1802.

Welsbach, Carl Auer von (September 1, 1858-August 4, 1929): Austrian. In 1890, von Welsbach invented an efficient mantle for gas lamps. In 1898, he developed an osmium-tungsten filament for incandescent light bulbs.

Wenström, Jonas (1855-1893): Swedish. In 1880, Wenström invented the slotted armature for electric motors, which improved efficiency.

Westinghouse, George* (October 6, 1846-March 12, 1914): American. A prolific inventor and vigorous entrepreneur, Westinghouse made his fortune initially with an air brake system for trains.

Weston, Edward (May 9, 1850-August 20, 1936): English American. West held hundreds of patents but is best known for his portable voltmeter (1886), which measured electrical current.

Wetzel, Don* (b. 1928): American. Wetzel designed a successful automated teller machine (ATM), introduced in 1969, and conceived the management concepts to make it profitable for banks.

Wheatstone, Charles* (February 6, 1802-October 19, 1875): English. A physicist who produced inventions in acoustic and telegraph technology, Wheatstone invented an eerie musical instrument, the enchanted lyre (or acoucryptophone) in 1821.

Whipple, Squire (December 16, 1804-March 15, 1888): American. Whipple invented the iron truss for bridges in 1841, and his 1847 *A Work on Bridge Building* was the first thorough scientific study of bridge construction.

Whitcomb, Richard T. (b. February 21, 1921): American. Whitcomb, an engineer for the National Aeronautics and Space Administration (NASA), is best known for creating the supercritical airfoil in the 1970's and vertical wing-tip winglets that reduce drag.

Whitney, Eli* (December 8, 1765-January 8, 1825): American. Most famously the inventor of the cotton gin for stripping cottonseed from the fiber, Whitney also introduced interchangeable parts in the manufacture of firearms.

Whittle, Sir Frank* (June 1, 1907-August 8, 1996): English American. Whittle designed, built, and in 1937 tested a turbojet engine that helped launch the jet age.

Wichterle, Otto* (October 27, 1913-August 18, 1998): Czech. Wichterle discovered the hydrogel polyhydroxyethyl methacrylate (poly-HEMA) in 1952 and in 1957 how to mold it into flexible contact lenses.

Widnall, Sheila* (b. July 13, 1938): American. Widnall revolutionized her specialty, fluid dynamics, in her work on aircraft turbulence, vortices, and spiraling airflows.

Wilcox, Stephen (February 12, 1830-November 27, 1893): American. Wilcox and George Babcock devised a safety water-tube boiler in 1856 and a steam generator in 1867.

Williams, Robert R., Jr. (February 16, 1886-October 2, 1965): American. Williams isolated vitamin B_1 (thiamine) in 1933 and two years later found a method to synthesize it.

Williams, Sam (b. May 7, 1921): American. In 1968, Williams patented his small fanjet engine, forerunner to the engines that propel cruise missiles.

Wilmut, Ian (b. June 7, 1944): Scottish. In 1996, Wilmut became the first scientist to clone a mammal, a Finn Dorset ewe named Dolly, from differentiated adult mammary cells.

Winchell, Paul* (December 21, 1922-June 24, 2005): American. Best known as a television entertainer, Winchell was also an inventor. He designed an artificial heart, patented in 1963, that was a forerunner of the Jarvik-7 heart.

Winton, Alexander* (June 20, 1860-June 21, 1932): American. The Winton Motor Carriage Company was among America's first automobile manufacturers, and Winton introduced the first American diesel engine and the first marine engines.

Wong-Staal, Flossie (b. 1947): Chinese American. Wong-Staal cloned the HIV virus in 1985 and was the first person to determine its structure.

Wood, A. Baldwin (1879-1956): American. Wood invented hydraulic equipment, including the low-maintenance, efficient Wood screw pump (1913), which was used to drain water from New Orleans.

Woods, Granville T.* (April 23, 1856-January 30, 1910): American. Among Woods's sixty or so patents were an egg incubator, emergency braking systems for subways, and the synchronous multiplex railway telegraph, which improved communications between train crews and stations.

Woodward, Robert Burns (April 10, 1917-July 8, 1979): American. Woodward received the 1965 Nobel Prize in Chemistry for his work in organic chemistry, including his synthesis of complex substances, such as cholesterol, cortisone, vitamin B_{12}, and quinine.

Wouk, Victor (1919-May 19, 2005): American. Wouk was an early advocate of hybrid cars, converting a Buick Skylark in 1972, and held numerous patents in hybrid and electric car technology.

Wozniak, Steve* (b. August 11, 1950): American. A cofounder of Apple Computer in 1976, Wozniak led the design of the Apple II personal computer and produced several other key technological innovations in microcomputing.

Wright, Frank Lloyd* (June 8, 1867-April 9, 1959): American. Wright transformed American architecture during his nearly seventy-five-year career and was responsible for many innovations in structure and materials.

Wright, Wilbur and Orville* (April 16, 1867-May 30, 1912 [Wilbur]; August 19, 1871-January 30, 1948 [Orville]): American. The heavier-than-air Wright Flyer, piloted by Orville, lifted a human in powered flight for the first time at Kitty Hawk, North Carolina, on December 17, 1903.

Wynne, Arthur (1862-1945): English American. Wynne invented the crossword puzzle in 1913.

Y

Yablochkov, Pavel (September 14, 1847-March 31, 1894): Russian. The Yablochkov candle, invented in 1876, was the first practical arc lamp.

Yagi, Hidetsugu (1886-1976): Japanese. Yagi and Shintaro Uta patented the Yagi Antenna in 1926. Its simple structure and high performance made it useful in a variety of systems, including radio and radar.

Yalow, Rosalyn* (b. July 19, 1921): American. Yalow received the 1977 Nobel Prize in Physiology or Medicine for developing the radioimmunoassay (RIA), which detects small concentrations of compounds, such as hormones, in body fluids.

Yi Xing (683-727): Chinese. Yi Xing invented the escapement mechanism (permitting a regulated escape of energy from a spring or weight) for his water clock, built about 725.

Yokoi, Gumpei (September 10, 1941-October 4, 1997): Japanese. Yokoi created the Nintendo Game Boy and was part of the team that developed the Nintendo Entertainment System.

Young, Arthur M. (1905-1995): American. Young designed Bell Helicopter's first helicopter, the Model 30, first tested in 1946, and patented a flybar (rotor stabilizer bar).

Yunus, Muhammad (b. June 28, 1940): Bangladeshi. Founder of the Grameen Bank and recipient of the 2006 Nobel Peace Prize, Yunus introduced microcredit, loans tailored to entrepreneurs who do not qualify for traditional loans.

Z

Zaid, Hajib (b. 1951): Palestinian American. Zaid patented his corrosion inhibitor industrial chemical mixtures in 1987. Mixtures of oil- and water-soluble compounds, they keep oil wells and pipes free from bacteria and corrosion.

Zamboni, Frank (September 16, 1901-July 27, 1988): American. In 1949, Zamboni invented an ice-resurfacing machine for ice-skating rinks that afterward was known by his name.

Zara, Gregorio Y. (March 8, 1902-October 15, 1978): Filipino. Zara produced a two-way telephone-television, or videophone, in 1955.

Zelinsky, Nikolay (1861-1953): Russian. In 1902, Zelinsky helped develop a method to classify and purify oil; in 1915, he invented an activated charcoal mask.

Zeppelin, Ferdinand von* (July 8, 1838-March 8, 1917): German. Zeppelin pioneered the powered lighter-than-air vehicle, flying his first giant dirigible in 1900.

Ziegler, Karl (November 26, 1898-August 12, 1973): German. Ziegler shared the 1963 Nobel Prize in Chemistry for developing catalysts that are widely used in the plastics industry.

Zinsser, Hans (November 17, 1878-September 4, 1940): American. In 1932, Zinsser proved that typhus is caused by the microorganism *Rickettsia prowazekii* and with M. Ruiz Castañeda developed a vaccine.

Zsigmondy, Richard* (April 1, 1865-September 24, 1929): Austrian German. Zsigmondy developed the ultramicroscope in 1903 for his foundational investigation into colloids, for which he received the 1925 Nobel Prize in Chemistry.

Zuse, Konrad* (June 22, 1910-December 18, 1995): German. Zuse designed and built early computers and wrote the first book about digital physics.

Zworykin, Vladimir* (July 30, 1889-July 29, 1982): Russian American. Considered by some as the "true inventor of the television," Zworykin demonstrated his television camera, the iconoscope, and its receiver, the kinescope, in 1929.

Electronic Resources

Web Sites

The following sites were visited by the editors of Salem Press in 2009. Because URLs frequently change, the accuracy of these addresses cannot be guaranteed; however, long-standing sites, such as those of colleges and universities, national organizations, and government agencies, generally maintain links when sites are moved or updated.

About.com: Inventors
http://inventors.about.com/

About.com Inventors provides a great deal of useful information for would-be inventors and anyone else who is interested in inventions. The "Famous Inventions: A to Z" page contains an alphabetical list of inventions, from adhesive glue through the Zamboni ice resurfacing machine, with links to a separate page of information for each invention. Similarly, "Famous Inventors: A to Z" offers an alphabetical listing of investors with links to pages containing biographical information about them and descriptions of their inventions. "Black History Month" focuses on African American inventors and patent holders, including Benjamin Banneker, George Washington Carver, and Madam C. J. Walker. Users also can access a wide range of time lines, including chronologies of inventions from the fifteenth through the twenty-first centuries, as well as chronologies of specific inventions, technologies, and inventors' lives. Advice for prospective investors, including information about patents, trademarks, and marketing, also is available.

