A S T R O N O M Y

TS the knowledge of the nature and properties of the heavenly bodies; their magnitudes, distances, and motions, both real and apparent; together with the natural causes by which their revolutions are performed.

History of Astronomy.

It is probable that astronomy has existed almost from the beginning of the world. As there is nothing more surprising than the regularity of those great luminous bodies, that seem to turn incessantly round the earth, it is easy to judge, that one of the first curiosities of mankind was to consider their courses, and observe their periods. But it was not curiosity only that induced men to apply themselves to astronomical speculations: necessity itself may be said to have obliged them to it; for if the seasons are not observed, which are distinguished by the motion of the sun, it is impossible to succeed in agriculture. If the times proper for making voyages were not previously known, commerce could not be carried on. If the duration of the month and year were not determined, a certain order could not be established in civil affairs, nor the days allotted to the exercise of religion be fixed. Thus, as neither agriculture, commerce, polity, nor religion, could dispense with the want of astronomy, it is evident that mankind were obliged to apply themselves to that science from the beginning of the world.

What Ptolemy relates of the observations of the heavens, by which Hipparchus reformed astronomy almost 2000 years ago, proves sufficiently, that, in the most ancient times, this science was much studied.

It is agreed that astronomy was cultivated in a particular manner by the Chaldeans. The height of the tower of Babel, which the vanity of men erected about 150 years after the flood, the level and extensive plains of that country, the nights in which they breathed the fresh air after the troublesome heats of the day, an unbroken horizon, a pure and serene sky, all conspired to engage that people to contemplate the vast extent of the heavens, and the motions of the stars. From Chaldea astronomy passed into Egypt, and soon after was carried into Phœnicia, where they began to apply its speculative observations to the uses of navigation, by which the Phœnicians soon became masters of the sea and of commerce.

What made them bold in undertaking long voyages, was their custom of steering their ships by the observation of one of the stars of the little bear, which, be-

ing near the immoveable point of the heavens called the *pole*, is the most proper to serve as a guide in navigation. Other nations, less skilful in astronomy, observed only the great bear in their voyages: but as that constellation is too far from the pole to be capable of serving as a certain guide in long voyages, they did not dare to stand out so far to sea as to lose sight of the coasts; and if a storm happened to drive them into the ocean, or upon some unknown shore, it was impossible for them to know by the heavens into what part of the world the tempest had carried them.

Thales, having at length brought the science of the stars from Phœnicia into Greece, taught the Greeks to know the constellation of the little bear, and to make use of it as their guide in navigation. He also taught them the theory of the motion of the sun and moon, by which he accounted for the length and shortness of the days, determined the number of the days of the solar year, and not only explained the cause of eclipses, but shewed the art of predicting them, which he even reduced to practice, foretelling an eclipse which happened soon after. The merit of a knowledge so uncommon in those days, made him pass for the oracle of his times, and occasioned his being reckoned the first of the seven sages of Greece.

Anaximander was his disciple, to whom Pliny and Diogenes Laertius ascribed the invention of the terrestrial globe; or, according to Strabo, geographical maps. Anaximander is said also to have erected a gnomon at Sparta, by the means of which he observed the equinoxes and solstices, and to have determined the obliquity of the ecliptic more exactly than had ever been done before; which was necessary for dividing the terrestrial globe into five zones, and for distinguishing the climates, that were afterwards used by geographers for shewing the situation of all the places of the earth. The Greeks, assisted by the instructions they had received from Thales and Anaximander, ventured to make considerable voyages, and planted several colonies in remote countries.

Commerce having induced the learned men of Greece to visit other nations, they greatly increased their astronomical knowledge from conversing with the Egyptian priests, who had long made the science of the stars their profession. They also learned many things from the Pythagorean philosophers in Italy, who by some are said to have made so considerable a progress in this science, that they had rejected the common opinions, and

and asserted that the earth and planets moved round the sun, which was at rest in the centre of the system. But others affirm that Pythagoras only mentioned this as a conjecture, which he did not pretend to establish as a system.

Meton greatly distinguished himself at Athens by his profound knowledge in astronomy. He lived in the time of the Peloponnesian war; and was the inventor of the golden number, still placed in the calendar.

The Greeks also improved their knowledge from conversing with the druids, who, according to Julius Cæsar, instructed their pupils in the knowledge of the stars, and of the magnitudes of the heavenly bodies.

This species of learning was more ancient in Gaul than is generally imagined. Strabo has preserved a famous observation, made by Pytheas at Marseilles about 2000 years ago, with regard to the proportion of the sun's shadow to the height of a gnomon at the time of the solstice. Were the circumstances of this observation exactly known, it would be sufficient to resolve the important question, Whether the obliquity of the ecliptic be or be not subject to variation?

Pytheas was not contented with making observations in his own country. His passion for astronomy and geography induced him to travel through Europe, from the pillars of Hercules to the mouths of the Tanais. He also advanced along the shore of the western ocean, towards the north pole, and observed that the days grew longer about the summer solstice, in proportion as he travelled; so that, in the island of Thule, the sun rose almost as soon as it set, the tropic continuing entirely above the horizon. By this means he proved the fallacy of what some philosophers had advanced, namely, that those climates were not habitable; and at the same time shewed the method of distinguishing the climates by the length of the days and nights.

About the time of Pytheas, several of the Greeks applied themselves to astronomy in emulation of each other. Eudoxus, the disciple of Plato, not being satisfied with what was taught on that subject in the schools of Athens, repaired to Egypt, to cultivate astronomy at its source; and having a letter of recommendation from Agesilaus king of Sparta, to Nectanebus king of Egypt, he remained 16 months with the astronomers of that country. At his return, he composed several books upon astronomy; and, among others, a description of the constellations, which Aratus, some time after, turned into verse, by order of Antigonus.

Aristotle, the disciple of Plato, and the contemporary of Eudoxus, made use of astronomy for improving physics and geography. He attempted to determine, by means of astronomical observations, both the figure and magnitude of the earth. He demonstrated, that it was of a spherical form, by the circular appearance of its shadow on the disk of the moon in eclipses; and from the inequality of the meridian altitudes of the sun, which are different in different latitudes.

Callisthenes, who attended Alexander the Great, having been sent to Babylon, found there astronomical observations made by the Babylonians during the space of 1903 years, and sent them to Aristotle.

The princes who succeeded Alexander in the kingdom of Egypt were very careful to draw the most famous astronomers to their courts by their liberality; so that Alexandria soon became the seat of astronomy.

The famous Conon made a vast number of observations; but they have not reached our hands. Ariftyllus and Timoclares observed the places of the fixed stars, in order to improve navigation and geography. Eratosthenes measured a degree of the meridian, in order to determine the magnitude of the earth. Hipparchus, who also resided at Alexandria, laid the foundation for a methodical system of astronomy; for a new star happening to appear, he made a catalogue of the fixed stars, consisting of 1022. He also described their motion round the poles of the ecliptic, and at the same time applied himself to establish a theory of the solar and lunar motion.

The Romans, who aspired to the empire of the world, encouraged astronomy, and endeavoured to carry it nearer to perfection; and in the reign of Antoninus it began to assume a new face: for Ptolemy, who may be called the restorer of this science, improving from the lights of his predecessors, and adding the observations of Hipparchus, Timoclares, and those of the Babylonians, to his own, composed a system of astronomy, entitled, "The Great Syntaxis." It contained the theory and tables of the motion of the sun, moon, and other planets, and of the fixed stars.

But as the beginning of great works are never perfect, it is no wonder that Ptolemy's work was not free from errors and defects. Many ages, however, elapsed without any one's presuming either to correct or complete it. At last, the Arabian princes, having conquered the countries where astronomy had long flourished, procured the work of Ptolemy to be translated into their own language, and called it the *Almagest*. Nor did they stop here; they caused many observations to be made, by which it appeared, that the greatest declination of the sun was one-third of a degree less than what Ptolemy had made it; and that the motion of the fixed stars was not so slow as he believed it. They also ordered a large extent of country under the same meridian to be measured, in order to determine the length of a degree.

This example of the khalifs excited the princes of Europe to promote the improvement of astronomy. The emperor Frederic the second, willing that the Christians should understand astronomy as well as the Barbarians, caused the *Almagest* of Ptolemy to be translated from the Arabic into Latin; and Alfonso king of Castile assembled the most able astronomers from all parts. By his orders they applied themselves to reform astronomy, and compose new tables, which from him were called the *Alphonstine Tables*.

This work awakened the curiosity of the learned of Europe; they applied themselves to invent instruments for facilitating the observations of the heavenly bodies; they calculated ephemerides, and composed tables for finding the declinations of the planets; and laboured successfully to facilitate the calculation of eclipses. The noble Dane Tycho Brahe was a far more accurate observer than any that preceded him. He published from his own observations, a catalogue of 770 fixed stars; and Nicholas Copernicus revived the ancient Pythagorean system.

John Kepler, a most excellent astronomer, discovered, by the help of Tycho's labours, the true system of the world, and the laws that regulate the motion of the celestial bodies. Galileo, the Florentine philosopher,

pher, is commonly said to have first directed a telescope to the heavens, and by the assistance of that instrument discovered a great many new and surprising phenomena, as the satellites of Jupiter, and their motion, the various phases of Saturn, the increase and decrease of the light of Venus, the mountains and uneven surface of the moon, the spots of the sun, and the revolution of that luminary about its own axis. This honour, however, Dr Pricilly is of opinion, belongs to Zacharias Janfen, who was undoubtedly the first inventor of telescopes. He says, that, having directed his telescope toward the celestial bodies, he plainly discovered the spots of the moon, and several new stars; and that the full moon evidently appeared through this instrument not to be flat, but spherical, the middle part being prominent. Jupiter appeared round, and rather spherical. Sometimes, he said, he saw one, sometimes two, three, and at the most four small stars a little above or below him; and which, as far as he could observe, performed their revolutions round him; but that, he said, he left to the consideration of astronomers.

Hevelius has given us a catalogue of the fixed stars, much larger than that of Tycho, composed from his own curious observations. Huygens and Cassini first saw the satellites of Saturn, and discovered his ring. The indefatigable Mr Flamsteed watched the motion of the stars for more than 40 years; and has obliged the world with such accurate observations on the motions, &c. of the different luminaries, as will transmit his name to the latest posterity: he also published what is called the *Britannic catalogue of fixed stars*, containing above 3000 stars, from his own observations.

The merit of Sir Isaac Newton is too well known to need any encomium, and his discoveries too numerous to be particularly mentioned in this place. It is sufficient to say, that the science is perhaps more indebted to him than to all the other astronomers that ever existed.

The great Dr Halley has obliged the world with the astronomy of comets, a catalogue of the southern stars, astronomical tables, &c.

Other astronomical writers are, Albatengius, Sacro Bosco, Regio Montanus, Purbachius, Lansbergius, Longomontanus, Clavius, Boyer, Dr Hook, Ricciolus, Horrox, Sir Jonas Moore, Taquet, Bullialdus, Seth Ward, count Pagan, Wing, Street, De la Hire, Dr Gregory, Mercator, Whifton, Dr Keil, the two Cassini's, Leadbetter, Hodgson, Brent, Dr Long, the Abbe le Caille, Wright, Ferguson, De la Lande, &c.

Sect. I. *Of the apparent Motions, Magnitudes, and Changes, in the celestial Bodies, as seen by the naked eye.*

As the true motions of bodies at a great distance are to be gathered only from a careful observation of their apparent ones, it is absolutely necessary for those who want to become acquainted with the true motions of the heavenly bodies, to know perfectly the different changes which take place in the heavens as seen from this earth, the only place from which any observation can be made. By carefully attending to these, a little knowledge of optics will enable us to understand with great certainty not only the true system of nature, but also what appearance the heavens would make to a spectator placed in any part of the visible creation.

Vol. I.

The first and most obvious phenomenon is the daily rising of the sun in the east, and his setting in the west; after which the moon and stars appear, still keeping the same westerly course, till we lose sight of them altogether. This cannot be long taken notice of, before we must likewise perceive that neither the sun nor moon always rise exactly in the same point of the heavens. If we begin to observe the sun, for instance, in the beginning of March, we will find that he seems to rise almost every day sensibly more to the northward than he did the day before, to continue longer above the horizon, and to be more vertical at mid-day. This continues till towards the end of June, when he is observed to move backward in the same manner; and this retrograde motion continues to the end of December, or near it, when he begins again to move forwards, and so on.

The motion of the moon through the heavens, as well as her appearance at different times, are still more remarkable than those of the sun. When she first becomes visible at the time she is called the *new-moon*, she appears in the western part of the heavens, and seems to be at no great distance from the sun himself. Every night she not only increases in size, but removes to a greater distance from the sun, till at last she appears in the eastern part of the horizon, just at the time the sun disappears in the western. After this she gradually moves farther and farther eastward, and therefore rises every night later and later, till at last she seems to approach the sun as nearly in the east as she did in the west, and rises only a little before him in the morning, as in the first part of her course she set in the west not long after him. All these different appearances are completed in the space of a month, after which they begin in the same order as before. They are not, however, at all times regular; for at some seasons of the year, particularly in harvest, the moon appears for several days to be stationary in the heavens, and to recede no farther from the sun, in consequence of which she rises for that time nearly at the same hour every night.

In contemplating the stars, it is observed that some of them have the singular property of neither rising in the east, nor setting in the west; but seem to turn round one immoveable point, near which is placed a single star called the *pole* or *pole-star*. This point is more or less elevated according to the different parts of the earth from which we take our view. The inhabitants of Lapland, for instance, see it much more elevated above the horizon, or more vertical, than we do; we see it more vertical than it appears to the inhabitants of France and Spain; and they, again, see it more elevated than the inhabitants of Barbary. By continually travelling south, this star would at length seem depressed in the horizon, and another point would appear in the south part of the horizon, round which the stars in that quarter would seem to turn. In this part of the heavens, however, there is no star so near the pole as there is in the northern part, neither is the number of stars in the southern part of the heavens so great as in the northern. Supposing us still to travel southward, the north-pole would then entirely disappear, and the whole hemisphere would appear to turn round a single point in the south, as the northern hemisphere appears to us to turn round the pole-star.—The general appearance

Of the stars.

ance of the heavens, therefore, is that of a vast concave sphere, turning round two points fixed in the north and south parts of it, once in 24 hours.

⁴ Fixed stars, and planets.

When we further consider the stars, we will find the greatest part of them to keep their places with respect to one another; that is, if we observe two stars having a certain apparent distance from each other this night, we will observe them to have the same tomorrow, and every other succeeding night; but we will by no means observe them to have the same places either with respect to the sun or moon, as must be readily understood from what we have already said. Neither do all the stars in the heavens appear to be of this fixed kind. Some of them, on the contrary, change their places very remarkably with regard to the fixed stars, and with regard to one another. Of these there are only five, distinguished by the name of *planets*, (from *πλανω*, to err or wander), and called by the names of *Mercury, Venus, Mars, Jupiter, and Saturn*.

Mercury is a small star, but emits a very bright white light: though, by reason of his always keeping near the sun, he is seldom to be seen; and when he does make his appearance, his motion towards the sun is so swift, that he can only be discerned for a short time. He appears a little after sunset, and again a little before sunrise.

Venus, the most beautiful star in the heavens, known by the names of the *morning* and *evening star*, likewise keeps near the sun, though he recedes from him almost double the distance of Mercury. In consequence of this property she is never seen in the eastern quarter of the heavens when the sun is in the western; but always seems to attend him in the evening, or to give notice of his approach in the morning.

Mars is of a red fiery colour, and always gives a much duller light than Venus, though sometimes he equals her in size. He is not subject to the same limitation in his motions as Mercury or Venus; but appears sometimes very near the sun, and sometimes at a great distance from him; sometimes rising when the sun sets, or setting when he rises. Of this planet it is remarkable, that when he approaches any of the fixed stars, which all the planets frequently do, these stars change their colour, grow dim, and often become totally invisible, though at some little distance from the body of the planet.

Jupiter and Saturn likewise often appear at great distances from the sun. The former shines with a bright light somewhat reddish, and the latter with a pale faint one; and the motion of Saturn among the fixed stars is so slow, that, unless carefully observed, he will not be thought to move at all.

Besides the motions which we observe in all these planets, their apparent magnitudes are very different at different times. Every person must have observed that Venus, though she constantly appears with great splendour, is not always equally big. But this apparent difference of magnitude is most remarkable in the planet Mars, which sometimes appears no less than 25 times larger than at others. This increase of magnitude is likewise very remarkable in Jupiter, but less so in Saturn and Mercury.

Though we have thus described the motions of the planets, with respect to their apparent distances from

the sun, they by no means appear to us to move regularly in the heavens, but, on the contrary, in the most complex and confused manner that can be imagined, sometimes going forward, sometimes backward, and sometimes seeming to be stationary. Plate XLIV. fig. 2. represents the apparent paths of Mercury and Venus, as traced by Cassini and Mr Ferguson. They all seem to describe looped curves; but it is not known when any of these curves would return into themselves, except that of Venus, which returns into itself every eighth year. In the figure referred to, that which has the fewest loops is the apparent path of Venus, the other that of Mercury. On each side of the loops they appear stationary; in that part of each loop near the earth, retrograde; and in every other part of their path, direct.

These, however, are not the only moving bodies which are to be observed in the celestial regions. The five above mentioned are indeed the only ones which appear almost constantly, or disappear only at certain intervals, and then as certainly return. But there are others which appear at uncertain intervals, and with a very different aspect from the planets. These are called *Comets*, from their having a long tail, somewhat resembling the appearance of hair. This, however, is not always the case; for some comets have appeared which were as well defined and as round as planets: but in general they have a luminous matter diffused around them, or projecting out from them, which to appearance very much resembles the Aurora Borealis. When these appear, they come in a direct line towards the sun, as if they were going to fall into his body; and after having disappeared for some time in consequence of their proximity to that luminary, they fly off again on the other side as fast as they came, projecting a tail much greater and brighter in their recede from him than when they advanced towards him; but, getting daily at a farther distance from us in the heavens, they continually lose of their splendour, and at last totally disappear. Their apparent magnitude is very different: sometimes they appear only of the bigness of the fixed stars; at other times they will equal the diameter of Venus, and sometimes even of the sun or moon themselves. So, in 1652, Hevelius observed a comet which seemed not inferior to the moon in size, though it had not so bright a splendour, but appeared with a pale and dim light, and had a dismal aspect. These bodies will also sometimes lose their splendour suddenly, while their apparent bulk remains unaltered. With respect to their apparent motions, they have all the inequalities of the planets; sometimes seeming to go forwards, sometimes backwards, and sometimes to be stationary.

Though the fixed stars are the only marks by which astronomers are enabled to judge of the courses of the moveable ones, and though they have never been observed to change their places, yet they seem not to be ended with the permanency even of the earth and planets, but to be perishable or destructible by accident, and likewise generable by some natural cause. Several stars observed by the ancients are now no more to be seen, but are destroyed; and new ones have appeared, which were unknown to the ancients. Some of them have also disappeared for some time, and again become visible. Of these, a very remarkable one is mentioned by Dr Keil, in that part of the heavens

⁷ Comets.

⁸ Fixed stars seemingly destructible and generable.

⁵ Apparent magnitudes of the planets different at different times.

⁶ Their irregular motion.

called the *neck of the whale*; which for eight or nine months of the year withdrew itself from the sight, and for the other three or four months was constantly changing its lustre and bigness. Its appearances were attended with the greatest irregularities; sometimes it appeared much smaller than at others; sometimes it disappeared in three months, and sometimes appeared for four months; nor did the increase or decrease of its magnitude answer to the difference of the times of its appearance.

We are also assured from the observations of astronomers, that some stars have been observed which never were seen before, and for a certain time they have distinguished themselves by their superlative lustre; but afterwards decreasing, they vanished by degrees, and were no more to be seen. One of these stars being first seen and observed by Hipparchus, the chief of the ancient astronomers, set him upon composing a catalogue of the fixed stars, that by its posterity might learn whether any of the stars perish, and others are produced afresh.

After several ages, another new star appeared to Tycho Brahe and the astronomers that were cotemporary with him; which put him on the same design with Hipparchus, namely, the making a catalogue of the fixed stars. Of this, and of the other stars which have appeared since that time, we have the following history by Dr Halley: "The first new star in the chair of Cassiopeia, was not seen by Cornelius Gemma on the eighth of November 1572, who says, he that night considered that part of the heaven in a very serene sky, and saw it not: but that the next night, November 9, it appeared with a splendour surpassing all the fixed stars, and scarce less bright than Venus. This was not seen by Tycho Brahe before the 11th of the same month: but from thence he assures us that it gradually decreased and died away, so as in March 1574, after sixteen months, to be no longer visible; and at this day no signs of it remain. The place thereof in the sphere of fixed stars, by the accurate observations of the same Tycho, was $0^{\circ} 9' 17''$ a $1^{\text{m}} 8^{\text{s}}$, with $53^{\circ} 45'$ north latitude.

"Such another star was seen and observed by the scholars of Kepler, to begin to appear on Sept. 30. *β. vet.* anno 1604, which was not to be seen the day before: but it broke out at once with a lustre surpassing that of Jupiter; and like the former, it died away gradually, and in much about the same time disappeared totally, there remaining no footsteps thereof in January 1605. This was near the ecliptic, following the right leg of Serpentarius; and by the observations of Kepler and others, was in $7^{\circ} 20' 00''$ a $1^{\text{m}} 8^{\text{s}}$, with north latitude $1^{\circ} 56'$. These two seem to be of a distinct species from the rest, and nothing like them has appeared since.

"But between them, *viz.* in the year 1596, we have the first account of the wonderful star in Collo Ceti, seen by David Fabricius on the third of August, *β. vet.* as bright as a star of the third magnitude, which has been since found to appear and disappear periodically, its period being precisely enough seven revolutions in six years, tho' it returns not always with the same lustre. Nor is it ever totally extinguished, but may at all times be seen with a six-foot tube. This was singular in its kind, till that in Collo Cygni was discovered. It pre-

cedes the first star of Aries $1^{\circ} 40'$, with $15^{\circ} 57'$ south latitude.

"Another new star was first discovered by William Janfonius in the year 1600, in *pectore*, or rather in *eductione*, Colli Cygni, which exceeded not the third magnitude. This having continued some years, became at length so small, as to be thought by some to have disappeared entirely: but in the years 1657, 58, and 59, it again arose to the third magnitude; though soon after it decayed by degrees to the fifth or sixth magnitude, and at this day is to be seen as such in $9^{\circ} 18' 38''$ a $1^{\text{m}} 8^{\text{s}}$, with $55^{\circ} 29'$ north latitude.

"A fifth new star was first seen by Hevelius in the year 1670, on July 15. *β. vet.* as a star of the third magnitude, but by the beginning of October was scarce to be perceived by the naked eye. In April following it was again as bright as before, or rather greater than of the third magnitude, yet wholly disappeared about the middle of August. The next year, in March 1672, it was seen again, but not exceeding the sixth magnitude: since when, it has been no further visible, though we have frequently sought for its return; its place is $9^{\circ} 3' 17''$ a $1^{\text{m}} 8^{\text{s}}$, and has lat. north $47^{\circ} 28'$.

"The sixth and last is that discovered by Mr G. Kirch in the year 1686, and its period determined to be of $404\frac{1}{2}$ days; and though it rarely exceeds the fifth magnitude, yet it is very regular in its returns, as we found in the year 1714. Since then we have watched, as the absence of the moon and clearness of the weather would permit, to catch the first beginning of its appearance in a six-foot tube, that, bearing a very great aperture, discovers most minute stars. And on June 15, last, it was first perceived like one of the very least telescopic stars: but in the rest of that month and July, it gradually increased, so as to become in August visible to the naked eye; and so continued all the month of September. After that, it again died away by degrees; and on the eighth of December, at night, was scarce discernible by the tube; and, as near as could be guessed, equal to what it was at its first appearance on June 25: so that this year it has been seen in all near six months, which is but little less than half its period: and the middle, and consequently the greatest brightness, falls about the 10th of September."

Concerning the changes which happen among the fixed stars, Mr Montanere, professor of mathematics at Bononia, gave the following account, in a letter to the Royal Society, dated April 30th, 1670. "There are now wanting in the heavens two stars of the second magnitude in the stem of the ship Argo, and its yard; Bayerus marked them with the letters β and γ . I, and others, observed them in the year 1664, upon the occasion of the comet that appeared that year: when they disappeared first, I know not: only I am sure that in the year 1668, upon the 10th of April, there was not the least glimpse of them to be seen; and yet the rest about them, even of the third and fourth magnitudes, remained the same. I have observed many more changes among the fixed stars, even to the number of an hundred, though none of them are so great as those I have shewed."

A very remarkable appearance in the heavens is that called the *galaxy* or *milky-way*. This is a broad milky-way circle, sometimes double, but for the most part single; surrounding the whole celestial concave. It is of a

whitish colour, somewhat resembling a faint Aurora Borealis; but Mr Brydone, in his journey to the top of mount *Ætna*, found that phenomenon to make a glorious appearance, being, as he expresses it, like a pure flame that shot across the heavens*.

* See the article *Ætna*.
12
Eclipses.

The only appearances, besides those already mentioned, which are very observable by the unassisted eye, are those unexpected obscurations of the sun and moon, commonly called *eclipses*. These are too well known, and attract the attention too much, to need any particular description. We have, however, accounts very well authenticated, of obscurations of the sun continuing for a much longer time than a common eclipse possibly can do, and likewise of the darkness being much greater than it usually is on such occasions; and that these accounts are probably true, we shall afterwards have occasion to observe.

Sect. II. *Of the Appearances of the Celestial Bodies through Telescopes.*

13
Why the celestial bodies appear dim through telescopes.

By means of this instrument we are enabled in some measure to ascend into the celestial regions, and view the sun, moon, and stars, as they would appear to us if we were brought as many times nearer to them as the telescope magnifies, provided the light proceeding from the luminary we view was diminished in the same proportion. Thus, supposing we view the moon through a telescope magnifying 1000 times, her face will appear 1000 times bigger to us than it does to our naked eye, and we will perceive vast numbers of spots in it which are imperceptible to our naked eye: but then she will also appear 1000 times more dim through the telescope than she does to the naked eye; so that those who look at her through a telescope for the first time, will be greatly disappointed, if they are not warned of this diminution of light. The reason of this is, that the telescope cannot increase the quantity of light which falls upon itself from the moon, and by which only she is or can be visible to us. This quantity of light, however, is by the magnifying powers of the telescope spread over a proportionally large surface; and therefore the moon or other body appears magnified indeed, but with a splendor vastly inferior to that with which she appears to the naked eye.

Hence we may see, that the advantages arising from telescope, with regard to the giving us a near view of the celestial bodies, are not near so great as one would at first imagine: for though we should suppose a telescope capable of magnifying 240,000 times, by which we could see the moon at the distance of only a single mile, we could only have this view with a light 240,000 times less than the moon at present affords us; and how imperfectly objects at the distance of a mile could be seen by such a light, any one may easily imagine. We are not, however, to imagine, that the light here spoken of would be 240,000 times less than moon-light; it would only be 240,000 times less than that wherewith she appears illuminated at present. The moon, we know, is enlightened by the sun, as well as the earth is; and could the telescope increase the quantity of light as much as it does the apparent surface, we would, with a telescope magnifying 240,000 times, see all objects in the moon as well as we do terrestrial objects at a mile's distance when the sun shines bright-

ly: but by reason of this incapacity of the telescope to increase the quantity of light, we could only see the lunar objects as well as we would do terrestrial ones a mile distant, with a light 240,000 times less than the light of the sun, or with a light little better than moon-light; for the light of the sun is computed to be 300,000 times stronger than that of the moon.

What we have here said of the moon is applicable to all the other celestial bodies, but not in the same degree. If we look at the sun, for instance, whose lustre is too great for our naked eye to bear, supposing the telescope to magnify as many millions of times as there are miles between us and the sun, we would perceive objects in him as distinctly as could be done at the distance of a mile, not with the light of sunshine upon this earth, but with that intense light which is emitted from the sun at a mile's distance from his body. This is on the supposition that the telescope could increase the quantity of the light as well as magnify the apparent surface; but, being destitute of this power, the light with which the sun would be seen through such a telescope is as many millions of times less than the above-mentioned intense light, as the number of times the telescope magnifies, and which, according to the latest calculations, behaved to be upwards of 95 millions. It must be observed, however, that no telescopes ever have been, or probably ever will be, invented, whose magnifying powers are so great as either of those we have mentioned. The greatest magnifying power we have yet heard of in any telescope is in one made by the late Mr James Short, which magnifies 1,200 times; and, by having another applied to it, is said to magnify 60,000 times.

From these considerations it will be apparent, that our telescopic views of the celestial objects can be but imperfect, and that conjectures drawn from them must be very vague and uncertain. It is also plain, that, *ceteris paribus*, our views of Venus and Mercury, the planets nearest the sun, ought to be more distinct than of the more remote ones, Mars, Jupiter, and Saturn; because Venus and Mercury are much more strongly illuminated than the others: but this is not found to hold in fact; which is very surprising, as a strong light ought to be much farther and more strongly reflected from any object than a weak one. The general appearances of each of the celestial bodies, when viewed with the best telescopes, the large one by Mr Short above-mentioned excepted, are as follow.

1. The sun, when viewed with but an ordinary instrument, and sometimes through a piece of smoked glass without any telescope, discovers on his surface numbers of black, or rather less bright, spots, of various shapes and sizes. Sometimes these spots will vanish in a very short time from their first appearance; sometimes they travel over his whole disk, or visible surface, from west to east, when they disappear; and in 12 or 13 days they appear again, so as to be known, by their size and shape, to be the same that formerly disappeared. Those, however, which are of the longest continuance, never appear to have any durability or solidity of consistence, but soon vanish and become bright like the rest of the surface.

The most remarkable phenomena of these spots have been remarked by Scheiner and Hevelius, and are as follow. 1. Every spot, which hath a nucleus, or con-

14
Spots on the sun discovered by telescopes.

15
Account of their phenomena by Scheiner & Hevelius.

siderably

siderably dark part, hath also an umbra, or fainter shade, surrounding it. 2. The boundary betwixt the nucleus and umbra is always distinct and well defined. 3. The increase of a spot is gradual, the breadth of the nucleus and umbra dilating at the same time. 4. In like manner, the decrease of a spot is gradual, the breadth of the nucleus and umbra contracting at the same time. 5. The exterior boundary of the umbra never consists of sharp angles; but is always curvilinear, how irregular soever the outline of the nucleus may be. 6. The nucleus of a spot, whilst on the decrease, often changes its figure by the umbra encroaching irregularly upon it, inasmuch that in a small space of time new encroachments are discernible, whereby the boundary betwixt the nucleus and umbra is perpetually varying. 7. It often happens, by these encroachments, that the nucleus of a spot is divided into two or more nuclei. 8. The nuclei of spots vanish sooner than the umbra. 9. Small umbrae are often seen without nuclei. 10. An umbra of any considerable size is seldom seen without a nucleus in the middle of it. 11. When a spot which consisted of a nucleus and umbra is about to disappear, if it is not succeeded by a *facula*, or spot brighter than the rest of the disk, the place where it was is soon after not distinguishable from the rest.

16
By Dr Wilson of Glasgow.

In the Philosophical Transactions, Vol. LXIV. Dr Wilson, professor of astronomy at Glasgow, hath given a dissertation on the nature of the solar spots, and mentions the following appearances. 1. When the spot is about to disappear on the western edge of the sun's limb, the eastern part of the umbra first contracts, then vanishes, the nucleus and western part of the umbra remaining; then the nucleus gradually contracts and vanishes, while the western part of the umbra remains. At last this disappears also; and if the spot remains long enough to become again visible, the eastern part of the umbra first becomes visible, then the nucleus; and when the spot approaches the middle of the disk, the nucleus appears environed by the umbra on all sides, as already mentioned. 2. When two spots lie very near to one another, the umbra is deficient on that side which lies next the other spot: and this will be the case, though a large spot should be contiguous to one much smaller; the umbra of the large spot will be totally wanting on that side next the small one. If there are little spots on each side of the large one, the umbra does not totally vanish; but appears flattened, or pressed in towards the nucleus on each side. When the little spots disappear, the umbra of the large one extends itself as usual. This circumstance, he observes, may sometimes prevent the disappearance of the umbra in the manner above-mentioned; so that the western umbra may disappear before the nucleus, if a small spot happens to break out on that side.

17
By Mr Wollaston.

In the same volume, p. 337. Mr Wollaston observes, that the appearances mentioned by Dr Wilson are not constant. He positively affirms, that the *faculae* or bright spots on the sun are often converted into dark ones. "I have many times (says he) observed, near the eastern limb, a bright *facula* just come on, which has the next day shewn itself as a spot, though I do not recollect to have seen such a *facula* near the western one after a spot's disappearance. Yet I believe, both these circumstances have been observed by others; and perhaps not only near the limbs. The circumstance

of the *faculae* being converted into spots I think I may be sure of. That there is generally (perhaps always) a mottled appearance over the face of the sun, when carefully attended to, I think I may be as certain. It is most visible towards the limbs, but I have undoubtedly seen it in the centre; yet I do not recollect to have observed this appearance, or indeed any spots, towards his poles. Once I saw, with a 12 inch reflector, a spot burst to pieces while I was looking at it. I could not expect such an event, and therefore cannot be certain of the exact particulars: but the appearance as it struck me at the time was like that of a piece of ice when dashed on a frozen pond, which breaks to pieces and slides in various directions." He also acquaints us, that the nuclei of the spots are not always in the middle of the umbra; and gives the figure of one seen November 13th 1773, which is a remarkable instance to the contrary. Mr Dunn, however, in his new Atlas of the mundane system, gives some particulars very different from the above. "The face of the sun (says he) has frequently many large black spots, of various forms and dimensions, which move from east to west, and round the sun, according to some observations in 25 days, according to others in 26, and according to some in 27 days. The black or central part of each spot is in the middle of a great number of very small ones, which permit the light to pass between them. The small spots are scarce ever in contact with the central ones: but what is most remarkable, when the whole spot is near the limb of the sun, the surrounding small ones form nearly a straight line, and the central part projects a little over it, like Saturn in his ring."

3^d Plate
XLII. fig. 6.
18
Mr Dunn's account.

The spots are by no means confined to one part of the sun's disk; though we have not heard of any being observed about his polar regions: and though their direction is from east to west, yet the paths they describe in their course over the disk are exceedingly different; sometimes being straight lines, sometimes curves, sometimes descending from the northern to the southern part of the disk, sometimes ascending from the southern to the northern, &c. This was observed by Mr Derham, (Philos. Trans. N^o. 330.) who hath given figures of the apparent paths of many different spots, wherein the months in which they appeared, and their particular progress each day, are marked.

Besides these spots, there are others which sometimes appear very round and black, travelling over the disk of the sun in a few hours. They are totally unlike the others, and will be shewn to proceed from an interposition of the planets Mercury and Venus between the earth and the sun. Excepting the two kinds of spots above-mentioned, however, no kind of object is discoverable on the surface of the sun, but he appears like an immense ocean of elementary fire or light.

1^d Plate
XLII. fig. 1.

2. With the moon the case is very different. Many darkish spots appear in her to the naked eye; and, through a telescope, their number is prodigiously increased: she also appears very plainly to be more protuberant in the middle than at the edges, or to have the figure of a globe, and not a flat circle. This protuberance, or globular figure, may also be perceived in some degree by the naked eye, when she does not shine very bright. When the moon is horned or gibbous, the one side appears very ragged and uneven,

19
Telescopic view of the moon.

but

but the other always exactly defined and circular. The spots in the moon always keep their places exactly; never vanishing, or going from one side to the other, as those of the sun do.

The astronomers Florentius, Langrenus, John Hevelius of Dantzic, Grimaldus, and Ricciolus, have drawn the face of the moon as she is seen through telescopes magnifying between two and 300 times. Particular care has been taken to note all the shining parts in her surface; and, for the better distinguishing them, each has been marked with a proper name. Langrenus and Ricciolus have divided the lunar regions among the philosophers, astronomers, and other eminent men; but Hevelius, fearing lest the philosophers should quarrel about the division of their lands, has spoiled them of their property, and given the names belonging to different countries, islands, and seas on earth, to different parts of the moon's surface, without regard to situation or figure.

We have already observed, that when the planet Mars approaches any of the fixed stars, they lose their light, and sometimes totally disappear before he seems to touch them: but it is not so with the moon; for though she very often comes in betwixt us and the stars, they preserve their lustre till immediately in seeming contact with her, when they suddenly disappear, and as suddenly re-appear on the opposite side. When Saturn, however, was hid by the moon in June 1762, Mr Dunn, who watched his appearance at the emerſion, observed a kind of faint shadow to follow him for a little from the edge of the moon's disk. This appearance is represented 6th Plate XLII. fig. 2.

3. Mercury, when looked at through telescopes magnifying about 200 or 300 times, appears equally luminous throughout his whole surface, without the least dark spot. He appears indeed to have the same difference of phases with the moon, being sometimes horned, sometimes gibbous, and sometimes shining with a full round face; but at all times perfectly well defined, without any ragged edge, and very bright.

4. Venus puts on the same appearances with the Moon, or with Mercury; only she is not so bright as the latter. Spots have sometimes been seen in her, which appeared of the nature of those in the sun; others have been observed more permanent. In 1666, October 14th, Mr Cassini observed, towards the middle of the disk of this planet, a part more luminous than the rest, and two dark spots to the westward of it. He could make nothing of his observations at that time, nor had he any opportunity of observing the spots again till April 28th 1667. At this time Venus had an horned appearance, and a quarter of an hour before sun-rising the bright spot was distant from the southern horn little more than $\frac{1}{2}$ of its diameter. Near the eastern part of the circumference he saw an oblong spot, which was nearer to the northern than the southern horn. At the rising of the sun, he perceived the bright part distant from the southern horn by $\frac{1}{2}$ of its diameter; so that it was plainly moving from south to north. He was very much surprised, however, to find, that though this spot appeared to move from south to north while it remained on the southern part of the disk, yet, when he saw it on the northern part, it was plainly moving from north to south. From frequent observation, he imagined that this bright spot finished its mo-

tion, and returned to the same place of the disk from whence it set out, in about 23 hours, though not without some irregularity. The same irregular motion he observed in the obscure spots. In 1672 and 1686, with a telescope 54 feet long, Mr Cassini thought he saw a moon, or satellite, belonging to this planet, and having the same phases with Venus herself, but not so well defined. It was not above $\frac{1}{2}$ of the diameter of Venus distant from her body. Mr Short also made the like observation some years ago.

5. Mars viewed through a telescope, sometimes appears gibbous, but never horned. He has one very large spot in his disk, which at different times changes its figure, as well as shifts its place. Dr Hook observed this spot carefully in 1665, and Mr Cassini in 1666; and the latter, by diligently continuing his observations, found it to return to the same place in the space of 24 hours and 40 minutes. Through a 36 foot telescope, made use of by Dr Hook, this planet appeared almost as big as the full moon. The phases are represented 4th Plate XLII. fig. 3.

Besides these spots, Mars sometimes appears to have darkish fillets or belts along his disk, which are called *fasciæ*, and appear parallel to his equator. The fixed stars which he approaches, suffer the same diminution of their light when observed through a telescope, as when seen by the naked eye.

6. Jupiter has the same general appearance with Mars; only that the fixed stars never suffer any diminution of light by his approaching them. In 1666, Mr Hook observed the body of Jupiter through a telescope 60 feet long, and found the apparent diameter to be about four times as great as that of the full moon. This planet has more remarkable and more distinct fasciæ than Mars, which are terminated by parallel lines. They do not, however, appear to be permanent substances, being often interrupted and broken, and sometimes vanishing entirely. In some of these belts large black spots have appeared, which moved swiftly over the disk from east to west, and returned again to the same place; those nearest the planet's equator in nine hours 56 minutes; and those nearer the poles, according to Dr Smith, in 9 hours and 50 minutes. In 1665, Mr Cassini saw a very large spot in one of Jupiter's belts, which he observed continually for the space of two years, and determined exactly the time of its appearance and disappearance. In 1672, he observed it to return to the same place from whence it had set out in one night, having had an opportunity of viewing Jupiter during 10 hours that night, and thus thoroughly ascertained himself of the exact time it took. In 1677, this spot vanished, and was not seen again till 1679; afterwards, for the space of almost three years, it continually shewed itself, and then gradually vanished; and since that time has frequently appeared and disappeared. From the year 1665, in which it first appeared, to the year 1708, it appeared and vanished no fewer than eight times. The apparent motion of these spots over the disk is very unequal when they first appear; on the eastern limb of the disk, their motion is slow, and they appear narrow; but, as they advance towards the middle, they grow broader, and their motion becomes much quicker; and when they approach the western limb, they again change their figure, and move more slowly. The belts undergo several changes with-

out being broken; sometimes becoming narrower, sometimes increasing in breadth, sometimes advancing towards each other, sometimes receding, &c.

What is most remarkable of this planet is, that it is attended by four satellites or moons, which evidently circulate round it; as they sometimes recede a little from, and then come nearer to, the disk; sometimes are hid behind the body of the planet, and then appear again on the other side, receding to a little distance, then come near and pass over it: and it is observed that when they pass between us and the disk of Jupiter, they often resemble black round spots, like Mercury and Venus passing over the disk of the sun; their shadows in the mean time travelling over the disk like other spots, having the same appearance, and marching either before or behind the satellites according to the situation of the earth and Jupiter with respect to the sun. With good telescopes, black spots have also been observed on the disks of these secondary planets themselves.

24
His four moons.

25
Saturn, with his ring and satellites.

7. Saturn, the most remote of all the planets, makes a still more remarkable appearance; being encompassed with a luminous ring, represented 2^d Plate XLII. fig. 1. and Plate XLIII. fig. 5. This ring appears double when seen thro' good telescopes, as represented in the figures, and keeps always parallel to itself; by which means it disappears once every fifteen years, according to the situation of the earth and Saturn with regard to the Sun. The reason of its disappearance is, that it is turned edge-wise to us, when its thinness renders it invisible. When it begins to turn its edge towards us, it appears somewhat thicker on one side than another, and the thickest edge has been observed on different sides of the planet. On the body of Saturn, facie have likewise been sometimes seen, but much more obscurely than those of Mars or Jupiter; and no dark spots have ever been observed on his surface. This planet is attended by five moons, whose general appearances resemble those of Jupiter; only they are more obscure, and require better telescopes to discover them on account of their great distance.

26
Of the comets.

8. The Comets, viewed through a telescope, have a very different appearance from any of the planets. The nucleus, or star, seems much more dim. Sturmius tells us, that observing the comet of 1680 with a telescope, it appeared like a coal dimly glowing; or a rude mass of matter illuminated with a dusky smoky light, less sensible at the extremes than in the middle; and not at all like a star, which appears with a round disk and a vivid light.