The Alexander Graham Bell Family Papers at the Library of Congress, 1862-1939
http://memory.loc.gov/ammem/bellhtml/bellhome.html

A collection of almost 4,700 archival items, containing more than 51,000 images, that chronicle Bell's invention of the telephone and involvement in the first telephone company, as well as his family life, interest in education for the deaf, and aeronautical and other scientific research. Users can access a range of digitized materials, including selected correspondence, scientific notebooks, journals, blueprints, and photographs. The experimental notebook from March 10, 1876, describing Bell's first successful experiment with the telephone, during which he spoke through the new invention to his assistant the famous words, "Mr. Watson—Come here—I want to see you," is included in the collection.

Canadian Patents Database
http://patents.ic.gc.ca/cipo/cpd/en/introduction.html

This page is part of the official site of the Canadian Intellectual Property Office and enables users to retrieve more than seventy-five years of patent descriptions and images. Four search engines provide a variety of ways to access this material.

Computer History Museum: Online Exhibits
http://www.computerhistory.org/exhibits/

The museum, located in Mountain View, California, maintains a time line of computer history and a number of online exhibits on its Web site. "The Babbage Engine" describes Charles Babbage's invention of the first automatic computing engine. "The Silicone Empire" chronicles the history of semiconductors in computers. "Selling the Computer" is a collection of computer company marketing brochures. Other exhibits outline Internet history from 1962 through 1992, provide an overview of the microprocessing industry from 1971 through 1996, and display images of computing artifacts. Additional information about inventors and other computer industry leaders can be found in the biographies of the persons who have been inducted into the museum's Hall of Fame.

Early Office Museum
http://www.officemuseum.com/

A virtual museum that chronicles the evolution of the business office, office machinery and equipment, and business technology. The exhibits include vintage photographs and other images of offices from the 1770's through the 1950's and displays of antique typewriters, adding machines and calculators, copying machines, staplers, fasteners, paper clips, and writing implements.

Emile Berliner and the Birth of the Recording Industry
http://memory.loc.gov/ammem/berlhtml/berlhome.html

A record of the life and work of Emile Berliner, inventor of the microphone and the flat recording disc gramophone player. The site features selected correspondence, articles, lectures, speeches, photographs, and other items from Berliner's papers. Its most interesting feature, however, is its access to more than one hundred early sound recordings that users can listen to via RealPlayer, Media Player, QuickTime, and other MP3 players. The recordings are organized by category, such as band and orchestra, instrumentalists, spoken comedy, popular music vocalists and vocal groups, classical and opera, spoken word, and foreign language, and include a rendition of "Stars and Stripes Forever" by the Sousa Band and Buffalo Bill's lecture "Sentiments on the Cuban Question."

Famous Black Inventors
http://www.black-inventor.com/

An easy-to-use site containing eighteen biographies of black inventors and descriptions of their inventions. Some of the inventors are George Edward Alcorn, creator of the imaging X-ray spectrometer, blood bank inventor Charles Richard Drew, and Garrett Augustus Morgan, who invented a gas mask and traffic light. The site links to other resources related both to African American inventors and to other aspects of invention.

Famous Women Inventors
http://www.women-inventors.com/

Similar to Famous Black Inventors (above), this site contains nineteen biographies about women inventors and their creations; among these women are Mary Anderson, the inventor of windshield wipers, disposable diapers inventor Marion Donovan, and actress Hedy Lamarr, who helped create a wireless communication system to combat the Nazis in World War II. The site offers links to other Web resources with information about invention in general and women inventors in particular.

The Great Idea Finder
http://www.ideafinder.com/history/

While some of its information is aimed at children, The Great Idea Finder is a comprehensive, user-friendly source of information for anyone interested in inventions. Its "Invention Facts and Myths" section contains information about inventions that can be retrieved via an alphabetical listing of invention titles; information also can be accessed via a list of invention categories, including "Everyday Life History," which describes the histories of apparel, food and drink, household items, toys and games, and office equipment. Other sections of the site feature inventor biographies and pages of information about inventors from Canada, France, Germany, and several other nations. The "Innovation Timeline" chronicles inventions created from ancient times to the present day. The "Resources Center" is especially useful because it offers recommendations for numerous Web sites, books, and videos about inventors and inventions.

Inside an American Factory: Films of the Westinghouse Works, 1904
http://memory.loc.gov/ammem/papr/west/westhome.html

Users can view twenty-one "actuality films" depicting the working conditions at the Westinghouse Air Brake, Westinghouse Electric and Manufacturing, and Westinghouse Machine companies. The exterior and interior shots of the factories, along with employees performing their tasks, were meant to highlight the companies' operations. The site also provides a biography of George Westinghouse, a time line of his life and inventions, and a discussion of working conditions at his factories.

Inventing Entertainment: The Motion Pictures and Sound Recordings of the Edison Companies
http://memory.loc.gov/ammem/edhtml/edhome.html

Focusing on Thomas Alva Edison's contributions to the entertainment industry, this site provides access to 341 motion pictures filmed by his company and eighty-one disc sound recordings designed to be played on the Edison disc phonograph. Users can find these films via indexes of their titles, genres, or years they were produced, as well as through a list of their subjects; the selected disc recordings are accessible via indexes of their titles or genres. The site describes what computerized equipment users need to view the motion pictures and to hear the recordings, as well as offering an Edison biography and a time line of his life that links to additional information about his entertainment-related inventions.

Invention Now: National Inventors Hall of Fame Foundation Inc.
http://www.invent.org

Invention Now is a nonprofit organization that aims to foster the spirit of invention by maintaining the National Inventors Hall of Fame. The hall honors men and women who are, in the words of the site, "responsible for great technological advances that make social and economic progress possible." Inventors are inducted annually, and as of January, 2009, almost four hundred people had been included. The Web site provides a database that allows users to obtain information via lists of inventors, inventions, dates of induction to the Hall of Fame, and the decade in which an invention was patented. Users also can obtain information by "channel," or category of invention, such as agriculture, electricity, medical, and chemistry. In addition, the site provides information about the National Inventors Hall of Fame Museum, located in Akron, Ohio, and Invention Now's other programs.

Lemelson Center for the Study of Invention and Innovation
http://invention.smithsonian.org/home

Since 1995, the center has been housed at the Smithsonian Institution's National Museum of American History. The center's Web site provides a range of virtual information about inventors and inventions that is contained in the "Centerpieces" section. These virtual exhibits include "Inventing Ourselves," a description of inventions that are wearable or able to be implanted in the human body, including running shoes and nutritional supplements; "Doodles, Drafts, and Designs," a selection of industrial drawings from the Smithsonian's archives, including designs for an electromechanical flycatcher, tennis racket, and Binney and Smith's Crayola crayons; "Whole Cloth," a history of the American textile industry; and exhibits explaining the invention of the electric guitar and the quartz watch. An extensive "Resources" section includes links to Web sites, a bibliography of books about invention, and access to information from the National Museum of American History Archives Center.

The Medieval Technology Pages
http://scholar.chem.nyu.edu/tekpages/Technology.html

Paul J. Gans, a chemistry professor at New York University, created and maintains these pages, which provide referenced information on technological innovation and related subjects in western Europe during the Middle Ages. The information can be accessed in three ways: The "Subjects Index "is an alphabetical list of medieval inventions with links to pages about agricultural tools, cannons, soap, the wine press, and other inventions of the era. "Timeline Epochs" provides a chronological listing of inventions created from 500 through 1600. "References" is a bibliography of print resources about medieval technology.

The Museum for the Preservation of Elevating History
http://www.theelevatormuseum.org/

Created by the founder and former editor of *Elevator World* magazine, this virtual museum chronicles, in its own words, "how lifting evolved through the ages." The museum's virtual wings provide information about the genesis of lifting, the creation of powered-mechanical systems, the age of electric power, and the major components of the elevator; another wing focuses on the various inventors of the elevator, including Michael Faraday, Jesse W. Reno, and Elisha Graves Otis. A time line of lifting-related technology from 4500 B.C.E. to 1948 C.E. also is available.

Samuel F. B. Morse Papers at the Library of Congress, 1793-1919
http://memory.loc.gov/ammem/sfbmhtml/sfbmhome.html

This digitized collection comprises about 6,500 items that chronicle Morse's invention of the telegraph, his participation in the development of telegraph companies in the United States and abroad, and other aspects of his life and career. Some of the items include correspondence, diaries, scrapbooks, and maps; the highlight of the collection is the original paper tape of the first telegraph message, "What hath God wrought?," that was sent on May 24, 1844. The site also features a time line of significant events in Morse's life and a Morse family tree.

Smith College History of Science: Museum of Ancient Inventions
http://www.smith.edu/hsc/museum/ancient_inventions/home.htm

This Web site was created by Smith College students enrolled in a course on ancient inventions. It is a virtual museum, whose exhibits consist of forty-five inventions created from antiquity through 1700, including woven cloth, eyeliner, and the tumbler lock. Each invention is displayed on a separate page containing descriptions and photographs.

United States Patent and Trademark Office
http://www.uspto.gov/

A division of the Department of Commerce, the U.S. Patent and Trademark Office (USPTO) is the federal agency authorized to patent inventions. The agency's Web site includes a separate page (http://www.uspto.gov/main/patents.htm) providing information about the patent process, including basic facts about patents, how to get a patent, and the types of patents available; inventors can use the site to file an online patent application. The page also offers access to information about trademarks, service laws, copyrights, and patent laws and regulations. Users can search the site's database to locate full-page images of patents issued from 1790 through 1975, the full text of patents issued since 1976, and patent applications published since March, 2001.

The Wilbur and Orville Wright Papers at the Library of Congress
http://memory.loc.gov/ammem/wrighthtml/wrighthome.html

A digitized collection of more than 10,120 items, including correspondence, diaries, and notebooks, that chronicles the lives of the two brothers and their work leading to the first successful flight of their airplane at Kitty Hawk, North Carolina, on December 17, 1903. Among the site's items are the brothers' collection of glass-plate photograph negatives. A time line about the brothers' lives and work is also featured.

The Wright Brothers and the Invention of the Aerial Age
http://www.nasm.si.edu/wrightbrothers/

In 2003, the Smithsonian Institution's National Air and Space Museum mounted an exhibition to commemorate the centennial of the first successful flight of the Wright brothers' airplane. Some of the information from that exhibit remains available on this Web site and is organized by three categories: "Who Were Wilbur and Orville?" provides biographical information about the brothers. "Inventing a Flying Machine" highlights the research the brothers conducted in order to create the first successful powered airplane in 1903 and a refined version of that plane two years later. "The Aerial Age Begins" documents the scientific and social impact of the brothers' invention, with information about competing aeronautical inventions, the brothers' airplane manufacturing company, and how the airplane became part of popular culture.

Zoom Inventors and Inventions
http://www.enchantedlearning.com/inventors/indexa.shtml

Created by Enchanted Learning, an organization that produces educational Web sites, Zoom Inventors and Inventions offers useful, easily accessible information, including descriptions of important inventions and capsule biographies of inventors. Users can access a series of time lines chronicling inventions from ancient times through 2000 or can retrieve information by categories, such as clothing, food, medicine, and transportation. Another set of pages lists inventions by African Americans and women, as well as by inventors from the United States and Canada, the British Isles, China, and several other nations and world regions.

Electronic Databases

Electronic databases usually do not have their own URLs. Instead, public, college, and university libraries subscribe to these databases, provide links to them on their Web sites, and make them available to library card holders or specified patrons. Readers can check library Web sites or ask reference librarians to check on availability.

Biography Collection Complete

EBSCO's Biography Collection Complete is a comprehensive collection of more than 177,000 full-text biographies from many different sources. The biographies cover a wide range of areas, including historical figures and persons who have made significant contributions in science and business.

Biography Resource Center

Gale's Biography Resource Center provides more than 444,000 biographies on more than 340,000 individuals, including notable figures in science, history, and other fields of endeavor. Its other features include links to related Web sites, the full text of magazine and newspaper articles, and the ability to search by a person's name or by selected biographical facts, such as years of birth or death, nationality, gender, and ethnicity.

History Reference Center

EBSCO's History Reference Center contains the full text of more than 2,400 reference books, encyclopedias, and nonfiction books from Houghton Mifflin, Lerner Publishing Group, Oxford University Press, Salem Press, and other publishers, as well as the full text of articles from 135 history periodicals. It also provides access to more than 61,100 historical documents, more than 57,000 biographies of historical figures, more than 110,200 historical photographs and maps, and more than eighty hours of historical video.

History Resource Center: U.S. and World

These two databases are produced by Gale and feature full-text articles from academic journals and periodicals, numerous primary source documents, electronic versions of reference works, topic overviews, biographies, and links to related Web sites.

Salem History

Produced by Salem Press, this database offers the full contents of the publisher's *Great Lives from History, Great Events from History*, and *Decades* sets, as well as from *Milestone Documents*, a new primary source series. Users also have access to entries from Salem's many history and social science encyclopedias.

Wilson Biographies Illustrated

Wilson Biographies Illustrated, produced by the H. W. Wilson Company, contains more than 100,000 biographies and obituaries and more than 31,000 photographs of the subjects. The database also offers the full text of more than one hundred biographical reference books published by H. W. Wilson, including *Current Biography.*

–Rebecca Kuzins

Bibliography

Aaseng, Nathan. *Twentieth Century Inventors*. New York: Facts On File, 1991. Written for a juvenile audience, this book provides personal profiles of ten inventors, with a historical perspective. Illustrations, bibliography, index.

Abbate, Janet. *Inventing the Internet*. Cambridge, Mass.: MIT Press, 2000. Abbate's history of the Internet provides a clear explanation of the workings of the technology that came together to create the "information superhighway." What makes this work valuable is that Abbate also takes the time to introduce the reader to the people behind the technology.

Altman, Linda Jacobs. *Women Inventors*. New York: Facts On File, 1997. Stories of the inventions of nine women: Elizabeth Lee Hazen and Rachel Brown, fungicidal drug Nystatin; Sara Josephine Baker, measured-dose eyedropper; Carrie Everson, ore flotation system; Amanda Jones, vacuum canning process; Madam C. J. Walker, hair care products for African American women; Ida Rosenthal, Maidenform lingerie; Bette Nesmith Graham, Liquid Paper correction fluid; Ruth Handler, Barbie doll; and Katharine Burr Blodgett, gas mask, smokescreen, and nonreflective glass.

Anderson, John D. *Inventing Flight: The Wright Brothers and Their Predecessors*. Baltimore: The Johns Hopkins University Press, 2004. An account of the technical developments that led to the Wright brothers' Kitty Hawk flight on December 3, 1903, by a noted aeronautical engineer. Traces attempts at flight from the Middle Ages forward, demonstrating the knowledge that the Wrights inherited.

Bass, Thomas A. *Reinventing the Future: Conversations with the World's Leading Scientists*. Reading, Mass.: Addison-Wesley, 1994. Includes eleven interviews with leading scientists, some controversial. A biographical sketch precedes the question-and-answer segment. Illustrated, bibliography.

Bays, Carter. *The Encyclopedia of Early American and Antique Sewing Machines: Identification and Values*. 3d ed. New York: Collector Books, 2006. Aside from information on early sewing machines, this encyclopedia includes abundant colored photographs.

Beek, Leo. *Dutch Pioneers of Science*. Assen, the Netherlands: Van Gorcum, 1985. Spanning five centuries, Beek's work discusses noteworthy Dutch inventions and inventors, from Gerardus Mercator, the cartographer, to Frits Zernike, inventor of the phase-contrast microscope. Illustrations, bibliography, index.

Bendick, Jeanne, and Robert Bendick. *Eureka! It's Television*. Brookfield, Conn.: Millbrook Press, 1993. In a background history, discusses the other inventions and discoveries that were necessary to make the invention of the television possible. Well illustrated; poses many questions to inspire interest. Glossary and index.

Berlin, Leslie. *The Man Behind the Microchip: Robert Noyce and the Invention of Silicon Valley*. New York: Oxford University Press, 2005. Argues that Noyce and Fairchild Semiconductor were primarily responsible for Santa Clara County, California, becoming a major center of the computer industry.

Berners-Lee, Tim. *Weaving the Web: The Original Design and the Ultimate Destiny of the World Wide Web by Its Inventor*. New York: HarperCollins, 2000. Concentrates more on the Web than on its creators. Appendix, glossary, index.

Bernstein, Mark. *Grand Eccentrics: Turning the Century—Dayton and the Inventing of America*. Wilmington, Ohio: Orange Frazer Press, 1996. Interesting look at early Dayton, Ohio, inventors and their accomplishments and quirks. Pictures, index.

Bertolotti, Mario. *The History of the Laser*. Philadelphia: Institute of Physics, 2005. Covers not only the laser but also the history of optics. Bibliography and index.

Bowers, Brian. *Lengthening the Day: A History of Lighting Technology*. New York: Oxford University Press, 1998. Informative book by the science curator of London's Science Museum that traces lighting from antiquity to modern times. Includes a chapter on the electric arc. Illustrations, bibliographical references, index.

Bown, Stephen R. *A Most Damnable Invention: Dynamite, Nitrates, and the Making of the Modern World*. New York: Thomas Dunne, 2005. Addresses the basic technical questions involved in the development of dynamite and discusses other explosives used through the period of World War I.

Brain, Marshall. *Marshall Brain's How Stuff Works*. New York: Hungry Minds, 2001. Written in an easy-to-understand, conversational style and organized into eleven categories of inventions ranging from aircraft to household appliances.

_______. *Marshall Brain's More How Stuff Works*. New York: John Wiley & Sons, 2003. Follows up his 2001 book with eleven additional categories of inventions; written in the same readable style as the earlier volume.

Bridgman, Roger. *One Thousand Inventions and Discoveries*. New York: Dorling Kindersley, 2006. Bridgman reviews some of the most important inventions and discoveries in history, from ancient times through the information age. The entries are written primarily for young readers, with descriptions and cross-references to valuable resources.

Brodie, James Michael. *Created Equal: The Lives and Ideas of Black American Inventors*. New York: William Morrow, 1993. Features more than sixty African American inventors. Lists patents of all inventors treated.

Brown, David. *Inventing Modern America: From the Microwave to the Mouse*. Cambridge, Mass.: MIT Press, 2002. Indispensable and highly readable investigation into postwar American ingenuity that profiles thirty-five visionaries whose inventions reshaped modern culture. Illustrations, bibliography, index.

Brown, Travis. *Popular Patents: America's First Inventions, from the Airplane to the Zipper*. Lanham, Md.: Scarecrow Press, 2000. Eight inventions are presented in narratives that include a profile of the inventor and a discussion of how the invention has found its way into American culture.

Bugliarello, George, and Dean B. Doner, eds. *The History and Philosophy of Technology*. Chicago: University of Illinois Press, 1979. A collection of selected essays from a 1973 symposium on the history and philosophy of technology. The twenty-three essays are divided into three categories: the history of technology, the philosophy of technology, and the future of technology.

Burke, James. *Connections*. Boston: Little, Brown, 1978. Cites eight modern inventions that may be the most influential in causing an increase in future change: the atomic bomb, telephone, computer, production-line system of manufacture, aircraft, plastics, guided rocket, and television.