Hevelius observed of the comet in 1661, that its body was of a yellowish colour, bright and conspicuous, but without any glittering light. In the middle was a dense ruddy nucleus, almost equal to Jupiter, encompassed with a much fainter, thinner matter.—Feb. 5th. The nucleus was somewhat bigger and brighter, of a gold colour, but its light more dusky than the rest of the stars; it appeared also divided into a number of parts.—Feb. 6th. The nuclei still appeared, though less than before. One of them on the left side of the lower part of the disk appeared to be much denser and brighter than the rest; its body round, and representing a little lucid star; the nuclei still encompassed with another kind of matter.—Feb. 10th. The nuclei more obscure and confused, but brighter

at top than at bottom.—Feb. 13th. The head diminished much both in brightness and in magnitude.—March 2^d. Its roundness a little impaired, and the edges lacerated.—March 28th. Its matter much dispersed; and no distinct nucleus at all appearing.

Weigelius, who saw through a telescope the comet of 1664, the moon, and a little cloud illuminated by the sun, at the same time; observed that the moon appeared of a continued luminous surface, but the comet very different, being perfectly like the little cloud enlightened by the sun's beams.

The comets, too, are to appearance surrounded with their atmospheres and phases. ²⁷ Their atmospheres and phases. They have often likewise different phases, like the moon. Those of 1744 and 1769 had both of them this appearance, 5th Plate XLII. fig. 6. The latter also, when viewed through a telescope, seemed to turn swiftly round on its axis, and to emit flashes or sparks of electric light from all parts of it; which sparks were instantly impelled with great violence towards the tail.

As for the tails of comets, they resemble the streams of electric light more than any thing else. That of 1769 seemed perpetually to shoot out in straight lines of a pale silver hue, lengthening and shortening at each instant, and forming frequently some of the configurations assumed by the Aurora Borealis. Dr Halley, about the year 1716, hath observed the same thing. Speaking of a remarkable Aurora Borealis, he says, "That the great streams of light so much resembled the tails of comets, that at first sight they might well be taken for such;" and afterwards adds, "This light seems to have a great affinity with that which electric bodies emit in the dark."

9. The fixed stars, when viewed through the best telescopes, appear not at all magnified, but rather diminished in bulk, by reason that the telescope takes off that twinkling appearance they make to the naked eye, and which increases their apparent magnitude. Their number, however, appears increased to prodigiously, that 70 stars have been counted in the constellation called the *Pleiades*, and no fewer than 2000 in that of *Orion*. The galaxy, or milky-way, appears in a manner made up of stars so small and so close, that they cannot be discerned singly. To these stars it owes a good part of its light, though not the whole, as some small specks called *nebule* are discovered in the heavens, having much the same appearance, and which have not always stars within them. Of these we have the following account in the Philosophical Transactions, N^o 347. "Some of these bright spots discover no sign of a star in the middle of them; and the irregular form of those that do, shews them not to proceed from the illumination of a central body. These are six in number, all which we will describe in the order of time, as they were discovered; giving their places in the sphere of fixed stars, to enable the curious, who are furnished with good telescopes, to take the satisfaction of contemplating them."

29
Number of the fixed stars increased by telescopes.

29
Account of the nebule.

"The first and most considerable is that in the middle of *Orion's sword*, marked with ϵ by Bayer in his *Uranometria*, as a single star of the third magnitude; and is so accounted by Ptolemy, Tycho Brahe, and Hevelius; but it is in reality two very contiguous stars, environed with a very large transparent bright spot, thro' which they appear with several others. These are curiously

33
Conjectures
concerning
the Solar
spots.

whose parts are kept from fuming away by the vast weight and density of their superincumbent atmospheres, and whose heat is preserved by the prodigious action and reaction of their parts upon one another? Agreeable to this idea, Mr Derham and many others have formed conjectures concerning the solar spots, taking them for the smoke of new volcanoes breaking out in that fiery body; which smoke, being more dense towards the middle, and more rare towards the edges, gives the appearance of a nucleus and umbra. Many, however, are of opinion that they are only exhalations raised by the intense heat of the sun, and consequently a kind of clouds flying in his atmosphere. Some have taken them for planets nearer the sun than Mercury; but this their perishableness will by no means allow us to believe. Others have imagined, that they were new and unformed worlds in a chaotic state, as our earth originally was. In the abovementioned dissertation, Dr Wilson is of opinion, that the solar spots are vast cavities in the body of the sun himself, and even gives the following method for measuring their depth. "All the foregoing appearances, when taken together, and when duly considered, seem to prove in the most convincing manner, that the nucleus of this spot (December 1769) was considerably beneath the level of the sun's spherical surface.

"The next thing which I took into consideration, was to think of some means whereby I could form an estimate of its depth. At the time of the observation I had on Dec^r 12th, I had remarked that the breadth of the side of the umbra next the limb was about 14"; but, for determining the point in question, it was also requisite to know the inclination of the shelving side of the umbra to the sun's spherical surface. And here it occurred, that, in the case of a large spot, this would in some measure be deduced from observation. For, at the time when the side of the umbra is just hid, or begins first to come in view, it is evident, that a line joining the eye and its observed edge, or uppermost limit, coincides with the plane of its declivity. By measuring therefore the distance of the edge from the limb, when this change takes place, and by representing it by a projection, the inclination or declivity may in some measure be ascertained. For in fig. 2. let ILDK be a portion of the sun's limb, and ABCD a section of the spot, SL the sun's semidiameter, LG the observed distance from the limb, when the side of the umbra changes, then will the plane of the umbra CD coincide with the line EDG drawn perpendicular to SL at the point G. Let FH be a tangent to the limb at the point D, and join SD.

"Since GL, the versed sine of the angle LSD, is given by observation, that angle is given, which by the figure is equal to FDE, or GDH; which angle is therefore given, and is the angle of inclination of the plane of the umbra to the sun's spherical surface. In the small triangle therefore CMD, which may be considered as rectangular, the angle MDC is given, and the side DC equal to AB is given nearly by observation; therefore the side MC is given, which may be regarded as the depth of the nucleus without any material error.

"I had not an opportunity, in the course of the foregoing observations, to measure the distance GL, not having seen the spot at the time when either

of the sides of the umbra changed. It is, however, certain, that when the spot came upon the disk for the second time, this change happened some time in the night between the 11th and 12th of December, and I judge that the distance of the plane of the umbra, when in a line with the eye, must have been about 1' 55" from the sun's eastern limb; from which we may safely conclude, that the nucleus of the spot was, at that time, not less than a semidiameter of the earth below the level of the sun's spherical surface, and made the bottom of an amazing cavity, from the surface downwards, whose other dimensions were of much greater extent."

Having thus established it, as an absolute certainty, that the solar spots are vast cavities in the sun, the Doctor next proceeds to offer some queries and conjectures concerning the nature of the sun himself, and to answer some objections to his hypothesis, which it must be confessed is somewhat uncommon. He begins with asking, Whether it is not reasonable to think, that the vast body of the sun is made up of two kinds of matter very different in their qualities; that by far the greatest part is solid and dark; and that this dark globe is encompassed with a thin covering of that resplendent substance, from which the sun would seem to derive the whole of his vivifying heat and energy. — This, if granted, will afford a satisfactory solution of the appearance of spots; because, if any part of this resplendent surface shall be by any means displaced, the dark globe must necessarily appear; the bottom of the cavity corresponding to the nucleus, and the shelving sides to the umbra. The shining substance, he thinks, may be displaced by the action of some elastic vapour generated within the substance of the dark globe. This vapour, swelling into such a volume as to reach up to the surface of the luminous matter, would thereby throw it aside in all directions: and as we cannot expect any regularity in the production of such a vapour, the irregular appearance and disappearance of the spots is by that means accounted for; as the reflux of the luminous matter must always occasion the dark nucleus gradually to decrease, till at last it becomes indistinguishable from the rest of the surface.

Here an objection occurs, *viz.* That, on this supposition, the nucleus of a spot whilst on the decrease should always appear nearly circular, by the gradual descent of the luminous matter from all sides to cover it. But to this the Doctor replies, that in all probability the surface of the dark globe is very uneven and mountainous, which prevents the regular reflux of the shining matter. This, he thinks, is rendered very probable by the enormous mountains and cavities which are observed in the moon; and why, says he, may there not be the same on the surface of the sun? He thinks his hypothesis also confirmed by the dividing of the nucleus into several parts, which might arise from the luminous matter flowing in different channels in the bottom of the hollow. — The appearance of the umbra after the nucleus is gone, he thinks, may be owing to a cavity remaining in the luminous matter, tho' the dark globe is entirely covered.

As to motion of the spots, distinct from what they are supposed to receive from the rotation of the sun round his axis, he says he never could observe any, except what might be attributed to the enlargement or diminution of them when in the neighbourhood of one

36

their
depth.

another. "But," says he, "what would further contribute towards forming a judgement of this kind is, the apparent alteration of the relative place, which must arise from the motion across the disk on a spherical surface, a circumstance which I am uncertain if it has been sufficiently attended to." This is the circumstance from which we deduced the objection against the sun's motion; and from comparing the figures given by Mr Derham and others, we cannot help thinking that it hath never been attended to as it ought.

The abovementioned hypothesis, the Doctor thinks, is further confirmed by the disappearance of the umbra on the sides of spots contiguous to one another; as the action of the elastic vapour must necessarily drive the luminous matter away from each, and thus as it were accumulate it between them, so that no umbra can be perceived. As to the luminous matter itself, he conjectures, that it cannot be any very ponderous fluid, but that it rather resembles a dense fog which broods on the surface of the sun's dark body. His general conclusion being somewhat extraordinary, we shall give it in his own words.

"According to the view of things given in the foregoing queries, there would seem to be something very extraordinary in the dark and unignited state of the great internal globe of the sun. Does not this seem to indicate that the luminous matter that encompasses it derives not its splendour from any intensity of heat? For, if this were the case, would not the parts underneath, which would be perpetually in contact with that glowing matter, be heated to such a degree, as to become luminous and bright? At the same time it must be confessed, that although the internal globe was in reality much ignited, yet when any part of it forming the nucleus of a spot is exposed to our view, and is seen in competition with a substance of such amazing splendour, it is no wonder that an inferior degree of light should, in these cases, be unperceivable.

37
Experiment
proposed in
order to con-
firm his hy-
pothesis.

"In order to obtain some knowledge of this point, I think an experiment might be tried, if we had an opportunity of a very large spot, by making a contrivance in the eye-piece of a telescope, whereby an observer could look at the nucleus alone with the naked eye, without being in danger of light coming from any other part of the sun. In this case, if the observer found no greater splendour than what might be expected from a planet very near the sun, and illumined by as much of his surface as corresponds to the spot's umbra, we might reasonably conclude, that the solar matter, at the depth of the nucleus, is in reality not ignited. But from the nature of the thing, doth there seem any necessity for thinking that there prevails such a raging and fervent heat as many have imagined? It is proper here to attend to the distinction betwixt this shining matter of the sun, and the rays of light which proceed from it. It may perhaps be thought, that the reaction of the rays upon the matter, at their emission, may be productive of a violent degree of heat. But whoever would urge this argument in favour of the sun being intensely heated, as arising from the nature of the thing, ought to consider that all polished bodies are less and less disposed to be heated by the action of the rays of light, in proportion as their surfaces are more polished, and as their powers of reflection are brought to a greater degree of perfection. And is there not a strong ana-

logy betwixt the reaction of light upon matter in cases where it is reflected, and in cases where it is emitted?"

With regard to this hypothesis, a decisive argument against it is what we have already taken notice of from Mr Wollaston, (Phil. Trans. Vol. LXIV. p. 337), if his assertion be just, that the appearance of an hollow in the body of the sun, on which the Doctor founds his arguments, is not constant. To himself, he says, they had the appearance of hollows in the tops of volcanoes. Mr Marshall of Pennsylvania too, in a letter to Dr Franklin, gives it as his opinion, that the spots are near, if not closely adhering to, the sun's surface; and tells us, that he never observed the same spot appear again on the eastern limb, in the same figure and position. At any rate, Dr Wilson's hypothesis seems exceptionable for the following reasons.

1. The notion of a shelving declivity formed in a fluid substance by an elastic vapour, is utterly irreconcilable with the nature of any fluid with which we are acquainted. If we suppose the luminous matter of the sun to have any kind of fluidity analogous to that of water, melted metals, &c. we know that a discharge of elastic vapour through them could occasion nothing but a prodigious bubbling: or if we suppose the vapour to issue with immense force, perhaps a round spot might be formed, but without any umbra, as the expansive power must decrease every moment after getting vent, and the fluid would contract the orifice on all sides, till a round mouth was left just sufficient to allow the emission of the quantity of vapour generated. If the luminous matter is supposed to be endowed with any degree of viscosity, the same effect must happen in a greater degree; and it is impossible that any shelving cavity could be produced. With regard to a fog, as it is not a fluid *per se*, but a multitude of aqueous particles floating in our atmosphere, if we compare the luminous matter of the sun to these aqueous particles, we must also suppose them swimming in some other fluid; and, at any rate, the *shelving sides* of a cavity of fog appear inconsistent, and also its running in channels in the bottom of a hollow, which last the Doctor gives as a reason for the breaking of the nucleus of a spot in pieces.

38
Reasons in
opposition
to his hypo-
thesis.

2. The vulgar prejudice in favour of the immense heat at the body of the sun seems to be extremely well founded, because we know of no substance that emits a bright white light like the sun, but what is also capable of burning very violently. We see the effect of the rays of the sun himself in burning mirrors *, which exceed any degree of heat we can raise by other means. No plausible reason can therefore be given why the heat should not increase in proportion as we come near the sun. Sir Isaac Newton hath clearly been of this opinion; and we apprehend it must be the opinion of every person who is resolved not to reject the evidence of sense entirely. At the outer surface of the luminous matter of the sun, therefore, any solid body must be heated beyond all imagination, by the intensity of the light proceeding from that matter. Now, we know that light is emitted from luminous bodies in all directions, down as well as up, and backward as well as forward. If a most violent heat behoved to take place at the outer surface of the luminous matter, the same must take place at the inner surface also, which is contiguous to the dark globe of the sun according to the Doctor's supposition. It is impossible then to imagine, that a globe

* See the ar-
ticle Burn-
ing-glasses.

globe of any solid matter could have resisted for near 6000 years such a violent heat, without being in a state of ignition more violent than we can have any idea of.

On the whole, we cannot help thinking, that with regard to the solar spots, no reasonable hypothesis hath been yet formed. Those who think they are the smoke of volcanoes, or clouds exhaled from the body of the sun, ought first to prove that the sun hath a solid body like our earth. It is true, we cannot produce fire on this earth without terrestrial fuel: but this is no reason why it cannot be done in the celestial spaces; on the contrary, we have the most convincing proofs that it really can be done. The explosions of electrical batteries, flashes of lightning, and some kinds of meteors, resemble the bright light of the sun much more than any fire we can make with our fuel. It is true, these are momentary, and it is proper they should be so for the safety of this world and its inhabitants: but this is no reason for supposing that there is not a natural cause sufficient for the preservation of a pure flame of that kind where it is proper it always should exist; and if this should be granted, the body of the sun may reasonably enough be supposed only to consist of elementary fire or light.

Concerning the moon, it is allowed on all hands, that there are prodigious inequalities on her surface. This is proved by looking at her through a telescope, at any other time than when she is full: for then there is no regular line bounding light and darkness; but the confines of these parts appear as it were toothed and cut with innumerable notches and breaks; and even in the dark part, near the borders of the lucid surface, there are seen some small spaces enlightened by the sun's beams. Upon the fourth day after new moon, there may be perceived some shining points like rocks or small islands within the dark body of the moon; but not far from the confines of light and darkness there are observed other little spaces which join to the enlightened surface, but run out into the dark side, which by degrees change their figure, till at last they come wholly within the illuminated face, and have no dark parts round them at all. Afterwards many more shining spaces are observed to arise by degrees, and to appear within the dark side of the moon, which before they drew near to the confines of light and darkness were invisible, being without any light, and totally immersed in the shadow. The contrary is observed in the decreasing phases, where the lucid spaces which joined the illuminated surface by degrees recede from it, and, after they are quite separated from the confines of light and darkness, remain for some time visible, till at last they also disappear. Now it is impossible that this should be the case, unless these shining points were higher than the rest of the surface, so that the light of the sun may reach them.

Not content with perceiving the bare existence of these lunar mountains, astronomers have endeavoured to measure their height in the following manner. Let EGD be the hemisphere of the moon illuminated by the sun, ECD the diameter of the circle bounding light and darkness, and A the top of a hill within the dark part when it first begins to be illuminated. Observe with a telescope the proportion of the right line AE, or the distance of the point A from the lucid surface to the diameter of the moon ED; and, because in this

case the ray of light ES touches the globe of the moon, AEC will be a right angle by 16 prop. of Euclid's third book; and therefore in the triangle AEC having the two sides AE and EC, we can find out the third side AC; from which subtracting BC or EC, there will remain AB the height of the mountain. Riccioli affirms, that upon the fourth day after new moon he has observed the top of the hill called *St Catherine's* to be illuminated, and that it was distant from the confines of the lucid surface about a sixteenth part of the moon's diameter. Therefore, if CE=8, AE will be 1, and AC²=CE²+AE² by prop. 47. of Euclid's first book. Now, the square of CE being 64, and the square of AE being 1, the square of AC will be 65, whose square root is 8,062, which expresses the length of AC. From which deducting BC=8, there will remain AB=0,062. So that CB or CE is therefore to AB, as 8 is to 0,062, that is, as 8000 is to 62. If the diameter of the moon therefore was known, the height of this mountain would also be known. This demonstration is taken from Dr Keil, who supposes the semidiameter of the moon to be 1182 miles; according to which, the mountain must be somewhat more than nine miles of perpendicular height: but astronomers having now determined the moon's semidiameter to be only 1090 miles, the height of the mountain will be nearly 8½ miles.

Here we cannot help remarking, that it is extremely improbable such enormous mountains should exist in so small a planet. The abovementioned height is almost three times what is allowed to the highest mountains on earth; and it is certainly altogether contrary to the proportions and analogy wisely observed throughout nature, to imagine that the moon should have hills 8½ miles high, while the earth, which is more than 40 times as large, should have none exceeding three miles in height. At any rate, the extreme disagreement and contradiction among geometers with regard to the height of terrestrial mountains, must make all their calculations concerning the heights of lunar ones appear still less worthy of credit.

Concerning the nature of the moon's substance there have been many conjectures formed. Some have imagined, that, besides the light reflected from the sun, the moon hath also some obscure light of her own, by which she would be visible without being illuminated by the sun-beams. In proof of this it is urged, that during the time of even total eclipses the moon is still visible, appearing of a dull red colour, as if obscured by a great deal of smoke. In reply to this it hath been advanced, that this is not always the case; the moon sometimes disappearing totally in the time of an eclipse, so as not to be discernible by the best glasses, while little stars of the fifth and sixth magnitudes were distinctly seen as usual. This phenomenon was observed by Kepler twice, in the year 1580 and 1583; and by Hevelius in 1620. Riccioli and other Jesuits at Bologna, and many people throughout Holland, observed the same on April 14th, 1642; yet at Venice and Vienna, she was all the time conspicuous. In the year 1703, Dec 23, there was another total obscuration. At Arles, she appeared of a yellowish brown; at Avignon, ruddy and transparent, as if the sun had shone through her; at Marcellis, one part was reddish and the other very dusky; and at length,

Method of measuring the lunar mountains. 3^d Plate XLII. fig. 1.

though in a clear sky, she totally disappeared. The general reason for her appearance at all during the time of eclipses shall be given afterwards: but as for these particular phenomena, they have not yet, as far as we know, been satisfactorily accounted for; and indeed astronomers in general seem industriously to avoid speaking of them.

Different conjectures have also been formed concerning the spots on the moon's surface. Some philosophers have been so taken with the beauty of the brightest places observed in her disk, that they have imagined them to be rocks of diamonds; and others have compared them to pearls and precious stones. Dr Keil and the greatest part of astronomers now are of opinion that these are only the tops of mountains, which by reason of their elevation are more capable of reflecting the sun's light than others which are lower. The dusky spots, he says, cannot be seas, nor any thing of a liquid substance; because when examined by the telescope, they appear to consist of an infinity of caverns and empty pits, whose shadows fall within them, which can never be the case with seas, or any liquid substance: but, even within these spots, brighter places are also to be observed; which, according to his hypothesis, ought to be the points of rocks standing up within the cavities.

On the other side, it has been urged, that if all the dark spots observed in the moon's surface were really the shadows of mountains, or of the sides of deep pits, they could not possibly be so permanent as they are found to be, but behaved to vary according to the position of the moon with regard to the sun, as we find shadows on earth are varied according as the earth is turned towards or from the sun. Accordingly it is pretended, that variable spots are actually discovered on the moon's disk, and that the direction of these is always opposite to the sun. Hence they are found among those parts which are soonest illuminated in the increasing moon, and in the decreasing moon lose their light sooner than the intermediate ones; running round, and appearing sometimes longer, and sometimes shorter. The permanent dark spots, therefore, it is said, must be some matter which is not fitted for reflecting the rays of the sun so much as the bright parts do; and this property, we know by experience, belongs to water rather than land: whence these philosophers conclude, that the moon, as well as our earth, is made up of land and seas.

It hath been much disputed whether there is about the moon any kind of atmosphere similar to what we breathe. Against the existence of this it hath been urged, that the moon constantly appears with the same lustre when there are no clouds in our air; which could not be expected, were she surrounded with an atmosphere like ours, the different changes of which behaved sometimes to diminish and at other times to increase her lustre. The strongest argument, however, is drawn from the refractive power of our atmosphere, which is well known to have a great influence on the rays of light proceeding either from celestial or terrestrial bodies, so as to cause them deviate from a straight line, and of consequence behaved to have the same effect on those which passed through the atmosphere of the moon, if any such there was. But no such effect has ever been perceived. The smallest fixed stars, as hath been already observed, preserve their lustre undiminished till they are suddenly covered by the moon's limb, and as suddenly appear on

the other side, without being at all affected by their approach to her, as they are by the planet Mars. For this reason, too, the same philosophers maintain, that there can neither be clouds nor rain in the lunar regions, but that she enjoys a perpetual and unintermitted serenity.

To these arguments it hath been replied, 1. That the appearances on which they are founded are not constant. Hevelius writes, that he has several times found in skies perfectly clear, when even stars of the sixth and seventh magnitude were visible, that at the same altitude of the moon, and the same elongation from the earth, and with one and the same telescope, the moon and its macule do not appear equally lucid, clear, and conspicuous, at all times; but are much brighter and more distinct at some times than at others. From the circumstances of this observation, say they, it is evident that the reason of this phenomenon is not either in our air, in the tube, in the moon, or in the spectator's eye; but must be looked for in something existing about the moon. Along with this, the phenomena already mentioned of the different appearances of the moon in the total eclipses are also urged, and are derived from the different constitutions of the lunar atmosphere at that time. Cassini frequently observed Saturn, Jupiter, and the fixed stars, to have their circular figure changed into an elliptical one, when they approached either the illuminated or dark edge of the moon's limb, and in other occultations found no change of figure at all. Mr Dunn particularly viewed Saturn at his emergence from behind the moon, in order to determine this question; and the appearance which he then observed, inclined him to think there was an atmosphere about the moon. 2. In the total eclipses of the sun, we find the moon encompassed with a lucid ring parallel to her periphery. Of this we have too many observations to doubt: In the great eclipse of 1713, the ring was very visible at London and elsewhere. The same was observed by Kepler in 1605, at Naples and Antwerp. Wolfius relates the same of an eclipse in 1606 at Leipzig, which is described at large in the *Acta Eruditorum*, with this notable circumstance, that the part next the moon was visibly the most illuminated, being considerably brighter than that furthest from it; which is also confirmed by the observations of the French astronomers in 1706.

For these reasons, it is concluded by many, that there is about the moon some fluid, which conforms itself to her figure, and is more dense near her surface than at a distance from it, and that it both reflects and refracts the rays of the sun. It is also concluded, that the lunar atmosphere is not always in the same state, as it sometimes changes the figures of the stars, and sometimes not: and in the several eclipses just mentioned, there was observed a trembling of the moon's limb immediately before immersion, with an appearance of thin smoke flying over it during immersion, very visible in England. Hence, as these phenomena are observed to happen in our atmosphere when full of vapours, it is concluded that the lunar atmosphere has been in a similar state at these times: and since at other times these appearances are not to be observed, it is thought that then the lunar air has been clear and transparent, by reason of rain, dew, or snow, having fallen.

The strongest argument for a lunar atmosphere is that drawn from the luminous ring around her in solar eclipses;

43
Whether
the moon
has an at-
mosphere.

eclipses; and this seems to conclusive, that Dr Halley himself was almost convinced of the existence of such an atmosphere by it. He tells us, however, that several very great astronomers did not think such a thing at all probable. Other astronomers have imagined that it proceeded from a solar atmosphere, because it followed the centre of the sun, and not that of the moon. Some there are who ridicule both these opinions, and take this appearance to be an undeniable proof of the moon's being included within the atmosphere of the earth. We observe, say they, at all times, when the sky is clear, the body of the sun to be surrounded with a very bright and dazzling circle, which extends to a considerable distance, and whose centre always coincides with that of the sun. This circle we never ascribe to the atmosphere of the sun, but to that of the earth. If the sun is hid by a mountain, part of this circle continues visible after his body disappears; and that part of the luminous circle is brightest, which is apparently nearest the mountain: yet we never ascribe this to the atmosphere of the mountain, but to the common atmosphere of the earth which lies beyond the mountain. In the case of solar eclipses, therefore, why should we imagine the luminous circle to proceed from any thing else than that part of the earth's atmosphere which lies beyond the moon? In this case, it will also follow the centre of the sun; and the tremulations of that part of our atmosphere lying between us and the moon being observed by means of the sun's strong light, will occasion the apparent tremulation of the moon's limb already taken notice of at the time of immersion. To have recourse in this case, say they, to such an *emissionis* as the solar or lunar atmosphere, is truly solving *obscurum per obscurius*. As for the small refractions of the light of the planets and fixed stars which have sometimes been observed when they approach the moon's limb, the abovementioned persons think they may be reasonably accounted for on the same principles with the tides; namely, by an accumulation of the aqueous vapours floating in our atmosphere under that part of the heavens where the moon is; and consequently the light of the stars will be more or less refracted, according as it passes through a larger or lesser quantity of the accumulated vapour. This last hypothesis might give some encouragement to bishop Wilkins's scheme of flying to the moon, which the want of a continued atmosphere between that luminary and the earth would be an effectual bar against: but tho' we should suppose the art of flying possible, and likewise that the air all the way up were fit for supporting our life, the bishop's journey would be rather too long; for allowing him to fly 60 miles an hour, and to proceed day and night without intermission, he must be five months before he came to his journey's end, supposing the moon's mean distance 240,000 miles, as it is commonly thought to be.

44
Conjectures
concerning
the planets.

With regard to the planets Mercury, Venus, Mars, Jupiter, and Saturn, few conjectures have been formed: only that the temperature of the two inferior ones, Mercury and Venus, must be much hotter, and that of the superior ones, Mars, Jupiter, and Saturn, considerably colder, than that of the earth. That the latter are much less enlightened than this earth, we are absolutely certain: but whether they are not encompassed with atmospheres, which prevent them from suffering any

violent excess of cold, we are entirely ignorant; as well as whether those of Mercury and Venus may not diminish the heat which at first would appear to be so violent at the small distances from the sun at which they circulate. Mars, we are certain, has an atmosphere about his body which is capable of refracting and absorbing the light of other stars; but what its other properties are, we have no means of knowing. The spots on Venus, Mr Dunn informs us, are thought to be seas. The belts observable on the superior planets have occasioned much speculation. Some have thought that they were inherent on the surfaces of the planets; and thus some philosophers have said, that greater changes take place on the body of the planet Jupiter, than what would happen to this earth were the ocean and dry land to change places. Others, however, have imagined that they are similar to our clouds: but their constant appearance seems contradictory to such a supposition; for tho' it is true that they are but of a transitory nature, they are vastly more permanent than any clouds to be observed on earth. For this reason, some have imagined that they are only certain parts of the atmosphere of the planet of a different constitution, and less capable of transmitting the sun's light than others. These dark zones, they think, may have arisen from the superior planets enjoying a perpetual equinox, the reason of which shall be given when we come to speak of the causes of the different seasons on earth. The moons of Jupiter and Saturn, and the ring with which the latter is surrounded, are thought to be designed for reflecting the sun's light upon these planets; and their number is imagined to be sufficient to compensate in some measure for the great distance at which they are placed from the sun.

We cannot conclude this article without taking notice, that astronomers seem not to be agreed whether the belts of Jupiter are really darker or brighter than the rest of his disk. In Chambers's Dictionary, we have the following account of them, under the word *Fasciæ*. "Fasciæ, in astronomy, two rows of bright spots, observed on Jupiter's body; appearing like swaths, or belts. The fasciæ or belts of Jupiter are more lucid than the rest of his disk, and are terminated by parallel lines. They are sometimes broader, and sometimes narrower; nor do they always possess the same part of the disk. M. Huygens, likewise, observed a very large kind of fasciæ in Mars; but it was darker than the rest of the disk, and took up the middle part thereof." Most of the astronomical writers, at least the more common ones, seem to be pretty silent on the subject, but generally incline us to think that they are dark. In Mr Wollaston's paper already quoted from Phil. Trans. Vol. LXIV. he mentions both bright and dark belts.

With regard to comets, innumerable conjectures have been formed. The ancients in general were of opinion that they were meteors formed in our atmosphere, only of a more permanent substance than the common ones; and that they were signs of the wrath of God: which last opinion hath been preserved among the vulgar to this day. Some, however, thought otherwise; and asserted them to be a kind of planets that revolved round the sun, but in more extensive circles than the others: but these were few in number; and the general opinion of their being signs of divine wrath, and pre-

Of Comets.

sages of terrible calamities to mankind, prevailed till the revival of learning in the 16th century.

It was not, however, till some time after people began to throw off the fetters of superstition and ignorance which had long held them, that any rational hypothesis was formed concerning comets. Kepler, in other respects a very great genius, indulged the most extravagant conjectures, not only concerning comets, but the whole system of nature in general. The planets he imagined to be huge animals who swam round the sun by means of certain fins acting upon the ethereal fluid, as those of fishes do on the water; and agreeable to this notion, he imagined the comets to be monstrous and uncommon animals generated in the celestial spaces; and he explained how the air engendered there by an animal faculty. A yet more ridiculous opinion, if possible, was that of John Bodin, a learned man of France in the 16th century. He maintained that comets "are spirits, which having lived on the earth innumerable ages, and being at last arrived on the confines of death, celebrate their last triumph, or are recalled to the firmament like shining stars! This is followed by famine, plague, &c. because the cities and people destroy the governors and chiefs who appease the wrath of God." This opinion, ridiculous as it is, he says he borrowed from the philosopher Democritus, who imagined them to be the souls of famous heroes: but this opinion being irreconcilable with Bodin's Christian sentiments, he was obliged to suppose them to be a kind of geni, or spirits subject to death, like those so much mentioned in the Mahometan fables. Others, again, have denied the existence of comets, and maintained that they were only false appearances occasioned by the refraction or reflection of light; as if the light could refract or reflect of itself, without any substance from whence it was so reflected or refracted.

The first rational conjecture we meet with is that of James Bernoulli, an Italian astronomer, who imagined them to be the satellites of some very distant planet, which was invisible to us on account of its distance, as were also the satellites unless when in a certain part of their course. But though we call this a rational conjecture, in comparison of the others, it is nevertheless very absurd; as it supposes a satellite to leave its primary planet in darkness, in order to enlighten other orbs with which it has nothing to do.

The first rate astronomers of England, as Newton, Flamsteed, Halley, &c. have been perfectly satisfied that the comets were a kind of planets which revolved round the sun in very eccentric ellipses; and have accordingly calculated the returns of some of them, and made conjectures concerning the use they may probably be of in the general system of nature. Cassini and some of the French philosophers thought this opinion highly probable; but De La Hire and others opposed it. The whole event of the dispute, however, it is plain, behoved to turn on the observation of the return of comets, and the calculation of their periodical times like those of other planets; which, whenever it was fully done, behoved to put the matter beyond a doubt: but until this was done, not at once or twice, but a great number of times, there behoved still to be an uncertainty, let the arguments for their return be supposed as probable as we please. This Sir Isaac Newton and Dr Halley attempted to do. Having observed the

accounts of comets in history, and found some of them to appear at equal intervals of time, it was concluded that these were the same comets, and would appear again after an interval of equal length. Thus, Sir Isaac Newton having observed a comet in the year 1680, of great apparent magnitude; and found that such an one had appeared before, at an interval of 575 years between each appearance; he concluded that these were different appearances of the same comet, and that it would again appear 575 years afterwards. The same celebrated philosopher, along with Dr Halley and others, calculated the period of the comet which appeared in 1682, and found that it ought to appear again in the year 1758, its periodical time being about 75½ years. The most important objection that arose to the return of this comet, was the inequality of its periods, which were as follows: "That from August 25th 1531, to the 26th of October 1607, was performed in 76 years and two months; that from October 26th 1607, to September 14th 1682, was rather less than 75 years; and its last period, from the 14th of September 1682, to the 13th of March 1759, which was the longest of all, was 76 years and six months, or 27,937 days, amounting to 583 days more than in the preceding period.

"Dr Halley was aware of these differences, and at first confessed himself to be a little staggered by them; nor would he have had the courage to pronounce its return so positively, if history had not informed him, that comets had appeared in 1456, 1380, and 1305, which put their identity out of all doubt.

"The appearances happening alternately in 75 and 76 years, and as the preceding period was only of 75 years, it was natural to suppose that the next would amount to 76. But as the difficulties arising from these inequalities in the periods were foreseen and obviated by Dr Halley, we cannot do better than to insert his own words.

"Perhaps some may object to the diversity of their inclinations and periods, which is greater than what is observed in the revolutions of the same planet; seeing one period exceeded the other by more than the space of one year, and the inclination of the comet of the year 1682 exceeded that of the year 1607 by 22 entire minutes. But let it be considered what I mentioned at the end of the tables of Saturn, where it was proved that one period of that planet is sometimes longer than another by 13 days; and that is evidently occasioned by the force of gravity tending towards the centre of Jupiter, which force indeed in equal distances is only the 1000th part of that force tending to the sun itself, by which the planets are retained in their orbits. But by a more accurate computation, the force of Jupiter upon Saturn, for example, in the great conjunction as they call it, January 26, in the year 1683, was found to be to the force of the sun upon the same Saturn, as 1 to 186; the sum of the forces therefore is to the force of the sun, as 187 to 186. But at the same distance from the centre, the periodic times of bodies revolving in a circle are in the subduplicate ratio of the forces with which they are urged: wherefore the gravity being increased by the 186th part of itself, the periodic time will be shortened by about the 374th part, that is by a whole month in Saturn. How much more is a comet liable to these errors, which makes its excursion

near four times higher than Saturn; and whose velocity being increased by less than the 120th part of itself, would change its elliptic orbit into a parabolic trajectory?

‘ But it happened in the summer of 1681, that the comet seen in the following year, in its descent towards the sun, was in conjunction with Jupiter in such a manner, and for several months so near him, that during all that time it must have been urged likewise towards the centre of Jupiter with near the 50th part of that force by which it tended towards the sun: whence, according to the theory of gravity, the arc of the elliptic orbit, which it would have described had Jupiter been absent, must be bent inwards towards Jupiter in an hyperbolic form winding, and as hitherto not to be managed by the geometers; in which the velocity and direction of the moving body, in proportion to the cause, would be very different from what it otherwise had been in the ellipses.

‘ Hence a reason may be assigned for the change of its inclination: for as the comet in this part of its path had Jupiter on the north almost in a perpendicular direction to its path, that portion of its orbit must be bent towards that quarter; and therefore its tangent being inclined to a greater angle towards the plane of the ecliptic, the angle of the inclination of the plane itself must be necessarily increased. Besides the comet continuing long in the neighbourhood of Jupiter, after it had come towards him from parts much more remote from the sun with a slower motion, and now being urged with the joint central forces of both, must have acquired more accelerated velocity, than it could lose in its recess from Jupiter by forces acting a contrary way, its motion being more swift, and the time being less.’

‘ When the comet of 1682 descended towards the sun and became visible, Europe had scarce recovered from the terrible panic into which it had been thrown but 18 months before by the great comet. However, this was comparatively too inconsiderable to be much regarded; for it was little imagined then, that the least of the two would become the most interesting, and that it would be for ever celebrated by posterity for having taught mankind how to know all the rest. But however inferior to the other this comet may have appeared in vulgar eyes, astronomers observed it with the greatest attention. Hevelius at Dantzick, Kitch at Leipzig, Flamsteed and Halley in England, Zimmerman at Nuremberg, Baert at Toulon, Montanori at Padua, and Picard, Cassini, and la Hire, at Paris. This list of names will suffice to shew that there can be no scarcity of good observations upon this comet during that appearance.

‘ In 1607 it was observed by the famous Kepler, who published his observations together with his general theory. The 16th of September old style, the sky being very clear, Kepler first saw this comet upon the bridge at Prague; and though it had no tail when he first discovered it, yet afterwards it had one of a considerable length and splendour. It was likewise observed by Longomontanus, September 18. He says it appeared as large as Jupiter, though with a very obscure and pale light; that the tail was pretty long and more dense than the tails of comets usually are, but as pale in co-

lour as the comet itself.

‘ In the preceding revolution of 1531, we find our comet observed by the astronomer Appian at Ingoldstadt, the same who first remarked that the tails of comets were always in an opposite direction to the sun; which to him was an evident proof that the sun was the cause of such eruptions.

‘ In 1456, there was a very remarkable exhibition of the same comet. *Cometa inaudita magnitudinis toto mense Junii cum praelonga cauda, ita ut duo ferè signa cæli comprehenderit, (Theatrum Comet.)*

‘ It is difficult to comprehend how the comet, whose tail was so inconsiderable in its last appearance, should in this have one of sixty degrees: but M. de la Lande, in his Theory of Comets, p. 127. accounts for this difference in the following manner. ‘ I find, says this active astronomer, that if the comet reached its perihelion in the beginning of June, it ought to have appeared at night towards the middle of the month with 60 degrees of elongation and a very northern latitude, its distance from the earth being less than the semidiameter of the sun: so that in this position, which of all others is the most favourable, it must have appeared in all the splendour allowed to it by the old chronicles. Perhaps by *duo signa* they only mean the extent of two constellations, which is often much less than two signs of the ecliptic.’

‘ In 1379 and 1380 we find two comets mentioned by Alstedius and Lubienietzki, but without any particulars as to the time or form of their appearance.

‘ In 1305, our comet again appears, according to the historians of that time, in all its terrors. *Cometa horrendæ magnitudinis visus est circa ferias paschalis, quem secuta est pestilentia maxima.* It is very likely that the horror occasioned by the plague had augmented the terrible impression left by the comet; however, upon calculation, it does appear that the comet must this year have passed very near the earth.

‘ The history of this comet might be traced much higher by consulting Eckstormus, Riccioli, Alstedius, and Lubienietzki. Among the 415 comets mentioned by this last writer, we find one for the year 1230, which appears to be the very comet in question; another 1005, three periods before; it is found in 930, and higher up in the year 550, marked by the taking of Rome by Totila. All the historians of the empire speak of a great comet in the year 399, which may have been the same. *Cometa fuit prodigiosæ magnitudinis, horribili aspectu, comam ad terram usque demittere visus.*

‘ In 323, that is to say, 76 years before, a comet also appeared in Virgo; and in short it would be easy to mount, without quitting the same periods, as high as 130 years before Christ, when, according to Justin, one appeared at the birth of Mithridates. But, in these early periods, there would be great danger of meeting with some of those fabulous comets with which it was thought necessary perhaps to embellish every famous reign.’

As this comet engaged the attention of the most celebrated astronomers more than any other, and as its course was calculated by Newton, Halley, Maupeituis, Clairault, De Lisle, Le Monnier, La Caille, Messier, La Lande, Pingre, &c. who unanimously determined that it ought to appear in 1758, it is not to be wondered

dered that those who respected these illustrious names, should expect its return in that year, with absolute certainty, and even with no small degree of fear, as Dr Halley himself had thought that these bodies might possibly strike upon the earth in some of their revolutions, and occasion its utter destruction, or come so near as at least to occasion terrible calamities to those parts which were most exposed to their malignant influences. A mortal fear accordingly seized the minds of great numbers; and this panic seems to have been kept up by some astronomers of inferior note probably strike upon the earth in some of their revolutions. Of this the following sentence in a book entitled *The Theory of Comets illustrated*, &c. by B. Martin, 1757, is a remarkable instance. "It is well known to astronomers how near that dreadful comet of 1680 approached to the earth's orbit. Also the comets of 1472, 1618, 1684, and the comet which we now expect, with many others, pass so near the orbit of the earth, that it will not be without reason if our fears and apprehensions are considerably raised thereat. However, the reader need not be under any needless terror about the return of this comet: for if it appears before the beginning of next May, it can do no harm; as he may be easily convinced by the view of the comet's orbit which I published some time ago."

52
Disappointment
of a-
stronomers
in 1758.

The fatal period at length arrived; but no comet appeared. This was a prodigious disappointment to astronomers; and as they were now in danger of being turned into ridicule, it became absolutely necessary to find out some reasons for the retardation of this comet which had been so certainly expected. These were happily found out by Mr Clairault; who accounted for its nonappearance, from retardations occasioned by the attraction of Jupiter and Saturn, which two planets are found to have an effect upon each other's motions, and must have the same upon any other body that comes near them, as shall be more fully explained in the next section. He found, "that the action of Jupiter upon the comet, during the whole revolution of 1531 to 1607, had occasioned a diminution of 19 days in its period, which would not have happened by the mere force of the sun; and at the same time had altered its elements so as to produce an acceleration of near 31 days in the following period.

53
Why the
comet did
not then ap-
pear.

"Proceeding afterwards to the revolution from 1607 to 1682, the action of Jupiter turns out much more considerable: for it occasions an acceleration of about 420 days, which added to the 31 resulting from the action of the same planet during the preceding period, amounts in all to 451 days of diminution in the time of its period; which would not have happened merely by its inclination to the sun.

"Now if we take the difference of these two accelerations, in order to know how much shorter the second period was than the first, it appears to be 432 days; which differs only 37 days from the time resulting from the observations.

"And this period appears to be still diminished by the action of Saturn. Indeed this diminution is not much, because the effects of Saturn's force are almost reciprocally destroyed in the two first periods.

"Hence we see that the theory gives within a month the difference so remarkable between the two known revolutions of this comet. Now if we consider the length

of these periods, the complication of the two causes of their irregularity, and the nature of the problem by which they are measured; this new demonstration of the Newtonian system will perhaps be found as striking as any one that has hitherto been given.

"By comparing, in like manner, the force of the action of Jupiter, during the second period of the comet, with that which will be terminated at its approaching return; I find the revolution about which we are at present interested will be 518 days longer than the preceding, occasioned by the action of Jupiter upon the comet, from its last mean distance to its perihelion; that is, for the last seven or eight years; an interval, during which there can hardly be more than 15 days alteration.

"As to Saturn, the result of its action on the comet is much more considerable compared with the two first revolutions; for I find the present period protracted more than 100 days by it, independent likewise of its action since 1751, and another small object which I have not had time to determine. From these considerations, then, it appears to me, that the expected comet ought to arrive at its perihelion about the middle of the month of April next ensuing."

This period of M. Clairault was found to be somewhat too long; for on the 21st of January 1759, a comet made its appearance, and was seen at different

54
Appears in
January
1759.

times, to the third of June the same year. The following is Mr Messier's description of it, as viewed April 1st. "When I saw this comet again on the first of April, I could very plainly discern its tail; but could not ascertain its length, because of the morning twilight, which was then beginning, and soon increased much: it filled the field of the telescope; and must have extended far beyond: according to what I have observed, the tail of the comet must have spread to more than 25 degrees: the nucleus was considerable, but not well terminated, and it apparently exceeded the size of stars of the first magnitude; it was of a pale whitish colour, not unlike that of Venus. The nebulousity which surrounded the nucleus, and went on lessening, shewed reddish colours; and these colours grew more vivid towards the brightest part of the tail. The morning twilight, which increased apace, soon put an end to these appearances, and afterwards made the comet itself disappear: however, I had been able to perceive it with the naked eye, when it was somewhat disengaged from the vapours of the horizon." On the first of May it appeared to the naked eye larger than stars of the first magnitude, the nucleus being surrounded with a great coma. Its light was but faint, like that of the planets seen thro' the thick vapours of the horizon. It would have appeared brighter but for the light of the moon. In this last appearance the comet was in the sextant, or 60° from the sun, and was observed by most of the astronomers of Europe.

The triumph of the astronomers seemed now to be complete; and accordingly Dr Bevis exultingly says, Phil. Trans. Vol. LI. "I think I may now venture to pronounce this to be the same as the comet of 1682; and am about making out its future track. If I presume rightly, it will in a short time become in a manner stationary, but diminish very fast both in size and light, the earth and it receding from one another almost in a direct line. It is at this time about four times

near

ject.

nearer than the sun is.²⁹ Thus we have given the strength of the evidence for the return of comets; and the appearance of that in 1759 is commonly urged as an undeniable proof of their revolution round the sun, and consequently being a kind of planets: but, however strong this evidence may be reckoned, a regard for truth obliges us to take notice, that M. Clairault could not be mistaken, whether he had concluded the comet to have been accelerated or retarded by the action of Jupiter and Saturn; for a comet appeared in the year 1757, in the months of September and October. Had he determined the retardation of the comet to be twice as great as he actually did, still he would have been right by the event, for another comet appeared in 1760. It must be owned that these are perplexing circumstances. It is very singular, that out of four years, in which three comets appeared, the only one in which no comet was to be seen should be that very year in which the greatest astronomers that ever existed had foretold the appearance of one. How far this consideration renders the real accomplishment of Dr Halley's prediction uncertain, we submit to the judgment of the impartial: but, as it is certain that small comets are very frequently to be seen; so, till some better marks for distinguishing one from another than any yet known are found out, perhaps this part of astronomy may not appear to be sufficiently established. Another comet is expected in the year 1789, when some further evidence either one way or another may be hoped for.

56
Newton's
computa-
tion of the
heat of co-
mets, and
conjectures
concerning
them.

The revolution of comets round the sun, and their permanent existence as planets, being granted, we are naturally led to inquire what kind of substances they are, and for what use designed. Sir Isaac Newton, considering the near approach of that of 1680 to the sun, has computed the heat they sometimes undergo to be inconceivably great. That one, in particular, he thought to be heated to a degree 2000 times greater than red-hot iron. In consequence of this calculation he naturally imagined that they were bodies of extreme solidity, in order to sustain such an intensity of heat; and that, notwithstanding their running out into the vast regions of space, where they were exposed to the most intense degrees of cold, they would hardly be cool on their returning again to the sun. Indeed, according to his calculation, the comet of 1680 must be for ever in a violent state of ignition. He hath computed that a globe of red-hot iron of the same dimensions with the earth would scarce be cool in 50,000 years. If then the comet be supposed to cool 100 times faster than red-hot iron, as its heat was 2000 times greater, it must require upwards of a million of years to cool it. In the short period of 575 years, therefore, its heat would be in a manner scarce diminished; and therefore, in its next and every succeeding revolution it must acquire an increase of heat; so that, since the creation, having received a proportional addition in every succeeding revolution, it must now be in a state of ignition very little inferior to that of the sun himself. Sir Isaac hath farther concluded, that this comet must be considerably retarded in every revolution by the atmosphere of the sun within which it enters; and thus must continually come nearer and nearer his body, till at last it falls into it. This, he thinks, may be one use of the comets: viz. to furnish fuel for the sun, which

would otherwise be in danger of wasting, from the continual emission of its light.

As to the tails with which comets are almost constantly attended, Sir Isaac Newton shews, that the atmospheres of comets will furnish vapour sufficient to form their tails. This he argues from that wonderful rarefaction observed in our air, at a distance from the earth: a cubic inch of common air, at the distance of half the earth's diameter, or 4000 miles, would expand itself so as to fill a space larger than the whole region of the stars. Since then the coma or atmosphere of a comet is ten times higher than the surface of the nucleus, counting from the centre thereof; the tail, ascending much higher, must needs be immensely rare: so that it is no wonder the stars should be visible through it.

Now, the ascent of vapours into the tail of the comet, he supposes to be occasioned by the rarefaction of the matter of the atmosphere at the time of the perihelion. Sinoke, it is observed, ascends a chimney by the impulse of the air wherein it floats; and air, rarefied by heat, ascends by the diminution of its specific gravity, taking up the smoke along with it: why then should not the tail of a comet be supposed to be raised after the same manner by the sun? for the sun-beams do not act on the mediums they pass through, any otherwise than by reflection and refraction.

The reflecting particles, then, being warmed by the action, will again warm the ether wherewith they are compounded; and this, rarefied by the heat, will have its specific gravity, whereby it before tended to descend, diminished by the rarefaction, so as to ascend, and to carry along with it those reflecting particles whereof the tail of the comet is composed.

This ascent of the vapours will be promoted by their circular motion round the sun; by means whereof they will endeavour to recede from the sun, while the sun's atmosphere, and the other matters in the celestial spaces, are either at rest, or nearly so, as having no motion but what they receive from the sun's circumrotation.

Thus are the vapours raised into the tails of comets in the neighbourhood of the sun, where the orbits are most curve; and where the comets, being within the denser atmosphere of the sun, have their tails of the greatest length.

The tails thus produced, by preserving that motion, and at the same time gravitating towards the sun, will move round his body in ellipses, in like manner as their heads; and by this means will ever accompany and freely adhere to their head. In effect, the gravitation of the vapours towards the sun will no more occasion the tails of comets to forsake their heads, and fall down towards the sun, than the gravitation of their heads will occasion them to fall off from their tails; but, by their common gravitation, they will either fall down together to the sun, or be together suspended or retarded. This gravitation, therefore, does not at all hinder, but that the heads and tails of comets may receive and retain any position towards each other, which either the abovementioned causes, or any other, may occasion.

The tails therefore, thus produced in the perihelion of comets, will go off along with their head into remote regions; and either return thence, together with the comets, after a long series of years; or rather be there lost, and vanish by little and little, and the comet

be left bare; till, at its return, descending towards the sun, some little short tails be gradually and slowly produced from the heads; which afterwards, in the perihelion, descending down into the sun's atmosphere, will be immenſely increaſed.

The vapours thus dilated, rarefied, and diffuſed thro' all the celeftial regions, the ſame author obſerves, may probably, by little and little, by means of their own gravity, be attracted down to the planets, and become intermingled with their atmospheres.

He adds, that for the conſervation of the water and moiſture of the planets, comets ſeem abſolutely requiſite; from whoſe condenſed vapours and exhalations all that moiſture which is ſpent in vegetations and putrefactions, and turned into dry earth, &c. may be ſupplied and recruited. For all vegetables grow and increaſe wholly from fluids; and, again, as to their greateſt part, turn by putrefaction into earth, an earthy ſlime being perpetually precipitated to the bottom of putrefying liquors. Hence, the quantity of dry earth muſt continually increaſe, and the moiſture of the globe decreaſe, and at laſt be quite evaporated; if it have not a continual ſupply from ſome part or other of the univerſe. And I ſuſpect, adds our great author, that the ſpirit, which makes the fineſt, ſubtleſt, and beſt part of our air, and which is abſolutely requiſite for the life and being of all things, comes principally from the comets.

On this principle, there ſeems to be ſome foundation for the popular opinion of preſages from comets: ſince the tail of a comet, thus intermingled with our atmosphere, may produce changes very ſenſible in animal and vegetable bodies.

58
Controverted
by Dr
Hamilton.

This account of the formation of the tails of comets, we find controverted by Dr Hamilton of Dublin, in a little treatiſe intitled *Conjectures on the nature of the Aurora Borealis, and on the tails of Comets*. His hypotheſis is, that the comets are of uſe to bring back the electric fluid to the planets, which is continually diſcharged from the higher regions of their atmospheres. Having given at length the abovementioned opinion of Sir Iſaac, "We find (ſays he) in this account, that Sir Iſaac aſcribes the aſcent of comets tails to their being rarer and lighter, and moving round the ſun more ſwiftly, than the ſolar atmosphere, with which he ſuppoſes them to be ſurrounded whilſt in the neighbourhood of the ſun; he ſays alſo, that whatever poſition (in reſpect to each other) the head and tail of a comet then receive, they will keep the ſame afterwards moſt freely; and in another place he obſerves, 'That the celeftial ſpaces muſt be entirely void of any power of reſiſting, ſince not only the ſolid bodies of the planets and comets, but even the exceeding thin vapours of which comets tails are formed, move thro' thoſe ſpaces with immenſe velocity, and yet with the greateſt freedom.' I cannot help thinking that this account is liable to many difficulties and objections, and that it ſeems not very conſiſtent with itſelf or with the phenomena.

"I do not know that we have any proof of the exiſtence of a ſolar atmosphere of any conſiderable extent, nor are we any where taught how to gueſs at the limits of it. It is evident that the exiſtence of ſuch an atmosphere cannot be proved merely by the aſcent of comets tails from the ſun, as that phenomenon may

poſſibly ariſe from ſome other cauſe. However, let us ſuppoſe, for the preſent, that the aſcent of comets tails is owing to an atmosphere ſurrounding the ſun, and ſee how the effects ariſing from thence will agree with the phenomena. When a comet comes into the ſolar atmosphere, and is then descending almoſt directly to the ſun, if the vapours which compoſe the tail are raiſed up from it by the ſuperior density and weight of that atmosphere, they muſt riſe into thoſe parts that the comet has left, and therefore at that time they may appear in a direction oppoſite to the ſun. But as ſoon as the comet comes near the ſun, and moves in a direction nearly at right angles with the direction of its tail, the vapours which then ariſe, partaking of the great velocity of the comet, and being ſpecifically lighter than the medium in which they move, and being vaſtly expanded through it, muſt neceſſarily ſuffer a reſiſtance immenſely greater than what the ſmall and denſe body of the comet meets with, and conſequently cannot poſſibly keep up with it, but muſt be left behind, or, as it were, driven backwards by the reſiſtance of that medium into a line directed towards the parts which the comet has left, and therefore can no longer appear in a direction oppoſite to the ſun. And, in like manner, when a comet paſſes its perihelion, and begins to aſcend from the ſun, it certainly ought to appear ever after with its tail behind it, or in a direction pointed towards the ſun; for if the tail of the comet be ſpecifically lighter than the medium in which it moves with ſo great velocity, it muſt be juſt as impoſſible it ſhould move forward, as it is that a torch moved ſwiftly thro' the air ſhould project its flame and ſmoke before it. Since therefore we find that the tail of a comet, even when it is aſcending from the ſun, moves forward, and appears in a direction nearly oppoſite to the ſun, I think we muſt conclude that the comet and its tail do not move in a medium heavier and denſer than the matter of which the tail conſiſts, and conſequently that the conſtant aſcent of the tail from the ſun muſt be owing to ſome other cauſe. For that the ſolar atmosphere ſhould have density and weight ſufficient to raiſe up the vapours of a comet from the ſun, and yet not be able to give any ſenſible reſiſtance to theſe vapours in their rapid progreſs through it, are two things inconſiſtent with each other. And therefore, ſince the tail of a comet is found to move as freely as the body does, we ought rather to conclude that the celeftial ſpaces are void of all reſiſting matter, than that they are filled with a ſolar atmosphere, be it ever ſo rare.

"But there is, I think, a further conſideration which will ſhew, that the received opinion, as to the aſcent of comets tails, is not agreeable to the phenomena, and may at the ſame time lead us to ſome knowledge of the matter of which theſe tails conſiſt: which I ſuſpect is of a very different nature from what it has been hitherto ſuppoſed to be. Sir Iſaac ſays, the vapours, of which the tail of a comet conſiſts, grow hot by reflecting the rays of the ſun, and thereby warm and rarefy the medium which ſurrounds them; which muſt therefore aſcend from the ſun, and carry with it the reflecting particles of which the tail is formed; for he alſo ſpeaks of the tail as ſhining by reflected light. But one would rather imagine, from the phenomena, that the matter which forms a comet's tail has not the leaſt ſenſible power of reflecting the rays of
light.

light. For it appears from Sir Isaac's observation, which I have quoted already, that the light of the smallest stars, coming to us through the immense thickness of a comet's tail, does not suffer the least diminution. And yet, if the tail can reflect the light of the sun so copiously, as it must do if its great splendour be owing to such reflection, it must undoubtedly have the same effect on the light of the stars; that is, it must reflect back the light which comes from the stars behind it, and by so doing must intercept them from our sight, considering its vast thickness, and how exceedingly slender a ray is that comes from a small star; or if it did not intercept their whole light, it must at least increase their twinkling. But we do not find that it has even this small effect, for those stars that appear through the tail are not observed to twinkle more than others in their neighbourhood. Since therefore this fact is supported by observations, what can be a plainer proof that the matter of a comet's tail has no power of reflecting the rays of light? and consequently that it must be a self-shining substance. But the same thing will further appear, from considering that bodies reflect and refract light by one and the same power; and therefore if comets tails want the power of refracting the rays of light, they must also want the power of reflecting them. Now, that they want this refracting power appears from hence: If that great column of transparent matter which forms a comet's tail, and moves either in a vacuum, or in some medium of a different density from its own, had any power of refracting a ray of light coming through it from a star to us, that ray must be turned far out of its way in passing over the great distance between the comet and the earth; and, therefore, we should very sensibly perceive the smallest refraction that the light of the stars might suffer in passing through a comet's tail. The consequence of such a refraction must be very remarkable: the stars that lie near the tail would, in some cases, appear double; for they would appear in their proper places by their direct rays, and we should see their images behind the tail, by means of their rays which it might refract to our eyes; and those stars that were really behind the tail would disappear in some situations, their rays being turned aside from us by refraction. In short, it is easy to imagine what strange alterations would be made in the apparent places of the fixed stars by the tails of comets, if they had a power of refracting their light, which could not fail to be taken notice of, if any such ever happened. But since astronomers have not mentioned any such apparent changes of place among the stars, I take it for granted that the stars seen through all parts of a comet's tail appear in their proper places, and with their usual colours, and consequently I infer that the rays of light suffer no refraction in passing through a comet's tail. And thence I conclude (as before) that the matter of a comet's tail has not the power of refracting or reflecting the rays of light, and must therefore be a lucid or self-shining substance."

But, whatever probability the Doctor's conjecture concerning the materials whereof the tails are formed may have in it, his criticism on Sir Isaac Newton's account of them seems not to be just: for that great philosopher supposes the comets to have an atmosphere peculiar to themselves; and consequently, in their nearest

approaches to the sun, both comet and atmosphere are immersed in the atmosphere of that luminary. In this case, the atmosphere of the comet being prodigiously heated on the side next to the sun, and consequently the equilibrium in it broken, the denser parts will continually pour in from the regions farthest from the sun; for the same reason, the more rarefied part which is before, will continually fly off opposite to the sun, being displaced by that which comes from behind; for tho' we must suppose the comet and its atmosphere to be heated on all sides to an extreme degree, yet still that part which is farthest from the sun will be less hot, and consequently more dense, than what is nearest to his body. The consequence of this is, that there must be a constant stream of dense atmosphere descending towards the sun, and another stream of rarefied vapours and atmosphere ascending on the contrary side; just as, in a common fire, there is a constant stream of dense air descending, which pushes up another of rarefied air, flame, and smoke. The resistance of the solar atmosphere may indeed be very well supposed to occasion the curvature observable in the tails of comets, and their being better defined in the fore part than behind; and this appearance we think Dr Hamilton's hypothesis is incapable of solving. We grant, that there is the utmost probability that the tails of comets are streams of electric matter; but they who advance a theory of any kind ought to solve every phenomenon, otherwise their theory is insufficient. It was incumbent on Dr Hamilton, therefore, to have explained how this stream of electric matter comes to be bent into a curve, and also why it is better defined and brighter on the outer side of the arch than on the inner. This indeed he attempts, in the following manner: "But that this curvature was not owing to any resisting matter appears from hence, that the tail must be bent into a curve though it met with no resistance; for it could not be a right line, unless all its particles were projected in parallel directions, and with the same velocity, and unless the comet moved uniformly in a right line. But the comet moves in a curve, and each part of the tail is projected in a direction opposite to the sun, and at the same time partakes of the motion of the comet; so that the different parts of the tail must move on in lines which diverge from each other; and a line drawn from the head of a comet to the extremity of the tail will be parallel to a line drawn from the sun to the place where the comet was when that part of the tail began to ascend, as Sir Isaac observes; and so all the chords, or lines drawn from the head of the comet to the intermediate parts of the tail, will be respectively parallel to lines drawn from the sun to the places where the comet was when these parts of the tail began to ascend. And therefore, since these chords of the tail will be of different lengths, and parallel to different lines, they must make different angles, with a great circle passing through the sun and comet, and consequently a line passing through their extremities will be a curve.

"It is observed, that the convex side of the tail which is turned from the sun is better defined, and shines a little brighter, than the concave side. Sir Isaac accounts for this, by saying, that the vapour on the convex side is fresher (that is, has ascended later) than that on the concave side; and yet I cannot see how the particles on the

Dr Hamilton's hypothesis insufficient.

59
Sir Isaac's account defended.

the convex side can be thought to have ascended later than those on the concave side which may be nearer to the head of the comet. I think it rather looks as if the tail, in its rapid motion, met with some slight resistance just sufficient to cause a small condensation in that side of it which moves foremost, and which would occasion it to appear a little brighter and better defined than the other side; which slight resistance may arise from that subtle ether which is supposed to be dispersed through the celestial regions, or from this very electric matter dispersed in the same manner, if it be different from the ether.⁶¹

On the last part of this observation we must remark, that though a slight resistance in the ethereal medium would have served Sir Isaac Newton's turn, it will by no means serve Dr Hamilton's; for though a stream of water or air may be easily destroyed or broken by resistance, yet a stream of electric matter seems to set every obstacle at defiance. If a sharp needle is placed on the conductor of an electric machine, and the machine set in motion, we will perceive a small stream of electric matter issuing from the point; but though we blow against this stream of fire with the utmost violence, it is impossible either to move it, or to brighten it on the side against which we blow. If the celestial spaces then are full of a subtle ether capable of thus affecting a stream of electric matter, we may be sure that it also will resist very violently; and we are then as much diffculted to account for the projectile motion continuing amidst such violent resistance; for if the ether resists the tail of the comet, it is impossible to prove that it doth not resist the head also.

This objection may appear to some to be but weakly founded, as we perceive the electric fluid to be endowed with such extreme subtilty, and to yield to the impression of solid bodies with such facility, that we easily imagine it to be of a very passive nature in all cases. But we are inclined to think, that this fluid only shews itself passive where it passes from one body into another, which it seems very much inclined to do of itself. We are also much mistaken, if it will not be found, on proper examination of all the phenomena, that the only way we can manage the electric fluid at all is by allowing it to direct its own motions. In all cases where we ourselves attempt to assume the government of it, it shews itself the most untractable and stubborn being in nature. But these things come more properly under the article ELECTRICITY, where they are fully considered. Here, it is sufficient to observe, that a stream of electric matter resists air, and from the phenomena of electric repulsion we are sure that one stream of electric matter resists another; from which we may be also certain, that if a stream of electric matter moves in an aerial fluid, such fluid will resist it, and we can only judge of the degree of resistance it meets with in the heavens from what we observe on earth. Here we see the most violent blast of air has no effect upon a stream of electric fluid; in the celestial regions, either air, or some other fluid, has an effect upon it according to Dr Hamilton. The resistance of that fluid, therefore, must be greater than that of the most violent blast of air we can imagine.

As to the Doctor's method of accounting for the curvature of the comet's tail, it might do very well on Sir Isaac Newton's principles, but cannot do so on his.

There is no comparison between the celerity with which rarefied vapour ascends in our atmosphere, and that whereby the electric fluid is discharged. The velocity of the latter seems to equal that of light; of consequence, supposing the velocity of the comet to be equal to that of the earth in its annual course, and its tail equal in length to the distance of the sun from the earth, the curvature of the tail could only be to a straight line, as the velocity of the comet in its orbit is to the velocity of light, which, according to the calculations of Dr Bradley, is as 10,201 to 1.—The apparent curvature of such a comet's tail, therefore, would at this rate only be $\frac{1}{10201}$ part of its visible length, and thus behoved always to be imperceptible. The velocity of comets is indeed sometimes inconceivably great. Mr Brydone observed one at Palermo, in July 1770, which in 24 hours described an arch in the heavens upwards of 50 degrees in length; according to which he supposes, that, if it was as far distant as the sun, it must have moved at the rate of upwards of 60 millions of miles in a day. But this comet was attended with no tail, so that we cannot be certain whether the curvature of the tails of these bodies corresponds with their velocity or not.

On this occasion Mr Brydone observes, that the comets without tails seem to be of a very different species from those which have tails: to the latter, he says, they appear to bear a much less resemblance than they do even to planets. He tells us that comets with tails have seldom been visible but on their recedes from the sun; that they are kindled up, and receive their alarming appearance, in their near approach to this glorious luminary; but that those without tails are seldom or never seen but on their way to the sun, and he does not recollect any whose return has been tolerably well ascertained. "I remember indeed (says he), a few years ago, a small one, that was said to have been discovered by a telescope after it had passed the sun, but never more became visible to the naked eye. This assertion is easily made, and nobody can contradict it; but it does not at all appear probable that it should have been so much less luminous after it had passed the sun, than before it approached him: and I will own to you, when I have heard that the return of these comets had escaped the eyes of the most acute astronomers, I have been tempted to think that they did not return at all, but were absorbed in the body of the sun, which their violent motion towards him seemed to indicate." He then attempts to account for the continual emission of the sun's light without waste, by supposing that there are numberless bodies throughout the universe that are attracted into the body of the sun, which serve to supply the waste of light, and which for some time remain obscure, and occasion spots on his surface, till at last they are perfectly dissolved and become bright like the rest. This hypothesis will account for the dark spots becoming as bright, or even brighter than the rest of the disk, but will by no means account for the brighter spots becoming dark. Of this comet too, Mr Brydone remarks, that it was evidently surrounded by an atmosphere which refracted the light of the fixed stars, and even seemed to cause them change their places as the comet came near them.

A very strange opinion we find set forth in a book Mr Cole's entitled hypothesis.

entitled "Observations and Conjectures on the nature and properties of light, and on the theory of comets, by William Cole." This gentleman supposes that the comets belong to no particular system; but were originally projected in such directions as would successively expose them to the attraction of different centres, and thus they would describe various curves of the parabolic and the hyperbolic kind. This treatise is written in answer to some objections thrown out in Mr Brydson's tour, against the motions of the comets by means of the two forces of gravitation and projection, which were thought sufficient for that purpose by Sir Isaac Newton; of which we shall treat as fully as our limits will allow, in the next section.

65
Fixed stars
supposed to
be suns.

With regard to the fixed stars, they are generally supposed to be of the same nature with our sun, each of them attended by planets as he is; and these planets, as well as those which attend our sun, are supposed like this earth to be inhabited by rational creatures.—The strongest argument for the fixed stars being suns is taken from the impossibility of magnifying their diameters by the best telescopes, which is thought to arise from the vast distance at which they are placed from the earth. As it is impossible that they can be seen by any reflection of light from the sun at such immense distances, we must therefore necessarily suppose them endowed with a power of emitting light from their own bodies; and by comparing the apparent diameters of objects at different distances, it is conjectured that our sun would appear but like a star, was he to be removed to the distance at which they are placed. Of consequence, the fixed stars are supposed to be equal if not superior in magnitude to that which is the centre of our system; and as it would be absurd to suppose the wife Author of nature to have made so many suns without any thing to shine upon, it is thence concluded that they are attended by planets, which receive the same benefit from them that the earth does from our sun. In like manner, it would be absurd to suppose so many habitable worlds enlightened by suns without having any inhabitants; and therefore it is concluded, that all the planets of every system are inhabited: to corroborate which hypothesis the infinite benevolence of the Deity is urged, who would not, it is thought, suffer any part of the visible creation to want living creatures that might be spectators of his goodness. It is also asserted, that even the planets belonging to our own system are but of a very trifling use to this earth, their whole combined light being much less than that of the moon alone. Much less can we suppose the fixed stars to be made for the use of this earth: for many of them are utterly invisible without the assistance of telescopes; and when they are thus seen, only appear as so many shining points; and it would be absurd to the highest degree to think that they were created merely to be seen by astronomers.

The fixed stars are not supposed to be at equal distances from us, but to be more remote in proportion to their apparent smallness. This supposition is necessary to prevent any interference of their planets; and thus there may be as great a distance between a star of the first magnitude and one of the second apparently close to it, as between the earth and the fixed stars first mentioned.

Those who take the contrary side of the question,

affirm that the disappearance of some of the fixed stars is a demonstration that they cannot be suns, as it would be to the highest degree absurd to think that God would create a sun which might disappear of a sudden and leave its planets and their inhabitants in endless night. Yet this opinion, we find adopted by Dr Keil, who tells us, "It is no ways improbable that these stars lost their brightness by a prodigious number of spots which entirely covered and overwhelmed them. In what dismal condition must their planets remain, who have nothing but the dim and twinkling light of the fixed stars to enlighten them?" Others, however, have made suppositions more favourable to the benevolent character of the Deity. Sir Isaac Newton thinks that the sudden blaze of some stars may have been occasioned by the falling of a comet into them, by which means they would be enabled to emit a prodigious light for a little time, after which they would gradually return to their former state. Others have thought that the variable ones, which disappear for a time, were planets, which were only visible during some part of their course: but this their apparent immobility, notwithstanding their decrease of lustre, will not allow us to think. Some have imagined, that one side of them might be naturally much darker than the other, and when by the revolution of the star upon its axis the dark side was turned towards us, the star became invisible, and, for the same reason, after some interval, resumed its former lustre. Lastly, Mr Dunn, (Phil. Transf. Vol. LII.) in a dissertation concerning the apparent increase of magnitude in the heavenly bodies when they approach the horizon, conjectures that the interposition of some gross atmosphere may solve the phenomena both of nebulous and new stars. "The phenomena of nebulous and new stars (says he) have engaged the attention of curious astronomers; but none that I know of have given any reason for the appearance of nebulous stars. Possibly what has been before advanced may also be applicable for investigating reasons for those strange appearances in the remotest parts of the universe.

66
Arguments
for the plu-
rality of
worlds.

"From many instances which might be produced concerning the nature and properties of lights and illuminations on the earth's surface, concerning the nature and properties of the earth's atmosphere, and concerning the atmospheres and illuminations of comets, we may safely conclude, that the atmospheres of comets and of our earth are more gross in their nature than the ethereal medium which is generally diffused through the solar system. Possibly a more aqueous vapour in the one than the other makes the difference. Now, as the atmospheres of comets and of planets in our solar system are more gross than the ether which is generally diffused through our solar system, why may not the ethereal medium diffused throughout those other solar systems (whose centres are their respective fixed stars) be more gross than the ethereal medium diffused throughout our solar system? This indeed is an hypothesis, but such an one as agrees exactly with nature. For these nebulous stars appear so much like comets, both to the naked eye and through telescopes, that the one cannot always, by any difference of their extraneous light, be known from the other.

"Such orbs of gross ether reflecting light more copiously, or like the atmospheres of comets, may help

us to judge of the magnitudes of the orbs illuminated by those remote suns, when all other means seem to fail.

“The appearance of new stars, and disappearance of others, possibly may be occasioned by the interposition of such an ethereal medium, within their respective orbs, as either admits light to pass freely, or wholly absorbs it at certain times, whilst light is constantly pursuing its journey through the vast regions of space.”

70
Fixed stars
supposed to
by some to
be polished
globes.

The other arguments for the plurality of worlds, the opposers of this doctrine attempt to evade, by telling us that the not being able to magnify the fixed stars with telescopes is not a sufficient proof of their immense distance. We know, say they, that light may be reflected so as that no telescope whatever could magnify the object from which it is reflected; and this without supposing it at any great distance. Thus, the light of the sun reflected from a polished globe of metal, or of glass quick-silvered, shews an image of him like a small star, and which would be visible at a great distance, without a possibility of being magnified. If we then suppose the fixed stars to be polished globes reflecting the sun's light, we may account for the impossibility of magnifying them without ascribing to them such an extravagant distance. An hypothesis something similar to this was published a few years ago at London. A formidable objection against it seems to be the apparent immobility of the stars with regard to one another, notwithstanding the continual motion of the earth, which one would naturally imagine behoved to cause a considerable variation of the apparent places of the fixed stars at different times of the year.

Sect. IV. Of the different Systems by which the Celestial Phenomena have been accounted for.

In treating of the various systems which have been invented in different ages, we do not mean to give an account of all, or even the greatest part, of the absurdities that have been broached by individuals on this subject; but shall confine ourselves to those systems which have been of considerable note, and been generally followed for a number of years. Concerning the opinions of the very first astronomers about the system of nature, we are necessarily as ignorant as we are of those afterwards themselves. Whatever opinions are handed down to us, must be of a vastly later date than the introduction of astronomy among mankind. If we may hazard a conjecture, however, we are inclined to think that the first opinions on this subject were much more just than those that were held afterwards for many ages.

71
Pythagorean system.

We are told that Pythagoras maintained the motion of the earth, which is now universally believed, but at that time appears to have been the opinion of only a few detached individuals of Greece. As the Greeks borrowed many things from the Egyptians, and Pythagoras had travelled into Egypt and Phenice, it is probable he might receive an account of this hypothesis from thence: but whether he did so or not, we have now no means of knowing, neither is it of any importance whether he did or not. Certain it is, however, that this opinion did not prevail in his days, nor for many ages after. In the 2^d century after Christ, the very name of the Pythagorean hypothesis was suppressed by a system erected by the famous geographer

72
Suppressed by the Ptolemaic.

and astronomer Claudius Ptolemæus. This system, which commonly goes by the name of the *Ptolemaic*, he seems not to have originally invented, but adopted as the prevailing one of that age; and perhaps made it somewhat more consistent than it was before. He supposed the earth at rest in the centre of the universe. Round the earth, and the nearest to it of all the heavenly bodies, the moon performed its monthly revolutions. Next to the moon, was placed the planet Mercury; then Venus; and above that the Sun, Mars, Jupiter, and Saturn, in their proper orbits; then the sphere of the fixed stars; above these, two spheres of what he called *crystalline* heavens; above these was the primum mobile, which by turning round once in 24 hours, by some unaccountable means or other, carried all the rest along with it. This primum mobile was encompassed by the empyrean heaven, which was of a cubic form, and the seat of angels and blessed spirits. Besides the motions of all the heavens round the earth once in 24 hours, each planet was supposed to have a particular motion of its own; the moon, for instance, once in a month, performed an additional revolution, the sun in a year, &c.

73
Ptolemy's system insufficient.

It is easy to see, that, on this supposition, the confused motions of the planets already described, could never be accounted for. Had they circulated uniformly round the earth, their apparent motion ought always to have been equal and uniform, without appearing either stationary, or retrograde, in any part of their courses. In consequence of this objection, Ptolemy was obliged to invent a great number of circles interfering with each other, which he called *epicycles* and *excentrics*. These proved a ready and effectual salvo for all the defects of his system; as whenever a planet was deviating from the course it ought, on his plan, to have followed, it was then only moving in an epicycle or an excentric, and would in due time fall into its proper path. As to the natural causes by which the planets were directed to move in these epicycles and excentrics, it is no wonder that he found himself much at a loss, and was obliged to have recourse to divine power for an explanation, or, in other words, to own that his system was unintelligible.

74
Pythagorean system revived by Copernicus.

This system continued to be in vogue till the beginning of the 16th century, when Nicolaus Copernicus, a native of Thorn (a city of regal Prussia), and a man of great abilities, began to try whether a more satisfactory manner of accounting for the apparent motions of the heavenly bodies could not be obtained than was afforded by the Ptolemaic hypothesis. He had recourse to every author upon the subject, to see whether any had been more consistent in explaining the irregular motions of the stars, than the mathematical schools; but received no satisfaction, till he found, first from Cicero, that Nicetas the Syracusan had maintained the motion of the earth; and next, from Plutarch, that others of the ancients had been of the same opinion. From the small hints he could obtain from the ancients, Copernicus then deduced a most complete system capable of solving every phenomenon in a satisfactory manner. From him this system hath ever afterwards been called the *Copernican*, and represented Plate XLIII. fig. 1. Here the sun is supposed to be in the centre; next him revolves the planet Mercury; then Venus; next, the Earth, with the Moon; beyond these, Mars, Jupiter, and Sa-

turn;

turn; and far beyond the orbit of Saturn, he supposed the fixed stars to be placed, which formed the boundaries of the visible creation.

Though this hypothesis afforded the only natural and satisfactory solution of the phenomena which so much perplexed Ptolemy's system, it met with great opposition at first; which is not to be wondered at, considering the age in which he lived. Even the famous astronomer Tycho Brahe could never assent to the earth's motion, which was the foundation of Copernicus's scheme. He therefore invented another system, whereby he avoided the ascribing of motion to the earth, and at the same time got clear of the difficulties with which Ptolemy was embarrassed. In this system, the earth was supposed the centre of the orbits of the sun and moon; but the sun was supposed to be the centre of the orbits of the five planets; so that the sun with all the planets were by Tycho Brahe supposed to turn round the earth, in order to save the motion of the earth round its axis once in 24 hours. This system was never much followed, the superiority of the Copernican scheme being evident at first sight.

The system of Copernicus coming soon into universal credit, philosophers began to inquire into the causes of the planetary motions; and here, without entering upon what has been advanced by detached individuals, we shall content ourselves with giving an account of the three famous systems, the Cartesian, the Newtonian, and what is sometimes called the *Mechanical* system.

Des Cartes, the founder of that system which since his time has been called the *Cartesian*, flourished about the beginning of the 17th century. His system seems to have been borrowed from the philosophers Democritus and Epicurus; who held, that every thing was formed by a particular motion of very minute bodies called *atoms*, which could not be divided into smaller parts. But tho' the philosophy of Des Cartes resembled that of the Corporealians, in accounting for all the phenomena of nature merely from matter and motion; he differed from them in supposing the original parts of matter capable of being broken. To this property his *Materia Subtilis* owes its origin. To each of his atoms, or rather small masses of matter, Des Cartes attributed a motion on its axis, and likewise maintained that there was a general motion of the whole matter of the universe round like a vortex or whirlpool. From this complicated motion, those particles, which were of an angular form, would have their angles broke off; and the fragments which were broke off being smaller than the particles from which they were abraded, behaved to form a matter of a more subtle kind than that made of large particles; and as there was no end of the abrasion, different kinds of matter of all degrees of fineness would be produced. The finest sorts, he thought, would naturally separate themselves from the rest, and be accumulated in particular places. The finest of all would therefore be collected in the sun, which was the centre of the universe, whose vortex was the whole ethereal matter in the creation. As all the planets were immersed in this vortex, they behaved to be carried round by it, in different times, proportioned to their distances; those which were nearest the sun, circulating the most quickly; and those farthest off, more slowly; as those parts of a vortex which are farthest removed from the centre are observed to circulate more slowly

than those which are nearest. Besides this general vortex of the sun, each of the planets had a particular vortex of their own by which their secondary planets were carried round, and any other body that happened to come within reach of it would likewise be carried away.

It is easy to see, from this short account of Des Cartes's system, that the whole of it was a mere *petitio principii*: for had he been required to prove the existence of his *materia subtilis*, he must undoubtedly have failed in the attempt; and hence, though his hypothesis was for some time followed for want of a better, yet it gave way to the Newtonian almost as soon as the latter was proposed.

When Sir Isaac Newton undertook the reformation of philosophy, he proceeded upon a very different plan from all those who had gone before him, as he proposed to assume nothing as an hypothesis which was not deduced from what is obvious to our eyes; and thus, by arguing from those things which are within our reach, he thought we might come to know with certainty, what must happen in the celestial regions, to which access is denied us. The manner in which he was first led to form his system of gravitation, which hath since been so universally received, is said to have been as follows. He was sitting alone in a garden, when some apples, falling from a tree, led his thoughts upon the subject of gravity; and reflecting on the power of that principle, he began to consider, that, as this power is not found to be sensibly diminished at the remotest distance from the centre of the earth to which we can rise, neither at the tops of the loftiest buildings, nor on the summits of the highest mountains, it appeared to him reasonable to conclude that this power must extend much further than was usually thought.

"Why not as far as the moon? (said he to himself); and if so, her motion must be influenced by it; perhaps she is retained in her orbit thereby: however, though the power of gravity is not sensibly weakened in the little change of distance at which we can place ourselves from the centre of the earth, yet it is very possible, that, as high as the moon, this power may differ much in strength from what it is here." To make an estimate what might be the degree of this diminution, he considered with himself, that if the moon be retained in her orbit by the force of gravity, no doubt the primary planets are detained in their orbits by a similar gravitation towards the sun; and by comparing the periods of the several planets with their distances from the sun, he found, that if any power like gravity held them in their courses, its strength must decrease in the duplicate proportion of the increase of distance. This was concluded from a supposition that these bodies moved in perfect circles round the sun; which though they are not found to do exactly, yet the error was but of little consequence. The fact itself will be understood from the following considerations. Let B Y U (Plate XLIV. fig. 3.) be the orbit of a planet round the sun S. It is manifest from inspection, that during the time in which the planet moves from B to Y, it deviates in a perpendicular direction from the tangent line A B X, by the space X Y, equal to B y which is the versed sine of the arch B Y. Were the planet therefore retained in its orbit by a gravitating power towards the sun, it would require for this purpose a power of gra-

vity.

gra-

gravitation sufficient to make it fall towards the sun, or, at least, to deviate from a tangent, by the whole length of the versed sine of the arch which it describes in the same time. Thus, suppose the planet is observed to move from B to Y in the space of a minute; we thence know, that, had it been left to the force of gravity alone, it would have fallen from B to y in the same time. In proportion as the radius is lengthened, the length of the arch B Y will become a proportionably smaller part of the circle, and thus approach more nearly to the right line A B X; so that, if we suppose one planet both to take longer time to describe the same space in its orbit, and likewise to deviate less from a straight line in describing that space than another does, it is plain that the force of gravity must be much greater in the latter than in the former. By comparing in this manner the distances of the several planets from the sun, and of the secondary planets from their primaries, Sir Isaac Newton observed the gravitating power towards each body to decrease in a duplicate proportion to the increase of distance from the sun, or from the primary planet, as already mentioned.

81
Gravity not proportioned to the bulks of the celestial bodies.

In the course of these observations a very singular circumstance occurred, namely, that the force of gravity was not at all proportioned to the apparent bulk of the planets, or even of the sun himself. In this respect the earth seems to have the advantage over all the other bodies in the system. This is discovered by comparing the bulk of the sun with that of the several planets, and the bulk of the earth with that of the moon, and her distance from the earth. From this comparison it appears, that our moon is vastly larger in proportion than any of those belonging to Jupiter or Saturn, and consequently more difficult to be retained in her orbit: her distance is also much greater than that of the most remote satellites of these planets, as is obvious from their figures.

82
An objection drawn from thence.

This seemed to be a difficulty in Sir Isaac's hypothesis of gravity: for if such a property existed in all bodies, and was proportioned to their quantities of matter, it was naturally asked why it was not in proportion to the bulk of the sun or planets. To obviate this objection, Sir Isaac, observing the effect of fire on our earth to rarefy bodies and make them occupy more space than they did before, naturally enough concluded that the sun was of a more rare substance, or contained less matter in proportion to his bulk than the earth did; and having considered the matter mathematically, he concluded the sun to be four times rarer than the earth.

But though the difficulty was removed with regard to the sun, it still remained as to Jupiter and Saturn; both of these planets being found by observations of the distances and periodical times of their satellites, to be rarer than the earth; whereas, in the opinion of Des Cartes and other philosophers, they were more dense, as being placed at a greater distance from the sun, and in a colder region. Indeed, according to the above-mentioned cause of the sun's rarefaction, these planets ought to have been accounted more dense bodies than this earth; but whatever was the reason, Sir Isaac and all philosophers who followed him have considered them as much rarer. For this supposition, they have not assigned any natural cause; but chosen to refer it to the will of the Deity, and think his wisdom is

manifested in placing the densest planets next the sun, that they may be able to resist his heat, and the rarest at a distance from him, that they may not be too much consolidated by the cold.

As for Des Cartes's method of accounting for the planetary motions, Sir Isaac Newton entirely overturned it, by shewing, that, if they were carried about in a vortex of fluid matter, their periodical times behaved to be directly as the squares of their distances from the sun; whereas from observation it is found, that the squares of the periodical times of the planets are as the cubes of their distances. He also shewed, that no motion could be continued in a fluid medium, because whatever body moved in such a medium behaved to communicate its motion to the fluid. In proportion as motion was communicated to the fluid, it behaved to be lost to the body; which, besides, would be resisted by the fluid itself, and this resistance would be in the proportion of the square of the velocity where-with the body moved: and for these reasons he concluded that the celestial regions were entirely void of matter, excepting perhaps some exceedingly rare exhalations from the planets and comets, and the rays of light, which were considered by him as substances of such extreme tenuity as to give no sensible resistance to any body whatever.

83
Cartes's vortices proved to have no existence.

To account for the perpetual motions of the planets and comets in their orbs, Newton had recourse to the force of gravity already mentioned, and a projectile force compounded with it. These two forces had indeed been proposed by Mr Horrox some time before with the same view, and the power of gravity as existing in the celestial regions had been hinted at by several philosophers; but before Sir Isaac, little notice had been taken of this scheme; owing, no doubt, to the inferiority of those geniuses who had proposed it, to that of our celebrated philosopher. As Sir Isaac was ignorant of any natural power by which the planets could be impelled in the direction of a tangent line to any part of their orbits, he was obliged to have recourse for one of his forces to the immediate action of the Deity himself. According to him, God having created this world, and impressed the universal law of attraction or gravitation upon matter, impelled each of the planets in the direction of a right line touching their orbits. Being immediately acted upon by the attraction of the sun, their courses were bent from a straight line into a circle; and the same causes still continuing to act, the original rectilinear direction was changed into one nearly circular, which has continued ever since. The same reason was given for the continued motion of the secondary planets round their primaries; but as for the motion of the earth, sun, and planets, round their axis, we have not heard that the Newtonian philosophers assign any natural cause.