Burlingame, Roger. *March of the Iron Men: A Social History of Union Through Invention*. New York: Charles Scribner's Sons, 1938. A fascinating book, contemporaneous with its subject, well researched, and well organized. As an interpreter of social history, Burlingame has strong opinions, which he defends admirably. Outstanding bibliography, chronology chart, and illustrations. Examines inventors' motives.

_______. *Out of Silence into Sound*. New York: Harcourt, Brace & World, 1960. Identifies those who provided insights to persons credited with inventions: Dr. Joseph Black and James Watt; Benjamin Silliman and Charles Goodyear; Joseph Henry and Michael Faraday; and Michael Pupin and Thomas Alva Edison, for example.

Burness, Ted. *Ultimate Auto Album: An Illustrated History of the Automobile*. Iola, Wis.: Krause, 2001. Traces more than two hundred years of automobile history. A wonderfully illustrated book.

Camp, Carole Ann. *American Women Inventors*. Berkeley Heights, N.J.: Enslow, 2004. Includes a chapter on each of ten American female inventors, most of whom are featured in *Great Lives from History: Inventions and Inventors*.

Cardwell, D. S. L. *Turning Points in Western Technology: A Study of Technology, Science, and History*. New York: Science History Publications, 1972. Identifies four stages in the development of technology. The first coincided with the rise of European technics during the middle ages; the second began in the early seventeenth century; the third at the time of the Industrial Revolution; and the fourth at the time of the establishment of industrial research laboratories, with the renaissance of German technology and science, and with the rise of new technological powers—the United States and Japan.

Carlisle, Rodney. *Inventions and Discoveries*. Hoboken, N.J.: John Wiley & Sons, 2004. A useful compendium of inventions, arranged into six historical periods, for general readers. Examines 418 inventions.

Casey, Susan. *Women Invent: Two Centuries of Discoveries That Have Shaped Our World*. Chicago: Chicago Review Press, 1997. This simple, straightforward book, written at a child's reading level, traces the history of a handful of female inventors, from conception of their ideas through the actual manufacturing and sale of their products. The author also addresses general questions about inventing and patenting a product.

Chamberlain, John. *The Enterprising Americans: A Business History of the United States*. New York: Harper & Row, 1963. Originally a series in *Fortune* magazine on famous American businesspeople, this book includes an extensive and helpful bibliography and is written in a lively and engaging style. A good book for the high school student.

Chandler, Alfred D., Jr. *Inventing the Electronic Century: The Epic Story of the Consumer Electronics and Computer Industries*. Boston, Mass.: Harvard University Press, 2005. Traces the origins and worldwide development of consumer electronics and computers from the 1920's to the present. Provides an excellent analysis of the breakthroughs and discoveries that led to modern digital technology. Index.

Chang, Hasok. *Inventing Temperature: Measurement and Scientific Progress*. New York: Oxford University Press, 2004. Philosophical survey and critique of the whole history of the study of temperature.

Cipolla, Carlo M., and Derek Birdsall. *The Technology of Man: A Visual History*. New York: Holt, Rinehart & Winston, 1979. A history of technological development from that of the earliest known tools to space age inventions. Photographs and drawings.

Clark, Ronald William. *The Scientific Breakthrough: The Impact of Modern Invention*. New York: G. P. Putnam's Sons, 1974. Focuses on the upsurge of inventions and discoveries that followed the 1851 Great Exhibition in London. Discusses cameras and picture taking, the airplane, the electromagnetic spectrum, plastics, nuclear power, and the birth control pill.

_______. *Works of Man: A History of Invention and Engineering, from the Pyramids to the Space Shuttle*. New York: Viking Press, 1985. Chronologically traces the inventions of the ancient world. Categories include steam, artificial waterways, locomotives, bridges, textiles, electricity, airplanes, tunnels, computers, nuclear power, and space technology.

Clarke, Donald, ed. *The Encyclopedia of How It Works: From Abacus to Zoom Lens*. New York: A & W, 1977. Provides brief stories of the invention of 125 items, along with photographs or drawings of most. Organized alphabetically.

Coe, Lewis. *The Telegraph: A History of Morse's Invention and Its Predecessors in the United States*. 1993. Reprint. Jefferson, N.C.: McFarland, 2003. Highly readable, balanced account of the development of the Morse telegraph. Contextualizes the controversy between Joseph Henry and Samuel F. B. Morse. Bibliography, index.

Creswell, Toby, and Samantha Trenoweth. *One Thousand One Australians You Should Know*. North Melbourne: Pluto Press Australia, 2006. Brief illustrated biographies of important Australians.

Croft, William J. *Under the Microscope: A Brief History of the Microscope*. Hackensack, N.J.: World Scientific, 2006. A brief history of the development and evolution of the microscope and microscopy from the use of water drops by the ancient Greeks to recent innovations in electron and confocal microscopy.

Crone, G. R. *Maps and Their Makers: An Introduction to the History of Cartography*. New York: Hutchinson House, 1953. Reviews contributions of cartographers from ancient and medieval times through post-World War II atlas production.

Crouch, Tom D., and Peter L. Jakab. *The Wright Brothers and the Invention of the Aerial Age*. Smithsonian National Air and Space Museum. Washington, D.C.: National Geographic, 2003. An oversized book filled with many photographs of the Wrights and their experiments, written in commemoration of the one hundredth anniversary of the Kitty Hawk flight. An indispensable volume for anyone studying the subject. Also includes an excellent bibliography.

Crump, Thomas. *A Brief History of the Age of Steam: The Power That Drove the Industrial Revolution*. New York: Carroll & Graf, 2007. Begins with the invention, by Thomas Newcomen, of the first steam machine in England in 1710 and explains how steam changed the world by introducing the Industrial Revolution.

Csikszentmihalyi, Mihaly. *Creativity: Flow and Psychology of Discovery of Invention*. New York: HarperCollins, 1996. An analysis of creativity through understanding the fields, hard work, and inspirations of ninety-one people.

Darrow, Floyd L. *Masters of Science and Invention*. New York: Harcourt, Brace & World, 1951. Provides inspirational, readable biographical sketches of thirty-six inventors, some of whom are less well known.

Daumas, Maurice, ed. *The Origin of Technological Civilization*. Vol. 1 in *A History of Technology and Invention: Progress Through the Ages*. New York: Crown, 1969. After outlining the birth and early development of technology, Daumas organizes the discussion geographically from the areas of the Mediterranean, southern and Far Eastern Asia, Islamic lands, and Byzantium to pre-Columbian America and the medieval age of the West (fifth century to 1350).

_______. *The First Stages of Mechanization*. Vol. 2 in *A History of Technology and Invention: Progress Through the Ages*. New York: Crown, 1969. Divides a discussion of the development of mechanization into two parts. Part 1 details progress during the fifteenth and sixteenth centuries in the Western world, and part 2 identifies the major stages of transition in technological mechanization.

_______. *The Expansion of Mechanization*. Vol. 3 in *A History of Technology and Invention: Progress Through the Ages*. New York: Crown, 1979. Divided into nine sections: Methods of producing power; machine industries having to do with automation, time measurement, and standardized measuring systems; transportation and communication; military techniques; constructing and equipping urban buildings; extraction and exploitation of natural resources; textiles; techniques of expression; and the spread of technical progress.

Davis, Kenneth S. *The Cautionary Scientists: Priestley, Lavoisier, and the Founding of Modern Chemistry*. New York: G. P. Putnam's Sons, 1966. This dual biography emphasizes, besides Joseph Priestley's and Antoine Lavoisier's scientific accomplishments, the social, political, and religious contexts within which each lived and worked. Bibliography and index.

Denny, Mark. *Five Machines That Changed the World*. Baltimore: The Johns Hopkins University Press, 2007. Provides useful insights into advanced physics, combining history and technology to examine the development and influence of the bow and arrow, waterwheels and windmills, counterpoise siege engines, pendulum clock anchor escapement, and the centrifugal governor. Time line, index.

Derry, T. K., and Trevor I. Williams. *A Short History of Technology: From the Earliest Times to A.D. 1900*. New York: Oxford University Press, 1961. A shortened version of the compendium *History of Technology*, edited by Traver I. Williams, et al.

Douglas, Susan J. *Inventing American Broadcasting, 1899-1922*. Baltimore: The Johns Hopkins University Press, 1987. Detailed examination of early attempts to develop commercially viable wireless technology.

Dyer, Frank Lewis, and Thomas Commerford Martin. *Edison: His Life and Inventions*. Introduction by Robert J. Crawford. New York: Barnes & Noble Books, 2005. Reprint of the 1910 account by Edison's lawyer that depicts the inventor's innovative laboratory.

Eckermann, Erik. *World History of the Automobile*. Translated by Peter L. Albrecht. Warrendale, Pa.: Society of Automotive Engineers, 2001. Offers an extensive history of the development of the automobile throughout the world. Abundantly illustrated.

Eco, Umberto, and G. R. Zorzoli. *The Picture History of Inventions: From Ploughs to Polaris*. Translated by Anthony Lawrence. New York: Macmillan, 1963. Provides historical background and brief descriptions of more than seven hundred inventions, from the abacus to the zoopraxiscope, with hundreds of pictures of inventions.

Ehrenberg, Ralph E. *Mapping the World: An Illustrated History of Cartography*. Washington, D.C.: National Geographic Society, 2006. More than one hundred maps are presented, illustrating a history of mapmaking.

Ferguson, Eugene S. *Oliver Evans: Inventive Genius of the American Industrial Revolution*. Greenville, Del.: The Hagley Museum, 1980. Ferguson uses newly discovered material to construct his own interpretation of Evans as a pioneer of the American Industrial Revolution. Illustrated, notes, and index.

Flehr, Paul D. *Inventors and Their Inventions: A California Legacy Seen Through the Eyes of a Patent Attorney*. Palo Alto, Calif.: Pacific Books, 1990. Discusses advances in television technology from the point of view of patent law. Not very helpful on the technical side, but offers a clearer picture than do the standard television histories of the legal issues involved.

Fortey, Jacqueline. *Great Scientists*. New York: Dorling Kindersley, 2007. This book, written for young people, includes profiles of several eminent scientists. Full-color artwork and graphs.

Fouché, Rayvon. *Black Inventors in the Age of Segregation: Granville T. Woods, Lewis H. Latimer, and Shelby J. Davidson*. Baltimore: The Johns Hopkins University Press, 2003. Fouché focuses on three African American inventors whose careers reflect the challenges of intellectual achievement and professional advancement in a society defined by racial prejudice.

Fraden, Jacob. *Adventures of an Inventor: Or, How to Survive and Succeed in Inventing Business*. San Diego, Calif.: Hurricane Books, 1996. An autobiographical account of a Soviet inventor who came to the United States, where life as an inventor was very frustrating. Fraden shares the ups and downs of bringing dreams to fruition while trying to find capital to make them possible.

Francastel, Pierre. *Art and Technology in the Nineteenth and Twentieth Centuries*. Translated by Randall Cherry. New York: Zone Books, 2000. Treats the importance of mechanization and how technology transformed artistic creativity over two centuries.

Freedman, Russell. *The Wright Brothers: How They Invented the Airplane*. New York: Holiday House, 1991. Although written for young readers, this book includes a good summary of Wilbur and Orville Wrights' invention. Among the many photographs included are those taken by the Wright brothers themselves; the text also includes information concerning how and when the photos were taken. A list of places to visit encourages young students to learn more about the Wrights.

Freeman, Allyn, and Bob Golden. *Why Didn't I Think of That? Bizarre Origins and Ingenious Inventions We Couldn't Live Without*. New York: John Wiley & Sons, 1997. Discusses the origins of inventions, business aspects of production, and marketing and distributing. Bibliography, index.

Furukawa, Yasu. *Inventing Polymer Science: Staudinger, Carothers, and the Emergence of Macromolecular Chemistry*. Philadelphia: University of Pennsylvania Press, 1998. Places polymer research developments in context with scientific and public perception of chemistry's role during World War I and the interwar period.

Gardner, Robert. *Experimenting with Inventions*. New York: Franklin Watts, 1990. Organized according to categories such as accidental inventions, new uses for old objects, and inventions out of necessity. Bibliography, index, appendixes on patents, and answers to puzzles posed in early chapters.

Gies, Joseph. *Cathedral, Forge, and Waterwheel: Technology and Invention in the Middle Ages*. New York: HarperCollins, 1994. Discusses the triumphs and failures of ancient technology in what Gies calls the "not so dark" Middle Ages. Finds little, if any, break in technological continuity in the fall of Rome.

_______. *The Wonders of the Modern World*. New York: Thomas Crowell, 1966. Rather than write about inventions chronologically or by category, Gies focuses on superlatives, such as the fastest railroad, the biggest bridge, the tallest building. Contains appendixes that list major bridges, dams, tunnels, structures, satellites, miscellaneous modern inventions, top engineering projects of the 1960's, and projected future "wonders."

Gillispie, Charles Coulston. *The Montgolfier Brothers and the Invention of Aviation, 1783-1784: With a Word on the Importance of Ballooning for the Science of Heat and the Art of Building Railroads*. Princeton, N.J.: Princeton University Press, 1983. Exhaustive study by a professional historian of the brothers' lives and their inventions within the social and scientific context of their times. Numerous diagrams and maps, some in color, and detailed notes.

Giscard d'Estaing, Valerié-Anne, and Mark Young, eds. *Inventions and Discoveries, 1993: What's Happened, What's Coming, What's That?* New York: Facts On File, 1993. Contains brief descriptions of more than one hundred inventions in twelve categories. Lists Nobel Prize winners in the fields that apply to the topics of invention and discovery: chemistry, physics, and medicine.

Goldmark, Peter C., and Lee Edson. *Maverick Inventor: My Turbulent Years at CBS*. New York: Saturday Review Press, 1973. An interesting personal account of Goldmark's discoveries during his years working at the Columbia Broadcasting System (CBS). Describes how company executives too frequently failed to take advantage of his ideas to develop new technology (such as his audio system for automobiles and a video recording system).

Grafton, Anthony. *Magic and Technology in Early Modern Europe*. Washington, D.C.: Smithsonian Institution, 2005. Concise, vivid sketch of the milieu of late Renaissance Italy that roused the interest of scholars. Illustrations, bibliography.

Gribbin, John. *The Scientists: A History of Science Told Through the Lives of Its Greatest Inventors*. New York: Random House, 2003. A well-written biographical narrative that clearly explains scientific theories.

Grissom, Fred, and David Pressman. *The Inventor's Notebook*. 5th ed. Berkeley, Calif.: Nolo Press, 2008. A practical discussion of inventing, with some interesting insights on the patent process.

Grosvenor, Edwin S., and Morgan Wesson. *Alexander Graham Bell: The Life and Times of the Man Who Invented the Telephone*. New York: Harry N. Abrams, 1997. Chronicles Bell's most famous invention, from its roots in deaf education to the growth of AT&T. Covers experiments later in his career and includes historical and family anecdotes.

Haber, Louis. *Black Pioneers of Science and Invention*. New York: Harcourt, Brace & World, 1970. Includes fourteen chapters on African American innovators, inventors, and scientists.

Hallion, Richard P. *Taking Flight: Inventing the Aerial Age, from Antiquity Through the First World War*. New York: Oxford University Press, 2003. Includes an extensive look at what is termed "prehistory" attempts at flight, a survey of flight experiments before the Renaissance.

Harris, Laurie Lanzen. *Biography for Beginners: Inventors*. Pleasant Ridge, Mich.: Favorable Impressions, 2006. Written for a juvenile audience, this work discusses inventors from Archimedes to modern times. Illustrations, bibliography, index.

Haskins, Jim. *Outward Dreams: Black Inventors and*

Their Inventions. New York: Walker Books, 2003. Collection of brief chapters on inventors, written for very young readers.

Hassan, Ahmad al-, and Donald R. Hill. *Islamic Technology: An Illustrated History*. New York: Cambridge University Press, 1988. Al-Hassan tempers Hill's technical explanations. Together they produce an engaging history for the nonscientist. Bibliography, index, maps, illustrations.

Hayden, Robert C. *Nine African American Inventors*. New York: Twenty-first Century Books, 1992. Brief, simple collection of essays about African Americans whose work affects areas of contemporary living.

Heiney, Paul. *The Nuts and Bolts of Life: Willem Kolff and the Invention of the Kidney Machine*. Charleston, S.C.: The History Press, 2003. Definitive chronicle of Kolff's groundbreaking theoretical work and construction of the first dialysis machine. Emphasizes Kolff's knack for problem-solution thinking and his unshakeable belief in the medical profession's obligation to relieve suffering as his guiding premise. Written with the cooperation of Kolff.

Helden, Albert Van. *The Invention of the Telescope*. Philadelphia: American Philosophical Society, 1977. Relies on the original sources uncovered by Cornelis de Waard and published in his *De uitvinding der verrekijkers* (1906) for the most thorough discussion of the invention of the telescope. These original sources are translated and included in the appendix.

Henderson, Susan K. *African-American Inventors: Lonnie Johnson, Frederick McKinley Jones, Marjorie Stewart Joyner, Elijah McCoy, Garrett Augustus Morgan*. Mankato, Minn.: Capstone Press, 1998. Profiles key African American inventors. Photographic illustrations.

Henderson, Susan K., Stanley P. Jones, and Fred Amram. *African-American Inventors II: Bill Becoat, George Carruthers, Meredith Gourdine, Jesse Hoagland, Wanda Sigur*. Mankato, Minn.: Capstone Press, 1998. This short book is intended for high school-age readers. Provides the basic facts about the lives of five outstanding black inventors.

Henderson, Susan K. *African-American Inventors III: Patricia Bath, Philip Emeagwali, Henry Sampson, Valerie Thomas, Peter Tolliver*. Mankato, Minn.: Capstone Press, 1998. Presents a set of short biographies stressing the subjects' ability to persevere and overcome obstacles. Photographic illustrations.

Hermes, Matthew E. *Enough for One Lifetime: Wallace Carothers, Inventor of Nylon*. Washington, D.C.: American Chemical Society and the Chemical Heritage Foundation, 1996. Former DuPont researcher Matthew Hermes consulted archival records and Carothers's family, coworkers, and associates for this detailed account. Includes appendix of chemical formulas associated with Carothers's research and photographs from Carothers's relatives and friends.

Hodges, Henry. *Technology in the Ancient World*. London: Allen Lane, 1970. Organizes discussion chronologically from biblical times through the early great dynasties and empires to the early "barbarians" of the West.

Houze, Herbert G., et al. *Samuel Colt: Arms, Art, and Invention*. New Haven, Conn.: Yale University Press, 2006. A beautiful book with hundreds of photographs of firearms, the manufacturing process, paintings, the Colt family tree, and other Colt memorabilia, assembled for a special Colt exhibit at the Wadsworth Atheneum in Hartford. The book also contains extensive text, well researched and footnoted, about Samuel Colt and the business he built.

Hubbard, Geoffrey. *Cooke and Wheatstone and the Invention of the Electric Telegraph*. New York: Routledge, 2008. A new edition of a book first published in 1965, which offers a definitive account of the problematic relationship between Charles Wheatstone and his collaborator, William Fothergill Cooke, and their joint contribution to the development of telegraphy in Britain. The book endeavors to strike a judicious balance in weighing up the two men's rival claims and is more successful in that regard than most earlier accounts.