84
Planetary revolutions accounted for.

Upon this plan Sir Isaac Newton accounted for the motion both of planets and comets; the latter of which had been, and still is, an insuperable objection to the system of Des Cartes: for, if such a vast whirlpool of fluid matter, as that philosopher supposed, had existed, it is absolutely impossible, without a continued miracle, but it must have carried along with it the comets as well as the planets. The manner in which Sir Isaac Newton demonstrates the operation of the projectile and gravitating forces upon the planets so as to direct them

them in circles round the sun, is by supposing the orbit they describe divided into a vast number of infinitely small parts, each of which will not differ from a right line, and consequently the whole curve may be considered as consisting of the diagonals of parallelograms infinitely small, one of whose sides is represented by the space the planet would have moved through by the projectile force alone, and the other by that which it would have moved through by the force of gravity alone in the same time. Those who want to enter deeply into this speculation will find themselves amply satisfied by looking into Newton's *Principia*; but for the sake of those who may be less learned, and yet want to have a general knowledge of these things, we subjoin the following explanation by Mr Ferguson.

85
Explanation
by Mr
Ferguson.

Plate XLIV.
fig. 3.

“From the uniform projectile motion of bodies in straight lines, and the universal power of attraction which draws them off from these lines, the curvilinear motions of all the planets arise. If the body *A* be projected along the right line *A B X*, in open space, where it meets with no resistance, and is not drawn aside by any other power, it will for ever go on with the same velocity, and in the same direction. For the force which moves it from *A* to *B* in any given time, will carry it from *B* to *X* in as much more time, and so on, there being nothing to obstruct or alter its motion. But if, when this projectile force has carried it, suppose to *B*, the body *S* begins to attract it, with a power duly adjusted, and perpendicular to its motion at *B*, it will then be drawn from the straight line *A B X*, and forced to revolve about *S* in the circle *B Y T U*. When the body *A* comes to *U*, or any other part of its orbit, if the small body *u*, within the sphere of *U*'s attraction, be projected as in the right line *Z*, with a force perpendicular to the attraction of *U*, then *u* will go round *U* in the orbit *W*, and accompany it in its whole course round the body *S*. Here, *S* may represent the sun, *U* the earth, and *u* the moon.

“If a planet at *B* gravitates, or is attracted, toward the sun, so as to fall from *B* to *y*, in the time that the projectile force would have carried it from *B* to *X*, it will describe the curve *B Y* by the combined action of these two forces, in the same time that the projectile force singly would have carried it from *B* to *X*, or the gravitating power singly have caused it to descend from *B* to *y*; and these two forces being duly proportioned, and perpendicular to each other, the planet obeying them both will move in the circle *B Y U*. To make the projectile force balance the gravitating power so exactly, as that the body may move in a circle, the projectile velocity of the body must be such as it would have acquired by gravity alone in falling through half the radius of the circle.

“But if, whilst the projectile force would carry the planet from *B* to *b*, the sun's attraction (which constitutes the planet's gravitation) should bring it down from *B* to *1*, the gravitating power would then be too strong for the projectile force, and would cause the planet to describe the curve *B C*. When the planet comes to *C*, the gravitating power (which always increases as the square of the distance from the sun *S* diminishes) will be yet stronger for the projectile force; and, by conspiring in some degree therewith, will accelerate the planet's motion all the way from *C* to *K*; causing it to describe the arcs *B C*, *C D*, *D E*, *E F*,

&c. all in equal times. Having its motion thus accelerated, it thereby gains so much centrifugal force, or tendency to fly off at *K* in the line *K k*, as overcomes the sun's attraction: and the centrifugal force being too great to allow the planet to be brought nearer the sun, or even to move round him in the circle *K l m n*, &c. it goes off, and ascends in the curve *K L M N*, &c. its motion decreasing as gradually from *K* to *B*, as it increased from *B* to *K*, because the sun's attraction now acts against the planet's projectile motion just as much as it acted with it before. When the planet has got round to *B*, its projectile force is as much diminished from its mean state about *G* or *N*, as it was augmented at *K*; and so the sun's attraction being more than sufficient to keep the planet from going off at *B*, it describes the same orbit over again, by virtue of the same forces or powers.

“A double projectile force will always balance a quadruple power of gravity. Let the planet at *B* have twice as great an impulse from thence towards *X*, as it had before; that is, in the same length of time that it was projected from *B* to *b*, as in the last example, let it now be projected from *B* to *c*; and it will require four times as much gravity to retain it in its orbit: that is, it must fall as far as from *B* to *d* in the time that the projectile force would carry it from *B* to *c*; otherwise it could not describe the curve *BD*, as is evident by the figure. But, in as much time as the planet moves from *B* to *C* in the higher part of its orbit, it moves from *I* to *K*, or from *K* to *L*, in the lower part thereof; because, from the joint action of these two forces, it must always describe equal areas in equal times throughout its annual course. These areas are represented by the triangles *BSC*, *CSD*, *DSE*, *ESF*, &c. whose contents are equal to one another, quite round the figure.

“As the planets approach nearer the sun, and recede farther from him, in every revolution; there may be some difficulty in conceiving the reason why the power of gravity, when it once gets the better of the projectile force, does not bring the planets nearer and nearer the sun in every revolution, till they fall upon and unite with him; or why the projectile force, when it once gets the better of gravity, does not carry the planets farther and farther from the sun, till it remove them quite out of the sphere of his attraction, and cause them to go on in straight lines for ever afterward. But by considering the effects of these powers as described in the two last articles, this difficulty will be removed. Suppose a planet at *B* to be carried by the projectile force as far as from *B* to *b*, in the time that gravity would have brought it down from *B* to *1*: by these two forces it will describe the curve *B C*. When the planet comes down to *K*, it will be but half as far from the sun *S* as it was at *B*; and therefore, by gravitating four times as strongly towards him, it would fall from *K* to *V* in the same length of time that it would have fallen from *B* to *1* in the higher part of its orbit, that is, through four times as much space; but its projectile force is then so much increased at *K*, as would carry it from *K* to *k* in the same time; being double of what it was at *B*; and is therefore too strong for the gravitating power, either to draw the planet to the sun, or cause it go round him in the circle *K l m n*, &c. which would require its falling from *K* to *u*, thro'

a greater space than gravity can draw it, whilst the projectile force is such as would carry it from K to k; and therefore the planet ascends in its orbit KLMN, decreasing in its velocity for the causes already assigned.

“By the above-mentioned law, bodies will move in all kinds of ellipses, whether long or short, if the spaces they move in be void of resistance. Only, those which move in the longer ellipses, have so much the less projectile force impressed upon them in the higher parts of their orbits; and their velocities, in coming down towards the sun, are so prodigiously increased by his attraction, that their centrifugal forces in the lower parts of their orbits are so great as to overcome the sun's attraction there, and cause them to ascend again towards the higher parts of their orbits; during which time, the sun's attraction acting so contrary to the motions of those bodies, causes them to move slower and slower, until their projectile forces are diminished almost to nothing; and then they are brought back again by the sun's attraction, as before.

86
Gravity and
projectile
force ac-
counted for.

“The sun and planets mutually attract each other: the power by which they do so we call *gravity*. But whether this power be mechanical or not, is very much disputed. Observation proves, that the planets disturb one another's motions by it; and that it decreases according to the squares of the distances of the sun and planets; as light, which is known to be material, likewise does. Hence gravity should seem to arise from the agency of some subtle matter pressing towards the sun and planets, and acting, like all mechanical causes, by contact. But, on the other hand, when we consider that the degree or force of gravity is exactly in proportion to the quantities of matter in those bodies, without any regard to their bulks or quantities of surface, acting as freely on their internal as external parts; it seems to surpass the power of mechanism; and to be either the immediate agency of the Deity, or effected by a law originally established and impressed on all matter by him. But some affirm that matter, being altogether inert, cannot be impressed with any law even by almighty power; and that the Deity, or some subordinate intelligence, must therefore be constantly impelling the planets toward the sun, and moving them with the same irregularities and disturbances which gravity would cause, if it could be supposed to exist. But, if a man may venture to publish his own thoughts, it seems to me no more an absurdity, to suppose the Deity capable of infusing a law, or what laws he pleases, into matter, than to suppose him capable of giving it existence at first. The manner of both is equally inconceivable to us; but neither of them imply a contradiction in our ideas, and what implies no contradiction is within the power of Omnipotence.

“That the projectile force was at first given by the Deity, is evident. For, since matter can never put itself in motion, and all bodies may be moved in any

direction whatsoever; and yet the planets, both primary and secondary, move from west to east, in planes nearly coincident; whilst the comets move in all directions, and in planes very different from one another; these motions can be owing to no mechanical cause or necessity, but to the free will and power of an intelligent Being.

“Whatever gravity be, it is plain that it acts every moment of time: for if its action should cease, the projectile force would instantly carry off the planets in straight lines from those parts of their orbits where gravity left them. But, the planets being once put into motion, there is no occasion for any new projectile force, unless they meet with some resistance in their orbits; nor for any amending hand, unless they disturb one another too much by their mutual attractions.

“It is found that there are disturbances among the planets in their motions, arising from their mutual attractions when they are in the same quarter of the heavens; and the best modern observers find that our years are not always precisely of the same length (A). Besides, there is reason to believe that the moon is somewhat nearer the earth now than she was formerly; her periodical month being shorter than it was in former ages. For our astronomical tables, which in the present age shew the times of solar and lunar eclipses to great precision, do not answer so well for very ancient eclipses. Hence it appears, that the moon does not move in a medium void of all resistance; and therefore her projectile force being a little weakened, whilst there is nothing to diminish her gravity, she must be gradually approaching nearer the earth, describing smaller and smaller circles round it in every revolution, and finishing her period sooner, although her absolute motion with regard to space be not so quick now as it was formerly: and, therefore, she must come to the earth at last; unless that Being which gave her a sufficient projectile force at the beginning, adds a little more to it in due time. And, as all the planets move in spaces full of ether and light, which are material substances, they too must meet with some resistance. And therefore, if their gravities are not diminished, nor their projectile forces increased, they must necessarily approach nearer and nearer the sun, and at length fall upon and unite with him.

87
Planets disturb one another's motions.

88
Must necessarily approach the sun.

“Here we have a strong philosophical argument against the eternity of the world. For, had it existed from eternity, and been left by the Deity to be governed by the combined actions of the above forces or powers, generally called *Laws*, it had been at an end long ago. And if it be left to them, it must come to an end. But we may be certain that it will last as long as was intended by its Author, who ought no more to be found fault with for framing so perishable a work, than for making man mortal (B).”

89
World not eternal.

Though this system hath now obtained in a manner universal

(A) If the planets did not mutually attract one another, the areas described by them would be exactly proportionate to the times of description. But observations prove, that these areas are not in such exact proportion, and are most varied when the greatest number of planets are in any particular quarter of the heavens. When any two planets are in conjunction, their mutual attractions, which tend to bring them nearer to one another, draws the inferior one a little farther from the sun, and the superior one a little nearer to him; by which means, the figure of their orbits is somewhat altered; but this alteration is too small to be discovered in several ages.

(B) A difficulty of this kind we find obviated in a pamphlet intitled *Thoughts on General Gravitation, &c. &c. &c.* The author of this performance, after considering how necessary a projectile force is to counteract the power of gravity acting

jections come more properly to be noticed under the article GRAVITY. As to the particular phenomenon in question, namely, the revolutions of the celestial bodies in orbits nearly circular, the following objections are raised against the Newtonian scheme.

92
Gravitation
and project-
ile force
objected to.

1. "It is highly absurd, not to say impious, to think of compounding a motion by a mixture of Divine and created power. If the Deity projects the planets in a right line, how can a created *quality* make them deviate from that line? If we are to suppose the Deity to project them at all, why do we not suppose him to project them in a circular or elliptical direction? Or can God only project bodies in a right line as men can do?"

2. "The Newtonian method of explaining the celestial motions by the diagonals of parallelograms infinitely small, involves us in a contradiction no less than that of supposing the radii of a circle to be parallel to one another. This is evident from an inspection of fig. 3. Plate XLIV. When the planet lets out from B, it is drawn by the force of gravity towards S in the direction SB. When it arrives at Y, gravity no longer draws it in the direction SB, or XY, but in that of a radius drawn from S to Y. Unless therefore we suppose these two radii to be parallel to one another, which is evidently absurd, we cannot say that the planet moves from B to Y by a force compounded of those represented by BX and BY; as the latter is every moment varying in its direction. By supposing the arches to be infinitely small indeed, we may think to get over the difficulty; but it is a mere deception. Perhaps it may be thought no absurdity to say, that one radius of a circle is parallel to another drawn at an infinitely small distance from it: but to a Being whose eyes are *infinitely good*, the absurdity will appear as great as it does to us to say that the lines SD and SB are parallel to one another; and whatever appears an absurdity to him, will also appear an absurdity to us when multiplied so as to become visible.

3. "Granting that there is no absurdity in the abovementioned supposition, it is absolutely impossible that the power of gravity, acting in the manner which it is found to do on earth, can be the means of retaining any body in a circular or any other kind of orbit, but must at last overcome the strongest projectile force we can imagine. Neither will any law, by which we can suppose this power to be regulated, answer our purpose better. If we suppose gravity to be a power acting uniformly, the planet will run off in a curve approaching every moment nearer to a straight line. If it is accelerated in any proportion whatever, the projectile force, however strong, must at last be overcome; and the planet for some time behaved to describe a strange kind of curve, very different either from a circle, parabola, or ellipsis, and would at last come to the centre.

5th Plate
XLII. fig. 1.

"To illustrate this, let S represent the sun, diffusing the attractive rays SB, Sa, Sb, &c. Let us next suppose a planet projected from B, in the direction B₁, in such a manner that it would move through the spaces Ba, Bb, Bc, &c. by the force of projection alone, in the same times that it would describe the spaces B₁, B₂, B₃, &c. by the force of gravity alone. According to the laws of compound forces, therefore, it must describe the diagonal of the parallelogram Bx, in the same time that it would have described the side

Bz by the projectile force alone. The diagonal of a right-angled parallelogram is always longer than its side: the planet therefore has, in the same time in which it would have described the space Ba, described that of Bx, which is larger; and consequently has received an addition of velocity. Let us now suppose the force of gravity to be annihilated, or to cease its action. It is plain that the planet, by reason of the acceleration it has already received, would move from x to y in the same time that it would have moved from a to b by the projectile force originally impressed upon it. The diagonal of the former parallelogram must therefore become the side of the next one, and if we suppose gravity again to begin its action, the planet will evidently acquire an additional acceleration during the next moment, and thus describe the line yz. For the same reason, it is plain, that the side of every succeeding parallelogram must be the diagonal of the former; and thus the planet will describe the curve Bxyzm, &c. which, if traced out, would become a kind of increasing spiral, that would carry it, after the first half revolution, farther and farther off from the centre S.

"Let us now suppose the gravitating power to accelerate bodies in the celestial regions in the same proportion that it is found to do on earth, and the case will be still worse. We must always consider, that the power of gravity tends to bring bodies to a centre, and not merely away from the tangent line B*i*. In proportion, therefore, as the force of gravity is increased, the planet must every moment come nearer the centre than it would have been had it moved uniformly on in the straight line B*i*. By the time, therefore, it would have arrived at a by the original force of projection, it must be nearer the centre S by the space B₁, and consequently be at x. By the time it would have arrived at b, it must be nearer the centre by the space B₄, and consequently be at s. For the same reasons it must come continually nearer and nearer the centre, describing a kind of curve Bxsm, &c. till at last it falls into it altogether.

"This matter is equally capable of being illustrated from the figure by which Mr Ferguson illustrates the Newtonian hypothesis. For, supposing the planet to have moved from B to Y, by the united forces of projection and gravitation, in the same time that it would have moved from B to X by the force of projection, it is plain, that supposing the power of gravity to cease when the planet has arrived at Y, it would then fly off in a line touching the point Y, with a velocity increased in the proportion of the length of the arch BY to the line BX. Thus the projectile velocity behaved to be for ever increased, if we suppose the gravitating power to act uniformly; and to be entirely destroyed, if it is supposed to increase in the proportion 1, 3, 5, 7, &c. as it is found to do on earth.

"To state this in a different manner: Whatever power, motion, or velocity, receives a continual addition, must ultimately become *infinite*, or greater than any assignable quantity. If the power of gravity, therefore, acts on a planet uniformly, it must continually increase its projectile force, because it obliges it to move in the diagonal of a parallelogram, of which the projectile velocity is one side, and the gravitating power another. The projectile force, therefore, receiving a continual addition, will be ultimately increased beyond all cal-

calculation, and consequently the planet will perpetually remove farther and farther from the centre. If the power of gravity increases every moment after it first begins to act, as it is found to do on earth, it is equally plain that it must ultimately become infinite, and cannot be overcome by any projectile force whatever."

We have already observed, that by the two forces of gravitation and projection, Sir Isaac Newton accounted for the motion of the comets as well as planets. The former he supposed to revolve in very excentric ellipses; on account of their having got only a small degree of projection at first, by which means they are brought very near the sun by the force of gravity, from which they again acquire a prodigious degree of projectile force that carries them off on the other side, till, being gradually weakened by the attractive power, they return; and so on. To this doctrine in the particular instance of comets, Mr Brydone hath made some objections, on the occasion of the comet observed at Palermo, which we shall here lay before our readers in his own words.

"The astronomy of comets, from what I can remember of it, appears to be clogged with very great difficulties, and even some seeming absurdities. It is difficult to conceive, that these immense bodies, after being drawn to the sun with the velocity of a million of miles in an hour; when they have at last come almost to touch him, should then fly off from his body with the same velocity they approach it; and that too, by the power of this very motion that his attraction has occasioned. The demonstration of this I remember is very curious and ingenious; but I wish it may be entirely free from sophistry. No doubt, in bodies moving in curves round a fixed centre, as the centripetal motion increases, the centrifugal one increases likewise:—but how this motion, which is only generated by the former, should at last get the better of the power that produces it; and that too, at the very time this power has acquired its utmost force and energy; seems somewhat difficult to conceive. It is the only instance I know, wherein, the effect increasing regularly with the cause, at last, whilst the cause is still acting with full vigour, the effect entirely gets the better of the cause, and leaves it in the lurch. For the body attracted is at last carried away with infinite velocity from the attracting body:—by what power is it carried away?—Why, say our philosophers, by the very power of this attraction, which has now produced a new power superior to itself, to wit, the centrifugal force. However, perhaps all this may be reconcilable to reason; far be it from me to presume attacking so glorious a system as that of attraction. The law that the heavenly bodies are said to observe, in describing equal areas in equal times, is supposed to be demonstrated; and by this it would appear, that the centripetal and centrifugal forces alternately get the mastery of one another.

"However, I cannot help thinking it somewhat hard to conceive, that gravity should always get the better of the centrifugal force, at the very time that its action is the smallest, when the comet is at its greatest distance from the sun; and that the centrifugal force should get the better of gravity, at the very time that its action is the greatest, when the comet is at its nearest point to the sun.

"To a common observer, it would rather appear, that the sun, like an electric body, after it had once charged the objects that it attracted with its own effluvia or atmosphere, by degrees loses its attraction, and at last even repels them; and that the attracting power, like what we likewise observe in electricity, does not return again till the effluvia imbibed from the attracting body is dispelled or dissipated; when it is again attracted, and so on alternately. For it appears (at least to an unphilosophical observer) somewhat repugnant to reason to say that a body flying off from another body some thousands of miles in a minute, should all the time be violently attracted by that body, and that it is even by virtue of this very attraction that it is flying off from it.—He would probably ask, What more could it do, pray, were it really to be repelled?

"Had the system of electricity, and of repulsion as well as attraction, been known and established in the last age, I have little doubt that the profound genius of Newton would have called it to his aid; and perhaps accounted in a more satisfactory manner for many of the great phenomena of the heavens. To the best of my remembrance, we know of no body that possesses, in any considerable degree, the power of attraction, that in certain circumstances does not likewise possess the power of repulsion; the magnet, the tourmalin, amber, glass, and every electrical substance. Now, from analogy, as we find the sun so powerfully endowed with attraction, why may we not likewise suppose him to be possessed of repulsion? Indeed, this very power seems to be confessed by the Newtonians to reside in the sun in a most wonderful degree; for they assure us he repels the rays of light with such amazing force, that they fly upwards of 80 millions of miles in seven minutes. Now why should we confine this repulsion to the rays of light only? as they are material, may not other matter brought near his body be affected in the same manner? Indeed one would imagine, that their motion alone would create the most violent repulsion; and that the force with which they are perpetually flowing from the sun, would most effectually prevent every other body from approaching him; for this we find is the constant effect of a rapid stream of any other matter. But let us examine a little more his effects on comets. The tails of these bodies are probably their atmospheres rendered highly electrical, either from the violence of their motion, or from their proximity to the sun. Of all the bodies we know, there is none in so constant and so violent an electrical state as the higher regions of our own atmosphere. Of this I have been long convinced; for, send up a kite with a small wire about its string, only to the height of 12 or 1300 feet, and at all times it will produce fire, as I have found by frequent experience; sometimes when the air was perfectly clear, without a cloud in the hemisphere; at other times, when it was thick and hazy, and totally unfit for electrical operations below. Now, as this is the case at so small a height, and as we find the effect still grows stronger in proportion as the kite advances, (for I have sometimes observed, that a little blast of wind, suddenly raising the kite about 100 feet, has more than doubled the effect) what must it be in very great elevations? Indeed we may often judge of it from the violence with which the clouds are agitated, from the meteors formed above the regions of

the

93
Mr. Brydone's objections.

the clouds, and particularly from the Aurora Borealis, which has been observed to have much the same colour and appearance as the matter that forms the tails of comets.

“ Now what must be the effect of so vast a body as our atmosphere, made strongly electrical, when it happens to approach any other body? It must always be either violently attracted or repelled, according to the positive or negative quality (in the language of electricians) of the body that it approaches.

“ It has ever been observed, that the tails of comets (just as we should expect from a very light fluid body attached to a solid heavy one) are drawn after the comets as long as they are at a distance from the sun; but as soon as the comet gets near his body, the tail veers about to that side of the comet that is in the opposite direction from the sun, and no longer follows the comet, but continues its motion sideways, opposing its whole length to the medium through which it passes, rather than allow it in any degree to approach the sun. Indeed, its tendency to follow the body of the comet is still observable, were it not prevented by some force superior to that tendency; for the tail is always observed to bend a little to that side from whence the comet is flying. This perhaps is some proof too, that it does not move in an absolute vacuum.

“ When the comet reaches its perihelion, the tail is generally very much lengthened; perhaps by the rarefaction from the heat; perhaps by the increase of the sun's repulsion, or that of his atmosphere. It still continues projected, exactly in the opposite direction from the sun; and when the comet moves off again to the regions of space, the tail, instead of following it, as it did on its approach, is projected a vast way before it, and still keeps the body of the comet exactly opposed betwixt it and the sun; till by degrees, as the distance increases, the length of the tail is diminished; the repulsion probably becoming weaker and weaker.

“ It has likewise been observed, that the length of these tails are commonly in proportion to the proximity of the comet to the sun. That of 1680 threw out a train that would almost have reached from the sun to the earth. If this had been attracted by the sun, would it not have fallen upon his body, when the comet at that time was not one fourth of his diameter distant from him? but, instead of this, it was darted away to the opposite side of the heavens, even with a greater velocity than that of the comet itself. Now what can this be owing to, if not to a repulsive power in the sun, or his atmosphere?

“ And indeed it would at first appear but little less absurd, to say that the tail of the comet is all this time violently attracted by the sun, although it be driven away in an opposite direction from him, as to say the same of the comet itself. It is true, this repulsion seems to begin much sooner to affect the tail than the body of the comet; which is supposed always to pass the sun before it begins to fly away from him, which is by no means the case with the tail. The repulsive force, therefore, (if there is any such), is in a much less proportion than the attractive one; and probably just only enough to counterbalance the latter, when these bodies are in their perihelions, and to turn them so much aside as to prevent their falling into the body of the sun. The projectile force they have acquired will

then carry them out to the heavens, and repulsion probably diminishing as they recede from the sun's atmosphere, his attraction will again take place and retard their motion regularly, till they arrive at their apelia, when they once more begin to return to him.”

The only system which appears at present in opposition to the Newtonian is that which we formerly called *Mechanical*, and was first published by John Hutchinson Esq; with a pretence of its being extracted from the sacred writings. He was cotemporary with Sir Isaac, and expressed no small inveteracy against him, but without success; his unintelligible manner of writing rendering him in a great measure inaccessible even to his friends, and his malvolence disgusting every body else. The system, however, still continues, with some considerable alterations and improvements. The most confident account we have been able to procure of it as it stands at present, is what follows.

“ The motions of the celestial bodies are all of them entirely dependent on the action of the sun, and this action consists in the emission of his light. As we see that no fire can be preserved on earth without the influx of air, so it is reasonable to think that the sun himself cannot be supported without the influx of a stream of air from every side, proportioned to his immense magnitude. This air, by which the sun's heat and light are preserved, is of a purer nature than what we breathe, as being perfectly destitute of aqueous and other vapours with which our air is always loaded. The matter of which the fire, the light, and the air, are composed, is ultimately the same: the only difference we perceive is, that when the ethereal matter appears to us as fire or light, it acts with violence from a centre to a circumference; when as air, it acts more mildly, as from a circumference to a centre. The reason of this apparent mildness of the action of air, in comparison with that of fire or light, is owing only to the grossness of the particles of the former which make its action less sensible; as a push with the head of a pin is much less sensible than one with the point of it, though the one be given with no more force than the other.

“ The manner in which the gross air is formed, appears from the following consideration. The light being emitted from the sun, in particles inconceivably minute, must very soon strike against other particles of the same nature with itself, of which the universe is supposed to be perfectly full, which either are not moving at all, or with a slower motion, or in a contrary direction. When a particle has thus lost its motion in a direct line from the sun, it will move along with the particle by which it was stopped, as one body. The reason of this is the pressure of the circumambient fluid; for till the violent action of the light from the sun overcomes the pressure behind and on each side, the two particles cannot separate, having no motion but what is given them by the rest of the fluid. The consequence of this is, that such particles must every moment come nearer the sun: for, the universe being supposed an absolute plenum, if any particle of matter goes out from the centre, another must return to it, otherwise there could be no motion. The light, therefore, consisting of all those particles which have a tendency outwards, cannot possibly be emitted without displacing those which have no such tendency, and consequently bringing them nearer to the centre: and thus they must always continue to approach, till at

24
Hutchinson, or mechanical system.

25
Formation of air.

last

last they fall into it altogether, where, the action being extremely violent, and the pressure outwards equivalent to that inwards, the cohesion of every particle of air must be dissolved, and the matter reduced to its original fineness and fluidity, when it is again sent forth; and so on.

“ Thus it appears that the light consists of the very finest particles, each of which moves by itself, and unconnected with any other. When two or more particles of light lose their motion while contiguous to one another, they cannot be separated till they come to the sun himself, or at least to some place where the action from the centre is nearly equal to that from the circumference. This, it is evident, can only take place perfectly in the sun himself; and hence, though our common fires do reduce the air to a greater degree of fineness than when it enters them, they are far from being sufficient to reduce it to the utmost degree of fineness possible; therefore their light is always weak and obscure, compared with that of the sun; and for the same reason, the sun-beams excite a stronger heat than can be raised by any furnace. Hence it is easy to see, that between the light of the sun, and the grossest air, there may, and necessarily will, be fluids of all degrees of grossness or density, in which sense only the word *density* can be used on this plan. Each of these fluids will constitute a *natural power*, or *secondary cause*, which will act according to its degree of density in particular circumstances, and thus be subservient to the production of different natural phenomena, according to the original appointment of the Creator. A fluid of this intermediate degree of density we evidently see in electricity, which appears vastly more subtle than air, though not quite so much as light.

96
Of the atmospheres of planets.

“ Thus we have considered the universe as consisting only of the ethereal matter which appears to us in the different modifications of fire, light, air, electric fluid, fixed air, &c. Let us now suppose a planet, or any other porous body, our earth for instance, introduced into it, or created out of nothing by Divine power. Immediately upon its immersion into this mixture of fluids, it is evident that the finer parts would be impelled by the pressure of the rest into the smallest pores of the body, while, by the pressure of the grosser fluids, its particles would be brought as close as those of the finest ethereal fluid which had already insinuated themselves would permit. The consequence of this behaved to be the formation of an *atmosphere* denser than that of the common ethereal fluid with which the whole universe is filled; for the finer parts being as it were drained out from among that part of the common fluid, and insinuating themselves into the pores of the earth or other planet, the more gross fluids must necessarily be driven towards the surface, where they will remain, without a possibility of their being separated; unless the planet should fall into the sun; because, in any other part of the creation, the pressure from without must be greater than that from within, and consequently let us suppose the atmosphere to be ever so much rarified, it never could be destroyed, or leave the body to which it originally belonged.

“ Having now seen how, on the foregoing principles, every planet must be surrounded with a particular atmosphere of its own, distinct from that of the common ethereal fluid, which we shall henceforth call the *atmosphere of the sun*, we must now consider the

consequences. In the first place, it is obvious, that by means of this atmosphere the violent action of the sun's light will be moderated, as well as of the particles of air that are continually returning towards him; so that, let their impulse be ever so strong, they cannot act on the planet or its inhabitants but through the medium of the atmosphere; and thus the earth becomes a comfortable habitation, when it would otherwise be utterly unfit for the residence of living creatures. The atmosphere of the sun is, as we have already seen, in a perpetual motion, the one part going out, and the other returning. The earth, with its atmosphere, or any other planet, therefore, cannot be supposed in any part of the creation where this action subsists, but that its fore part, or that which is turned towards the sun, must be subject to the impulse of those particles of light which are issuing out from him, as the back-part is to the impulse of the particles of air returning towards him. By the one it is pushed out from, and by the other impelled towards, the sun; but as these two impulses are necessarily equal to one another, the planet must still continue at the same distance, without being able to approach or recede in the least. Nevertheless, as both impulses are inconceivably violent, the planet must make an effort to get away, proportionable to the strength of both of them. It must therefore fly off at the side, because the resistance there is least (it being easier to cross a stream at right angles, than to go directly against it); and having once begun to do so, it must continue its motion, as long as the cause subsists by which it was originally produced; and as the impetus of the light ascending, and the air descending, are in all places equal, it is plain the planet can neither approach nearer to, nor recede farther from, the sun, but must continually circulate round him.

97
Circular orbits accounted for.

“ In this way it is easy to see how the earth or any other planet might continue to move round the sun in a perfect circle; but to explain the planetary motions in elliptic orbits, requires a farther consideration. We have hitherto supposed the planet to be perfectly impenetrable even by the finest part of the solar atmosphere; but it can scarce be supposed that any body in nature is perfectly so; and a little consideration will easily shew us, that, unless the body is perfectly impenetrable, it must describe an ellipsis, more or less excentric, according to its degree of penetrability. The reason of this is, that, in proportion to the transmission of the finer parts, the impulse of the grosser ones from behind becomes stronger, and consequently the planet must approach the sun, till, the impulse of the light becoming so violent that by its plentiful transmission the air behind is somewhat repelled, and of consequence the pressure from that quarter lessened, the planet gradually recedes to its former distance.

“ That this is really the case, is evident to our senses in the comets. Being formed in a different manner from the planets, they transmit great part of the light, and finer parts of the solar atmosphere: of consequence their lateral motion is but small, and they move almost directly towards the sun. The nearer they approach him, the greater must their velocity be; for it is demonstrable, that the quantity of light emitted from any luminous body, and of consequence the impulse of it, increases in a duplicate proportion to the decrease of distance from that body. If the impulse of light from

99
Motions and tails of the comets accounted for.

the

the sun increases in this manner, so must the impulse of the air towards him; for as the quantity of light emitted is always equal to that of the air which flows in, the impetus of the one must always be equal to that of the other. As the comet gets nearer the sun, the finer parts of the solar atmosphere are transmitted in great quantity, and form its tail, which is nothing else than a stream of electric fluid with which the celestial regions every where abound, and which is driven with violence through the body of the comet by the impulse of the light before it. It is not to be supposed that such an immense stream of this matter can be discharged without affecting the air behind the comet. We see that this is the case by the bending of the tail, which indicates a very violent resistance; and this resistance, together with the impulse of the light before, regulates the motion of the comet, and prevents it from flying with the velocity of light itself. When the comet draws near the sun, the tail increases prodigiously; and the body, being now heated, begins to repel the air on all sides; in consequence of which, a lateral motion is at first begun, as if it was to describe a circle round the sun at a very small distance from his body; but the heat still increasing, it is at last hurried off by the impulse of the light, while the electric stream goes before, as it were to clear its way, and keep off the too great pressure of the air which would retard its progress. As the comet gets farther from the sun into the more dense regions of his atmosphere, the heat begins to abate, and the gross air to act with its full force; and then, most of the finer parts of his atmosphere being again transmitted imperceptibly, it begins to circulate for a little way, and soon descends again towards the sun.

“ With this hypothesis, which consists merely in reasoning analogically from what we observe on earth to what is observed in the celestial motions, all the phenomena of nature are in perfect conformity. By it the revolutions of the planets round their axes is easily accounted for, and for which the Newtonian philosophers have never assigned any reason. Such a revolution must be the necessary consequence of the resistance made to the planet's motion, while it flies off from between the ascending stream of light, and the descending one of air. According to this hypothesis too, the velocities of the planets nearest the sun ought to be greatest in their orbits, and their revolutions on their axes the slowest. This is confirmed by experience; Mercury moves swifter than Venus, and Venus swifter than the earth. If Mr Bianchini's observations also are to be credited, Venus moves on her axis 23 times slower than the earth. This slowness in the diurnal revolutions necessarily follows from the greater fluidity of the solar atmosphere near the body of the sun than at a distance; and consequently its being less able to make a lateral resistance. For the same reason, the superior planets, Mars, Jupiter, and Saturn, ought to revolve more slowly in their orbits, and more quickly round their axis. This is remarkably the case with Jupiter, who revolves round his axis with great rapidity, though his motion in his orbit is much slower than that of the earth. Mars seems to be an exception; for though he moves more slowly in his orbit, his motion

round his axis is also a little slower than that of the earth. But here we must consider the size of the planet, which is greatly inferior to that of the earth; so that though he moves in a denser medium than the earth does, yet the smallness of his body, and slowness of motion in his orbit, lessen the lateral resistance in such a manner, that his diurnal revolution cannot be completed in such a short time as it could be were his body equal to the earth in size. The magnitude of Jupiter's body also, as well as the density of the medium he moves in, probably contribute to his quick diurnal revolution, which is vastly more swift than that of either the earth or Mars. As for Saturn and Mercury, no spots having ever been observed on them whereby their diurnal revolution could be ascertained, nothing can be determined with regard to them in this particular.

“ It remains now only to account for the motions of the secondary planets round their primaries; and here there are some appearances which make it probable that the secondary planets are retained in their orbits by the power of electricity. It is observed, that our moon keeps always the same side towards the earth; and this any small electrified body is constantly observed to do towards the body which electrifies it. It hath been observed, that the moons of Jupiter, when passing over his disk, appear to us like black spots; whence it is probable that only one side of the secondary planets is capable of reflecting the light, and therefore that all of them keep constantly the same side towards their primaries. That the combined powers of light and electricity are capable of producing a motion round a centre, may be proved by experiment, which in all cases is worth a thousand speculations.

“ Let a light hollow ball of cork covered over with brags or gold leaf be suspended by a pretty long silk thread, so as just to touch the knob of an electrified vial placed on a table. It will instantly be driven off to some distance, and, after a few vibrations, will remain at rest. If a lighted candle is now placed at some distance behind it, so that the flame of the candle may be nearly as high as the knob of the vial, the cork will instantly be agitated, and, after some irregular motions, will describe a curve round the knob of the vial, seemingly of the elliptic kind; and this it will continue to do, sometimes moving in one direction, sometimes in another, till the force of electricity in the vial is almost exhausted. It must be owned, that the circulation here is far from being regular; for sometimes the ellipsis is very excentric, sometimes it hath very little excentricity; very often the cork ball will strike upon the knob of the vial, &c. but these irregularities can only be attributed to want of skill in the operator to adjust the forces to one another in a proper manner. But if we, by a few sparks from an electric conductor, can make a cork perform some hundreds of revolutions in an irregular manner round the knob of a vial, what cannot the Deity do, who hath the whole powers of light and electricity at his command, who knows their nature perfectly, and whose mechanical skill hath no limits besides the nature of the materials he employs (D).

“ The electric power is by most philosophers allowed to have a principal share in all the natural operations

(D) This experiment we have repeated with success; but whether the consequences deduced from it by the author of this account can be justly drawn, we must submit to better Judges.

tions on this earth. Experience shews, that, so far from diminishing, it grows much stronger the higher we ascend. As we can, therefore, set no bounds to this increase of power, it seems most reasonable to suppose that the moon receives it from the earth, as the cork ball in the experiment receives it from the knob of the vial; and that, being continually drawn off by the fun, it occasions the circulation of the moon in a similar, though much more regular, manner."

Having now given an account of the principal systems that have appeared, and recounted a great number of arguments *pro* and *con*, on almost every particular, some general conclusion will naturally be expected from us; as otherwise many readers may think our intention has been to confound them, by advancing a multiplicity of opinions, and leading them into a chaos from which no real knowledge can be extracted.

103
Dispute concerning attraction, of little consequence.

Here we must observe, that all the arguments that ever have been brought against Sir Isaac Newton, only tend to invalidate what is called his *Physical System*, or that part of it which accounts for the phenomena of nature. As for that part of astronomy which consists in the knowledge of the phenomena themselves, what Sir Isaac hath advanced on that head may be looked upon as absolutely certain, and is controverted by nobody. With regard to the dispute concerning attraction, it is of little consequence whether it is cause or effect. The word *attraction*, or some other perhaps equally improper, must be made use of, though we even were already acquainted with the cause of gravity. But it must be remembered, that if attraction is ever discovered to be the effect of a material cause, the cause itself must be destitute of all attraction, or tendency of one part to another, and consequently have very different properties from other matter.

104
Objections to the gravitating and projectile forces, hitherto unanswered.

As to the two powers of gravitation and projection which Sir Isaac Newton assumed as the causes of the planetary revolutions, it is of the utmost importance to a *physical astronomer* to be ascertained whether these forces are capable of producing the effects ascribed to them or not. Objections similar to those above inserted have been published long ago, and we are surpris'd that no plain and direct answer hath yet been given to them. In 1762, a book entitled "The Principles of Natural Philosophy, &c. by William Jones," made its appearance, in which, among other things, the author undertook to prove, that by a combination of gravitation and projectile force no lasting motion could be produced. As far as we know, no answer has ever been published to this treatise; and upon looking into the Monthly Review, Vol. xxvii. p. 122. we were surpris'd to find the author censured, rather uncan'didly, for controverting Sir Isaac's opinion, while not a single word is offered in answer to his objection, or a hint given where such a thing could be found. In other respects, the Reviewers own that Sir Isaac Newton himself has reason'd very weakly and inconclusively in physical matters. Such concessions as they will necessarily create doubts in the mind of every person that reads them; and therefore particular care ought to be taken in distinguishing where his reasoning is solid and invincible, and where it is not to be regarded. In 1764, another treatise of the same nature, entitled "Short Observations on the Principles and Moving Powers assumed by the present System of Philosophy," was

Vol. I.

published. In this the whole physical part of Sir Isaac's system was attacked and even ridiculed. The author asserted the insufficiency of the two forces of gravitation and projection to keep a planet in its orbit; and, if no other powers than these acted upon it, that it behoved to be hurried off in an excentric curve. Being unacquainted with any answer to this treatise, we were again oblig'd to have recourse to the Reviewers; when, in the Review for May 1764, we found the following answer, viz. that the "argument is fallacious, because he doth not take into consideration the time in which gravity acts on moving bodies." Certainly an objection of such a capital nature as this incited a more particular answer, or a direction to some other treatise where such an answer might be found. It is in a manner incredible, that such an excellent mathematician as Sir Isaac Newton should have assumed two powers as first principles, which were utterly insufficient to produce the effect he ascribed to them; and, on the other hand, if they are sufficient, we are entirely at a loss to account for the want of replies to such objections, in the common astronomical treatises, when others, of at least as little consequence, are fully obviated.

But further, we are afraid, that most philosophers, even the most zealous advocates for Sir Isaac Newton, are inclin'd to admit the existence of a power in the celestial regions, which must either be the cause of the planetary revolutions, or will utterly destroy their motions. The power we mean is that of electricity. We have already quoted Dr Hamilton conjecturing the tails of comets to be streams of electric matter; and indeed their resemblance to the Aurora Borealis is so great, that it is almost impossible to ascribe the one to electricity, and the other to any different cause. But let us attend to the consequences of this supposition.

105
Newtonian system overturned by admitting the action of electricity in the heavens.

The tails of comets are immensely large. Sir Isaac Newton computed that of the comet in 1680 to be eighty millions of miles in length. What inconceivable power must not such a stream of electric matter be attended with? We are free that by its means the comet would attract at the distance of 80,000,000 miles, and how much farther we cannot tell. If we suppose the fun to be the fountain of electricity as well as of heat and light, then undoubtedly he must attract and repel by means of his electric as well as his gravitating power; so that the law of gravity must either be an effect of the electrical power, or behoved to be perpetually interrupted by it. If, with Mr Henly, Cavallo, and others, we suppose the electric fluid to be a modification of the element of fire, there is an end of Sir Isaac Newton's physical system, to all intents and purposes, and downright Hutchinsonianism comes in place of it; for Hutchinson's very first and fundamental principle is, that elementary fire is sent forth as such from the sun, into the planetary regions and beyond them, where it is converted into a different substance, no matter whether air, or electric fluid.

These things we take notice of, in order to shew how cautious philosophers ought to be in indulging conjectures; as, by so doing, it may often happen, that they will pull down with one hand what they build up with the other. For our own part, we cannot pretend to decide; but as the Newtonian system is so generally made use of for the solution of the celestial phenomena,

106
Conjectures ought to be indulged with caution.

nomena, we shall still suppose it to be the only true one, and proceed to give a particular explanation of these phenomena according to it.

Sect. V. *The Copernican System particularly considered and explained, on the Newtonian Principles.*

THE sun, with the planets and comets which move round him as their centre, constitute the solar system. Those planets which are near the sun, not only finish their circuits sooner, but likewise move faster in their respective orbits, than those which are more remote from him. Their motions are all performed from west to east, in orbits nearly circular.

Pl. XLIII.
fig. 1.