Hudson, Wade. *Book of Black Heroes: Scientists, Healers, and Inventors*. East Orange, N.J.: Just Us Books, 2003. Covers many lesser-known African American inventors. Written for a juvenile audience.

Hughes, Thomas. *A Century of Invention and Technological Enthusiasm, 1870-1970*. Chicago: University of Chicago Press, 2004. Provides comprehensive information about inventors in the United States and the roles that prominent laboratories, such as General Electric Research Laboratory, have played in their discoveries.

Huurdeman, Anton A. *The Worldwide History of Telecommunications*. Hoboken, N.J.: Wiley-IEEE, 2003. A comprehensive history of technical innovation in a number of telecommunications fields, including telegraphy, telephony, and satellite communications.

Ifrah, Georges. *The Universal History of Computing: From the Abacus to the Quantum Computer*. New

York: John Wiley & Sons, 2001. Traces the history of computing from the development of number writing up to 1654 to the modern information age. Illustrations, references, bibliography, index.

Israel, Paul. *Edison: A Life of Invention*. New York: John Wiley & Sons, 1998. Scholarly work that provides technical detail on Thomas Alva Edison's inventive work in the nineteenth century and some biographical details. Relies heavily on documents annotated and published by the Edison Papers Project in New Jersey. Illustrations, bibliography, index.

_______. *From Machine Shop to Industrial Laboratory: Telegraphy and the Changing Context of American Invention, 1820-1930*. Baltimore: The Johns Hopkins University Press, 1992. Discusses the impact of the invention of the telegraph. Bibliography, index, illustrations.

Johnson, Steven. *The Secret of Apollo: Systems Management in American and European Space Programs*. Baltimore: The Johns Hopkins University Press, 2006. A valuable resource for anyone interested in the space program, its business and management operations, or Cold War history.

Jones, Charlotte. *Accidents May Happen: Fifty Inventions Discovered by Mistake*. New York: Delacorte Books, 1996. In addition to cellophane, the author discusses Worcestershire Sauce, ice-cream floats, dynamite, and peanut brittle. Suitable for children from third to sixth grade.

Kane, Joseph Nathan. *Necessity's Child: The Story of Walter Hunt, America's Forgotten Inventor*. Jefferson, N.C.: McFarland, 1997. Posits that the story of Walter Hunt is the tragedy of an inventive genius who lacked business acumen to match his inventive prowess, resulting in many inventors gaining great wealth from his ideas. An appendix lists twenty-seven dates for patents granted to Hunt.

Keller, Julia. *Mr. Gatling's Terrible Marvel: The Gun That Changed Everything and the Misunderstood Genius Who Invented It*. New York: Viking Press, 2008. Beautifully written biography by a Pulitzer Prize-winning columnist for the *Chicago Tribune*. Much of the text puts Richard Gatling in the broader context of nineteenth century America, an age whose virtues Gatling embodied.

Kemper, Steve. *Code Name Ginger: The Story Behind Segway and Dean Kamen's Quest to Invent a New World*. Cambridge, Mass.: Harvard Business School Press, 2003. An intimate and honest first-person chronicling of the invention of the Segway PT.

Kessler, James H., J. S. Kidd, Renée A. Kidd, and Katherine A. Morin. *Distinguished African American Scientists of the Twentieth Century*. Phoenix, Ariz.: Oryx Press, 1996. Encyclopedic book covers the lives and accomplishments of one hundred African American scientists and inventors. Full of biographical data, arranged alphabetically and including a photograph of each profiled person. Written for young readers in clear and rather plain language.

Klein, Aaron E., and Cynthia L. Klein. *The Better Mousetrap: A Miscellany of Gadgets, Labor-Saving Devices, and Inventions That Intrigue*. New York: Beaufort Books, 1982. Provides a context for discussion of inventions by combining a history of progress in the United States with accounts of inventions at different periods throughout the country's history. Categories of inventions include farm equipment, factory machines, transportation items, scientific inventions, construction tools, household items, printing equipment, sewing machines, medical and dental equipment, firearms, clocks, and musical instruments.

Klemm, Friedrich. *A History of Western Technology*. Translated by Dorothea Waley Singer. London: Allen & Unwin, 1959. Traces the development of technology from the Greco-Roman world through twentieth century America. Includes some lesser-known inventions.

Knapp, Zondra. *Super Invention Fair Projects*. Los Angeles: Lowell House Juvenile, 2000. After identifying characteristics of great inventors, Knapp outlines steps in getting started on and planning a project, discusses research procedures and design materials, and ends with a discussion of patents and trademarks. Appendix contains a list of invention contests and competitions in the United States.

Korman, Richard. *The Goodyear Story: An Inventor's Obsession and the Struggle for a Rubber Monopoly*. San Francisco: Encounter Books, 2002. A biography about the man who created one of the most important industrial products in history.

Kranzberg, Melvin, and Carroll W. Pursell, Jr., eds. *The Emergence of Modern Industrial Society*. Vol. 1 in *Technology in Western Civilization*. New York: Oxford University Press, 1967. Tells the story of the development of technology in Western civilization from the beginning of mankind through 1900.

_______. *Technology in the Twentieth Century*. New York: Oxford University Press, 1967. Vol. 2 in *Technology in Western Civilization*. New York: Oxford

University Press, 1967. This volume details the development of technology during the first half of the twentieth century.

Kranzberg, Melvin, and William H. Davenport, eds. *Technology and Culture: An Anthology*. New York: Schocken Books, 1972. A collection of essays intended to encourage study of technological development and how it relates to culture and society. Four parts cover technology and society, technology and the humanities, humans and machines, and invention and innovation.

Landau, Elaine. *The History of Everyday Life*. Minneapolis, Minn.: Twenty-first Century Books, 2005. Written for young readers, this book discusses indoor plumbing, household appliances, and central heating, among other topics.

Laurenza, Domenico, Mario Tadei, and Edoardo Zanon. *Leonardo's Machines: Da Vinci's Inventions Revealed*. Cincinnati, Ohio: David & Charles, 2006. Using detailed diagrams and color illustrations, the authors show how Leonardo's inventions could have been constructed, how they would have functioned, and how they had an impact on subsequent inventors and inventions.

Lay, Maxwell G. *Ways of the World: A History of the World's Roads and of the Vehicles That Used Them*. New Brunswick, N.J.: Rutgers University Press, 1992. Engaging, comprehensive account of transportation and roadways. Accessible to general readers as well as professional engineers. Includes extensive notes, bibliography, index.

Lindsay, David. *House of Invention: The Secret Life of Everyday Products*. New York: Lyons Press, 2000. Organized according to location in a house, this lively and readable book introduces tidbits of information about inventors of everyday products found in the bathroom (disposable razor, Vaseline, hair straightener), the kitchen (frozen food, blender, breakfast cereal), the foyer (intercom, bank notes, locks and keys), the office (Musak, pencil), the garage (intermittent windshield wiper, standard screw thread), the family room (television, exercise machine, Solitaire), and the bedroom (brassiere, condom).

Loewe, Michael, and Edward L. Shaughnessy. *The Cambridge History of Ancient China: From the Origins of Civilization to 221 B.C.* New York: Cambridge University Press, 1999. Covers pre-imperial China in the Shang, Western Zhou, Spring and Autumn, and Warring States periods. Essays written on archaeology, agriculture, language and writing, art and architecture, and classical philosophy preceding the age of Confucius.

Lord, John. *Memoir of John Kay of Bury, Inventor of the Fly-Shuttle, with a Review of the Textile Trade and Manufacture from Earliest Times*. Rochdale, Manchester, England: J. Clegg, 1903. A celebratory account of Kay's allegedly revolutionary achievement, heavily dependent on Thomas Sutcliffe's propagandizing, which provided the source of most twentieth century biographical accounts.

Macdonald, Anne L. *Feminine Ingenuity: How Women Inventors Changed America*. New York: Ballantine Books, 1992. Traces the history of female inventors from early U.S. history through the twentieth century. Contrasts the kinds of inventions that women made early on with later inventions considered "beyond woman's sphere." Cites the struggles, the small victories in women's rights, and the setbacks experienced before some sense of gender equity was achieved. Details the process of obtaining patents. Appendix lists patents of inventors cited in the text. Bibliography.

McGrayne, Sharon Bertsch. *Nobel Prize Women in Science: Their Lives, Struggles, and Momentous Discoveries*. Secaucus, N.J.: Carol, 1993. Very readable and well-researched biographies of fourteen female scientists who overcame gender discrimination as both students and researchers to accomplish groundbreaking scientific work. Illustrated. Notes and index.

Mackenzie, Donald. *Inventing Accuracy: A Historical Sociology of Nuclear Missile Guidance*. Cambridge, Mass.: MIT Press, 1990. Based on archival documents and interviews with those working in the field. Author discusses the relevant technology and explains it in a nonmathematical way. Focuses on social and historical contexts.

McKinley, Burt. *African-American Inventors*. Portland, Oreg.: National Book Company, 2000. Short studies on black inventors that includes bibliographic references.

Maclaurin, William Rupert. *Invention and Innovation in the Radio Industry*. New York: Arno Press, 1971. Surveys technological advancements in the radio industry. Explores the causes for these developments and examines the impact of the new medium on American society.

Maier, Pauline, Merritt Roe Smith, Alexander Keyssar, and Daniel J. Kevles. *Inventing America: A History of the United States*. New York: W. W. Norton, 2003. Innovation is the basic theme of this revisionist account. Illustrated, with appendixes and index.

Margulis, Lynn, and Eduardo Punset, eds. *Mind, Life, and Universe: Conversations with Great Scientists of Our Time*. White River Junction, Vt.: Chelsea Green, 2007. The authors interviewed thirty-six scientists about their thoughts and ideas regarding some of the most important concepts influencing their fields today. An index and bibliographical references are included.

Molella, Arthur, and Joyce Bedi, eds. *Inventing for the Environment*. Lemelson Center Studies in Invention and Innovation. Cambridge, Mass.: MIT Press, 2003. Describes the ways in which innovations, broadly considered, affect the environment and public health.

Moore, A. D. *Invention, Discovery, and Creativity*. Garden City, N.Y.: Doubleday, 1969. Delves into the qualities and traits that promote invention and discovery, focusing in particular on characteristics of creative people. Offers tips for would-be inventors.

Morgan, Michael Hamilton. *Lost History: The Enduring Legacy of Muslim Scientists, Thinkers, and Artists*. Washington, D.C.: National Geographic, 2007. Morgan includes biographies of a variety of Muslim figures whose works would leave a mark on Western endeavors in fields as diverse as medicine, astronomy, and mathematics.

Mosley, Thomas E., Jr. *Marketing Your Invention*. Dover, N.H.: Upstart, 1992. Points out the difficulty, expense, and dangers of marketing an invention. Identifies characteristics of successful new products, discusses licensing, and suggests ten temperaments and habits that lead to "invention suicide," among which are paranoia, greed, impatience, procrastination, and a sense of omnipotence.

Nachmansohn, David. *German-Jewish Pioneers in Science, 1900-1930: Highlights in Atomic Physics, Chemistry, and Biochemistry*. New York: Springer-Verlag, 1979. While some familiar names appear, the book treats some of the amazing scientific discoveries of a number of lesser-known scientists in chemistry, biochemistry, and physiology in particular. Provides a historical background and ends with a chapter on the worldwide effects on biochemistry due to persecution and subsequent flight from Germany.

Naughton, John. *A Brief History of the Future: From Radio Days to Internet Years in a Lifetime*. Woodstock, N.Y.: Overlook Press, 2000. Surveys the great minds who contributed to the birth of the Internet. Glossary, index.

Nye, Mary Jo, ed. *The Cambridge History of Science*. New York: Cambridge University Press, 2003. An acclaimed series and international standard in the history of science.

Oleksy, Walter. *Hispanic-American Scientists*. New York: Facts On File, 1998. Brief biographical sketches with a few photos and a useful chronology.

Owen, David. *Copies in Seconds: How a Lone Inventor and an Unknown Company Created the Biggest Communication Breakthrough Since Gutenberg—Chester Carlson and the Birth of the Xerox Machine*. New York: Simon & Schuster, 2004. A lively account of Carlson's life and work based on interviews with his widow and previously inaccessible manuscripts.

Pacey, Arnold. *The Maze of Ingenuity: Ideas and Idealism in the Development of Technology*. New York: Holmes & Meier, 1975. Divides discussion into two parts: a chronological history of technology and ideas, and technological trends. An introduction defines concepts and terms.

Petroski, Henry. *The Evolution of Useful Things*. New York: Alfred A. Knopf, 1992. Discusses the invention of small items such as forks, paper clips, and small tools.

Pilato, Denise E. *The Retrieval of a Legacy: Nineteenth Century American Women Inventors*. Westport, Conn.: Praeger, 2000. Dedicated exclusively to female inventors of the nineteenth century, this work focuses on technological invention. Notes, bibliography, index.

Platt, Richard, *Eureka! Great Inventions and How They Happened*. Boston: Kingfisher, 2003. Platt examines the circumstances in which some of the world's best-known inventions were conceived and discusses the genius of their inventors.

_______. *Smithsonian Visual Timeline of Inventions*. New York: Dorling Kindersley, 1994. Provides chronologically ordered pictures and descriptions of more than 250 inventors and more than 400 of their inventions in addition to an illustrated time line of world events.

Pritchard, J. Laurence. *Sir George Cayley: The Inventor of the Aeroplane*. New York: Horizon Press, 1962. The first full biography of George Cayley, the "father of aviation." Chapter notes, index.

Purcell, Carroll, ed. *A Hammer in Their Hands: A Documentary History of Technology and the African American Experience*. Cambridge, Mass.: MIT Press, 2005. This scholarly publication provides a collection of primary sources that document African American technological achievements.

Ravage, Barbara. *George Westinghouse: A Genius for*

Invention. Austin, Tex.: Raintree Steck-Vaughn, 1997. An account of Westinghouse's life and inventions written with an adolescent audience in mind. A pioneer of the electrical industry, Westinghouse was a major rival of Thomas Alva Edison.

Rees, Fran. *Johannes Gutenberg: Inventor of the Printing Press*. Minneapolis, Minn: Compass Point Books, 2006. Offers a brief history of the printing press. Written in a fluid style, the book is aimed at young readers. Includes glossary, illustrations, maps, bibliography, and additional resources.

Reid, T. R. *Chip: How Two Americans Invented the Microchip and Launched a Revolution*. New York: Random House, 2001. A journalist's fashioning of the independent and nearly simultaneous invention of the microchip, told as a suspense thriller with all technical questions reduced to layperson's language. A masterpiece of science reporting by a nonscientist.

Reiser, Stanley Joel. *Medicine and the Reign of Technology*. New York: Cambridge University Press, 1981. Landmark treatise that lays out the fundamental arguments and issues of the new field of biomedical engineering. Investigates the relationship between revolutionary medical procedures and quality-of-life issues, medical costs, and religious biases. Thoughtful, provocative, and careful to avoid taking sides. Extensive bibliography.

Richardson, Jacques G., ed. *Windows on Creativity and Invention*. Mt. Airy, Md.: Lomond, 1988. The fifth of a series of UNESCO-generated books, this five-part volume contains twenty-five essays related to creativity and invention. Topics include the natural sciences, art, music, and the creative process.

Rijper, Els. *Kodachrome: The American Invention of Our World, 1939-1959*. New York: Delano Greenidge Editions, 2002. More than two hundred photos, originally taken with black-and-white film, are displayed with Kodachrome colorization. The book contains perspectives of American cities, personalities, sports, fashion, politics, and culture of the mid-twentieth century.

Romano, Frank J. *Machine Writing and Typesetting: The Story of Sholes and Mergenthaler and the Invention of the Typewriter and the Linotype*. Salem, N.H.: GAMA, 1986. Linking Ottmar Mergenthaler's Linotype with the concurrent invention of the typewriter by Christopher Latham Sholes supplies a larger context of the development of print technology at the end of the nineteenth century.

Rubik, Ernö, et al. *Rubik's Cubic Compendium*. New York: Oxford University Press, 1987. A collection of essays and exercises related to the Rubik's cube. One chapter by Rubik himself relates the events that led to his perfecting the cube.

Rubin, Susan Goldman. *Toilets, Toasters, Telephones: The How and Why of Everyday Objects*. New York: Harcourt, 1998. Although this is classified as a juvenile book, the history and description of eleven types of common household items would appeal to adults as well. Ample bibliography.

Rudy, Lisa Jo. *The Ben Franklin Book of Easy and Incredible Experiments*. Hoboken, N.J.: John Wiley & Sons, 1995. Includes a brief biographical sketch of Benjamin Franklin and provides interesting juvenile experiments involving weather, electricity, music, printing, light, and sound. Glossary and index.

Schatzkin, Paul. *The Boy Who Invented Television: A Story of Inspiration, Persistence, and Quiet Passion*. Vancouver, B.C.: Tanglewood Books, 2004. Biography that provides details of Philo T. Farnsworth's life, his inventive genius, and his challenges in life. Covers the technological developments that Farnsworth made, the funding he received for various television experiments, and his struggle for patent protection. Also explores how isolated inventors were fast being replaced by funded corporate laboratories during the 1930's. Bibliography, index.

Schwartz, Evan I. *Juice: The Creative Fuel That Drives World-Class Inventors*. Boston: Harvard Business School Press, 2004. A theoretical look at the process of inventing.

Shagena, Jack L. *Who Really Invented the Steamboat? Fulton's "Clermont" Coup*. Amherst, N.Y.: Humanity Books, 2004. Highly readable account of the work of several inventors and thinkers. Shagena gives useful background on patent law and steam power and carefully assesses the claims to primacy of eight inventors.

Shectman, Jonathan. *Groundbreaking Scientific Experiments, Inventions, and Discoveries of the Eighteenth Century*. Westport, Conn.: Greenwood Press, 2003. The introduction gives an overview of the eighteenth century interest in science; several essays discuss scientific discoveries, applications, and investigations to provide background on the impact of scientific advances, such as the Leiden jar, on social and political history.

Shulman, Seth. *Unlocking the Sky: Glenn Hammond Curtiss and the Race to Invent the Airplane*. New York: HarperCollins, 2002. The author vividly describes the legal wrangling between the Wright brothers, who laid claim to all technology related to powered flight, and Curtiss, who represented all of the other aircraft pioneers who felt that the Wrights were claiming innovations developed by others. A very readable account, the book ends with Curtiss's eventual triumph over the Wrights when he acquired their aircraft company.

Singer, Charles Joseph, E. J. Holmyard, and A. R. Holt, eds. *From Early Times to the Fall of Ancient Empires*. Vol. 1 in *A History of Technology*. Oxford, England: Clarendon Press, 1954. A collection of essays treats seven sections of the period covered: basic social factors, food collecting, domestic activities, specializing industries, utilization of metals, transportation, and preparation for science.

_______. *The Mediterranean Civilization and the Middle Ages, c. 700 B.C. to c. A.D. 1500*. Vol. 2 in *A History of Technology*. Oxford, England: Clarendon Press, 1956. Essays discuss mining, metallurgy, agriculture, food and drink, leather, spinning and weaving, furniture, ceramics, glass and glazes, and prescientific chemistry.