The sun ☉, an immense globe of fire, is placed near the common centre, or rather in the lower focus, of the orbits of all the planets and comets (☿); and turns round his axis in 25 days 6 hours. His diameter is computed to be 890,000 miles; and, by the various attractions of the circumvolving planets, he is agitated by a small motion round the centre of gravity of the system. All the planets, as seen from him, move the same way, and according to the order of signs in the graduated circle ♈ ♉ ♊ ♋ &c. which represents the great ecliptic, or circle annually described by the earth round the sun; but, as seen from any one planet, the rest appear sometimes to go backward, sometimes forward, and sometimes to stand still; not in circles nor ellipses, but in looped curves which never return into themselves; as already observed n^o 6. Round the paths of Venus and Mercury is marked the graduated circle representing the ecliptic. The dotted lines from the earth to the ecliptic are added for shewing Mercury's apparent or geocentric motion therein for one year; in which time his path makes three loops, and goes on a little farther; which shews that he has three inferior, and as many superior, conjunctions with the sun in that time; and also that he is six times stationary, and thrice retrograde. Let us now trace his motion for one year in the figure.

107
Direction of the planets' motions.

Plate XLIV.
fig. 2.

108
Apparent motions of Mercury and Venus explained.

Suppose Mercury to be setting out from *A* towards *B* (between the earth and left-hand corner of the plate), and as seen from the earth, his motion will then be direct, or according to the order of the signs. But when he comes to *B*, he appears to stand still in the 23^d degree of ♈ at *F*, as shewn by the line *BF*. Whilst he goes from *B* to *C*, the line *BF*, supposed to move with him, goes backward from *F* to *E*, or contrary to the order of signs; and when he is at *C*, he appears stationary at *E*, having gone back 11 $\frac{1}{2}$ degrees. Now, suppose him stationary on the first of January at *G*, on the 10th thereof he will appear in the heavens as at 20, near *F*; on the 20th he will be seen as at *G*; on the 31st, at *H*; on the 10th of February, at *I*; on the 20th, at *K*; and on the 28th, at *L*; as the dotted lines shew, which are drawn through every tenth day's motion in his looped path, and continued to the ecliptic. On the 10th of March he appears at *M*; on the 20th, at *N*; and on

the 31st, at *O*. On the 10th of April he appears stationary at *P*; on the 20th he seems to have gone back again to *O*; and on the 30th he appears stationary at *Q*, having gone back 11 $\frac{1}{2}$ degrees. Thus Mercury seems to go forward 4 signs 11 degrees, or 131 degrees; and to go back only 11 or 12 degrees, at a mean rate. From the 30th of April to the 10th of May he seems to move from *Q* to *R*; and on the 20th he is seen at *S*, going forward in the same manner again, according to the order of letters; and backward when they go back; which it is needless to explain any farther, as the reader can trace him out so easily thro' the rest of the year. The same appearances happen in Venus's motion; but as she moves slower than Mercury, there are longer intervals of time between them. The comets come from all parts of the heavens, and move in all sorts of directions.

The axis of a planet is a line conceived to be drawn through its centre, about which it revolves as if on a real axis. The extremities of this line, terminating in opposite points of the planet's surface, are called its *poles*. That which points towards the northern part of the heavens, is called the *north pole*; and the other, pointing towards the southern part, is called the *south pole*. A bowl whirled from one's hand into the open air turns round such a line within itself, whilst it moves forward; and such are the lines we mean when we speak of the axes of the heavenly bodies.

109
Axes of the planets.

Let us suppose the earth's orbit to be a thin, even, solid plane; cutting the sun through the centre, and extended out as far as the starry heavens, where it will mark the great circle called the *ecliptic*. This circle we suppose to be divided into 12 equal parts, called *signs*; each sign into 30 equal parts, called *degrees*; each degree into 60 equal parts, called *minutes*; and every minute into 60 equal parts, called *seconds*: so that a second is the 60th part of a minute; a minute the 60th part of a degree; and a degree the 360th part of a circle, or 30th part of a sign. The planes of the orbits of all the other planets likewise cut the sun in halves; but, extended to the heavens, form circles different from one another, and from the ecliptic; one half of each being on the north side, and the other on the south side of it. Consequently the orbit of each planet crosses the ecliptic in two opposite points, which are called the planet's *nodes*. These nodes are all in different parts of the ecliptic; and therefore, if the planetary tracts remained visible in the heavens, they would in some measure resemble the different runs of waggon-wheels crossing one another in different parts, but never going far asunder. That node, or intersection of the orbit of any planet with the earth's orbit, from which the planet ascends northward above the ecliptic, is called the *ascending node* of the planet; and the other, which is directly opposite thereto, is called its *descending node*. Saturn's ascending node is in 21 deg. 13 min. of Cancer, ☿; Jupiter's in 7 deg. 29 min. of the same sign; Mars's in 17 deg. 17 min. of Taurus,

110
Nodes of the planet.

(☿) Astronomers are not far from the truth, when they reckon the sun's centre to be in the lower focus of all the planetary orbits. Though, strictly speaking, if we consider the focus of Mercury's orbit to be in the sun's centre, the focus of Venus's orbit will be in the common centre of gravity of the sun and Mercury; the focus of the earth's orbit in the common centre of gravity of the sun, Mercury, and Venus; the focus of the orbit of Mars in the common centre of gravity of the sun, Mercury, Venus, and the earth; and so of the rest. Yet, the focuses of the orbits of all the planets, except Saturn, will not be sensibly removed from the centre of the sun; nor will the focus of Saturn's orbit recede sensibly from the common centre of gravity of the sun and Jupiter.

Taurus, ♄; Venus's in 13 deg. 59 min. of Gemini, ♀; and Mercury's in 14 deg. 43 min. of Taurus. Here we consider the earth's orbit as the standard, and the orbits of all the other planets as oblique to it.

When we speak of the planets orbits, all that is meant is their paths through the open and unresisting space in which they move; and are kept in, by the attractive power of the sun, and the projectile force impressed upon them at first; between which power and force there is so exact an adjustment, that they continue in the same tracts without any solid orbits to confine them.

112
Distance of
Mercury from
the sun, his dia-
meter, &c.

Mercury, the nearest planet to the sun, goes round him (as in the circle marked ☿) in 87 days 23 hours of our time nearly; which is the length of his year. But being seldom seen, and no spots appearing on his surface or disk, the time of his rotation on his axis, or the length of his days and nights, is as yet unknown. His distance from the sun is computed to be 36,841,448 miles, and his diameter 3000. In his course round the sun, he moves at the rate of 109,699 miles every hour. His light and heat from the sun are almost seven times as great as ours, and the sun appears to him almost seven times as large as to us. The great heat on this planet is no argument against its being inhabited; since the Almighty could as easily suit the bodies and constitutions of its inhabitants to the heat of their dwelling, as he has done to the temperature of our earth. And it is very probable that the people there have such an opinion of us, as we have of the inhabitants of Jupiter and Saturn, namely, that we must be intolerably cold, and have very little light, at so great a distance from the sun.

The orbit of Mercury is inclined seven degrees to the ecliptic; and that node from which he ascends northward above the ecliptic, is in the 14th degree of Taurus; the opposite, in the 14th degree of Scorpio. The earth is in these points on the 6th of November, and 4th of May, new style; and when Mercury comes to either of his nodes at his inferior conjunction (☿) about these times, he will appear to pass over the disk or face of the sun, like a dark round spot. But in all other parts of his orbit his conjunctions are invisible, because he either goes above or below the sun.

113
When to be
seen as a spot
on the sun.

Mr Whiston has given us an account of several periods at which Mercury may be seen on the sun's disk, viz. in the year 1782, Nov. 12th, at 3 h. 44. m. in the afternoon; 1786, May 4th, at 6 h. 57 m. in the forenoon; 1789 Dec. 6th, at 3 h. 55 m. in the afternoon; and 1799, May 7th, at 2 hours 34 m. in the afternoon. There will be several intermediate transits, but none of them visible at London.

114
Distance,
&c. of Ven-
us.

Venus, the next planet in order, is computed to be 68,891,486 miles from the sun; and by moving at the rate of 80,295 miles every hour in her orbit (as in the circle marked ♀), she goes round the sun in 224 days 17 hours of our time nearly; in which, though it be the full length of her year, she has only 9 $\frac{1}{2}$ days according to Bianchini's observations: so that, to her, every day and night together is as long as 24 $\frac{1}{2}$ days and nights with us. This odd quarter of a day in every year makes every fourth year a leap-year to Venus; as the like does to our earth. Her diameter is 9330 miles. Her orbit is included by the earth's: for

if it were not, she might be seen as often in opposition to the sun, as she is in conjunction with him; but she was never seen 90 degrees, or a fourth part of a circle, from the sun.

When Venus appears west of the sun, she rises before him in the morning, and is called the *morning star*; when she appears east of the sun, she shines in the evening after he sets, and is then called the *evening star*; as being each in it's turn for 290 days. It may perhaps be surprising at first, that Venus should keep longer on the east or west of the sun, than the whole time of her period round him. But the difficulty vanishes when we consider that the earth is all the while going round the sun the same way, though not so quick as Venus: and therefore her relative motion to the earth must in every period be as much slower than her absolute motion in her orbit, as the earth during that time advances forward in the ecliptic; which is 220 degrees.

115
Why she
appears so
long on one
side of the
sun.

The axis of Venus is inclined 75 degrees to the axis of her orbit, which is 51 $\frac{1}{2}$ degrees more than our earth's axis is inclined to the axis of the ecliptic; and therefore her seasons vary much more than ours do. The north pole of her axis inclines toward the 20th degree of Aquarius, our earth's to the beginning of Cancer: consequently the northern parts of Venus have summer in the signs where those of our earth have winter, and *vice versa*.

The artificial day at each pole of Venus is as long as 112 $\frac{1}{2}$ natural days on our earth.

The sun's greatest declination on each side of her equator amounts to 75 degrees; therefore her tropics are only 15 degrees from her poles, and her polar circles as far from her equator. Consequently, the tropics of Venus are between her polar circles and her poles; contrary to what those of our earth are.

116
Great decli-
nation of the
sun as ob-
served from
Venus.

As her annual revolution contains only 9 $\frac{1}{2}$ of her days, the sun will always appear to go through a whole sign, or twelfth part of her orbit, in little more than three quarters of her natural day, or nearly in 18 $\frac{1}{2}$ of our days and nights.

Because her day is so great a part of her year, the sun changes his declination in one day so much, that if he passes vertically, or directly over head of any given place on the tropic, the next day he will be 26 degrees from it; and whatever place he passes vertically over when in the equator, one day's revolution will remove him 36 $\frac{1}{2}$ degrees from it. So that the sun changes his declination every day in Venus about 14 degrees more, at a mean rate, than he does in a quarter of a year on our earth. This appears to be providentially ordered, for preventing the too great effects of the sun's heat (which is twice as great on Venus as on the earth), so that he cannot shine perpendicularly on the same places for two days together; and on that account, the heated places have time to cool.

If the inhabitants about the north pole of Venus fix their south, or meridian line, through that part of the heavens where the sun comes to his greatest height, or north declination, and call those the east and west points of their horizon, which are 90 degrees on each side from that point where the horizon is cut by the meridian line, these inhabitants will have the following remarkable appearances:

117
Remarkable
appearances
to her inha-
bitants.

5 F 2

The

(F) When he is between the earth and the sun in the nearer part of his orbit.

The sun will rise $23\frac{1}{2}$ degrees north of the east; and going on $112\frac{1}{2}$ degrees, as measured on the plane of the horizon, he will cross the meridian at an altitude of $12\frac{1}{2}$ degrees: then, making an entire revolution without setting, he will cross it again at an altitude of $48\frac{1}{2}$ degrees: at the next revolution he will cross the meridian, as he comes to his greatest height and declination, at the altitude of 75 degrees; being then only 15 degrees from the zenith, or that point of the heavens which is directly over head: and thence he will descend in the like spiral manner; crossing the meridian first at the altitude of $48\frac{1}{2}$ degrees, next at the altitude of $12\frac{1}{2}$ degrees; and going on thence $112\frac{1}{2}$ degrees, he will set $22\frac{1}{2}$ degrees north of the west; so that, after having been $4\frac{1}{2}$ revolutions above the horizon, he descends below it to exhibit the like appearances at the fourth pole.

At each pole, the sun continues half a year without setting in summer, and as long without rising in winter; consequently the polar inhabitants of Venus have only one day and one night in the year; as it is at the poles of our earth. But the difference between the heat of summer and cold of winter, or of mid-day and mid-night, on Venus, is much greater than on the earth: because on Venus, as the sun is for half a year together above the horizon of each pole in its turn, he is for a considerable part of that time near the zenith; and during the other half of the year always below the horizon, and for a great part of that time at least 70 degrees from it. Whereas, at the poles of our earth, although the sun is for half a year together above the horizon; yet he never ascends above, nor descends below it, more than $23\frac{1}{2}$ degrees. When the sun is in the equinoctial, or in that circle which divides the northern half of the heavens from the southern, he is seen with one half of his disk above the horizon of the north-pole, and the other half above the horizon of the south-pole; so that his centre is in the horizon of both poles: and then, descending below the horizon of one, he ascends gradually above that of the other. Hence, in a year, each pole has one spring, one harvest, a summer as long as them both, and a winter equal in length to the other three seasons.

At the polar circles of Venus, the seasons are much the same as at the equator, because there are only 15 degrees between them; only the winters are not quite so long, nor the summers so short; but the four seasons come twice round every year.

At Venus's tropics, the sun continues for about 15 of our weeks together without setting in summer, and as long without rising in winter. Whilst he is more than 15 degrees from the equator, he neither rises to the inhabitants of the one tropic, nor sets to those of the other; whereas, at our terrestrial tropics, he rises and sets every day of the year.

At Venus's tropics, the seasons are much the same as at her poles; only the summers are a little longer, and the winters a little shorter.

At her equator, the days and nights are always of the same length; and yet the diurnal and nocturnal arches are very different, especially when the sun's declination is about the greatest: for then, his meridian altitude may sometimes be twice as great as his midnight depression, and at other times the reverse. When the sun is at his greatest declination, either north or south,

his rays are as oblique at Venus's equator, as they are at London on the shortest day of winter. Therefore, at her equator, there are two winters, two summers, two springs, and two autumns, every year. But because the sun stays for some time near the tropics, and passes so quickly over the equator, every winter there will be almost twice as long as summer; the four seasons returning twice in that time, which consists only of $9\frac{1}{2}$ days.

Those parts of Venus which lie between the poles and tropics, and between the tropics and polar circles, and also between the polar circles and equator, partake more or less of the phenomena of these circles, as they are more or less distant from them.

From the quick change of the sun's declination it happens, that if he rises due east on any day, he will not set due west on that day, as with us; for if the place where he rises due east be on the equator, he will set on that day almost west north-west, or about $18\frac{1}{2}$ degrees north of the west. But if the place be in 45 degrees north latitude, then on the day that the sun rises due east he will set north-west by west, or 33 degrees north of the west. And in 62 degrees north latitude, when he rises in the east, he sets not in that revolution, but just touches the horizon 10 degrees to the west of the north point; and ascends again, continuing for $3\frac{1}{2}$ revolutions above the horizon without setting. Therefore no place has the forenoon and afternoon of the same day equally long, unless it be on the equator, or at the poles.

The sun's altitude at noon, or any other time of the day, and his amplitude at rising and setting, being very different at places on the same parallel of latitude, according to the different longitudes of those places, the longitude will be almost as easily found on Venus, as the latitude is found on the earth: which is an advantage we can never have, because the daily change of the sun's declination is much too small for that important purpose.

On this planet, where the sun crosses the equator in any year, he will have 9 degrees of declination from that place on the same day and hour next year; and will cross the equator 90 degrees farther to the west; which makes the time of the equinox a quarter of a day (or about six of our days) later every year. Hence although the spiral in which the sun's motion is performed be of the same sort every year, yet it will not be the very same, because the sun will not pass vertically over the same places till four annual revolutions are finished.

We may suppose that the inhabitants of Venus will be careful to add a day to some particular part of every fourth year; which will keep the same seasons to the same days. For, as the great annual change of the equinoxes and solstices shifts the seasons a quarter of a day every year, they would be shifted through all the days of the year in 36 years. But by means of this intercalary day, every fourth year will be a leap-year: which will bring her time to an even reckoning, and keep her calendar always right.

At the transits of Venus over the sun in 1761 and 1769, astronomers were very careful to observe whether any satellite belonging to this planet could be discovered; but as none was to be seen, it is now generally concluded that she has none, but that Cassini and Mr Short were mistaken.

118

¹¹²
Distance,
&c. of the
earth.

The earth is the next planet above Venus in the system. It is 95,173,000 miles from the sun, and goes round him (as in the circle ☉) in 365 days 5 hours 49 minutes, from any equinox or solstice to the same again; but from any fixed star to the same again as seen from the sun, in 365 days 6 hours 9 minutes; the former being the length of the tropical year, and the latter the length of the sidereal. It travels at the rate of 68,000 miles every hour; which motion, tho' upwards of 140 times swifter than that of a cannon ball, is little more than half as swift as Mercury's motion in his orbit. The earth's diameter is 7970 miles; and by turning round its axis every 24 hours from west to east, it causes an apparent diurnal motion of all the heavenly bodies from east to west. By this rapid motion of the earth on its axis, the inhabitants about the equator are carried 1042 miles every hour, whilst those on the parallel of London are carried only about 580, besides the 68,000 miles by the annual motion above-mentioned, which is common to all places whatever.

The earth's axis makes an angle of 23½ degrees with the axis of its orbit, and keeps always the same oblique direction, inclining nearly to the same fixed stars (♄) throughout its annual course, which causes the returns of spring, summer, autumn, and winter. That the sun, and not the earth, is the centre of our solar system, may be demonstrated beyond a possibility of doubt, from considering the forces of gravitation and projection, by which all the celestial bodies are retained in their orbits. For, if the sun moves about the earth, the earth's attractive power must draw the sun towards it from the line of projection so, as to bend its motion into a curve. But the sun being at least 227,000 times as heavy as the earth, by being so much weightier as its quantity of matter is greater, it must move 227,000 times as slowly toward the earth, as the earth does toward the sun; and consequently the earth would fall to the sun in a short time, if it had not a very strong projectile motion to carry it off. The earth therefore, as well as every other planet in the system, must have a rectilinear impulse, to prevent its falling into the sun. To say, that gravitation retains all the other planets in their orbits without affecting the earth, which is placed between the orbits of Mars and Venus, is as absurd as to suppose that six cannon-bullets might be projected upwards to different heights in the air, and that five of them should fall down to the ground; but the sixth, which is neither the highest nor the lowest, should remain suspended in the air without falling, and the earth move round about it.

There is no such thing in nature as a heavy body moving round a light one as its centre of motion. A pebble fastened to a mill-stone by a string, may by an easy impulse be made to circulate round the mill-stone: but no impulse can make a mill-stone circulate round a loose pebble; for the mill-stone would go off, and carry the pebble along with it.

The sun is so immensely bigger and heavier than the earth, that, if he was moved out of his place, not only the earth, but all the other planets, if they were united into one mass, would be carried along with the sun,

as the pebble would be with the mill-stone.

By considering the law of gravitation, which takes place throughout the solar system, in another light, it will be evident that the earth moves round the sun in a year, and not the sun round the earth. It has been observed, that the power of gravity decreases as the square of the distance increases; and from this it follows with mathematical certainty, that when two or more bodies move round another as their centre of motion, the squares of their periodic times will be to one another in the same proportion, as the cubes of their distances from the central body. This holds precisely with regard to the planets round the sun, and the satellites round the planets; the relative distances of all which are well known. But, if we suppose the sun to move round the earth, and compare its period with the moon's by the above rule, it will be found that the sun would take no less than 173,510 days to move round the earth; in which case our year would be 475 times as long as it now is. To this we may add, that the affects of increase and decrease of the planets, the times of their seeming to stand still, and to move direct and retrograde, answer precisely to the earth's motion; but not at all to the sun's, without introducing the most absurd and monstrous suppositions, which would destroy all harmony, order, and simplicity, in the system. Moreover, if the earth be supposed to stand still, and the stars to revolve in free spaces about the earth in 24 hours, it is certain that the forces by which the stars revolve in their orbits are not directed to the earth, but to the centres of the several orbits; that is, of the several parallel circles which the stars on different sides of the equator describe every day; and the like inferences may be drawn from the supposed diurnal motion of the planets, since they are never in the equinoctial but twice, in their courses with regard to the starry heavens. But that forces should be directed to no central body, on which they physically depend, but to innumerable imaginary points in the axis of the earth produced to the poles of the heavens, is an hypothesis too absurd to be allowed of by any rational creature. And it is still more absurd to imagine that these forces should increase exactly in proportion to the distances from this axis; for this is an indication of an increase to infinity; whereas the force of attraction is found to decrease in receding from the fountain from whence it flows. But the farther any star is from the quiescent pole, the greater must be the orbit which it describes; and yet it appears to go round in the same time as the nearest star to the pole does. And if we take into consideration the twofold motion observed in the stars, one diurnal round the axis of the earth in 24 hours, and the other round the axis of the ecliptic in 25,920 years, it would require an explication of such a perplexed composition of forces, as could by no means be reconciled with any physical theory.

The strongest objection that can be made against the earth's motion round the sun, is, that in opposite points of the earth's orbit, its axis, which always keeps a parallel direction, would point to different fixed stars; which is not found to be fact. But this objection is easily removed, by considering the immense distance

ed.

(c) This is not strictly true, as will appear when we come to treat of the recession of the equinoctial points in the heavens, which recession is equal to the deviation of the earth's axis from its parallelism: but this is rather too invidious to be sensible in an age, except to those who make very nice observations.

distance of the stars in respect of the diameter of the earth's orbit; the latter being no more than a point when compared to the former. If we lay a ruler on the side of a table, and along the edge of the ruler view the top of a spire at ten miles distance; then lay the ruler on the opposite of the table in a parallel situation to what it had before, and the spire will still appear along the edge of the ruler; because our eyes, even when assisted by the best instruments, are incapable of distinguishing so small a change at so great a distance.

116
Earth's motion demonstrated from the aberration of light.

5th Plate
XLII.

Dr Bradley, our late astronomer royal, found by a long series of the most accurate observations, that there is a small apparent motion of the fixed stars, occasioned by the aberration of their light; and so exactly answering to an annual motion of the earth, as evinces the same, even to a mathematical demonstration. He considered this matter in the following manner: he imagined C A, fig. 5. to be a ray of light falling perpendicularly upon the line BD; that, if the eye is at rest at A, the object must appear in the direction AC, whether light be propagated in time or in an instant. But if the eye is moving from B towards A, and light is propagated in time, with a velocity that is to the velocity of the eye, as CA to BA; then light moving from C to A, whilst the eye moves from B to A, that particle of it by which the object will be discerned when the eye comes to A, is at C when the eye is at B. Joining the points BC, he supposed the line CB to be a tube, inclined to the line BD in the angle DBC, of such diameter as to admit but one particle of light. Then it was easy to conceive, that the particle of light at C, by which the object must be seen, when the eye, as it moves along, arrives at A, would pass through the tube BC, if it is inclined to BD in the angle DBC, and accompanies the eye in its motion from B to A; and that it could not come to the eye placed behind such a tube, if it had any other inclination to the line BD. If, instead of supposing CB so small a tube, we imagine it to be the axis of a larger; then, for the same reason, the particle of light at C would not pass through the axis, unless it is inclined to BD in the angle CBD. In like manner, if the eye moved the contrary way, from D towards A, with the same velocity, then the tube must be inclined in the angle BDC. Although, therefore, the true or real place of an object is perpendicular to the line in which the eye is moving, yet the visible place will not be so; since that, no doubt, must be in the direction of the tube; but the difference between the true and apparent place will be, *ceteris paribus*, greater or less, according to the different proportion between the velocity of light and that of the eye. So that, if we could suppose that light was propagated in an instant, then there would be no difference between the real and visible place of an object, although the eye was in motion; for in that case, AC being infinite with respect to AB, the angle ACB, the difference between the true and visible place, vanishes. But if light be propagated in time, it is evi-

dent, from the foregoing considerations, that there will be always a difference between the real and visible place of an object, unless the eye is moving either directly towards or from the object. And in all cases the sine of the difference between the real and visible place of the object will be to the sine of the visible inclination of the object to the line in which the eye is moving, as the velocity of the eye is to the velocity of light.

He then shews, that if the earth revolve round the sun annually, and the velocity of light be to the velocity of the earth's motion in its orbit, as 1000 to 1, that a star really placed in the very pole of the ecliptic would, to an eye carried along with the earth, seem to change its place continually; and, neglecting the small difference on the account of the earth's diurnal revolution on its axis, would seem to describe a circle round that pole every way distant from it $3\frac{1}{2}$; so that its longitude would be varied thro' all the points of the ecliptic every year, but its latitude would always remain the same. Its right ascension would also change, and its declination, according to the different situation of the sun with respect to the equinoctial points, and its apparent distance from the north pole of the equator, would be 7' less at the autumnal than at the vernal equinox.

By calculating exactly the quantity of aberration of the fixed stars from their place, he found that light came from the sun to us in 8'-13"; so that its velocity is to the velocity of the earth in its orbit, as 10,201 to 1.

It must here be taken notice of, however, that Mr Nevil Maskelyne, in attempting to find the parallax of Sirius with a ten-foot sector, observed, that by the friction of the plummet line on the pin which suspended it, an error of 10', 20', and sometimes 30', was committed. The pin was $\frac{1}{16}$ of an inch diameter; and though he reduced it to $\frac{1}{10}$ of an inch, the error still amounted to 3". All observations, therefore, that have hitherto been made in order to discover the parallax of the fixed stars, are to be disregarded; and even the quantity of aberration assigned by Dr Bradley to the fixed stars is to be doubted.

It is also objected, that the sun seems to change his place daily, so as to make a tour round the starry heavens in a year. But, whether the sun or earth moves, this appearance will be the same; for, when the earth is in any part of the heavens, the sun will appear in the opposite. And therefore, this appearance can be no objection against the motion of the earth.

It is well known to every person who has sailed on smooth water, or been carried by a stream in a calm, that, however fast the vessel goes, he does not feel its progressive motion. The motion of the earth is incomparably more smooth and uniform than that of a ship, or any machine made and moved by human art; and therefore it is not to be imagined that we can feel its motion.

We find that the sun, and those planets on which there are visible spots, turn round their axes: for the spots move regularly over their disks (σ). From hence we

(c) This, however, must be understood with some degree of limitation, as will evidently appear from what has been said concerning the spots of the sun. Nay, even in the planet Jupiter, whose rotation on his axis seems better ascertained than that of any other, the difference of time between the revolution of the spots about his equator, and those near his poles, is a phenomenon that hath puzzled the best astronomers. Mr M'Laurin (Phys. and Literary Essays, Vol. I. p. 206.) says, that it is "a phenomenon of that kind of which it is perhaps best not to attempt any explanation till confirmed by further experiments." Since his time it has been confirmed, but we have not heard of any satisfactory explanation.

117
Velocity of light.

Errors in the observation of small angles.

120
Another objection against the earth's motion answered.

we may reasonably conclude, that the other planets on which we see no spots, and the earth, which is likewise a planet, have such rotations. But being incapable of leaving the earth, and viewing it at a distance, and its rotation being smooth and uniform, we can neither see it move on its axis as we do the planets, nor feel ourselves affected by its motion. Yet there is one effect of such a motion, which will enable us to judge with certainty whether the earth revolves on its axis or not. All globes which do not turn round their axes will be perfect spheres, on account of the equality of the weight of bodies on their surfaces; especially of the fluid parts. But all globes which turn on their axes will be oblate spheroids; that is, their surfaces will be higher, or farther from the centre, in the equatorial than in the polar regions: for, as the equatorial parts move quickest, they will recede farthest from the axis of motion, and enlarge the equatorial diameter. That our earth is really of this figure, is demonstrable from the unequal vibrations of a pendulum, and the unequal lengths of degrees in different latitudes. Since then the earth is higher at the equator than at the poles, the sea, which naturally runs downward, or towards the places which are nearest the centre, would run towards the polar regions, and leave the equatorial parts dry, if the centrifugal force of these parts, by which the waters were carried thither, did not keep them from returning. The earth's equatorial diameter is 36 miles longer than its axis.

Bodies near the poles are heavier than those towards the equator, because they are nearer the earth's centre, where the whole force of the earth's attraction is accumulated. They are also heavier, because their centrifugal force is less, on account of their diurnal motion being slower. For both these reasons, bodies carried from the poles toward the equator gradually lose their weight. Experiments prove, that a pendulum, which vibrates seconds near the poles vibrates slower near the equator, which shews that it is lighter or less attracted there. To make it oscillate in the same time, it is found necessary to diminish its length. By comparing the different lengths of pendulums swinging seconds at the equator and at London, it is found that a pendulum must be $2\frac{1}{10000}$ lines shorter at the equator than at the poles. A line is a twelfth part of an inch.

If the earth turned round its axis in 84 minutes 43 seconds, the centrifugal force would be equal to the power of gravity at the equator; and all bodies there would entirely lose their weight. If the earth revolved quicker, they would all fly off, and leave it.

A person on the earth can no more be sensible of its undisturbed motion on its axis, than one in the cabin of a ship on smooth water can be sensible of the ship's motion when it turns gently and uniformly round. It is therefore no argument against the earth's diurnal motion, that we do not feel it: nor is the apparent revolutions of the celestial bodies every day a proof of the reality of these motions; for whether we or they revolve, the appearance is the very same. A person, looking through the cabin-windows of a ship, as strongly fancies the objects on land to go round when the ship turns, as if they were actually in motion.

If we could translate ourselves from planet to planet,

we should still find that the stars would appear of the same magnitudes, and at the same distances from each other, as they do to us here; because the width of the remotest planet's orbit bears no sensible proportion to the distance of the stars. But then, the heavens would seem to revolve about very different axes; and consequently, those quickest points, which are our poles in the heavens, would seem to revolve about other points, which, though apparently in motion as seen from the earth, would be at rest as seen from any other planet. Thus the axis of Venus, which lies at right angles to the axis of the earth, would have its motionless poles in two opposite points of the heavens lying almost in our equinoctial, where the motion appears quickest, because it is seemingly performed in the greatest circle; and the very poles, which are at rest to us, have the quickest motion of all as seen from Venus. To Mars and Jupiter the heavens appear to turn round with very different velocities on the same axis, whose poles are about $23\frac{1}{2}$ degrees from ours. Were we on Jupiter, we should be at first amazed at the rapid motion of the heavens; the sun and stars going round in 9 hours 56 minutes. Could we go from thence to Venus, we should be as much surpris'd at the slowness of the heavenly motions; the sun going but once round in 584 hours, and the stars in 540. And could we go from Venus to the moon, we should see the heavens turn round with a yet slower motion; the sun in 708 hours, the stars in 655. As it is impossible these various circumvolutions in such different times, and on such different axes, can be real, so it is unreasonable to suppose the heavens to revolve about our earth more than it does about any other planet. When we reflect on the vast distance of the fixed stars, to which 190,000,000 of miles, the diameter of the earth's orbit, is but a point, we are fill'd with amazement at the immensity of their distance. But if we try to frame an idea of the extreme rapidity with which the stars must move, if they move round the earth in 24 hours, the thought becomes so much too big for our imagination, that we can no more conceive it than we do infinity or eternity. If the sun was to go round the earth in 24 hours, he must travel upwards of 300,000 miles in a minute: but the stars being at least 400,000 times as far from the sun, as the sun is from us, those about the equator must move 400,000 times as quick. And all this to serve no other purpose than what can be as fully and much more simply obtained by the earth's turning round eastward, as on an axis, every 24 hours, causing thereby an apparent diurnal motion of the sun westward, and bringing about the alternate returns of day and night.

As to the common objections against the earth's motion on its axis, they are all easily answered and set aside. That it may turn without being seen or felt by us to do so, has been already shewn. But some are apt to imagine, that if the earth turns eastward (as it certainly does if it turns at all), a ball fired perpendicularly upward in the air must fall considerably westward of the place it was projected from. The objection, which at first seems to have some weight, will be found to have none at all, when we consider that the gun and ball partake of the earth's motion; and therefore the ball being carried forward with the air as quick as the earth and air turn, must fall down on the same place. A stone let fall from the top of a main-mast,

132
Earth's motion proved from the celestial appearances from different planets.

Weight of bodies increases towards the poles.

133
Another objection answered.

maft, if it meets with no obftacle, falls on the deck as near the foot of the maft when the fhip fails as when it does not. If an inverted bottle, full of liquor, be hung up to the ceiling of the cabin, and a fmall hole be made in the cork to let the liquor drop through on the floor, the drops will fall juft as far forward on the floor when the fhip fails as when it is at reft. And gnats or flies can as eafily dance among one another in a moving cabin as in a fixed chamber. As for thofe fcripture expreffions which feem to contradict the earth's motion, this general answer may be made to them all, *viz.* It is plain from many inftances, that the Scriptures were never intended to inftitute us in philofophy or aftronomy; and therefore on thofe fubjects expreffions are not always to be taken in the literal fenfe, but for the moft part as accommodated to the common apprehenfions of mankind. Men of fenfe in all ages, when not treating of the fciences purpofely, have followed this method: and it would be in vain to follow any other in addreffing ourfelves to the vulgar, or bulk of any community.

The following experiment will give a plain idea of the diurnal and annual motions of the earth, together with the different lengths of days and nights, and all the beautiful variety of feafons, depending on thofe motions.

ment.
Plate XLV.
fig. 3.

Take about feven feet of ftrong wire, and bend it into a circular form, as a bcd, which being viewed obliquely, appears elliptical, as in the figure. Place a lighted candle on a table; and having fixed one end of a filk thread K, to the north pole of a fmall terreftrial globe H, about three inches diameter, caufe another perfon to hold the wire circle, fo that it may be parallel to the table, and as high as the flame of the candle I, which fhould be in or near the centre. Then having twifted the thread as towards the left hand, that by untwifting it may turn the globe round eaftward, or contrary to the way that the hands of a watch move, hang the globe by the thread within this circle, almoft contiguous to it; and as the thread untwifts, the globe (which is enlightened half round by the candle as the earth is by the fun) will turn round its axis, and the different places upon it will be carried through the light and dark hemifpheres, and have the appearance of a regular fucceffion of days and nights, as our earth has in reality by fuch a motion. As the globe turns, move your hand flowly, fo as to carry the globe round the candle according to the order of the letters a b c d, keeping its centre even with the wire circle; and you will perceive, that the candle, being ftill perpendicular to the equator, will enlighten the globe from pole to pole in its whole motion round the circle; and that every place on the globe goes equally through the light and the dark, as it turns round by the untwifting of the thread, and therefore has a perpetual equinox. The globe thus turning round represents the earth turning round its axis; and the motion of the globe round the candle represents the earth's annual motion round the fun; and fhews, that if the earth's orbit had no inclination to its axis, all the days and nights of the year would be equally long, and there would be no different feafons. Hence alfo it appears why the planets Mars and Jupiter have a perpetual equinox, namely, becaufe their axis is perpendicular to the plane of their orbit, as the thread round which the

globe turns in this experiment is perpendicular to the plane of the area inclofed by the wire.—But now defire the perfon who holds the wire to hold it obliquely in the pofition ABCD, raifing the fide ∞ juft as much as he depreffes the fide ν ; that the flame may be ftill in the plane of the circle; and twifting the thread as before, that the globe may turn round its axis the fame way as you carry it round the candle; that is, from weft to eaft; let the globe down into the lowermoft part of the wire circle at ν ; and if the circle be properly inclined, the candle will fhine perpendicularly on the tropic of Cancer; and the frigid zone, lying within the arctic or north polar circle, will be all in the light, as in the figure; and will keep in the light let the globe turn round its axis ever fo often. From the equator to the north polar circle, all the places have longer days and shorter nights; but from the equator to the fouth polar circle, juft the reverfe. The fun does not fet to any part of the north frigid zone, as fhewn by the candle's fhining on it, fo that the motion of the globe can carry no place of that zone into the dark; and at the fame time the fouth frigid zone is involved in darknefs, and the turning of the globe brings none of its places into the light. If the earth were to continue in the like part of its orbit, the fun would never fet to the inhabitants of the north frigid zone, nor rife to thofe of the fouth. At the equator, it would be always equal day and night; and as places are gradually more and more diftant from the equator towards the arctic circle, they would have longer days and shorter nights; whilft thofe on the fouth fide of the equator would have their nights longer than their days. In this cafe, there would be continual fummer on the north fide of the equator, and continual winter on the fouth fide of it.

But as the globe turns round its axis, move your hand flowly forward, fo as to carry the globe from H towards E, and the boundary of light and darknefs will approach towards the north pole, and recede towards the fouth pole; the northern places will go through lefs and lefs of the light, and the fouthern places through more and more of it; fhewing how the northern days decrease in length, and the fouthern days increafe, whilft the globe proceeds from H to E. When the globe is at E, it is at a mean ftate between the loweft and higheft parts of its orbit; the candle is direclly over the equator, the boundary of light and darknefs juft reaches to both the poles, and all places on the globe go equally through the light and dark hemifpheres, fhewing that the days and nights are then equal at all places of the earth, the poles only excepted; for the fun is then fetting to the north pole, and rifing to the fouth pole.

Continue moving the globe forward, and as it goes through the quarter A, the north pole recedes ftill farther into the dark hemifphere, and the fouth pole advances more into the light, as the globe comes nearer to ∞ ; and when it comes there at F, the candle is direclly over the tropic of Capricorn; the days are at the fhorteft, and nights at the longeft, in the northern hemifphere, all the way from the equator to the arctic circle; and the reverfe in the fouthern hemifphere from the equator to the antarctic circle; within which circles it is dark to the north frigid zone, and light to the fouth.

Continue

Continue both motions; and as the globe moves through the quarter B, the north pole advances towards the light, and the fourth pole recedes towards the dark; the days lengthen in the northern hemisphere, and shorten in the southern; and when the globe comes to G, the candle will be again over the equator (as when the globe was at E), and the days and nights will again be equal as formerly: and the north pole will be just coming into the light, the fourth pole going out of it.

Thus we see the reason why the days lengthen and shorten from the equator to the polar circles every year; why there is sometimes no day or night for many turnings of the earth, within the polar circles; why there is but one day and one night in the whole year at the poles; and why the days and nights are equally long all the year round at the equator, which is always equally cut by the circle bounding light and darkness.

The inclination of an axis or orbit is merely relative, because we compare it with some other axis or orbit which we consider as not inclined at all. Thus, our horizon being level to us, whatever place of the earth we are upon, we consider it as having no inclination; and yet, if we travel 90 degrees from that place, we shall then have an horizon perpendicular to the former; but it will still be level to us.

Let us now take a view of the earth in its annual course round the sun, considering its orbit as having no inclination; and its axis as inclining 23½ degrees from a line perpendicular to the plane of its orbit, and keeping the same oblique direction in all parts of its annual course; or, as commonly termed, keeping always parallel to itself.

Let a, b, c, d, e, f, g, h be the earth in eight different parts of its orbit, equidistant from one another; N its axis, N its north pole, s its fourth pole, and S the sun nearly in the centre of the earth's orbit. As the earth goes round the sun according to the order of the letters $abcd$, &c. its axis N keeps the same obliquity, and is still parallel to the line MN . When the earth is at a , its north pole inclines towards the sun S , and brings all the northern places more into the light than at any other time of the year. But when the earth is at e in the opposite time of the year, the north pole declines from the sun, which occasions the northern places to be more in the dark than in the light, and the reverse at the southern places; as is evident by the figure, which is taken from Dr Long's astronomy. When the earth is either at c or g , its axis inclines not either to or from the sun, but lies sidewise to him, and then the poles are in the boundary of light and darkness; and the sun, being directly over the equator, makes equal day and night at all places. When the earth is at b , it is half-way between the summer solstice and harvest equinox; when it is at d , it is half-way from the harvest equinox to the winter solstice; at f , half-way from the winter solstice to the spring equinox; and at h , half-way from the spring equinox to the summer solstice.

From this oblique view of the earth's orbit, let us suppose ourselves to be raised far above it, and placed just over its centre S , looking down upon it from its north pole; and as the earth's orbit differs but very little from a circle, we shall have its figure in such a

view represented by the circle $ABCDEFGHI$. Let us suppose this circle to be divided into 12 equal parts, called *signs*, having their names affixed to them; and each sign into 30 equal parts, called *degrees*, numbered 10, 20, 30, as in the outermost circle of the figure, which represents the great ecliptic in the heavens. The earth is shewn in eight different positions in this circle; and in each position \mathcal{E} is the equator, T the tropic of Cancer, the dotted circle the parallel of London, U the arctic or north polar circle, and P the north pole, where all the meridians or hour-circles meet. As the earth goes round the sun, the north pole keeps constantly towards one part of the heavens, as it keeps in the figure towards the right-hand side of the plate.

When the earth is at the beginning of Libra, namely on the 20th of March, in this figure the sun S as seen from the earth appears at the beginning of Aries in the opposite part of the heavens, the north pole is just coming into the light, and the sun is vertical to the equator; which together with the tropic of Cancer, parallel of London, and arctic circle, are all equally cut by the circle bounding light and darkness, coinciding with the six-o'clock hour-circle, and therefore the days and nights are equally long at all places: for every part of the meridian $ETLa$ comes into the light at six in the morning, and revolving with the earth according to the order of the hour-letters, goes into the dark at six in the evening. There are 24 meridians or hour-circles drawn on the earth in this figure, to shew the time of fun-rising and setting at different seasons of the year.

As the earth moves in the ecliptic according to the order of the letters $ABCD$, &c. through the signs Libra, Scorpio, and Sagittarius, the north pole P comes more and more into the light; the days increase as the nights decrease in length, at all places north of the equator \mathcal{E} ; which is plain by viewing the earth at b on the 5th of May, when it is in the 15th degree of Scorpio, and the sun as seen from the earth appears in the 15th degree of Taurus. For then the tropic of Cancer T is in the light from a little after five in the morning till almost seven in the evening; the parallel of London, from half an hour past four till half an hour past seven; the polar circle U , from three till nine; and a large track round the north pole P has day all the 24 hours, for many rotations of the earth on its axis.

When the earth comes to c (Pl. XLV. fig. 4.) at the beginning of Capricorn, and the sun as seen from the earth appears at the beginning of Cancer, on the 21st of June, as in this figure, it is in the position C in fig. 1; and its north pole inclines towards the sun, so as to bring all the north frigid zone into the light, and the northern parallels of latitude more into the light than the dark from the equator to the polar circle; and the more so as they are farther from the equator. The tropic of Cancer is in the light from five in the morning till seven at night, the parallel of London from a quarter before four till a quarter after eight; and the polar circle just touches the dark, so that the sun has only the lower half of his disk hid from the inhabitants on that circle for a few minutes about midnight, supposing no inequalities in the horizon, and no refractions.

A bare view of the figure is enough to shew, that as the earth advances from Capricorn towards Aries, and

135
Different seasons particularly explained.

Plate XLV.
fig. 4.

the sun appears to move from Cancer towards Libra, the north pole recedes from the light, which causes the days to decrease, and the nights to increase in length, till the earth comes to the beginning of Aries, and then they are equal as before; for the boundary of light and darkness cuts the equator and all its parallels equally, or in halves. The north pole then goes into the dark, and continues therein until the earth goes half-way round its orbit; or, from the 23^d of September till the 20th of March. In the middle between these times, *viz.* on the 22^d of December, the north pole is as far as it can be in the dark, which is $23\frac{1}{2}$ degrees, equal to the inclination of the earth's axis from a perpendicular to its orbit: and then the northern parallels are as much in the dark as they were in the light on the 21st of June; the winter nights being as long as the summer days, and the winter days as short as the summer nights. Here it must be noted, that of all that has been said of the northern hemisphere, the contrary must be understood of the southern; for on different sides of the equator the seasons are contrary, because, when the northern hemisphere inclines towards the sun, the southern declines from him.

136
Why the
sun appears
bigger in
winter than
in summer.

The earth's orbit being elliptical, and the sun constantly keeping in its lower focus, which is 1,617,941 miles from the middle point of the longer axis, the earth comes twice so much, or 3,235,882 miles, nearer the sun at one time of the year than at another; for the sun appearing under a larger angle in our winter than summer, proves that the earth is nearer the sun in winter (1). But here this natural question will arise, Why have we not the hottest weather when the earth is nearest the sun? In answer it must be observed, that the eccentricity of the earth's orbit, or 1,617,941 miles, bears no greater proportion to the earth's mean distance from the sun than 17 does to 1000; and therefore, this small difference of distance cannot occasion any great difference of heat or cold. But the principal cause of this difference is, that in winter the sun's rays fall so obliquely upon us, that any given number of them is spread over a much greater portion of the earth's surface where we live; and therefore each point must then have fewer rays than in summer. Moreover, there comes a greater degree of cold in the long winter-nights, than there can return of heat in so short days; and on both these accounts the cold must increase. But in summer the sun's rays fall more perpendicularly upon us; and therefore come with greater force, and in greater numbers, on the same place; and by their long continuance, a much greater degree of heat is imparted by day than can fly off by night. Besides, those parts which are once heated, retain the heat for some time; which, with the additional heat daily imparted, makes it continue to increase, though the sun declines towards the south: and this is the reason why July is hotter than June, although the sun has withdrawn from the summer tropic; as we find it is generally hotter at three in the afternoon, when the sun has gone towards the west, than at noon when he is on the meridian. Likewise those places which are well cooled require time to be heated again; for the sun's rays do not heat even the surface of any body till they have

been some time upon it. And therefore we find January for the most part colder than December, altho' the sun has withdrawn from the winter tropic, and begins to dart his beams more perpendicularly upon us. An iron bar is not heated immediately upon being in the fire, nor grows cold till some time after it has been taken out.

It has been already observed, that by the earth's motion on it's axis, there is more matter accumulated all around the equatorial parts than any where else on the earth.

The sun and moon, by attracting this redundancy of matter, bring the equator sooner under them in every return towards it, than if there was no such accumulation. Therefore, if the sun sets out, as from any star, or other fixed point in the heavens, the moment when he is departing from the equinoctial or from either tropic, he will come to the same equinox or tropic again 20 min. $17\frac{1}{2}$ sec. of time, or 50 seconds of a degree, before he completes his course, so as to arrive at the same fixed star or point from whence he set out. For the equinoctial points recede 50 seconds of a degree westward every year, contrary to the sun's annual progressive motion.

When the sun arrives at the same equinoctial or solstitial point, he finishes what we call the *Tropical Year*; which, by observation, is found to contain 365 days 5 hours 48 minutes 57 seconds: and when he arrives at the same fixed star again, as seen from the earth, he completes the sidereal year, which contains 365 days 6 hours 9 minutes $14\frac{1}{2}$ seconds. The sidereal year is therefore 20 minutes $17\frac{1}{2}$ seconds longer than the solar or tropical year, and 9 minutes $14\frac{1}{2}$ seconds longer than the Julian or the civil year, which we state at 365 days 6 hours, so that the civil year is almost a mean between the sidereal and tropical.

As the sun describes the whole ecliptic, or 360 degrees, in a tropical year, he moves $59^{\circ} 8'$ of a degree every day at a mean rate; and consequently $50'$ of a degree in 20 minutes $17\frac{1}{2}$ seconds of time: therefore he will arrive at the same equinox or solstice when he is $50'$ of a degree short of the same star or fixed point in the heavens from which he set out the year before. So that, with respect to the fixed stars, the sun and equinoctial points fall back (as it were) 30 degrees in 2160 years, which will make the stars appear to have gone 30 deg. forward with respect to the signs of the ecliptic at that time: for the same signs always keep in the same points of the ecliptic, without regard to the constellations.

To explain this by a figure, let the sun be in conjunction with a fixed star at S, suppose in the 30th degree of γ , at any given time. Then, making 2160 revolutions through the ecliptic VWX, at the end of so many sidereal years, he will be found again at S: but at the end of so many Julian years, he will be found at M, short of S: and at the end of so many tropical years he will be found short of M, in the 30th degree of Taurus at T, which has receded back from S to T in that time, by the precession of the equinoctial points ψ Aries and $\underline{\omega}$ Libra. The arc ST will be equal to the amount of the precession of the

137
Precession
of the equi-
noxes ex-
plained.
Pl. XLVII.
fig. 1.

(1) It is denied by some that the sun appears bigger in winter on account of his greater proximity to the earth than in summer; the reason they give is the increase of refraction by reason of the more oblique position of the sun, and greater quantity of vapours in the air, at that time.

the equinox in 2160 years, at the rate of $50''$ of a degree, or 20 minutes $17\frac{1}{2}$ seconds of time annually; this, in so many years, makes 30 days $10\frac{1}{2}$ hours, which is the difference between 2160 sidereal and tropical years; and the arc MT will be equal to the space moved through by the sun in 2160 times 11 min. 8 sec. or 16 days 13 hours 48 minutes, which is the difference between 2160 Julian and tropical years.

The anticipation of the equinoxes, and consequently of the seasons, is by no means owing to the precession of the equinoctial and solstitial points in the heavens (which can only affect the apparent motions, places, and declinations, of the fixed stars), but to the difference between the civil and solar year, which is 11 minutes 3 seconds; the civil year containing 365 days 6 hours, and the solar year 365 days 5 hours 48 minutes 57 seconds.

The above 11 minutes 3 seconds, by which the civil or Julian year exceeds the solar, amounts to 11 days in 1433 years; and so much our seasons have fallen back with respect to the days of the months, since the time of the Nicene council in A. D. 325; and therefore, in order to bring back all the fasts and festivals to the days then settled, it was requisite to suppress 11 nominal days; and, that the same seasons might be kept to the same times of the year for the future, to leave out the bissextile-day in February at the end of every century of years not divisible by 4; reckoning them only common years, as the 17th, 18th, and 19th centuries, viz. the years 1700, 1800, 1900, &c. because a day intercalated every fourth year was too much; and retaining the bissextile-day at the end of those centuries of years which are divisible by 4, as the 16th, 20th, and 24th centuries, viz. the years 1600, 2000, 2400, &c. Otherwise, in length of time, the seasons would be quite reversed with regard to the months of the year; though it would have required near 23,783 years to have brought about such a total change. If the earth had made exactly 365 $\frac{1}{4}$ diurnal rotations on its axis, whilst it revolved from any equinoctial or solstitial point to the same again, the civil and solar years would always have kept pace together, and the style would never have needed any alteration.

Having thus mentioned the cause of the precession of the equinoctial points in the heavens, which occasions a slow deviation of the earth's axis from its parallelism, and thereby a change of the declination of the stars from the equator, together with a slow apparent motion of the stars forward with respect to the signs of the ecliptic, we shall now explain the phenomena by a diagram.

PL. XLVII.
fig. 2. Let NZSVL be the earth, SONA its axis produced to the starry heavens, and terminating in A, the present north pole of the heavens, which is vertical to N the north pole of the earth. Let EOQ be the equator, T ∞ Z the tropic of Cancer, and VT ∞ Z the tropic of Capricorn; VOZ the ecliptic, and BO its axis, both which are immovable among the stars. But as the equinoctial points recede in the ecliptic, the earth's axis SON is in motion upon the earth's centre O, in such a manner, as to describe the double cone NOB and SOZ, round the axis of the ecliptic BO, in the time that the equinoctial points move quite round the ecliptic, which is 25,920 years; and in that length of time, the north pole of the earth's axis produced, de-

scribes the circle ABCDA in the starry heavens, round the pole of the ecliptic, which keeps immovable in the centre of that circle. The earth's axis being 23 $\frac{1}{2}$ degrees inclined to the axis of the ecliptic, the circle ABCDA described by the north pole of the earth's axis produced to A, is 47 degrees in diameter, or double the inclination of the earth's axis. In consequence of this, the point A, which at present is the north pole of the heavens, and near to a star of the second magnitude in the tail of the constellation called *the little bear*, must be deserted by the earth's axis; which moving backwards a degree every 72 years, will be directed towards the star or point B in 6480 years hence; and in double of that time, or in 12,960 years, it will be directed towards the star or point C, which will then be the north pole of the heavens, although it is at present 8 $\frac{1}{2}$ degrees south of the zenith of London L. The present position of the equator EOQ, will then be changed into eOq, the tropic of Cancer T ∞ Z into Vt ∞ , and the tropic of Capricorn VT ∞ Z into tVZ; as is evident by the figure. And the sun, in the same part of the heavens where he is now over the earthly tropic of Capricorn, and makes the shortest days and longest nights in the northern hemisphere, will then be over the earthly tropic of Cancer, and make the days longest and nights shortest. So that it will require 12,960 years yet more, or 25,920 from the then present time, to bring the north pole N quite round, so as to be directed toward that point of the heavens which is vertical to it at present. And then, and not till then, the same stars which at present describe the equator, tropics, and polar circles, &c. by the earth's diurnal motion, will describe them over again.

From the shifting of the equinoctial points, and with them all the signs of the ecliptic, it follows that those stars which in the infancy of astronomy were in Aries are now got into Taurus; those of Taurus into Gemini, &c. Hence likewise it is that the stars which rose or set at any particular season of the year, in the times of Hesiod, Eudoxus, Virgil, Pliny, &c. by no means answer at this time to their descriptions.

The moon is not a planet, but only a satellite or At-¹³⁸ tendant of the earth, going round the earth from moon. change to change in 29 days 12 hours and 44 minutes, and round the sun with it every year. The moon's diameter is 2180 miles; and her distance from the earth's centre is 240,000. She goes round her orbit in 27 days 7 hours 43 minutes, moving about 2290 miles every hour; and turns round her axis exactly in the time that she goes round the earth, which is the reason of her keeping always the same side towards us, and that her day and night taken together is as long as our lunar month.

The moon is an opaque globe like the earth, and ¹³⁹ Reflects the shines only by reflecting the light of the sun: therefore, whilst that half of her which is towards the sun is enlightened, the other half must be dark and invisible. Hence she disappears when she comes between us and the sun; because her dark side is then towards us. When she is gone a little way forward, we see a little of her enlightened side; which still increases to our view, as she advances forward, until she comes to be opposite to the sun; and then her whole enlightened side is towards the earth, and she appears with a round illumined orb, which we call the *full moon*; her dark side being then ^{turned}

turned away from the earth. From the full she seems to decrease gradually as she goes through the other half of her course; shewing us less and less of her enlightened side every day, till her next change or conjunction with the sun, and then she disappears as before.

Pl. XLIII.
fig. 1.

Her orbit is represented in the scheme by the little circle m , upon the earth's orbit \odot : but it is drawn more than fifty times too large in proportion to the earth's; and yet is almost too small to be seen in the diagram.

The moon has scarce any difference of seasons; her axis being almost perpendicular to the ecliptic. What is very singular, one half of her has no darkness at all; the earth constantly affording it a strong light in the sun's absence; while the other half has a fortnight's darkness and a fortnight's light by turns.

140
Earth ap-
pears a
moon to our
moon.

Our earth is thought to be a moon to the moon; waxing and waning regularly, but appearing 13 times as big, and affording her 13 times as much light as she does us. When she changes to us, the earth appears full to her; and when she is in her first quarter to us, the earth is in its third quarter to her; and *vice versa*.

But from one half of the moon, the earth is never seen at all: from the middle of the other half, it is always seen over head; turning round almost 30 times as quick as the moon does. From the circle which limits our view of the moon, only one half of the earth's side next her is seen; the other half being hid below the horizon of all places on that circle. To her the earth seems to be the biggest body in the universe; for it appears 13 times as big as she does to us.

As the earth turns round its axis, the several continents, seas, and islands, appear to the moon's inhabitants like so many spots of different forms and brightness, moving over its surface; but much fainter at some times than others, as our clouds cover them or leave them. By these spots the Lunarians can determine the time of the earth's diurnal motion, just as we do the motion of the sun: and perhaps they measure their time by the motion of the earth's spots; for they cannot have a truer dial.

141
How the
Lunar in-
habitants can
measure
their year.

The moon's axis is so nearly perpendicular to the ecliptic, that the sun never removes sensibly from her equator; and the obliquity of her orbit, which is next to nothing as seen from the sun, cannot cause the sun to decline sensibly from her equator. Yet her inhabitants are not destitute of means for ascertaining the length of their year, tho' their method and ours must differ. For we can know the length of our year by the return of our equinoxes; but the Lunarians, having always equal day and night, must have recourse to another method: and we may suppose, they measure their year by observing when either of the poles of our earth begins to be enlightened, and the other to disappear, which is always at our equinoxes; they being conveniently situated for observing great tracks of land about our earth's poles, which are entirely unknown to us. Hence we may conclude, that the year is of the same absolute length both to the earth and moon, though very different as to the number of days: we having $365\frac{1}{4}$ natural days, and the Lunarians only $12\frac{1}{7}$, every day and night in the moon being as long as $29\frac{1}{2}$ on the earth.

142
Longitude
easily found.

The moon's inhabitants on the side next the earth may as easily find the longitude of their places as we

can find the latitude of ours. For the earth keeping constantly, or very nearly so, over one meridian of the moon, the east or west distances of places from that meridian are as easily found, as we can find our distance from the equator by the altitude of our celestial poles.

As the sun can only enlighten that half of the earth which is at any moment turned towards him, and being withdrawn from the opposite half, leaves it in darkness; so he likewise doth to the moon: only with this difference, that as the earth is surrounded by an atmosphere, we have twilight after the sun sets; but if the moon has none of her own, nor is included in that of the earth, the lunar inhabitants have an immediate transition from the brightest sun-shine to the blackest darkness. For, let r k s w be the earth, and A , B , C , D , E , F , G , H , the moon in eight different parts of her orbit. As the earth turns round its axis from west to east, when any place comes to t the twilight begins there, and when it revolves from thence to r the sun S rises; when the place comes to s the sun sets, and when it comes to w the twilight ends. But as the moon turns round her axis, which is only once a month, the moment that any point of her surface comes to r (see the moon at G), the sun rises there without any previous warning by twilight; and when the same point comes to s the sun sets, and that point goes into darkness as black as at midnight.

Pl. XLVII.
fig. 3.

The moon being an opaque spherical body (for her hills take off no more from her roundness than the inequalities on the surface of an orange takes off from its roundness), we can only see that part of the enlightened half of her which is towards the earth. And therefore, when the moon is at A , in conjunction with the sun S , her dark half is towards the earth, and she disappears, as at a , there being no light on that half to render it visible. When she comes to her first octant at B , or has gone an eighth part of her orbit from her conjunction, a quarter of her enlightened side is towards the earth, and she appears horned, as at b . When she has gone a quarter of her orbit from between the earth and sun to C , she shews us one half of her enlightened side, as at c , and we say she is a quarter old. At D , she is in her second octant; and by shewing us more of her enlightened side she appears gibbous, as at d . At E , her whole enlightened side is towards the earth; and therefore she appears round, as at e ; when we say it is full moon. In her third octant at F , part of her dark side being towards the earth, she again appears gibbous, and is on the decrease, as at f . At G , we see just one half of her enlightened side; and she appears half decreased, or in her third quarter, as at g . At H , we only see a quarter of her enlightened side, being in her fourth octant; where she appears horned, as at h . And at A , having completed her course from the sun to the sun again, she disappears; and we say it is new moon. Thus, in going from A to E , the moon seems continually to increase; and in going from E to A , to decrease in the same proportion; having like phases at equal distances from A to E , but as seen from the sun S she is always full.

143
Her phases
explained.

The moon appears not perfectly round when she is full in the highest or lowest part of her orbit, because we have not a full view of her enlightened side at that time. When full in the highest part of her orbit, a small

144
Never ap-
pears per-
fectly
round.

small deficiency appears on her lower edge; and the contrary when full in the lowest part of her orbit.

It is plain by the figure, that when the moon changes to the earth, the earth appears full to the moon; and *vice versa*. For when the moon is at A, new to the earth, the whole enlightened side of the earth is towards the moon; and when the moon is at E, full to the earth, its dark side is towards her. Hence a new moon answers to a full earth, and a full moon to a new earth. The quarters are also reversed to each other.

Between the third quarter and change, the moon is frequently visible in the forenoon, even when the sun shines; and then she affords us an opportunity of seeing a very agreeable appearance, where-ever we find a globular stone above the level of the eye, as suppose on the top of a gate. For, if the sun shines on the stone, and we place ourselves so as the upper part of the stone may just seem to touch the point of the moon's lower-moort horn, we shall then see the enlightened part of the stone exactly of the same shape with the moon; horned as she is, and inclined the same way to the horizon. The reason is plain; for the sun enlightens the stone the same way as he does the moon: and both being globes, when we put ourselves into the above situation, the moon and stone have the same position to our eyes; and therefore we must see as much of the illuminated part of the one as of the other.

The position of the moon's cusps, or a right line touching the points of her horns, is very differently inclined to the horizon at different hours of the same days of her age. Sometimes she stands, as it were, upright on her lower horn, and then such a line is perpendicular to the horizon: when this happens, she is in what the astronomers call the *nonageſimal degree*; which is the highest point of the ecliptic above the horizon at that time, and is 90 degrees from both sides of the horizon where it is then cut by the ecliptic. But this never happens when the moon is on the meridian, except when she is at the very beginning of Cancer or Capricorn.

That the moon turns round her axis in the time that she goes round her orbit, is quite demonstrable; for, a spectator at rest, without the periphery of the moon's orbit, would see all her sides turned regularly towards him in that time. She turns round her axis from any star to the same star again in 27 days 8 hours; from the sun to the sun again in 29½ days: the former is the length of her sidereal day, and the latter the length of her solar day. A body moving round the sun would have a solar day in every revolution, without turning on its axis; the same as if it had kept all the while at rest, and the sun moved round it: but without turning round its axis it could never have one sidereal day, because it would always keep the same side towards any given star.

If the earth had no annual motion, the moon would go round it so as to complete a lunation, a sidereal, and a solar day, all in the same time. But, because the earth goes forward in its orbit while the moon goes round the earth in her orbit, the moon must go as much

more than round her orbit from change to change in completing a solar day, as the earth has gone forward in its orbit during that time, i. e. almost a twelfth part of a circle.

If the earth had no annual motion, the moon's motion round the earth, and her track in open space, would be always the same (x). But as the earth and moon move round the sun, the moon's real path in the heavens is very different from her visible path round the earth; the latter being in a progressive circle, and the former in a curve of different degrees of concavity, which would always be the same in the same parts of the heavens, if the moon performed a complete number of lunations in a year without any fraction.

Let a nail in the end of the axle of a chariot-wheel represent the earth, and a pin in the nave the moon; if the body of the chariot be propped up so as to keep that wheel from touching the ground, and the wheel be then turned round by hand, the pin will describe a circle both round the nail and in the space it moves through. But if the props be taken away, the horses put to, and the chariot driven over a piece of ground which is circularly convex; the nail in the axle will describe a circular curve, and the pin in the nave will still describe a circle round the progressive nail in the axle, but not in the space through which it moves. In this case, the curve described by the nail will resemble in miniature as much of the earth's annual path round the sun, as it describes whilst the moon goes as often round the earth as the pin does round the nail: and the curve described by the pin will have some resemblance of the moon's path during so many lunations.

Let us now suppose that the radius of the circular curve described by the nail in the axle is to the radius of the circle which the pin in the nave describes round the axle, as $337\frac{1}{2}$ to 1; (L) which is the proportion of the radius or semidiameter of the earth's orbit to that of the moon's, or of the circular curve A 1 2 3 4 5 6 7 B, &c. to the little circle a; and then, whilst the progressive nail describes the said curve from A to E, the pin will go once round the nail with regard to the centre of its path, and in so doing will describe the curve *abcde*. The former will be a true representation of the earth's path for one lunation, and the latter of the moon's for that time. Here we may set aside the inequalities of the moon's motion, and also the earth's moving round its common centre of gravity and the moon's: all which, if they were truly copied in this experiment, would not sensibly alter the figure of the paths described by the nail and pin, even though they should rub against a plain upright surface all the way, and leave their tracks visible upon it. And if the chariot was driven forward on such a convex piece of ground, so as to turn the wheel several times round, the track of the pin in the nave would still be concave toward the centre of the circular curve described by the nail in the axle; as the moon's path is always concave to the sun in the centre of the earth's annual orbit.

In this diagram, the thickest curve line ABCDE, with

(x) In this place, we may consider the orbits of all the satellites as circular, with respect to their primary planets; because the eccentricities of their orbits are too small to affect the phenomena here described.

(L) The figure by which this is illustrated is borrowed from Mr Ferguon, whom we principally follow in our explanations of the phenomena. Later observations have determined the proportions to be different; but we cannot find that any delineation of this kind hath been given by astronomers, according to the new proportions.

with the numeral figures set to it, represents as much of the earth's annual orbit as it describes in 32 days from west to east; the little circles at A, B, C, D, E, shew the moon's orbit in due proportion to the earth's; and the smallest curve *a C f* represents the line of the moon's path in the heavens for 32 days, accounted from any particular new moon at *a*. The sun is supposed to be in the centre of the curve *A 1 2 3 4 5 6 7 B*, &c. and the small dotted circles upon it represent the moon's orbit, of which the radius is in the same proportion to the earth's path in this scheme, that the radius of the moon's orbit in the heavens was supposed to bear to the radius of the earth's annual path round the sun; that is, as 240,000, to 81,000,000, or as 1 to 337½.

When the earth is at A, the new moon is at *a*; and in the seven days that the earth describes the curve *1 2 3 4 5 6 7*, the moon in accompanying the earth describes the curve *a b*; and is in her first quarter at *b* when the earth is at B. As the earth describes the curve *B 8 9 10 11 12 13 14*, the moon describes the curve *b c*; and is at *c*, opposite to the sun, when the earth is at C. Whilst the earth describes the curve *C 15 16 17 18 19 20 21 22*, the moon describes the curve *c d*; and is in her third quarter at *d* when the earth is at D. And lastly, whilst the earth describes the curve *D 23 24 25 26 27 28 29*, the moon describes the curve *d e*; and is again in conjunction at *e* with the sun when the earth is at E, between the 29th and 30th day of the moon's age, accounted by the numeral figures from the new moon at A. In describing the curve *a C e*, the moon goes round the progressive earth as really as if she had kept in the dotted circle *A*, and the earth continued immovable in the centre of that circle.

148
Her path
always con-
cave to the
sun.

And thus we see, that although the moon goes round the earth in a circle, with respect to the earth's centre, her real path in the heavens is not very different in appearance from the earth's path. To shew that the moon's path is concave to the sun, even at the time of change, it is carried on a little farther into a second lunation, as to *f*.

The moon's absolute motion from her change to her first quarter, or from *a* to *b*, is so much slower than the earth's, that she falls 240,000 miles (equal to the semidiameter of her orbit) behind the earth at her first quarter in *b*, when the earth is in B; that is, she falls back a space equal to her distance from the earth. From that time her motion is gradually accelerated to her opposition or full at *c*; and then she is come up as far as the earth, having regained what she lost in her first quarter from *a* to *b*. From the full to the last quarter at *d*, her motion continues accelerated so as to be just as far before the earth at *d*, as she was behind it at her first quarter in *b*. But from *d* to *e* her motion is retarded so, that she loses as much with respect to the earth as is equal to her distance from it, or to the semidiameter of her orbit; and by that means she comes to *e*, and is then in conjunction with the sun as seen from the earth at E. Hence we find, that the moon's absolute motion is slower than the earth's from her third quarter to her first, and swifter than the earth's from her first quarter to her third; her path being less curved than the earth's in the former case, and more in the latter. Yet it is still bent the same way towards the sun; for if we imagine the concavity of the earth's orbit to be measured by the length of a per-

pendicular line *C g*, let down from the earth's place upon the straight line *b g d* at the full of the moon, and connecting the places of the earth at the end of the moon's first and third quarters, that length will be about 640,000 miles; and the moon when new only approaching nearer to the sun by 240,000 miles than the earth is, the length of the perpendicular let down from her place at that time upon the same straight line, and which shews the concavity of that part of her path, will be about 400,000 miles.

The moon's path being concave to the sun throughout, demonstrates that her gravity towards the sun, at her conjunction, exceeds her gravity towards the earth; and if we consider that the quantity of matter in the sun is vastly greater than the quantity of matter in the earth, and that the attraction of each body diminishes as the square of the distance from it increases, we shall soon find, that the point of equal attraction between the earth and the sun, is much nearer the earth than the moon is at her change. It may then appear surprising that the moon does not abandon the earth when she is between it and the sun, because she is considerably more attracted by the sun than by the earth at that time. But this difficulty vanishes when we consider, that a common impulse on any system of bodies affects not their relative motions; but that they will continue to attract, impel, or circulate round one another, in the same manner as if there was no such impulse. The moon is so near the earth, and both of them so far from the sun, that the attractive power of the sun may be considered as equal on both; and therefore the moon will continue to circulate round the earth in the same manner as if the sun did not attract them at all: like bodies in the cabin of a ship, which may move round or impel one another in the same manner when the ship is under sail, as when it is at rest; because they are all equally affected by the common motion of the ship. If by any other cause, such as the near approach of a comet, the moon's distance from the earth should happen to be so much increased, that the difference of their gravitating forces towards the sun should exceed that of the moon towards the earth; in that case, the moon, when in conjunction, would abandon the earth, and be either drawn into the sun, or comet, or circulate round about it.

The ruggedness of the moon's surface mentioned n°40, 41. is of great use to us, by reflecting the sun's light to all sides: for if the moon were smooth and polished like a looking-glass, or covered with water, she could never distribute the sun's light all round; only in some positions she would shew us his image, no bigger than a point, but with such a lustre as would be hurtful to our eyes.

The moon's surface being so uneven, many have wondered why her edge appears not jagged, as well as the curve bounding the light and dark places. But if we consider, that what we call the edge of the moon's disk is not a single line set round with mountains, in which case it would appear irregularly indented, but a large zone having many mountains lying behind one another from the observer's eye, we shall find that the mountains in some rows will be opposite to the vales in others; and so fill up the inequalities as to make her appear quite round: just as when one looks at an orange, although its roughness be very discernible on the

attraction
solved.

150
Why her
edge appears
always even.

the side next the eye, especially if the sun or a candle shines obliquely on that side, yet the line terminating the visible part still appears smooth and even.

151
Of Mars.

The planet Mars comes next in order, being the first above the earth's orbit. His distance from the sun is computed to be 145,014,148 miles; and by travelling at the rate of 55,287 miles every hour, as in the circle *G*, he goes round the sun in 686 of our days and 23 hours; which is the length of his year, and contains 667 $\frac{1}{2}$ of his days; every day and night together being 40 minutes longer than with us. His diameter is 5400 miles, and by his diurnal rotation the inhabitants about his equator are carried 669 miles every hour. His quantity of light and heat is equal but to one half of ours; and the sun appears but half as big to him as to us.

This planet being but a fifth part so big as the earth, if any moon attends him, he must be very small, and has not yet been discovered by our best telescopes. To Mars, our earth and moon appear like two moons, a bigger and a less; changing places with one another, and appearing sometimes horned, sometimes half or three quarters illuminated, but never full; nor at most above one quarter of a degree from each other, altho' they are 240,000 miles asunder.

Our earth appears almost as big to Mars as Venus does to us, and at Mars it is never seen above 48 degrees from the sun; sometimes it appears to pass over the disk of the sun, and so do Mercury and Venus: but Mercury can never be seen from Mars by such eyes as ours, unassisted by proper instruments; and Venus will be as seldom seen as we see Mercury. Jupiter and Saturn will appear bigger to Mars than to us. His axis is perpendicular to the ecliptic, and his orbit is two degrees inclined to it.

152
Of Jupiter.

Jupiter, the biggest of all the planets, is still higher in the system, being 494,990,976 miles from the sun; and going at the rate of 29,083 miles every hour in his orbit, as in the circle *J*, finishes his annual period in eleven of our years 314 days and 12 hours. He is above 1300 times as big as the earth; for his diameter is 94,000 miles, which is more than eleven times the diameter of the earth.

Jupiter turns round his axis in 9 hours 56 minutes; so that his year contains 10,470 days; and the diurnal velocity of his equatorial parts is greater than the swiftness with which he moves in his annual orbit; a singular circumstance, as far as we know. By this prodigious quick rotation, his equatorial inhabitants are carried 29,542 miles every hour (which is 4000 miles in one hour more than an inhabitant of our earth's equator moves in 24 hours), besides the 29,083 above-mentioned, which is common to all parts of his surface, by his annual motion. By this prodigiously swift rotation on his axis the centrifugal force of his equatorial parts is able to shorten his polar diameter by $\frac{1}{2}$ of the whole, so that the difference is very perceptible through a good telescope.

153
Has no sensible change of seasons.

The axis of Jupiter is so nearly perpendicular to his orbit, that he has no sensible change of seasons; which is a great advantage, and wisely ordered by the Author of Nature. For, if the axis of this planet were inclined any considerable number of degrees, just so many degrees round each pole would in their turn be almost fix of our years together in darkness. And, as

each degree of a great circle on Jupiter contains 820 of our miles at a mean rate, it is easy to judge what vast tracts of land would be rendered uninhabitable by any considerable inclination of his axis.

The sun appears but $\frac{1}{15}$ part so big to Jupiter as to us; and his light and heat are in the same small proportion, but compensated by the quick returns thereof, and by four moons (some bigger and some less than our earth) which revolve about him: so that there is scarce any part of this huge planet but what is during the whole night enlightened by one or more of these moons, except his poles, whence only the farthest moons can be seen, and where their light is not wanted, because the sun constantly circulates in or near the horizon, and is very probably kept in view of both poles by the refraction of Jupiter's atmosphere, which, if it be like ours, has certainly refractive power enough for that purpose.

The orbits of these moons are represented in the scheme of the solar system by four small circles marked 1. 2. 3. 4. on Jupiter's orbit *J*; but they are drawn greatly too large in proportion to it. The first moon, or that nearest to Jupiter, goes round him in 1 day 18 hours and 36 minutes of our time; and is 266,332 miles distant from his centre: The second performs its revolution in 3 days 13 hours and 15 minutes, at 423,000 miles distance: The third in 7 days 3 hours and 59 minutes, at the distance of 676,078 miles: and the fourth, or outermost, in 16 days 18 hours and 30 minutes, at the distance of 1,189,148 miles from his centre.

The angles under which the orbits of Jupiter's moons are seen from the earth, at its mean distance from Jupiter, are as follow: The first, 3' 55"; the second, 6' 14"; the third, 9' 58"; and the fourth, 17' 30". And their distances from Jupiter, measured by his semidiameters, are thus: The first 5 $\frac{1}{2}$; the second, 9; the third, 14 $\frac{3}{8}$; and the fourth, 25 $\frac{5}{8}$. This planet, seen from its nearest moon, appears 1000 times as large as our moon does to us; waxing and waning in all her monthly shapes, every 10 hours.

Jupiter's three nearest moons fall into his shadow, and are eclipsed in every revolution: but the orbit of the fourth moon is so much inclined, that it passeth by its opposition to Jupiter, without falling into his shadow, two years in every six. By these eclipses, astronomers have not only discovered that the sun's light takes up eight minutes of time in coming to us; but they have also determined the longitudes of places on this earth with greater certainty and facility, than by any other method yet known.

154
Longitude determined by eclipses of his satellites.

Jupiter's orbit is 1 degree 20 minutes inclined to the ecliptic. His north node is in the 7th degree of Cancer, and his south node in the 7th degree of Capricorn.

The curves which Jupiter's satellites describe, are all of different sorts from the path described by our moon, although these satellites go round Jupiter, as the moon goes round the earth. Let ABCDE, &c. be as much of Jupiter's orbit as he describes in 18 days from A to T; and the curves *a, b, c, d* will be the paths of his Pl. XLVII. four moons going round him in his progressive motion. fig. 5.

155
Defination of the paths of his satellites.

Now let us suppose all these moons to set out from a conjunction with the sun, as seen from Jupiter at A; then, his first or nearest moon will be at *a*, his second at *b*, his third at *c*, and his fourth at *d*. At the end of

of 24 terrestrial hours after this conjunction, Jupiter has moved to B, his first moon or satellite has described the curve *a* 1, his second the curve *b* 1, his third *c* 1, and his fourth *d* 1. The next day, when Jupiter is at C, his first satellite has described the curve *a* 2, from its conjunction, his second the curve *b* 2, his third the curve *c* 2, and his fourth the curve *d* 2, and so on. The numeral figures under the capital letters show Jupiter's place in his path every day for 18 days, accounted from A to T; and the like figures set to the paths of his satellites, shew where they are at the like times. The first satellite, almost under C, is stationary at + as seen from the sun, and retrograde from + to 2 : at 2 it appears stationary again, and thence it moves forward until it has past 3, and is twice stationary and once retrograde between 3 and 4. The path of this satellite intersects itself every $42\frac{1}{2}$ hours, making such loops as in the diagram at 2. 3. 5. 7. 9. 10. 12. 14. 16. 18. a little after every conjunction. The second satellite *b*, moving slower, barely crosses its path every 3 days 13 hours; as at 4. 7. 11. 14. 18. making only five loops and as many conjunctions in the time that the first makes ten. The third satellite *c* moving still slower, and having described the curve *c* 1. 2. 3. 4. 5. 6. 7. comes to an angle at 7 in conjunction with the sun at the end of 7 days four hours; and so goes on to describe such another curve 7. 8. 9. 10. 11. 12. 13. 14. and is at 14 in its next conjunction. The fourth satellite *d* is always progressive, making neither loops nor angles in the heavens; but comes to its next conjunction at *e* between the numeral figures 16 and 17, or in 16 days 18 hours.

The method used by Mr Ferguson to delineate the paths of these satellites was the following. Having drawn their orbits on a card, in proportion to their relative distances from Jupiter, he measured the radius of the orbit of the fourth satellite, which was an inch and $\frac{14}{1000}$ parts of an inch; then multiplied this by 424 for the radius of Jupiter's orbit, because Jupiter is 424 times as far from the sun's centre as his fourth satellite is from his centre; and the product thence arising was $483\frac{3}{1000}$ inches. Then taking a small cord of this length, and fixing one end of it to the floor of a long room by a nail, with a black-lead pencil at the other end he drew the curve ABCD &c. and set off a degree and half thereon, from A to T; because Jupiter moves only so much, whilst his outermost satellite goes once round him, and somewhat more; so that this small portion of so large a circle differs but very little from a straight line. This done, he divided the space AT into 18 equal parts, as AB, BC, &c. for the daily progress of Jupiter; and each part into 24 for his hourly progress. The orbit of each satellite was also divided into as many equal parts as the satellite is hours in finishing its synodical period round Jupiter. Then drawing a right line through the centre of the card, as a diameter to all the four orbits upon it, he put the card upon the line of Jupiter's motion, and transferred it to every horary division thereon, keeping always the said diameter-line on the line of Jupiter's path; and running a pin through each horary division in the orbit of each satellite as the card was gradually transferred along the line ABCD &c. of Jupiter's motion, he marked points for every hour through the card for the curves described by the satellites, as the

primary planet in the centre of the card was carried forward on the line; and so finished the figure, by drawing the lines of each satellite's motion through those (almost innumerable) points: by which means, this is perhaps as true a figure of the paths of the satellites as can be desired. And in the same manner might those of Saturn's satellites be delineated.

It appears by the scheme, that the three first satellites come almost into the same line or position every seventh day; the first being only a little behind with the second, and the second behind with the third. But the period of the fourth satellite is so incommensurate to the periods of the other three, that it cannot be guessed at by the diagram when it would fall again into a line of conjunction with them, between Jupiter and the sun. And no wonder; for supposing them all to have been once in conjunction, it will require $3,087,043,493,260$ years to bring them in conjunction again.

Saturn, the remotest of all the planets, is about $907,956,130$ miles from the sun; and, travelling at the rate of $22,101$ miles every hour, as in the circle marked H, performs its annual circuit in 29 years 167 days and 5 hours of our time; which makes only one year to that planet. Its diameter is $78,000$ miles; and therefore it is near 1000 times as big as the earth.

To Saturn the sun appears only $\frac{2}{3}$ part so big as to us; and the light and heat he receives from the sun are in the same proportion to ours. But, to compensate for the small quantity of sun-light, he has five moons, all going round him on the outside of his ring, and nearly in the same plane with it. The first or nearest moon to Saturn, goes round him in one day 21 hours 19 minutes; and is $140,000$ miles from his centre: the second, in 2 days 17 hours 40 minutes, at the distance of $187,000$ miles: the third, in 4 days 12 hours 25 minutes; at $263,000$ miles distance: the fourth, in 15 days 22 hours 41 minutes; at the distance of $600,000$ miles: and the fifth, or outermost, at $1,800,000$ miles from Saturn's centre, goes round him in 79 days 7 hours 48 minutes. Their orbits in the scheme of the solar system are represented by the five small circles marked 1. 2. 3. 4. 5. on Saturn's orbit; but these, like the orbits of the other satellites, are drawn vastly too large in proportion to the orbits of their primary planets.

The sun shines almost 15 of our years together on one side of Saturn's ring without setting, and as long on the other in its turn. So that the ring is visible to the inhabitants of that planet for almost 15 of our years, and as long invisible, by turns, if its axis has no inclination to its ring; but if the axis of the planet be inclined to the ring, suppose about 30 degrees, the ring will appear and disappear once every natural day to all the inhabitants within 30 degrees of the equator, on both sides, frequently eclipsing the sun on a Saturnian day. Moreover, if Saturn's axis be so inclined to his ring, it is perpendicular to his orbit; and thereby the inconvenience of different seasons to that planet is avoided. For, considering the length of Saturn's year, which is almost equal to thirty of ours, what a dreadful condition must the inhabitants of his polar regions be in, if they be half that time deprived of the light and heat of the sun? which is not their case alone, if the axis of the planet be perpendicular to the ring; for then the

156

157
Phenomena
of his
ring.

ring

ring must hide the sun from vast tracks of land on each side of the equator for 13 or 14 of our years together, on the fourth side and north side by turns, as the axis inclines to or from the sun: the reverse of which inconvenience is another good presumptive proof of the inclination of Saturn's axis to his ring, and also of his axis being perpendicular to his orbit.

158
Phenomena
of Saturn's
ring.

This ring, seen from Saturn, appears like a vast luminous arch in the heavens, as if it did not belong to the planet. When we see the ring most open, its shadow upon the planet is broadest; and from that time the shadow grows narrower, as the ring appears to do to us; until, by Saturn's annual motion, the sun comes to the plane of the ring, or even with its edge; which being then directed towards us, becomes invisible on account of its thinness; the ring disappears twice in every annual revolution of Saturn, namely, when he is in the 19th degree both of Pisces and of Virgo. And when Saturn is in the middle between these points, or in the 19th degree either of Gemini or of Sagittarius, his ring appears most open to us; and then its longest diameter is to its shortest, as 9 to 4.

As Saturn goes round the sun, his obliquely posited ring, like our earth's axis, keeps parallel to itself, and is therefore turned edgewise to the sun twice in a Saturnian year, which is almost as long as 30 of our years. But the ring, though considerably broad, is too thin to be seen by us when it is turned edgewise to the sun, at which time it is also edgewise to the earth; and therefore it disappears once in every 15 years to us. As the sun shines half a year together on the north pole of our earth, then disappears to it, and shines as long on the south pole; so, during one half of Saturn's year, the sun shines on the north side of his ring, then disappears to it, and shines as long on its south side. When the earth's axis inclines neither to nor from the sun, but sidewise to him, he instantly ceases to shine on one pole, and begins to enlighten the other; and when Saturn's ring inclines neither to nor from the sun, but sidewise to him, he ceases to shine on the one side of it, and begins to shine upon the other.

To such eyes as ours unassisted by instruments, Jupiter is the only planet that can be seen from Saturn, and Saturn the only planet that can be seen from Jupiter. So that the inhabitants of these two planets must either see much farther than we do, or have equally good instruments to carry their sight to remote objects, if they know that there is such a body as our earth in the universe: for the earth is no bigger seen from Jupiter, than his moons are seen from the earth; and if his large body had not first attracted our sight, and prompted our curiosity to view him with a telescope, we should never have known any thing of his moons; unless by chance we had directed the telescope toward that small part of the heavens where they were at the time of observation. And the like is true of the moons of Saturn.

The orbit of Saturn is 2½ degrees inclined to the ecliptic, or orbit of our earth, and intersects it in the 21st degree of Cancer and of Capricorn; so that Saturn's nodes are only 14 degrees from Jupiter's.

159
Quantity of
light he en-
joys.

The quantity of light afforded by the sun to Jupiter, being but $\frac{1}{15}$ part, and to Saturn only $\frac{1}{15}$ part, of what we enjoy, may at first thought induce us to believe that these two planets are entirely unfit for ra-

Vol. I.

tional beings to dwell upon. But that their light is not so weak as we imagine, is evident from their brightness in the night time; and also from this remarkable phenomenon, that when the sun is so much eclipsed to us, as to have only the 40th part of his disk left uncovered by the moon, the decrease of light is not very sensible; and just at the end of darkness in total eclipses when his western limb begins to be visible, and seems no bigger than a bit of fine silver wire, every one is surprised at the brightness wherewith that small part of him shines. The moon, when full, affords travellers light enough to keep them from mistaking their way; and yet, according to Mr Bogue, the light of the sun is 300,000 times as strong as that of the moon. Consequently, the sun gives almost 10,360 times as much light to Saturn, as the full moon does to us; and above 30,000 times as much to Jupiter. So that these two planets, even without any moons, would be much more enlightened than we at first imagine; and, by having few many, they may be very comfortable places of residence. Their heat, so far as it depends on the force of the sun's rays, is certainly much less than ours; to which no doubt the bodies of their inhabitants are as well adapted as ours are to the seasons we enjoy. And if we consider that Jupiter never has any winter, even at his poles, which probably is also the case with Saturn, the cold cannot be so intense on these two planets as is generally imagined. Besides, there may be something in the nature of their mould warmer than in that of our earth; and we find that all our heat depends not on the rays of the sun; for if it did, we should always have the same months equally hot or cold at their annual returns. But it is far otherwise, for February is sometimes warmer than May; which must be owing to vapours and exhalations from the earth.