_______. *From the Renaissance to the Industrial Revolution*. Vol. 3 in *A History of Technology*. Oxford, England: Clarendon Press, 1957. Follows technological progress for this time period by focusing on five areas: primary production (food and drink, metallurgy and assaying, coal mining and utilization, windmills), manufacturing (tradesmen's tools, farm tools, vehicles and harnesses, spinning and weaving, and glass), material civilization (building construction, town planning, land drainage and reclamation, machines and mechanisms, military technology, printing), communications (bridges, canals, shipbuilding, cartography, and navigation), and approaches to science (calendars, precision instruments, mechanical timekeepers, chemical inventions).

_______. *The Industrial Revolution, c. 1750-c. 1850*. Vol. 4 in *A History of Technology*. Oxford, England: Clarendon Press, 1958. Divides the discussion into six areas: primary production (agricultural inventions and techniques, fish preservation, ferrous and nonferrous metal extraction), energy (steam engines, watermills), manufacture, static engineering (building and civil engineering, sanitation engineering), communication, and the scientific basis of technology.

_______. *The Late Nineteenth Century*. Vol. 5 in *A History of Technology*. Oxford, England: Clarendon Press, 1958. Eight sections outline technological developments in primary production, engines, electricity, chemical industry, transport, civil engineering, manufacturing, and technology at the threshold of the twentieth century. Includes a discussion of the consequences of technology.

Sluby, Patricia Carter. *The Inventive Spirit of African Americans: Patented Ingenuity*. Westport, Conn.: Praeger, 2004. Using a historical approach beginning with African creations, the book moves on to inventions made during the period of slavery in the United States, treating both enslaved and free persons of color. Notes inventions by African Americans that were important to the war effort during World War I and the "balm" that the Civil Rights era afforded African Americans in terms of being able to demonstrate their skills and creativity. A lengthy appendix contains a roster of African American patentees from 1821 through the mid-1990's.

Spangenburg, Ray, and Kit Moser. *African Americans in Science, Math, and Invention*. New York: Facts On File, 2003. Outlines the lives of 160 African American scientists since 1731, highlighting not only the challenges and difficulties the subjects encountered in their scientific pursuits but also the barriers to their formal education and training. Includes a bibliography, special categorical index, and black-and-white photographs.

Stableford, Brian. *Science Fact and Science Fiction: An Encyclopedia*. New York: Routledge, 2006. Focusing on the nineteenth century to the present, Stableford examines how science has influenced science fiction and vice versa.

Sullivan, Otha Richard, and James Haskins. *African American Women Scientists and Inventors*. New York: John Wiley & Sons, 2002. A simple, straightforward presentation of African American women who have influenced science and technology. Written for a juvenile audience.

Sutcliffe, Andrea. *Steam: The Untold Story of America's First Great Invention*. New York: Palgrave Macmillan, 2004. Traces the development of steam power and its effects on American society.

Swedin, Eric C., and David L. Ferro. *Computers: The Life Story of a Technology*. Westport, Conn.: Greenwood Press, 2005. Provides a succinct and readable overview, from early calculators to modern computers. Illustrations, bibliography, index.

Tang, Joyce. *Scientific Pioneers: Women Succeeding in Science*. Lanham, Md.: University Press of America, 2006. Analyzes the lives and careers of ten female scientists in the context of personal, cultural, political, and economic factors. Bibliography, index.

Taylor, Nick. *Laser: The Inventor, the Nobel Laureate, and the Thirty-Year Patent War*. New York: Simon & Schuster, 2000. A 304-page description of the thirty-year patent battle over the invention of the laser.

Thompson, Holland. *The Age of Invention: A Chronicle of Mechanical Conquest*. New Haven, Conn.: Yale University Press, 1921. One volume in a series devoted to American life, history, and progress. Includes an ample bibliography as well as photographs and illustrations.

Thomson, Janet. *The Scot Who Lit the World: The Story of William Murdoch, Inventor of Gas Lighting*. Glasgow, Scotland: Janet Thomson, 2003. Concise and very readable account of Murdock's life and creativity—not only his work on gas lighting but also his many other contributions to the advancement of technology and society. A chapter is devoted to some of his many lesser-known inventions. Bibliography, index, tourist guide.

Time. *Great Inventions: Geniuses and Gizmos—Innovation in Our Time*. New York: Time Books, 2003. Organizes discussion of dozens of inventions according to function: how we explore, move, communicate, record, eat, live, think, work, and play.

Tracy, Kathleen. *Willem Kolff and the Invention of the Dialysis Machine*. Bear, Del.: Mitchell Lane, 2002. Geared for high school readers, Tracy's work offers a clear and helpfully illustrated explanation of Kolff's original design and the evolution of his basic theory into the dialysis machines of today. Quite a heroic depiction of Kolff; stresses the difficult wartime conditions under which he worked.

Trevithick, Francis. *Life of Richard Trevithick, with an Account of His Invention*. 2 vols. Whitefish, Mont.: Kessinger, 2006. A reprint of the highly detailed justificatory biography written by Trevithick's eldest son, first published in 1872, which provided the primary source for later synoptic biographies.

Usher, Abbot Payson. *A History of Mechanical Inventions*. Rev. ed. New York: Dover, 1954. Places technology in the context of economic history and analyzes social change over time. Discusses ten categories of inventions from 150 B.C. to the early twentieth century.

Van Dulken, Stephen. *American Inventions: A History of Curious, Extraordinary, and Just Plain Useful Patents*. New York: New York University Press, 2004. Looks at the world of patents and how the products they register have helped to create the American Dream. In an easy, conversational style, Van Dulken discusses dozens of inventions, especially those in the areas of children's devices, sports equipment, entertainment, health, the home, and the office.

Vare, Ethlie Ann, and Greg Ptacek. *Patently Female: From AZT to TV Dinners—Stories of Women Inventors and Their Breakthrough Discoveries*. New York: John Wiley & Sons, 2002. Includes brief, interview-based articles on women inventors, including what it was like to be a female scientist in the mid-twentieth century. Photographs, time lines, list of organizations and online resources related to female inventors, index.

Webster, Raymond B. *African American Firsts in Science and Technology*. Foreword by Wesley L. Harris. Detroit, Mich.: Gale, 1999. These brief, chronologically ordered biographies—about twelve hundred of them—offer a broad survey of African American "firsts."

Weightman, Gavin. *Signor Marconi's Magic Box: The Most Remarkable Invention of the Nineteenth Century and the Amateur Inventor Whose Genius Sparked a Revolution*. Cambridge, Mass.: Da Capo Press, 2003. A well-told narrative useful for those interested in the history of radio.

Williams, Michael R. *A History of Computing Technology*. 2d ed. Los Alamitos, Calif.: IEEE Computer Society Press, 1997. Contains chapters describing the various technologies and machines that contributed to the development of the modern computer. Illustrations, further reading lists, index.

Williams, Trevor I. *The History of Invention*. New York: Facts On File, 1987. Arranged in five parts, this work moves from the beginning of civilization and the agricultural revolution to paper and printing; traces the beginning of mechanization and the birth of the chemical industry; and then moves on to the modern era with its changing patterns and needs. Discusses the post-World War II era and information technology. Biographical dictionary, bibliography, index.

_______, ed. *The Twentieth Century, c. 1900-c. 1950.* Part 1. Vol. 6 in *A History of Technology*. Oxford, England: Clarendon Press, 1978. Continues the work of Singer, et al., above. Puts twentieth century technological developments in the wider world context. Discusses sources of innovation, economics of technology, management, trade unions, role of government, education in industrialized societies, fossil fuels, natural sources of power, and atomic energy.

_______. *The Twentieth Century, c. 1900-c. 1950.* Part 2.

Vol. 7 in *A History of Technology*. Oxford, England: Clarendon Press, 1978. Continues part 1 with accounts of the development of the world transport market, road vehicles, ships and shipbuilding, railways, aircraft, navigation equipment, space technology, civil engineering projects, land reclamation, building and architecture, town planning, electrical engineering, food technology, and other categories of invention that affect quality of life.

Wilson, Mitchell. *American Science and Invention: A Pictorial History*. New York: Simon & Schuster, 1954. A large volume that relies on period illustrations and photographs to describe the course of American invention.

Windelspecht, Michael. *Groundbreaking Scientific Experiments, Inventions, and Discoveries of the Nineteenth Century*. Westport, Conn.: Greenwood, 2003. A book in a series spanning the modern centuries. Describes more than sixty major inventions of the nineteenth century.

Wood, Gaby. *Edison's Eve: A Magical History of the Quest for Mechanical Life*. New York: Alfred A. Knopf, 2002. Discusses automata and the history of lifelike machines. Illustrated, with index and bibliography.

Wullfson, Don L. *The Kid Who Invented the Popsicle: And Other Surprising Stories About Inventions*. New York: Cobblehill Books/Dutton, 1997. A book for young people that describes the stories behind more than one hundred inventions.

Wyckoff, Edwin Brit. *Laser Man: Theodore H. Maiman and His Brilliant Invention*. Berkeley Heights, N.J.: Enslow, 2007. Written as a tribute to Maiman and his inventive genius in the development of the first operable laser. Gives a clear explanation of laser operation that is suitable for young readers starting at the fourth-grade level.

Yount, Lisa. *Contemporary Women Scientists*. New York: Facts On File, 1994. Profiles ten women and the gender discrimination they faced in their careers. Illustrated, with bibliography and index.

Zierdt-Warshaw, Linda, ed. *American Women in Technology*. Santa Barbara, Calif.: ABC-CLIO, 2000. Presenting a wide range of historical milestones from all fields, including engineering, medical, and aerospace, this book chronicles women's contributions and achievements in technology. Biographical information, illustrations, and an ample index and appendix list the major contributions of women and the recognition they received from such quarters as the Nobel Prize and the Society of Women Engineers.