In the Philosophical Transactions a method is ¹⁶⁰ Mr Azout's method of measuring the light on Jupiter and Saturn.

given by Mr Azout for knowing how much Jupiter or Saturn are illuminated experimentally. It is by admitting the sun's rays into a dark room through a convex lens; when being collected into a focus, they will afterwards diverge to any distance we please. This experiment, however, will be apt to raise doubts in the minds of those who try it, either with regard to the diminution of the sun's light at those distances, or with regard to the substances of the planets. For it is certain, that the brightness of the superior planets is far from being diminished in the proportion that it ought to be were all the wandering bodies in our system of a similar substance. Jupiter, for instance, as he hath not the 50th part of the light that Venus hath, seeing he is removed to such a distance as to appear as small as she does, ought to shine with only the 50th part of her lustre: but it is manifest he has much more; of consequence, either the sun's light must be stronger at Jupiter than is commonly supposed, or he must be formed of a substance more capable of reflecting the light than Venus.

In fig. 2. we have a view of the proportional breadth of the sun's face or disk, as seen from the different planets. The sun is represented N° 1. as seen from Mercury; N° 2. as seen from Venus; N° 3. as seen from the earth; N° 4. as seen from Mars; N° 5. as seen from Jupiter; and, N° 6. as seen from Saturn.

Let the circle B (fig. 3.) be the sun as seen from any planet, at a given distance: to another planet, at double

5 H

that

Pl. XLIII.

that distance, the sun will appear just half that breadth, as A; which contains only one fourth part of the area or surface of B. For all circles, as well as square surfaces, are to one another as the squares of their diameters. Thus, the square A (fig. 4.) is just half as broad as the square B; and yet it is plain to sight, that B contains four times as much surface as A. Hence, by comparing the diameters of the above circles (fig. 2.) together, it will be found, that, in round numbers, the sun appears 7 times larger to Mercury than to us, 90 times larger to us than to Saturn, and 630 times as large to Mercury as to Saturn.

Under fig. 3. are the names and characters of the twelve signs of the zodiac, which the reader should be perfectly well acquainted with, so as to know the characters without seeing the names. Each sign contains 30 degrees, as in the circle (fig. 1.) bounding the solar system; to which the characters of the signs are set in their proper places.

Part of the paths of three comets are delineated in the scheme of the solar system, and the years marked in which they made their appearance. It is believed, that there are at least 21 comets belonging to our system, moving in all sorts of directions. Of all these, the periods of the above-mentioned three only are known with any degree of certainty. The first of these comets appeared in the years 1531, 1607, 1682, and 1759; and is expected to appear every 75th year afterwards. The second of them appeared in 1532 and 1661; and may be expected to return in 1789, and every 120th year afterwards. The third, having last appeared in 1680, and its period being no less than 575 years, cannot return until the year 2255. This comet, at its greatest distance, is about 11,200,000,000 miles from the sun; and at its least distance from the sun's centre, which is 490,000 miles, is within less than a third part of the sun's semidiameter from his surface. In that part of its orbit which is nearest the sun, it flies with the amazing swiftness of 880,000 miles in an hour; and the sun, as seen from it, appears an hundred degrees in breadth; consequently, 40,000 times as large as he appears to us. The astonishing length that this comet runs out into empty space, suggests to our minds an idea of the vast distance between the sun and the nearest fixed stars; of whose attractions all the comets must keep clear, to return periodically, and go round the sun: and it shews us also, that the nearest stars, which are probably those that seem the largest, are as big as our sun, and of the same nature with him; otherwise, they could not appear so large and bright to us, as they do, at such an immense distance.

Sect. VI. *Of the Ebbing and Flowing of the Sea, and the Phenomena of the Harvest and Horizontal Moon.*

167
Cause of the tides discovered by Kepler.

THE cause of the tides was discovered by Kepler, who, in his *Introduction to the Physics of the Heavens*, thus explains it: "The orb of the attracting power, which is in the moon, is extended as far as the earth; and draws the waters under the torrid zone, acting upon places where it is vertical, insensibly on confined seas and bays, but sensibly on the ocean whose beds are large and where the waters have the liberty of reciprocation, that is, of rising and falling." And in the 70th

page of his *Lunar Astronomy*—"But the cause of the tides of the sea appears to be the bodies of the sun and moon drawing the waters of the sea." This hint being given, the immortal Sir Isaac Newton improved it, and wrote so amply on the subject, as to make the theory of the tides in a manner quite his own, by discovering the cause of their rising on the side of the earth opposite to the moon. For Kepler believed, that the presence of the moon occasioned an impulse which caused another in her absence.

It has been already observed, that the power of gravity diminishes as the square of the distance increases; and therefore the waters at Z on the side of the earth ABCDEFGH next the moon M are more attracted than the central parts of the earth O by the moon, and the central parts are more attracted by her than the waters on the opposite side of the earth at n; and therefore the distance between the earth's centre and the waters on its surface under and opposite to the moon will be increased. For, let there be three bodies at H, O, and D: if they are all equally attracted by the body M, they will all move equally fast toward it, their mutual distances from each other continuing the same. If the attraction of M is unequal, then that body which is most strongly attracted will move fastest, and this will increase its distance from the other body. Therefore, by the law of gravitation, M will attract H more strongly than it does O, by which the distance between H and O will be increased; and a spectator on O will perceive H rising higher toward Z. In like manner, O being more strongly attracted than D, it will move farther towards M than D does: consequently, the distance between O and D will be increased; and a spectator on O, not perceiving his own motion, will see D receding farther from him towards n: all effects and appearances being the same, whether D recedes from O, or O from D.

Suppose now there is a number of bodies, as A, B, C, D, E, F, G, H, placed round O, so as to form a flexible or fluid ring: then, as the whole is attracted towards M, the parts at H and D will have their distance from O increased; whilst the parts at B and F being nearly at the same distance from M as O is, these parts will not recede from one another; but rather, by the oblique attraction of M, they will approach nearer to O. Hence, the fluid ring will form itself into an ellipse ZIBLnKFNZ, whose longer axis nOZ produced will pass through M, and its shorter axis BOF will terminate in B and F. Let the ring be filled with fluid particles, so as to form a sphere round O; then, as the whole moves towards M, the fluid sphere being lengthened at Z and n, will assume an oblong or oval form. If M is the moon, O the earth's centre, A B C D E F G H the sea covering the earth's surface, it is evident, by the above reasoning, that whilst the earth by its gravity falls toward the moon, the water directly below her at B will swell and rise gradually towards her; also the water at D will recede from the centre [strictly speaking, the centre recedes from D], and rise on the opposite side of the earth; whilst the water at B and F is depressed, and falls below the former level. Hence as the earth turns round its axis from the moon to the moon again in 24 $\frac{1}{2}$ hours, there will be two tides of flood and two of ebb in that time, as we find by experience.

162.
Why the
tides are
high at full
moon.

As this explanation of the ebbing and flowing of the sea is deduced from the earth's constantly falling towards the moon by the power of gravity, some may find a difficulty in conceiving how this is possible, when the moon is full, or in opposition to the sun; since the earth revolves about the sun, and must continually fall towards it, and therefore cannot fall contrary ways at the same time: or if the earth is constantly falling towards the moon, they must come together at last. To remove this difficulty, let it be considered, that it is not the centre of the earth that describes the annual orbit round the sun, but the (M) common centre of gravity of the earth and moon together: and that whilst the earth is moving round the sun, it also describes a circle round that centre of gravity; going as many times round it in one revolution about the sun as there are lunations or courses of the moon round the earth in a year: and therefore the earth is constantly falling towards the moon from a tangent to the circle it describes round the said common centre of gravity. Let M be the moon, T W part of the moon's orbit, and C the centre of gravity of the earth and moon; whilst the moon goes round her orbit, the centre of the earth describes the circle *d g e* round C, to which circle *g a k* is a tangent; and therefore when the moon has gone from M to a little past W, the earth has moved from *g* to *e*; and in that time has fallen towards the moon, from the tangent at *a* to *e*: and so on, round the whole circle.

163
Influence of
the sun in
raising tides.

The sun's influence in raising the tides is but small in comparison of the moon's; for though the earth's diameter bears a considerable proportion to its distance from the moon, it is next to nothing when compared to its distance from the sun. And therefore the difference of the sun's attraction on the sides of the earth under and opposite to him, is much less than the difference of the moon's attraction on the sides of the earth under and opposite to her; and therefore the moon must raise the tides much higher than they can be raised by the sun.

164
Why they
are not
highest
when the
moon is in
the meri-
dian.

On this theory, the tides ought to be highest directly under and opposite to the moon; that is, when the moon is due north and south. But we find, that in open seas, where the water flows freely, the moon M is generally past the north and south meridian, as at *p*, when it is high water at Z and at *n*. The reason is obvious: for though the moon's attraction was to cease altogether when she was past the meridian, yet the motion of ascent communicated to the water before that time would make it continue to rise for some time after; much more must it do so when the attraction is only diminished; as a little impulse given to a moving ball will cause it still to move farther than otherwise it could have done; and as experience shews, that the day is hotter about three in the afternoon, than when the sun is on the meridian, because of the increase made to the heat already imparted.

The tides answer not always to the same distance of the moon from the meridian at the same places; but are variously affected by the action of the sun, which

brings them on sooner when the moon is in her first and third quarters, and keeps them back later when she is in her second and fourth: because, in the former case, the tide raised by the sun alone would be earlier than the tide raised by the moon; and, in the latter case, later.

The moon goes round the earth in an elliptic orbit; and therefore, in every lunar month, she approaches nearer to the earth than her mean distance, and recedes farther from it. When she is nearest, she attracts strongest, and so raises the tides most; the contrary happens when she is farthest, because of her weaker attraction. When both luminaries are in the equator, and the moon in perigeo, or at her least distance from the earth, she raises the tides highest of all, especially at her conjunction and opposition; both because the equatorial parts have the greatest centrifugal force from their describing the largest circle, and from the concurring actions of the sun and moon. At the change, the attractive forces of the sun and moon being united, they diminish the gravity of the waters under the moon, and their gravity on the opposite side is diminished by means of a greater centrifugal force. At the full, whilst the moon raises the tide under and opposite to her, the sun, acting in the same line, raises the tide under and opposite to him; whence their conjoint effect is the same as at the change; and, in both cases, occasion what we call the *Spring tides*. But at the quarters the sun's action on the waters at O and H diminishes the effect of the moon's action on the waters at Z and N; so that they rise a little under and opposite to the sun at O and H, and fall as much under and opposite to the moon at Z and N; making what we call the *Neap tides*, because the sun and moon then act cross-wise to each other. But these tides happen not till some time after; because in this, as in other cases, the actions do not produce the greatest effect when they are at the strongest, but some time afterward.

The sun, being nearer the earth in winter than in summer, is of course nearer to it in February and October than in March and September; and therefore the greatest tides happen not till some time after the autumnal equinox, and return a little before the vernal.

The sea, being thus put in motion, would continue to ebb and flow for several times, even though the sun and moon were annihilated, or their influence should cease; as, if a basin of water were agitated, the water would continue to move for some time after the basin was left to stand still; or like a pendulum, which, having been put in motion by the hand, continues to make several vibrations without any new impulse.

When the moon is in the equator, the tides are equally high in both parts of the lunar day, or time of the moon's revolving from the meridian to the meridian again, which is 24 hours 50 minutes. But as the moon declines from the equator towards either pole, the tides are alternately higher and lower at places having north or south latitude. For one of the highest elevations, which is that under the moon, follows her towards the pole to which she is nearest, and the other declines

5 H 2

declines

(M) This centre is as much nearer the earth's centre than the moon's as the earth is heavier, or contains a greater quantity of matter than the moon, namely, about 40 times. If both bodies were suspended on it, they would hang in equilibrium. So that dividing 240,000 miles, the moon's distance from the earth's centre, by 40, the excess of the earth's weight above the moon's, the quotient will be 6000 miles, which is the distance of the common centre of gravity of the earth and moon from the earth's centre.

declines towards the opposite pole; each elevation describing parallels as far distant from the equator, on opposite sides, as the moon declines from it to either side; and consequently, the parallels described by these elevations of the water are twice as many degrees from one another, as the moon is from the equator; increasing their distance as the moon increases her declination, till it be at the greatest, when the said parallels are, at a mean rate, 47 degrees from one another: and on that day, the tides are most unequal in their heights. As the moon returns towards the equator, the parallels described by the opposite elevations approach towards each other, until the moon comes to the equator, and then they coincide. As the moon declines towards the opposite pole, at equal distances, each elevation describes the same parallel in the other part of the lunar day, which its opposite elevation described before. Whilst the moon has north declination, the greatest tides in the northern hemisphere are when she is above the horizon; and the reverse whilst her declination is south. Let NESQ be the earth, NCS its axis, EQ the equator, T ∞ the tropic of Cancer, t ∞ the tropic of Capricorn, a b the arctic circle, c d the antarctic, N the north pole, S the south pole, M the moon, F and G the two eminences of water, whose lowest parts are at a and d, at N and S, and at b and c, always 90 degrees from the highest. Now, when the moon is in her greatest north declination at M, the highest elevation G under her is on the tropic of Cancer T ∞ , and the opposite elevation F on the tropic of Capricorn t ∞ ; and these two elevations describe the tropics by the earth's diurnal rotation. All places in the northern hemisphere ENQ have the highest tides when they come into the position b ∞ Q, under the moon; and the lowest tides when the earth's diurnal rotation carries them into the position a TE, on the side opposite to the moon; and the reverse happens at the same time in the southern hemisphere ESQ, as is evident to sight. The axis of the tides a C d has now its poles a and d (being always 90 degrees from the highest elevations) in the arctic and antarctic circles; and therefore it is plain, that at these circles there is but one tide of flood, and one of ebb, in the lunar day. For, when the point a revolves half round to b, in 12 lunar hours, it has a tide of flood; but when it comes to the same point a again in 12 hours more, it has the lowest ebb. In seven days afterward, the moon M comes to the equinoctial circle, and is over the equator EQ, when both elevations describe the equator; and in both hemispheres, at equal distances from the equator, the tides are equally high in both parts of the lunar day. The whole phenomena being reversed, when the moon has south declination, to what they were when her declination was north, require no farther description.

In the three last-mentioned figures, the earth is orthographically projected on the plane of the meridian; but, in order to describe a particular phenomenon, we now project it on the plane of the ecliptic. Let HZON (fig. 2.) be the earth and sea, FED the equator, T the tropic of Cancer, C the arctic circle, P the north pole, and the curves 1, 2, 3, &c. 24 meridians or hour-circles, intersecting each other in the poles; AGM is the moon's orbit, S the sun, M the moon, Z the water elevated under the moon, and N the opposite equal elevation. As the lowest parts of the water are

always 90 degrees from the highest, when the moon is in either of the tropics (as at M), the elevation Z is on the tropic of Capricorn, and the opposite elevation N on the tropic of Cancer; the low-water circle HCO touches the polar circles at C; and the high-water circle ETPG goes over the poles at P, and divides every parallel of latitude into two equal segments. In this case, the tides upon every parallel are alternately higher and lower; but they return in equal times: the point T, for example, on the tropic of Cancer (where the depth of the tide is represented by the breadth of the dark shade), has a shallower tide of flood at T, than when it revolves half round from thence to G, according to the order of the numeral figures; but it revolves as soon from G to T as it did from T to G. When the moon is in the equinoctial, the elevations Z and N are transferred to the equator at O and H, and the high and low water circles are got into each other's former places; in which case the tides return in unequal times, but are equally high in both parts of the lunar day: for a place at 1 (under D) revolving as formerly, goes sooner from 1 to 11 (under F) than from 11 to 1, because the parallel it describes is cut into unequal segments by the high-water circle HCO: but the points 1 and 11 being equidistant from the pole of the tides at C, which is directly under the pole of the moon's orbit MGA, the elevations are equally high in both parts of the day.

And thus it appears, that as the tides are governed by the moon, they must turn on the axis of the moon's orbit, which is inclined $23\frac{1}{2}$ degrees to the earth's axis at a mean rate: and therefore the poles of the tides must be so many degrees from the poles of the earth, or in opposite points of the polar circles, going round these circles in every lunar day. It is true, that according to fig. 4. when the moon is vertical to the equator ECQ, the poles of the tides seem to fall in with the poles of the world N and S: but when we consider that FGH is under the moon's orbit, it will appear, that when the moon is over H, in the tropic of Capricorn, the north pole of the tides (which can be no more than 90 degrees from under the moon) must be at C in the arctic circle, not at P the north pole of the earth; and as the moon ascends from H to G in her orbit, the north pole of the tides must shift from c to a in the arctic circle, and the south pole as much in the antarctic.

It is not to be doubted, but that the earth's quick rotation brings the poles of the tides nearer to the poles of the world, than they would be if the earth were at rest and the moon revolved about it only once a month; for otherwise the tides would be more unequal in their heights and times of their returns, than we find they are. But how near the earth's rotation may bring the poles of its axis and those of the tides together, or how far the preceding tides may affect those which follow, so as to make them keep up nearly to the same heights and times of ebbing and flowing, is a problem more fit to be solved by observation than by theory.

Those who have opportunity to make observations, and chuse to satisfy themselves whether the tides are really affected in the above manner by the different positions of the moon, especially as to the unequal times of their returns, may take this general rule for knowing when they ought to be so affected. When the earth's axis inclines to the moon, the northern tides, if

Tides turn
on the axis
of the
moon's or-
bit.

not retarded in their passage through shoals and channels, nor affected by the winds, ought to be greatest when the moon is above the horizon, least when she is below it; and quite the reverse when the earth's axis declines from her: but in both cases, at equal intervals of time. When the earth's axis inclines sidewise to the moon, both tides are equally high, but they happen at unequal intervals of time. In every lunation the earth's axis inclines once to the moon, once from her, and twice sidewise to her, as it does to the sun every year; because the moon goes round the ecliptic every month, and the sun but once in a year. In summer, the earth's axis inclines towards the moon when new; and therefore the day-tides in the north ought to be highest, and night-tides lowest, about the change: at the full, the reverse. At the quarters, they ought to be equally high, but unequal in their returns; because the earth's axis then inclines sidewise to the moon. In winter, the phenomena are the same at full moon as in summer at new. In autumn, the earth's axis inclines sidewise to the moon when new and full; therefore the tides ought to be equally high and uneven in their returns at these times. At the first quarter, the tides of flood should be least when the moon is above the horizon, greatest when she is below it; and the reverse at her third quarter. In spring, the phenomena of the first quarter answer to those of the third quarter in autumn; and *vice versa*. The nearer any time is to either of these seasons, the more the tides partake of the phenomena of these seasons; and in the middle between any two of them the tides are at a mean state between those of both.

In open seas, the tides rise but to very small heights in proportion to what they do in wide-mouthed rivers, opening in the direction of the stream of tide. For, in channels growing narrower gradually, the water is accumulated by the opposition of the contracting bank: like a gentle wind, little felt on an open plain, but strong and brisk in a street; especially if the wider end of the street be next the plain, and in the way of the wind.

The tides are so retarded in their passage thro' different shoals and channels, and otherwise so variously affected by striking against capes and headlands, that at different places they happen at all distances of the moon from the meridian, consequently at all hours of the lunar day. The tide propagated by the moon in the German ocean, when she is three hours past the meridian, takes 12 hours to come from thence to London bridge; where it arrives by the time that a new tide is raised in the ocean. And therefore, when the moon has north declination, and we should expect the tide at London to be greatest when the moon is above the horizon, we find it is least; and the contrary when she has south declination. At several places it is high-water three hours before the moon comes to the meridian; but that tide which the moon pushes as it were before her, is only the tide opposite to that which was raised by her when she was nine hours past the opposite meridian.

There are no tides in lakes, because they are generally so small, that when the moon is vertical she attracts every part of them alike, and therefore, by rendering all the water equally light, no part of it can be raised higher than another. The Mediterranean and

Baltic seas have very small elevations, because the inlets by which they communicate with the Ocean are so narrow, that they cannot, in so short a time, receive or discharge enough to raise or sink their surfaces sensibly.

Air being lighter than water, and the surface of the atmosphere being nearer to the moon than the surface of the sea, it cannot be doubted that the moon raises much higher tides in the air than in the sea. And therefore many have wondered why the mercury does not sink in the barometer when the moon's action on the particles of air makes them lighter as she passes over the meridian. But we must consider, that as these particles are rendered lighter, a greater number of them is accumulated, until the deficiency of gravity be made up by the height of the column; and then there is an equilibrium, and consequently an equal pressure upon the mercury as before; so that it cannot be affected by the aerial tides. It is very probable, however, that the stars which are seen through an aerial tide of this kind will have their light more refracted than those which are seen through the common depth of the atmosphere; and this may account for the supposed refractions by the lunar atmosphere that have been sometimes observed. See n^o 43.

It is generally believed that the moon rises about 50 minutes later every day than on the preceding; but this is true only with regard to places on the equator. In places of considerable latitude there is a remarkable difference, especially in the harvest-time. Here the autumnal full moons rise very soon after sun-set for several evenings together. At the polar circles, where the mild season is of very short duration, the autumnal full moon rises at sun-set from the first to the third quarter. And at the poles, where the sun is for half a year absent, the winter full-moons shine constantly without setting from the first to the third quarter.

All these phenomena are owing to the different angles made by the horizon and different parts of the moon's orbit; and may be explained in the following manner.

The plane of the equinoctial is perpendicular to the earth's axis: and therefore, as the earth turns round its axis, all parts of the equinoctial make equal angles with the horizon both at rising and setting; so that equal portions of it always rise or set in equal times. Consequently, if the moon's motion were equable, and in the equinoctial, at the rate of 12 degrees 11 min. from the sun every day, as it is in her orbit, she would rise and set 50 minutes later every day than on the preceding: for 12 deg. 11 min. of the equinoctial rise or set in 50 minutes of time in all latitudes.

But the moon's motion is so nearly in the ecliptic, that we may consider her at present as moving in it. Now the different parts of the ecliptic, on account of its obliquity to the earth's axis, make very different angles with the horizon as they rise or set. Those parts or signs which rise with the smallest angles set with the greatest, and *vice versa*. In equal times, whenever this angle is least, a greater portion of the ecliptic rises than when the angle is larger; as may be seen by elevating the pole of a globe to any considerable latitude, and then turning it round its axis in the horizon. Consequently, when the moon is in those signs which rise or set with the smallest angles, she rises or sets with the least difference of time; and with

167
Why the moon does not affect the barometer.

168
Of the harvest moon.

Irregularities of tides accounted for.

the greatest difference in those signs which rise or set with the greatest angles.

PL. XLVIII.
fig. 1.

Let FUP be the axis of a globe, \odot TR the tropic of Cancer, Lt $\frac{1}{2}$ the tropic of Capricorn, \odot EU $\frac{1}{2}$ the ecliptic touching both the tropics, which are 47 degrees from each other, and A B the horizon. The equator, being in the middle between the tropics, is cut by the ecliptic in two opposite points, which are the beginnings of Aries and Libra, K is the hour-circle with its index, F the north pole of the globe elevated to a considerable latitude, suppose 40 degrees above the horizon; and P the south pole depressed as much below it. Because of the oblique position of the sphere in this latitude, the ecliptic has the high elevation N \odot above the horizon, making the angle NU \odot of $73\frac{1}{2}$ degrees with it when Cancer is on the meridian, at which time Libra rises in the east. But let the globe be turned half round its axis, till Capricorn comes to the meridian and Aries rises in the east; and then the ecliptic will have the low elevation N L above the horizon, making only an angle NUL of $26\frac{1}{2}$ degrees with it; which is 47 degrees less than the former angle, equal to the distance between the tropics.

In northern latitudes, the smallest angle made by the ecliptic and horizon is when Aries rises, at which time Libra sets; the greatest when Libra rises, at which time Aries sets. From the rising of Aries to the rising of Libra (which is twelve (x) sidereal hours) the angle increases; and from the rising of Libra to the rising of Aries, it decreases in the same proportion. By this article and the preceding, it appears that the ecliptic rises fastest about Aries, and slowest about Libra.

On the parallel of London, as much of the ecliptic rises about Pisces and Aries in two hours as the moon goes through in six days: and therefore, whilst the moon is in these signs, she differs but two hours in rising for six days together; that is, about 20 minutes later every day or night than on the preceding, at a mean rate. But in 14 days afterwards, the moon comes to Virgo and Libra, which are the opposite signs to Pisces and Aries; and then she differs almost four times as much in rising; namely, one hour and about fifteen minutes later every day or night than the former, whilst she is in these signs.

As the moon can never be full but when she is opposite to the sun, and the sun is never in Virgo and Libra but in our autumnal months, it is plain that the moon is never full in the opposite signs, Pisces and Aries, but in these two months. And therefore we can have only two full moons in the year, which rise so near the time of sun-set for a week together, as a-bove-mentioned. The former of these is called the *harvest moon*, and the latter the *hunter's moon*.

169
Why the same phenomenon is not observed at other times.

Here it will probably be asked, why we never observe this remarkable rising of the moon but in harvest, seeing she is in Pisces and Aries twelve times in the year besides; and must then rise with as little difference of time as in harvest? The answer is plain: for in winter these signs rise at noon; and being then only a quarter of a circle distant from the sun, the moon in them is in

her first quarter: but when the sun is above the horizon, the moon's rising is neither regarded nor perceived. In spring, these signs rise with the sun, because he is then in them; and, as the moon changeth in them at that time of the year, she is quite invisible. In summer, they rise about midnight; and the sun being then three signs, or a quarter of a circle, before them, the moon is in them about her third quarter; when rising so late, and giving but very little light, her rising passes unobserved. And in autumn, these signs, being opposite to the sun, rise when he sets, with the moon in opposition, or at the full, which makes her rising very conspicuous.

At the equator, the north and south poles lie in the horizon; and therefore the ecliptic makes the same angle southward with the horizon when Aries rises, as it does northward when Libra rises. Consequently, as the moon rises and sets nearly at equal angles with the horizon all the year round, and about 50 minutes later every day or night than on the preceding, there can be no particular harvest-moon at the equator.

The farther that any place is from the equator, if it be not beyond the polar circle, the more the angle is diminished which the ecliptic and horizon make when Pisces and Aries rise: and therefore when the moon is in these signs, she rises with a nearly proportionable difference later every day than on the former; and is for that reason the more remarkable about the full, until we come to the polar circles, or 66 degrees from the equator; in which latitude the ecliptic and horizon become coincident every day for a moment, at the same sidereal hour (or 3 minutes 56 seconds sooner every day than the former), and the very next moment one half of the ecliptic containing Capricorn, Aquarius, Pisces, Aries, Taurus, and Gemini, rises, and the opposite half sets. Therefore, whilst the moon is going from the beginning of Capricorn to the beginning of Cancer, which is almost 14 days, she rises at the same sidereal hour; and in autumn just at sun-set, because all that half of the ecliptic, in which the sun is at that time, sets at the same sidereal hour, and the opposite half rises; that is, 3 minutes 56 seconds, of mean solar time, sooner every day than on the day before. So whilst the moon is going from Capricorn to Cancer, she rises earlier every day than on the preceding; contrary to what she does at all places between the polar circles. But during the above 14 days, the moon is 24 sidereal hours later in setting; for the six signs which rise all at once on the eastern side of the horizon are 24 hours in setting on the western side of it.

In northern latitudes, the autumnal full moons are in Pisces and Aries, and the vernal full moons in Virgo and Libra; in southern latitudes, just the reverse, because the seasons are contrary. But Virgo and Libra rise at as small angles with the horizon in southern latitudes, as Pisces and Aries do in the northern; and therefore the harvest-moons are just as regular on one side of the equator as on the other.

As these signs, which rise with the least angles, set with the greatest, the vernal full moons differ as much in their times of rising every night as the autumnal full moons

(N) The ecliptic, together with the fixed stars, make 366 $\frac{1}{4}$ apparent diurnal revolutions about the earth in a year; the sun only 365 $\frac{1}{4}$. Therefore the stars gain 3 minutes 56 seconds upon the sun every day: so that a sidereal day contains only 23 hours 56 minutes of mean solar time; and a natural or solar day 24 hours. Hence 12 sidereal hours are 11 minutes 58 seconds shorter than 12 solar.

moons differ in their times of setting; and set with as little difference as the autumnal full moons rise: the one being in all cases the reverse of the other.

Hitherto, for the sake of plainness, we have supposed the moon to move in the ecliptic, from which the sun never deviates. But the orbit in which the moon really moves is different from the ecliptic; one half being elevated $5\frac{1}{2}$ degrees above it, and the other half as much depressed below it. The moon's orbit therefore intersects the ecliptic in two points diametrically opposite to each other; and these intersections are called the *Moon's Nodes*. So the moon can never be in the ecliptic but when she is in either of her nodes, which is at least twice in every course from change to change, and sometimes thrice. For, as the moon goes almost a whole sign more than round her orbit from change to change; if she passes by either node about the time of change, she will pass by the other in about 14 days after, and come round to the former node two days again before the next change. That node from which the moon begins to ascend northward, or above the ecliptic, in northern latitudes, is called the *Ascending Node*; and the other the *Descending Node*, because the moon, when she passes by it, descends below the ecliptic southward.

The moon's oblique motion with regard to the ecliptic causes some difference in the times of her rising and setting from what is already mentioned. For when she is northward of the ecliptic, she rises sooner and sets later than if she moved in the ecliptic: and when she is southward of the ecliptic, she rises later and sets sooner. This difference is variable, even in the same signs, because the nodes shift backward about $19\frac{1}{2}$ degrees in the ecliptic every year; and so go round it contrary to the order of signs in 18 years 225 days.

When the ascending node is in Aries, the southern half of the moon's orbit makes an angle of $5\frac{1}{2}$ degrees less with the horizon than the ecliptic does, when Aries rises in northern latitudes: for which reason the moon rises with less difference of time whilst she is in Pisces and Aries, than she would do if she kept in the ecliptic. But in 9 years and 112 days afterward, the descending node comes to Aries; and then the moon's orbit makes an angle $5\frac{1}{2}$ degrees greater with the horizon when Aries rises, than the ecliptic does at that time; which causes the moon to rise with greater difference of time in Pisces and Aries than if she moved in the ecliptic.

To be a little more particular; when the ascending node is in Aries, the angle is only $9\frac{1}{2}$ degrees on the parallel of London when Aries rises; but when the descending node comes to Aries, the angle is $20\frac{1}{2}$ degrees. This occasions as great a difference of the moon's rising in the same signs every nine years, as there would be on two parallels $10\frac{1}{2}$ degrees from one another, if the moon's course were in the ecliptic.

As there is a complete revolution of the nodes in $18\frac{1}{2}$ years, there must be a regular period of all the varieties which can happen in the rising and setting of the moon during that time. But this shifting of the nodes never affects the moon's rising so much, even in her quickest descending latitude, as not to allow us still the benefit of her rising nearer the time of sun-set for a few days together about the full in harvest, than when she is full at any other time of the year.

At the polar circles, when the sun touches the summer tropic, he continues 24 hours above the horizon; and 24 hours below it, when he touches the winter tropic. For the same reason, the full moon neither rises in summer, nor sets in winter, considering her as moving in the ecliptic. For the winter full moon being as high in the ecliptic as the summer sun, must therefore continue as long above the horizon; and the summer full moon being as low in the ecliptic as the winter sun, can no more rise than he does. But these are only the two full moons which happen about the tropics, for all the others rise and set. In summer, the full moons are low, and their stay is short above the horizon, when the nights are short, and we have least occasion for moon light: in winter they go high, and stay long above the horizon, when the nights are long, and we want the greatest quantity of moon-light.

At the poles, one half of the ecliptic never sets, and the other half never rises: and therefore, as the sun is always half a year in describing one half of the ecliptic, and as long in going through the other half, it is natural to imagine that the sun continues half a year together above the horizon of each pole in its turn, and as long below it; rising to one pole when he sets to the other. This would be exactly the case if there were no refraction: but by the atmosphere's refracting the sun's rays, he becomes visible some days sooner, and continues some days longer in sight, than he would otherwise do: so that he appears above the horizon of either pole before he has got below the horizon of the other. And, as he never goes more than $23\frac{1}{2}$ degrees below the horizon of the poles, they have very little dark night; it being twilight there, as well as at other places, till the sun be 18 degrees below the horizon. The full moon, being always opposite to the sun, can never be seen while the sun is above the horizon, except when she is in the northern half of her orbit; for whenever any point of the ecliptic rises, the opposite point sets. Therefore, as the sun is above the horizon of the north pole from the 20th of March till 23^d of September, it is plain that the moon, when full, being opposite to the sun, must be below the horizon during that half of the year. But when the sun is in the southern half of the ecliptic, he never rises to the north pole; during which half of the year, every full moon happens in some part of the northern half of the ecliptic which never sets. Consequently, as the polar inhabitants never see the full moon in summer, they have her always in the winter, before, at, and after the full, shining for 14 of our days and nights. And when the sun is at his greatest depression below the horizon, being then in Capricorn, the moon is at her first quarter in Aries, full in Cancer, and at her third quarter in Libra. And as the beginning of Aries is the rising point of the ecliptic, Cancer the highest, and Libra the setting point, the moon rises at her first quarter in Aries; is most elevated above the horizon, and full in Cancer; and sets, at the beginning of Libra, in her third quarter, having continued visible for 14 diurnal rotations of the earth. Thus the poles are supplied one half of the winter-time with constant moon-light in the sun's absence; and only lose sight of the moon from her third to her first quarter, while she gives but very little light, and could be but of little and sometimes of no service to them. A bare view of the figure will make this plain:

177
Long moon-light
in winter at
the poles.

Pl. XLVIII.
fig. 3.

plain: in which let S be the sun; e , the earth in summer, when its north pole n inclines toward the sun; and E the earth in winter, when its north pole declines from him. SEN and NWS is the horizon of the north pole, which is coincident with the equator; and, in both these positions of the earth, $\varphi \varpi \varrho \wp$ is the moon's orbit, in which she goes round the earth, according to the order of the letters $a b c d$, $A B C D$. When the moon is at a , she is in her third quarter to the earth at e , and just rising to the north pole n ; at b she changes, and is at the greatest height above the horizon, as the sun likewise is; at c she is in her first quarter, setting below the horizon; and is lowest of all under it at d , when opposite to the sun, and her enlightened side toward the earth. But then she is full in view to the fourth pole p ; which is as much turned from the sun as the north pole inclines toward him. Thus, in our summer, the moon is above the horizon of the north pole whilst she describes the northern half of the ecliptic $\varphi \varpi \varrho$, or from her third quarter to her first; and below the horizon during her progress through the southern half $\varrho \wp \varphi$; highest at the change, most depressed at the full. But in winter, when the earth is at E , and its north pole declines from the sun, the new moon at D is at her greatest depression below the horizon NWS , and the full moon at B at her greatest height above it; rising at her first quarter A , and keeping above the horizon till she comes to her third quarter C . At a mean state she is $23\frac{1}{2}$ degrees above the horizon at B and b , and as much below it at D and d , equal to the inclination of the earth's axis $F. S \varpi$, or $S \wp$, are, as it were, a ray of light proceeding from the sun to the earth; and shews that when the earth is at e , the sun is above the horizon, vertical to the tropic of Cancer; and when the earth is at E , he is below the horizon, vertical to the tropic of Capricorn.

173
Horizontal
moon ac-
counted for
by Mr Fer-
guson.

Pl. XLV.
fig. 1.

The sun and moon generally appear larger near the horizon than when at a distance from it; for which there have been various reasons assigned. The following account is given by Mr Ferguson. "These luminaries, although at great distances from the earth, appear floating as it were on the surface of our atmosphere, HGF/cC , a little way beyond the clouds; of which, those about F , directly over our heads at E , are nearer us than those about H or c in the horizon HEC . Therefore, when the sun or moon appear in the horizon at e , they are not only seen in a part of the sky which is really farther from us than if they were at any considerable altitude, as about f ; but they are also seen through a greater quantity of air and vapours at c than at f . Here we have two concurring appearances which deceive our imagination, and cause us to refer the sun and moon to a greater distance at their rising or setting about c , than when they are considerably high, as at f : first, their seeming to be on a part of the atmosphere at c , which is really farther than f from a spectator at E ; and, secondly, their being seen through a grosser medium when at c than when at f , which, by rendering them dimmer, causes us to imagine them to be at a yet greater distance. And as, in both cases, they are seen much under the same angle, we naturally judgethem to be largest when they seem farthest from us.

"Any one may satisfy himself that the moon appears under no greater angle in the horizon than on the meridian, by taking a large sheet of paper, and rolling it

up in the form of a tube, of such a width, that, observing the moon through it when she rises, she may as it were just fill the tube: then tie a thread round it to keep it of that size; and when the moon comes to the meridian, and appears much less to the eye, look at her again through the same tube, and she will fill it just as much, if not more, than she did at her rising.

"When the full moon is in her perigee, or at her least distance from the earth, she is seen under a larger angle, and must therefore appear bigger than when she is full at other times: And if that part of the atmosphere where she rises be more replete with vapours than usual, she appears so much the dimmer; and therefore we fancy her to be still the bigger, by referring her to an unusually great distance, knowing that no objects which are very far distant can appear big unless they really be so."

To others this solution has appeared unsatisfactory; and accordingly Mr Dnnn has given the following disquisition on this phenomenon, Phil. Transf. Vol. LXIV.

173
By Mr Dnnn

1. "The sun and moon, when they are in or near the horizon, appear to the naked eye of the generality of persons, so very large in comparison with their apparent magnitudes when they are in the zenith, or somewhat elevated, that several learned men have been led to inquire into the cause of this phenomenon; and after endeavouring to find certain reasons, founded on the principles of physics, they have at last pronounced this phenomenon a mere optical illusion.

2. "The principal dissertations which I have seen conducing to give any information on this subject, or helping to throw any light on the same, have been those printed on the transactions of the Royal Society, the Academy of Sciences at Paris, the German Acts, and Dr Smith's Optics; but as all the accounts which I have met with in these writings any way relative to this subject, have not given me that satisfaction which I have desired, curiosity has induced me to inquire after the cause of this singular phenomenon in a manner somewhat different from that which others have done before me, and by such experiments and observations as have appeared to me pertinent; some of which have been as follows, viz.

3. "I have observed the rising and setting sun near the visible horizon, and near rising grounds elevated above the visible horizon about half a degree, and found him to appear largest when near to the visible horizon; and particularly a considerable alteration of his magnitude and light has always appeared to me from the time of his being in the horizon at rising, to the time of his being a degree or two above the horizon, and the contrary at his setting; which property I have endeavoured to receive as a prejudice, and an imposition on my sight and judgement, the usual reasons for this appearance.

4. "I have also observed that the sun near the horizon appears to put on the figure of a spheroid, having its vertical diameter appearing to the naked eye shorter than the horizontal diameter; and, by measuring those diameters in a telescope, have found the vertical one shorter than the other.

5. "I have made frequent observations and comparisons of the apparent magnitude of the sun's disk, with objects directly under him, when he has been near the horizon, and with such objects as I have found by measurement

measurement to be of equal breadth with the sun's diameter; but in the sudden transition of the eye from the sun to the object, and from the object to the sun, have always found the sun to appear least; and that when two right lines have been imaginarily produced by the sides of those equal magnitudes, they have not appeared to keep parallel, but to meet beyond the sun.

6. "From these and other like circumstances, I first began to suspect that a sudden dip of the sun into the horizontal vapours, might some how or other be the cause of a sudden apparent change of magnitude; although the horizontal vapours had been disallowed to be able to produce any other than a refraction in a vertical direction; and, reducing things to calculation, found, that from the time when the sun is within a diameter or two of the horizon, to the time when he is a semidiameter below the horizon, the sun's rays become passable through such a length of medium, reckoning in the direction of the rays, that the total quantity of medium (reckoning both depth and density) through which the rays pass, being compared with the like total depth and density through which they pass at several elevations, it was proportionable to the difference of apparent magnitude, as appearing to the naked eye.

7. "This circumstance of sudden increase and decrease of apparent magnitude, and as sudden decrease and increase of light (for they both go together), seemed to me no improbable cause of the phenomenon, although I could not then perceive how such vapours might contribute toward enlarging the diameter of the sun in a horizontal direction.

8. "I therefore examined the sun's disk again and again, by the naked eye and by telescopes, at different altitudes; and, among several circumstances, found the solar macule to appear larger and plainer to the naked eye, and through a telescope, the sun being near the horizon, than they had appeared the same days when the sun was on the meridian, and to appearance more strongly defined, yet obscured.

9. "A little before sun-setting, I have often seen the edge of the sun with such protuberances and indentures as have rendered him in appearance a very odd figure; the protuberances shooting out far beyond, and the indentures pressing into the disk of the sun; and always, through a telescope magnifying 55 times, the lower limb has appeared with a red glowing arch beneath it, and close to the edge of the sun, while the other parts have been clear.

10. "At sun-setting, these protuberances and indentures have appeared to slide along the vertical limbs, from the lower limb to the higher, and there vanishing, so as often to form a segment of the sun's upper limb, apparently separated from the disk for a small space of time.

11. "At sun-rising I have seen the like protuberances, indentures, and slices, above described; but with this difference of motion, that at sun-rising they first appear to rise in the sun's upper limb, and slide or move downward to the lower limb; or, which is the same thing, they always appear at the rising and setting of the sun, to keep in the same parallels of altitude by the telescope. This property has been many times so discernable, even by the naked eye, that I have observed the sun's upper limb to shoot out towards right and left, and move downwards, forming the upper part of the disk

an apparent portion of a lesser spheroid than the lower part at rising, and the contrary at setting. Through the telescope this has appeared more plain in proportion to the power of magnifying.

12. "These protuberances and indentures so easily measurable by the micrometer, whilst the telescope wires appeared strait, enabled me to conclude, that certain strata of the atmosphere have different refractive powers; and, lying horizontally across the conical or cycloidal space traced out by the rays between the eye and that part of the atmosphere first touched by the rays, must have been the cause of such apparent protuberances and indentures in an horizontal direction across the sun's vertical limbs; and also that the bottoms of those protuberances and indentures must be considerably enlarged, and removed to appearance farther from the centre of the disk than they would have been had there been no such strata to refract.

13. "Before sun-rising, when the sun has been near the tropic; and the sky, at the utmost extent of the horizon, hath appeared very clear; and when certain fogs have appeared in strata placed alternately between the hills, and over intervening rivers, valleys, &c. so as to admit a sight of the rising sun over those fogs; I have observed with admiration, the most distant trees and bushes, which at other times have appeared small to the naked eye, but while the sun has been passing along a little beneath the horizon obliquely under them, just before sun-rising, when the sun has been thus approaching towards trees and bushes, they have grown apparently very large to the naked eye, and also through a telescope; and they have lost that apparent largeness as the sun has been passed by them. Thus a few trees standing together on the rising ground, at the distance of a few miles, have appeared to grow up into an apparent mountain. Such apparent mountains formed from trees put on all forms and shapes, as sloping, perpendicular, over-leaning, &c. but soon recover their natural appearance when the sun is past by them, or got above the horizon.

14. "Mountains themselves, at a distance, sometimes appear larger than at other times. Beasts and cattle in the midst of, and being surrounded with, water, appear nearer to us than when no water surrounds them. Cattle, houses, trees, all objects on the summit of a hill, when seen through a fog, and at a proper distance, appear enlarged. All bodies admit of larger apparent magnitudes when seen through some mediums than others.

"But more particularly,

15. "I took a cylindrical glass vessel about two feet high; and having graduated its sides to inches, I placed it upright on a table, with a piece of paper under the bottom of the glass, on which paper were drawn parallel right lines at proper distances from each other; and having placed a shilling at the bottom of the vessel, it was nearly as low as the paper. Pouring water into the vessel, and viewing the shilling through the medium of water with one eye, whilst I beheld with the other eye where the edges of the shilling were projected on the paper and its parallels, I found the shilling appear larger at every additional inch depth of the water; and this was the case if either eye was used; and the same when the eye was removed far from the surface or near to it, or in any proportion thereto.

16. " I took large vessels; and, filling them with water, placed different bodies at the bottoms of those vessels. It always followed, that the greater depth of water I looked through, in the direction from my eye to the objects in the water, the nearer those objects appeared to me. Thus light bodies appeared more mellow and faint, and dark bodies rather better defined, than out of the water, when they were not deeply immerged. And thus they appeared under whatever directions or positions I viewed the bodies.

17. " I placed different bodies in proper vessels of fair water, and immerged my face in the water; viewing the bodies in and through the water. They all appeared to me plain, when not too far from the eye; and altho' a little hazy at the edges, they appeared much enlarged, and always larger through a greater depth of water. Thus a shilling appeared nearly as large as half a crown, with a red glowing arch on that side opposite to the sun, when the sun shined on the water. From this experiment I concluded, that divers see light objects not only larger, but very distinctly, in the water."

From these experiments he draws a confirmation of his doctrine, that the appearances treated of arise from the different strata of the atmosphere; and then concludes, that the rays coming from the sun are by the horizontal vapours "first obstructed, and many of them totally absorbed; the rest proceeding with a retarded motion, are thereby first reflected, and then less refracted through the humours of the eye; and lastly, that hereby the image on the retina becomes enlarged."

SECT. VII. *Of drawing a Meridian Line. Of Solar and Sidereal Time, and of the Equation of Time.*

THE foundation of all astronomical observations is a knowledge of the exact time when the sun, or any other of the celestial bodies, comes to the meridian; and therefore astronomers have been very attentive to the most proper methods of drawing a meridian line, by which only this can be exactly known. The easiest method of doing this is the following, recommended by Mr Ferguson.

Make four or five concentric circles, about a quarter of an inch from one another, on a flat board about a foot in breadth; and let the outmost circle be but little less than the board will contain. Fix a pin perpendicularly in the centre, and of such a length that its whole shadow may fall within the innermost circle for at least four hours in the middle of the day. The pin ought to be about an eighth part of an inch thick, and to have a round blunt point. The board being set exactly level in a place where the sun shines, suppose from eight in the morning till four in the afternoon, about which hours the end of the shadow should fall without all the circles; watch the times in the forenoon when the extremity of the shortening shadow just touches the several circles, and there make marks. Then, in the afternoon of the same day, watch the lengthening shadow; and where its end touches the several circles in going over them, make marks also. Lastly, with a pair of compasses, find exactly the middle point between the two marks on any circle, and draw a straight line from the centre to that point; which line will be covered at noon by the shadow of a small upright wire,

which should be put in the place of the pin. The reason for drawing several circles is, that in case one part of the day should prove clear, and the other part somewhat cloudy, if you miss the time when the point of the shadow should touch one circle, you may perhaps catch it in touching another. The best time for drawing a meridian line in this manner is about the summer solstice; because the sun changes his declination slowest, and his altitude fastest, in the longest days.

If the casement of a window on which the sun shines at noon be quite upright, you may draw a line along the edge of its shadow on the floor, when the shadow of the pin is exactly on the meridian line of the board; and as the motion of the shadow of the casement will be much more sensible on the floor than that of the shadow of the pin on the board, you may know to a few seconds when it touches the meridian line on the floor.

This method may suffice for ordinary purposes, but for astronomers the following is preferable. Take the gnomon of an horizontal dial for the latitude of the place, and to the hypotenusa fix two sights, whose centres may be parallel to the fame: let the eye-sight be a small hole, but the other's diameter must be equal to the tangent of the double distance of the north-star from the pole; the distance of the sights being made radius, let the stile be rivvited to the end of a straight ruler; then when you would make use of it, lay the ruler on an horizontal plane, so that the end to which the stile is fixed may overhang; then look through the eye-sight, moving the instrument till the north-star appears to touch the circumference of the hole in the other sight, on the same hand with the girdle of Cassiopeia, or on the opposite side to that whereon the star in the Great Bear's rump is at that time; then draw a line by the edge of the ruler, and it will be a true meridian line.

A meridian line being by either of these methods exactly drawn, the time when the sun or any other of the celestial bodies is exactly in the meridian may be found by a common quadrant, placing the edge of it along the line, and observing when the sun or other luminary can be seen exactly through its two sights, and noting exactly the time; which, supposing the luminary viewed to be the sun, will be exactly noon, or 12 o'clock; but as the apparent diameter of the sun is pretty large, it ought to be known exactly when his centre is in the meridian, which will be some short space after his western limb has arrived at it, and before his eastern limb comes thither. It will be proper, therefore, to observe exactly the time of the two limbs being seen through the sights of the quadrant; and the half of the difference between these times added to the one, or subtracted from the other, will give the exact time when the sun's centre is in the meridian. What we say with regard to the sun, is also applicable to the moon; but not to the stars, which have no sensible diameter. To render this more intelligible, the following short description of the quadrant, and method of taking the altitudes of celestial bodies by it, is subjoined.

In Plate XLIX. let HOX be a horizontal line, supposed to be extended from the eye at A to X, where the sky and earth seem to meet at the end of a long and level plain; and let S be the sun. The arc XY will be the sun's height above the horizon at X, and is found by the instrument EDC, which is a quadrant board, or plate of metal, divided into 90 equal parts

or degrees on its limb DPC; and has a couple of little brass plates, as *a* and *b*, with a small hole in each of them, called *fight-holes*, for looking through, parallel to the edge of the quadrant whereon they stand. To the centre E is fixed one end of a thread F, called the *plumb-line*, which has a small weight or plummet P fixed to its other end. Now, if an observer holds the quadrant upright, without inclining it to either side, and so that the horizon at X is seen through the fight-holes *a* and *b*, the plumb-line will cut or hang over the beginning of the degrees at *o*, in the edge EC: but if he elevates the quadrant so as to look through the fight-holes at any part of the heavens, suppose to the sun at S; just so many degrees as he elevates the fight-hole *b* above the horizontal line HOX, so many degrees will the plumb-line cut in the limb CP of the quadrant. For, let the observer's eye at A be in the centre of the celestial arc XYV (and he may be said to be in the centre of the sun's apparent and diurnal orbit, let him be on what part of the earth he will), in which arc the sun is at that time, suppose 25 degrees high, and let the observer hold the quadrant so that he may see the sun through the fight-holes; the plumb-line freely playing on the quadrant will cut the 25th degree in the limb CP, equal to the number of degrees of the sun's altitude at the time of observation. (N. B. Whoever looks at the sun, must have a smoked glass before his eyes, to save them from hurt. The better way is, not to look at the sun through the fight-holes, but to hold the quadrant facing the eye, at a little distance, and so that, the sun shining through one hole, the ray may be seen to fall on the other.)

By observations made in the manner above directed, it is found, that the stars appear to go round the earth in 23 hours 56 minutes 4 seconds, and the sun in 24 hours: so that the stars gain three minutes 56 seconds upon the sun every day, which amounts to one diurnal revolution in a year; and therefore, in 365 days as measured by the returns of the sun to the meridian, there are 366 days as measured by the stars returning to it: the former are called *solar days*, and the latter *sidereal*.

If the earth had only a diurnal motion, without an annual, any given meridian would revolve from the sun to the sun again in the same quantity of time as from any star to the same star again; because the sun would never change his place with respect to the stars. But, as the earth advances almost a degree eastward in its orbit in the time that it turns eastward round its axis, whatever star passes over the meridian on any day with the sun, will pass over the same meridian on the next day when the sun is almost a degree short of it; that is, 3 minutes 56 seconds sooner. If the year contained only 360 days, as the ecliptic does 360 degrees, the sun's apparent place, so far as his motion is equal, would change a degree every day; and then the sidereal days would be just 4 minutes shorter than the solar.

Let ABCDEFGHIKLM be the earth's orbit, in which it goes round the sun every year, according to the order of the letters, that is, from west to east; and turns round its axis in the same way from the sun to the sun again in every 24 hours. Let S be the sun, and R a fixed star at such an immense distance, that the diameter of the earth's orbit bears no sensible proportion to that distance. Let Nm be any particular

meridian of the earth, and N a given point or place upon that meridian when the earth is at A, the sun S hides the star R, which would always be hid if the earth never removed from A; and consequently, as the earth turns round its axis, the point N would always come round to the sun and star at the same time. But when the earth has advanced, suppose a twelfth part of its orbit, from A to B, its motion round its axis will bring the point N a twelfth part of a natural day, or two hours, sooner to the star than to the sun; for the angle of NBn is equal to the angle ASB; and therefore any star, which comes to the meridian at noon with the sun when the earth is at A, will come to the meridian at 10 in the forenoon when the earth is at B. When the earth comes to C, the point N will have the star on its meridian at 8 in the morning, or four hours sooner than it comes round to the sun; for it must revolve from N to n, before it has the sun in its meridian. When the earth comes to D, the point N will have the star on its meridian at 6 in the morning; but that point must revolve six hours more from N to n, before it has mid-day by the sun: for now the angle ASD is a right angle, and so is NDn; that is, the earth has advanced 90 degrees in its orbit, and must turn 90 degrees on its axis to carry the point N from the star to the sun: for the star always comes to the meridian when Nm is parallel to RSA; because DS is but a point in respect of RS. When the earth is at E, the star comes to the meridian at 4 in the morning; at F, at two in the morning; and at G, the earth having gone half round its orbit, N points to the star R at midnight, it being then directly opposite to the sun; and therefore, by the earth's diurnal motion, the star comes to the meridian 12 hours before the sun. When the earth is at H, the star comes to the meridian at 10 in the evening; at I, it comes to the meridian at 8, that is, 16 hours before the sun; at K, 18 hours before him; at L, 20 hours; at M, 22; and at A, equally with the sun again.

Thus it is plain, that an absolute turn of the earth on its axis (which is always completed when any particular meridian comes to be parallel to its situation at any time of the day before) never brings the same meridian round from the sun to the sun again; but that the earth requires as much more than one turn on its axis to finish a natural day, as it has gone forward in that time; which, at a mean state, is a 365th part of a circle. Hence, in 365 days, the earth turns 366 times round its axis; and therefore, as a turn of the earth on its axis completes a sidereal day, there must be one sidereal day more in a year than the number of solar days, be the number what it will, on the earth or any other planet. One turn being lost with respect to the number of solar days in a year, by the planet's going round the sun; just as it would be lost to a traveller, who, in going round the earth, would lose one day by following the apparent diurnal motion of the sun; and consequently would reckon one day less at his return (let him take what time he would to go round the earth) than those who remained all the while at the place from which he set out. So, if there were two earths revolving equally on their axes, and if one remained at A until the other had gone round the sun from A to A again, that earth which kept its place at A would have its solar and sidereal days always of the same

178
Difference between solar and sidereal days.

179
Sidereal year contains 366 days.

Pl. XLVI.
fig. 3.

length; and so would have one solar day more than the other at its return. Hence, if the earth turned but once round its axis in a year, and if that turn was made the same way as the earth goes round the sun, there would be continual day on one side of the earth, and continual night on the other.

180
Inequality
of solar
time.

The earth's motion on its axis being perfectly uniform, and equal at all times of the year, the sidereal days are always precisely of an equal length; and so would the solar or natural days be, if the earth's orbit were a perfect circle, and its axis perpendicular to its orbit. But the earth's diurnal motion on an inclined axis, and its annual motion in an elliptic orbit, cause the sun's apparent motion in the heavens to be unequal: for sometimes he revolves from the meridian to the meridian again in somewhat less than 24 hours, shewn by a well-regulated clock; and at other times in somewhat more: so that the time shewn by an equal going clock and a true sun-dial is never the same but on the 15th of April, the 16th of June, the 31st of August, and the 24th of December. The clock, if he goes equally, and true all the year round, will be before the sun from the 24th of December till the 15th of April; from that time till the 16th of June, the sun will be before the clock; from the 16th of June till the 31st of August, the clock will be again before the sun; and from thence to the 24th of December, the sun will be faster than the clock.

181
Equation of
time ex-
plained.

As the equation of time, or difference between the time shewn by a well-regulated clock and a true sundial, depends upon two causes, namely, the obliquity of the ecliptic, and the unequal motion of the earth in it, we shall first explain the effects of these causes separately considered, and then the united effects resulting from their combination.

The earth's motion on its axis being perfectly equal, or always at the same rate, and the plane of the equator being perpendicular to its axis, it is evident that in equal times equal portions of the equator pass over the meridian; and so would equal portions of the ecliptic, if it were parallel to, or coincident with, the equator. But, as the ecliptic is oblique to the equator, the equable motion of the earth carries unequal portions of the ecliptic over the meridian in equal times, the difference being proportionate to the obliquity; and as some parts of the ecliptic are much more oblique than others, those differences are unequal among themselves. Therefore, if two suns should start from the beginning either of Aries or Libra, and continue to move through equal arcs in equal times, one in the equator, and the other in the ecliptic, the equatorial sun would always return to the meridian in 24 hours time, as measured by a well regulated clock: but the sun in the ecliptic would return to the meridian sometimes sooner and sometimes later than the equatorial sun; and only at the same moments with him on four days of the year; namely, the 20th of March, when the sun enters Aries; the 21st of June, when he enters Cancer; the 23^d of September, when he enters Libra; and the 21st of December, when he enters Capricorn; and to this fictitious sun the motion of a well regulated clock always answers.

Pl. XLVI.
fig. 4.

Let $Z\varphi z$ be the earth; $ZFRz$, its axis; $abcde$, &c. the equator; $ABCDE$, &c. the northern half of the ecliptic from φ to ω of the side of the globe next

the eye; and $MNOP$, &c. the southern half on the opposite side from ω to φ . Let the points at A, B, C, D, E, F , &c. quite round from φ to φ again bound equal portions of the ecliptic, gone through in equal times by the real sun; and those at a, b, c, d, e, f , &c. equal portions of the equator described in equal times by the fictitious sun; and let $Z\varphi z$ be the meridian.

As the real sun moves obliquely in the ecliptic, and the fictitious sun directly in the equator, with respect to the meridian; a degree, or any number of degrees, between φ and F on the ecliptic, must be nearer the meridian $Z\varphi z$, than a degree, or any corresponding number of degrees, on the equator from φ to f ; and the more so, as they are the more oblique: and therefore the true sun comes sooner to the meridian every day whilst he is in the quadrant φF , than the fictitious sun does in the quadrant φf ; for which reason, the solar noon precedes noon by the clock, until the real sun comes to F , and the fictitious to f ; which two points, being equidistant from the meridian, both suns will come to it precisely at noon by the clock.

Whilst the real sun describes the second quadrant of the ecliptic $FGHIKL$ from Cancer to ω , he comes later to the meridian every day, than the fictitious sun moving through the second quadrant of the equator from f to ω ; for the points at G, H, I, K , and L , being farther from the meridian, their corresponding points at g, h, i , and l , must be later of coming to it: and as both suns come at the same moment to the point ω , they come to the meridian at the moment of noon by the clock.

In departing from Libra, through the third quadrant, the real sun going through $MNOPQ$ towards φ , and the fictitious sun through $mnoq$ towards r , the former comes to the meridian every day sooner than the latter, until the real sun comes to φ , and the fictitious to r , and then they both come to the meridian at the same time.

Lastly, as the real sun moves equally thro' $STUVW$, from φ towards φ ; and the fictitious sun thro' $stuvw$, from r towards φ , the former comes later every day to the meridian than the latter, until they both arrive at the point φ , and then they make it noon at the same time with the clock.

Having explained one cause of the difference of time shewn by a well-regulated clock and a true sun-dial, and considered the sun, not the earth, as moving in the ecliptic; we now proceed to explain the other cause of this difference, namely, the inequality of the sun's apparent motion, which is slowest in summer, when the sun is farthest from the earth, and swiftest in winter when he is nearest to it. But the earth's motion on its axis is equable all the year round, and is performed from west to east; which is the way that the sun appears to change his place in the ecliptic.

If the sun's motion were equable in the ecliptic, the whole difference between the equal time as shewn by the clock, and the unequal time as shewn by the sun, would arise from the obliquity of the ecliptic. But the sun's motion sometimes exceeds a degree in 24 hours, though generally it is less: and when his motion is slowest, any particular meridian will revolve sooner to him than when his motion is quickest; for it will overtake him in less time when he advances a less space than when

when he moves through a larger.

Now, if there were two suns moving in the plane of the ecliptic, so as to go round it in a year; the one describing an equal arc every 24 hours, and the other describing sometimes a less arc in 24 hours, and at other times a larger, gaining at one time of the year what it lost at the opposite; it is evident, that either of these suns would come sooner or later to the meridian than the other; as it happened to be behind or before the other; and when they were both in conjunction, they would come to the meridian at the same moment.

PL XLVII.
Fig. 1.

As the real sun moves unequally in the ecliptic, let us suppose a fictitious sun to move equally in a circle coincident with the plane of the ecliptic. Let ABCD be the ecliptic or orbit in which the real sun moves, and the dotted circle *abcd* the imaginary orbit of the fictitious sun; each going round in a year according to the order of letters, or from west to east. Let HIKL be the earth turning round its axis the same way every 24 hours; and suppose both suns to start from A and *a*, in a right line with the plane of the meridian EH, at the same moment: the real sun at A, being then at his greatest distance from the earth, at which time his motion is slowest; and the fictitious sun at *a*, whose motion is always equable, because his distance from the earth is supposed to be always the same. In the time that the meridian revolves from H to H again, according to the order of the letters HIKL, the real sun has moved from A to F; and the fictitious with a quicker motion from *a* to *f*, thro' a large arc: therefore, the meridian EH will revolve sooner from H to *h* under the real sun at F, than from H E to *h* under the fictitious sun at *f*; and consequently it will then be noon by the sundial sooner than by the clock.

As the real sun moves from A towards C, the swiftness of his motion increases all the way to C, where it is at the quickest. But notwithstanding this, the fictitious sun gains so much upon the real, soon after his departing from A, that the increasing velocity of the real sun does not bring him up with the equally moving fictitious sun till the former comes to C, and the latter to *c*, when each has gone half round its respective orbit; and then being in conjunction, the meridian EH, revolving to EK, comes to both suns at the same time, and therefore it is noon by them both at the same moment.

But the increased velocity of the real sun, now being at the quickest, carries him before the fictitious one; and therefore, the same meridian will come to the fictitious sun sooner than to the real: for whilst the fictitious sun moves from *c* to *g*, the real sun moves thro' a greater arc from C to G; consequently the point K has its noon by the clock when it comes to *k*, but not its noon by the sun till it comes to *l*. And although the velocity of the real sun diminishes all the way from C to A, and the fictitious sun by an equable motion is still coming nearer to the real sun, yet they are not in conjunction till the one comes to A and the other to *a*, and then it is noon by them both at the same moment.

Thus it appears, that the solar noon is always later than noon by the clock whilst the sun goes from C to A; sooner, whilst he goes from A to C; and at these two points the sun and clock being equal, it is noon by them both at the same moment.

The point A is called the sun's *apogee*, because

when he is there he is at his greatest distance from the earth; the point C his *perigee*, because when in it he is at his least distance from the earth: and a right line, as AEC, drawn through the earth's centre, from one of the points to the other, is called the *line of the Apogees*.

The distance that the sun has gone in any time from his apogee (not the distance he has to go to it, though ever so little) is called his *mean anomaly*, and is reckoned in signs and degrees, allowing 30 degrees to a sign. Thus, when the sun has gone suppose 174 degrees from his apogee at A, he is said to be 5 signs 14 degrees from it, which is his mean anomaly; and when he is gone suppose 355 degrees from his apogee, he is said to be 11 signs 25 degrees from it, although he be but 5 degrees short of A in coming round to it again.

From what was said above, it appears, that when the sun's anomaly is less than 6 signs, that is, when he is any where between A and C, in the half ABC of his orbit, the solar noon precedes the clock noon; but when his anomaly is more than 6 signs, that is, when he is any where between C and A, in the half CDA of his orbit, the clock noon precedes the solar. When his anomaly is 0 signs 0 degrees, that is, when he is in his apogee at A; or 6 signs 0 degrees, which is when he is in his perigee at C; he comes to the meridian at the moment that the fictitious sun does, and then it is noon by them both at the same instant.

Sect. VIII. Of calculating the Distances, Magnitudes, &c. of the Sun, Moon, and Planets.

THIS is accomplished by finding out the horizontal parallax of the body whose distance you desire to know; that is, the angle under which the semidiameter of the body would appear provided we could see it from that body: and this is to be found out in the following manner.

To find the moon's horizontal parallax.

Let BAG be one half of the earth, A C its semidiameter, S the sun, *m* the moon, and EKOL a quarter of the circle described by the moon in revolving from the meridian to the meridian again. Let CRS be the rational horizon of an observer at A, extended to the sun in the heavens; and HAO, his sensible horizon extended to the moon's orbit. ALC is the angle under which the earth's semidiameter AC is seen from the moon at L; which is equal to the angle OAL, because the right lines AO and CL which include both these angles are parallel. ASC is the angle under which the earth's semidiameter AC is seen from the sun at S; and is equal to the angle OAS, because the lines AO and CRS are parallel. Now, it is found by observation, that the angle OAL is much greater than the angle OAS; but OAL is equal to ALC, and OAS is equal to ASC. Now as ASC is much less than ALC, it proves that the earth's semidiameter AC appears much greater as seen from the moon at L than from the sun at S; and therefore the earth is much farther from the sun than from the moon. The quantities of these angles may be determined by observation in the following manner.

PL XLV.
Fig. 2.

Let a graduated instrument, as DAE (the larger the better), having a moveable index with sight-holes, be fixed in such a manner, that its plane surface may be parallel to the plane of the equator, and its edge

AD

AD in the meridian: so that when the moon is in the equinoctial, and on the meridian ADE, she may be seen through the sight-holes when the edge of the moveable index cuts the beginning of the divisions at o, on the graduated limb DE; and when she is so seen, let the precise time be noted. Now as the moon revolves about the earth from the meridian to the meridian again in about 24 hours 48 minutes, she will go a fourth part round it in a fourth part of that time, viz. in 6 hours 12 minutes, as seen from C, that is, from the earth's centre or pole. But as seen from A, the observer's place on the earth's surface, the moon will seem to have gone a quarter round the earth when she comes to the sensible horizon at O; for the index through the sights of which she is then viewed will be at *d*, 90 degrees from D, where it was when she was seen at E. Now let the exact moment when the moon is seen at O (which will be when she is in or near the sensible horizon) be carefully noted (o), that it may be known in what time she has gone from E to O; which time subtracted from six hours 12 minutes (the time of her going from E to L) leaves the time of her going from O to L, and affords an easy method for finding the angle OAL, (called the moon's horizontal parallax, which is equal to the angle ALC) by the following analogy: As the time of the moon's describing the arc EO is to 90 degrees, so is six hours 12 minutes to the degrees of the arc DAE, which measures the angle EAL; from which subtract 90 degrees, and there remains the angle OAL, equal to the angle ALC, under which the earth's semidiameter AC is seen from the moon. Now, since all the angles of a right-lined triangle are equal to 180 degrees, or to two right angles, and the sides of a triangle are always proportional to the sines of the opposite angles, say, by the Rule of Three, As the sine of the angle ALC at the moon L, is to its opposite side AC the earth's semidiameter, which is known to be 3985 miles; so is radius, viz. the sine of 90 degrees, or of the right angle ACL, to its opposite side AL, which is the moon's distance at L from the observer's place at A on the earth's surface; or, so is the sine of the angle CAL to its opposite side CL, which is the moon's distance from the earth's centre, and comes out at a mean rate to be 240,000 miles. The angle CAL is equal to what OAL wants of 90 degrees.

Other methods have been fallen upon for determining the moon's parallax, of which the following is recommended as the best, by Mr Ferguson, tho' hitherto it has not been put in practice. "Let two observers be placed under the same meridian, one in the northern hemisphere, and the other in the southern, at such a distance from each other, that the arc of the celestial meridian included between their two zeniths may be at least 80 or 90 degrees. Let each observer take the distance of the moon's centre from his zenith, by means of an exceeding good instrument, at the moment of her passing the meridian: add these two zenith-distances of the moon together, and their excess above the distance between the two zeniths will be the distance between the two apparent places of the moon. Then, as the sum of the natural sines of the two zenith-distances of the moon is to radius, so is the distance be-

tween her two apparent places to her horizontal parallax: which being found, her distance from the earth's centre may be found by the analogy mentioned above.

Thus, in fig. 1. (2^d Plate L.) let VECQ be the earth, M the moon, and Z_{baz} an arc of the celestial meridian. Let V be Vienna, whose latitude EV is 48° 20' north; and C the Cape of Good Hope, whose latitude EC is 34° 30' south: both which latitudes we suppose to be accurately determined before-hand by the observers. As these two places are on the same meridian *n*VEC, and in different hemispheres, the sum of their latitudes 82° 50' is their distance from each other. Z is the zenith of Vienna, and z the zenith of the Cape of Good Hope; which two zeniths are also 82° 50' distant from each other, in the common celestial meridian Zz. To the observer at Vienna, the moon's centre will appear at *a* in the celestial meridian; and at the same instant, to the observer at the Cape, it will appear at *b*. Now suppose the moon's distance Z*a* from the zenith of Vienna to be 38° 1' 53", and her distance z*b* from the zenith of the Cape of Good Hope to be 46° 4' 41": the sum of these two zenith-distances (Z*a*+z*b*) is 84° 6' 34"; from which subtract 82° 50", the distance of Zz between the zeniths of these two places, and there will remain 1° 16' 34" for the arc *ba*, or distance between the two apparent places of the moon's centre, as seen from V and from C. Then, supposing the tabular radius to be 10,000,000, the natural sine of 38° 1' 53" (the arc Z*a*) is 6,160,816, and the natural sine of 46° 4' 41" (the arc z*b*) is 7,202,821: the sum of both these sines is 13,363,637. Say therefore, As 13,363,637 is to 10,000,000, so is 1° 16' 34" to 57' 18" which is the moon's horizontal parallax.

If the two places of observation be not exactly under the same meridian, their difference of longitude must be accurately taken, that proper allowance may be made for the moon's declination whilst she is passing from the meridian of the one to the meridian of the other.

The parallax, and consequently the distance and bulk, of any primary planet, might be found in the above manner, if the planet was near enough to the earth, so as to make the difference of its two apparent places sufficiently sensible: but the nearest planet is too remote for the accuracy required.

The sun's distance from the earth might be found the same way, though with more difficulty, if his horizontal parallax, or the angle OAS equal to the angle ASC, were not so small as to be hardly perceptible, being found in this way to be scarce 10 seconds of a minute, or the 360th part of a degree. Hence all astronomers both ancient and modern have failed in taking the sun's parallax to a sufficient degree of exactness; but as some of the methods used are very ingenious, and shew the great acuteness and sagacity of the ancient astronomers, we shall here give an account of them. The first method was invented by Hipparchus; and has been made use of by Ptolemy and his followers, and many other astronomers. It depends on an observation of an eclipse of the moon: And the principles on which it is founded are, $\frac{1}{2}$. In a lunar eclipse, the horizontal parallax of the sun is equal to the difference between the apparent semidiameter of the sun,

(o) Here proper allowance must be made for the refraction, which being about 34 minutes of a degree in the horizon, will cause the moon's centre to appear 34 minutes above the horizon when her centre is really in it.

183
Another method.

184
Parallax of the sun difficult to be found.

185
Hipparchus's method of finding it.

6th Plate
XLII. fig. 3.

fun, and half the angle of the conical shadow; which is easily made out in this manner. Let the circle AFG represent the sun, and DHE the earth; let DHM be the shadow, and DMC the half angle of the cone. Draw from the centre of the sun the right line SD touching the earth, and the angle DSC is the apparent semidiameter of the earth, seen from the sun, which is equal to the horizontal parallax of the sun; and the angle ADS is the apparent semidiameter of the sun, seen from the earth: The external angle ADS is equal to the two internals DMS and DSM, by the 32^d Prop. Elem. I. And therefore the angle DSM, or DSC, is equal to the difference of the angles ADS and DMS. 2dly, Half the angle of the cone is equal to the difference of the horizontal parallax of the moon, and the apparent semidiameter of the shadow, seen from the earth at the distance of the moon. For let CDE be the earth, CME the shadow, which at the distance of the moon being cut by a plane, the section will be the circle FLH, whose semidiameter is FG, and is seen from the centre of the earth under the angle FTG. But by the 32^d Prop. Elem. I. the angle CFT is equal to the two internals FMT and FTM. Wherefore the angle FMT is the difference of the two angles CFT and GTF: But the angle CFT is the angle under which the semidiameter of the earth is seen from the moon, and this is equal to the horizontal parallax of the moon; and the angle GTF is the apparent semidiameter of the shadow seen from the earth's centre. It is therefore evident that the half angle of the cone is equal to the difference of the horizontal parallax of the moon, and the apparent semidiameter of the shadow seen from the earth. Wherefore, if to the apparent semidiameter of the sun there be added the apparent semidiameter of the shadow, and from the sun you take away the horizontal parallax of the moon, there will remain the horizontal parallax of the sun; which therefore, if these were accurately known, would be likewise known accurately: But none of them can be so exactly and nicely obtained, as to be sufficient for determining the parallax of the sun; for very small errors, which cannot be easily avoided in measuring these angles, will produce very great errors in the parallax; and there will be a prodigious difference in the distances of the sun, when drawn from these parallaxes. For example: Suppose the horizontal parallax of the moon to be 60' 15", the semidiameter of the sun 16', and the semidiameter of the shadow 44' 30"; we shall conclude from thence, that the parallax of the sun was 15", and his distance from the earth about 13,700 semidiameters of the earth. But if there be an error committed, in determining the semidiameter of the shadow, of 12" in defect (and certainly the semidiameter of the shadow cannot be had so precisely as not to be liable to such an error), that is, if instead of 44' 30" we put 44' 18" for the apparent diameter of the shadow, all the others remaining as before, we shall have the parallax of the sun 3", and its distance from the earth almost 70,000 semidiameters of the earth, which is five times more than what it was by the first position. But if the fault were in excess, or the diameter of the shadow exceeded the true by 12", so that we should put in 44' 42" the parallax would arise to 27", and the distance of the sun only 7700 of the earth's semidiameters; which is nine times less than what it comes to by a like error

186
This method insufficient.

in defect. If an error in defect was committed of 15", which is still but a small mistake, the sun's parallax would be equal to nothing, and his distance infinite. Wherefore, since from so small mistakes the parallax and distance of the sun vary so much, it is plain that the distance of the sun cannot be obtained by this method.

Since, therefore, the angle that the earth's semidiameter subtends at the sun is so small, that it cannot be determined by any observation, Aristarchus Samius, an ancient and great philosopher and astronomer, contrived a very ingenious way for finding the angle which the semidiameter of the moon's orbit subtends when seen from the sun: This angle is about 60 times bigger than the former, subtended only by the earth's semidiameter. To find this angle, he lays down the following principles.

187
Aristarchus's method.

From the phases of the moon, it hath been demonstrated, that if a plane passed through the moon's centre, to which the line joining the sun and moon's centre was perpendicular, this plane would divide the illuminated hemisphere of the moon from the dark one: And therefore, if this plane should likewise pass through the eye of a spectator on the earth, the moon would appear bifected, or like a half circle; and a right line, drawn from the earth to the centre of the moon, would be in the plane of illumination, and consequently would be perpendicular to the right line which joins the centres of the sun and moon. Let S be the sun, and T the earth, AL a quadrant of the moon's orbit; and let the line SL, drawn from the sun, touch the orbit of the moon in L; the angle TLS will be a right angle: And therefore, when the moon is seen in L, it will appear bifected, or just half a circle. At the same time take the angle LTS, the elongation of the moon from the sun, and then we shall have the angle LST, its complement to a right angle. But we have the side TL, by which we can find the side ST, the distance of the sun from the earth.

6th Plate
XLIII. fig. 4.

But the difficult point is to determine exactly the moment of time when the moon is bifected, or in its true dichotomy; for there is a considerable space of time both before and after the dichotomy, nay even in the quadrature, when the moon will appear bifected, or half a circle; so that the exact moment of bifection cannot be known by observation, as experience tells us: And consequently, the true distance of the sun from the earth cannot be obtained by this method.

188
This method insufficient.

Since the moment in which the true dichotomy happens is uncertain, but it is certain that it happens before the quadrature; Ricciolus takes that point of time which is in the middle, between the time that the phasis begins to be doubtful whether it be bifected or not, and the time of quadrature: but he had done better, if he had taken the middle point between the time when it becomes doubtful whether the moon's side is concave or straight, and the time again when it is doubtful whether it is straight or convex; which point of time is after the quadrature: and if he had done this, he would have found the sun's distance a great deal more than he has made it.

189
Ricciolus's method.

There is no need to confine this method to the phasis of a dichotomy or bifection, for it can be as well performed when the moon has any other phasis bigger or less than a dichotomy: for observe by a very good telescope,

190
Another by Dr Keil.

telescope, with a micrometer, she phasis of the moon, that is, the proportion of the illuminated part of the diameter to the whole; and at the same moment of time take her elongation from the sun: The illuminated part of the diameter, if it be less than the semidiameter, is to be subtracted from the semidiameter; but if it be greater, the semidiameter is to be subtracted from it, and mark the residue: then say, As the semidiameter of the moon is to the residue, so is the radius to the sine of an angle, which is therefore found: this angle added to, or subtracted from, a right angle, gives the exterior angle of the triangle at the moon: but we have the angle at the earth, which is the elongation observed; which therefore being subtracted from the exterior angle, leaves the angle at the sun. And in the triangle SLT, having all the angles and one side LT, we can find the other side ST, the distance of the sun from the earth. But it is almost impossible to determine accurately the quantity of the lunar phasis, so that there may not be an error of a few seconds committed; and consequently, we cannot by this method find precisely enough the true distance of the sun. However, from such observations, we are sure, that the sun is above 7000 semidiameters of the earth distant from us. Since therefore the true distance of the sun can neither be found by eclipses, nor by the phases of the moon, the astronomers are forced to have recourse to the parallaxes of the planets that are next to us, as Mars and Venus, which are sometimes much nearer to us than the sun is. Their parallaxes they endeavour to find by some of the methods above explained; and if these parallaxes were known, then the parallax and distance of the sun, which cannot directly by any observations be attained, would easily be deduced from them. For from the theory of the motions of the earth and planets, we know at any time the proportion of the distances of the sun and planets from us; and the horizontal parallaxes are in a reciprocal proportion to these distances. Wherefore, knowing the parallax of a planet, we may from thence find the parallax of the sun.

Mars, when he is in an achronal position, that is, opposite to the sun, is twice as near to us as the sun is; and therefore his parallax will be twice as great. But Venus, when she is in her inferior conjunction with the sun, is four times nearer to us than he is, and her parallax is greater in the same proportion: Therefore, though the extreme smallness of the sun's parallax renders it unobservable by our senses, yet the parallaxes of Mars or Venus, which are twice or four times greater, may become sensible. The astronomers have bestowed much pains in finding out the parallax of Mars; but some time ago Mars was in his opposition to the sun, and also in his perihelion, and consequently in his nearest approach to the earth: And then he was most accurately observed by two of the most eminent astronomers of our age, who have determined his parallax to have been scarce 30 seconds; from whence it was inferred, that the parallax of the sun is scarce 11 seconds, and his distance about 19,000 semidiameters of the earth.

As the parallax of Venus is still greater than that of Mars, Dr Halley proposed a method by it of finding the distance of the sun to within a 500th part of the whole. The times of observation were at her transits over the sun in 1761 and 1769. At these times the greatest attention was given by astronomers, but it was found impossible to observe the exact times of immersion and emersion with such accuracy as had been expected; so that the matter is not yet determined so exactly as could be wished. The method of calculating the sun's distance by means of these transits, is as follows.

In fig. 6. let DBA be the earth, V Venus, and TSR the eastern limb of the sun. To an observer at B, the point *t* of that limb will be on the meridian, its place referred to the heaven will be at E, and Venus will appear just within it at S. But at the same instant, to an observer at A, Venus is east of the sun, in the right line AVF; the point *t* of the sun's limb appears at *e* in the heaven; and if Venus were then visible, she would appear at F. The angle CVA is the horizontal parallax of Venus, which we seek; and is equal to the opposite angle FVE, whose measure is the arc FE. ASC is the sun's horizontal parallax, equal to the opposite angle e SE, whose measure is the arc e E; and FAe (the same as VAt) is Venus's horizontal parallax from the sun, which may be found by observing how much later in absolute time her total ingress on the sun is, as seen from A than as seen from B, which is the time she takes to move from V to v in her orbit OVv.

It appears by the tables of Venus's motion and the sun's, that at the time of her transit in 1761 she moved 4' of a degree on the sun's disk in 60 minutes of time; and consequently 4" of a degree in one minute of time.

Now let us suppose, that A is 90° west of B, so that when it is noon at B it will be six in the morning at A; that the total ingress as seen from B is at one minute past 12, but that as seen from A it is at seven minutes 30 seconds past six; deduct six hours for the difference of meridians of A and B, and the remainder will be six minutes 30 seconds for the time by which the total ingress of Venus on the sun at S, is later as seen from A than as seen from B; which time being converted into parts of a degree is 26", or the arc Fe of Venus's horizontal parallax from the sun; for, as 1 minute of time is to 4 seconds of a degree, so is 6½ minutes of time to 26 seconds of a degree.

The times in which the planets perform their annual revolutions about the sun are already known by observation.—From these times, and the universal power of gravity by which the planets are retained in their orbits, it is demonstrable, that if the earth's mean distance from the sun be divided into 100,000 equal parts, Mercury's mean distance from the sun must be equal to 38,710 of these parts—Venus's mean distance from the sun, to 72,333—Mars's mean distance, 152,369—Jupiter's, 520,096—and Saturn's, 954,006. Therefore when the number of miles contained in the mean distance of any planet from the sun is known, we can by these proportions find the mean distance in miles of all the rest.

At the time of the above-mentioned transit, the earth's distance from the sun was 1015 (the mean distance being here considered as 1000), and Venus's distance from the sun 726 (the mean distance being considered as 723), which differences from the mean distances arise from the elliptical figure of the planets orbits—

bits—Subtracting 726 parts from 1015, there remain 289 parts for Venus's distance from the earth at that time.

Now, since the horizontal parallaxes of the planets are inversely as their distances from the earth's centre, it is plain, that as Venus was between the earth and the sun on the day of her transit, and consequently her parallax at that time greater than the sun's, if her horizontal parallax was then ascertained by observation, the sun's horizontal parallax might be found, and consequently his distance from the earth.—Thus, suppose Venus's horizontal parallax was found to be $36''.34803$; then, As the sun's distance 1015 is to Venus's distance 289, so is Venus's horizontal parallax $36''.3480$ to the sun's horizontal parallax $10''.3493$ on the day of her transit. And the difference of these two parallaxes, viz. $25''.9987$ (which may be esteemed $26''$), will be the quantity of Venus's horizontal parallax from the sun.

To find the sun's horizontal parallax at the time of his mean distance from the earth, say, As 1000 parts the sun's mean distance from the earth's centre, is to 1015, his distance therefrom on the day of the transit, so is $10''.3493$, his horizontal parallax on that day, to $10''.5045$, his horizontal parallax at the time of his mean distance from the earth's centre.

194
Method of computing the sun's distance from his parallax.

The sun's parallax being thus (or any other way supposed to be) found, at the time of his mean distance from the earth, we may find his true distance therefrom, in semidiameters of the earth, by the following analogy. As the sine (or tangent of so small an arc as that) of the sun's parallax $10''.5045$ is to radius, so is unity or the earth's semidiameter to the number of semidiameters of the earth that the sun is distant from its centre; which number, being multiplied by 3985, the number of miles contained in the earth's semidiameter, will give the number of miles by which the sun is distant from the earth's centre.

195
Distances of the other planets how found.

Then, As 100,000, the earth's mean distance from the sun in parts, is to 38,710, Mercury's mean distance from the sun in parts, so is the earth's mean distance from the sun in miles to Mercury's mean distance from the sun in miles.—And,

As 100,000 is to 72,333, so is the earth's mean distance from the sun in miles to Venus's mean distance from the sun in miles.—Likewise,

As 100,000 is to 152,369, so is the earth's mean distance from the sun in miles to Mars's mean distance from the sun in miles.—Again,

As 100,000 is to 520,096, so is the earth's mean distance from the sun in miles to Jupiter's mean distance from the sun in miles.—Lastly,

As 100,000 is to 954,006, so is the earth's mean distance from the sun in miles to Saturn's mean distance from the sun in miles.

And thus, by having found the distance of any one of the planets from the sun, we have sufficient data for finding the distances of all the rest. And then from their apparent diameters at these known distances, their real diameters and bulks may be found. According to the calculations made from the transit in 1769, we have given the distance of each of the primary and secondary planets from one another, and from the sun. In Plate XLIII. their proportional bulks are shown, according to former calculations by Mr Ferguson; and in

VOL. II.

2^d Plate XLII. their relative magnitudes according to the latest calculations by Mr Dunn. In 3^d Plate XLII. fig. 3. 4. 5. are given three figures of Jupiter by Mr Wollaston; and in Plate XLVIII. fig. 1. the proportional distances of the satellites of Jupiter and Saturn, with the magnitudes of the sun, and orbit of our moon, by Mr Ferguson.

With regard to the fixed stars, no method of ascertaining their distance hath hitherto been found out. Those who have formed conjectures concerning them, have thought that they behaved to be at least 400,000 times farther from us than we are from the sun.

They are said to be fixed, because they have been generally observed to keep at the same distances from each other; their apparent diurnal revolutions being caused solely by the earth's turning on its axis. They appear of a sensible magnitude to the bare eye, because the retina is affected not only by the rays of light which are emitted directly from them, but by many thousands more, which falling upon our eye-lids, and upon the aerial particles about us, are reflected into our eyes so strongly as to excite vibrations not only in those points of the retina where the real images of the stars are formed, but also in other points at some distance round about. This makes us imagine the stars to be much bigger than they would appear if we saw them only by the few rays which come directly from them, so as to enter our eyes without being intermixed with others. Any one may be sensible of this, by looking at a star of the first magnitude through a long narrow tube; which, though it takes in as much of the sky as would hold 1000 such stars, yet scarce renders that one visible.

196
Distance of the fixed stars immeasurable.

197
Why they seem so big to our naked eye.

The more a telescope magnifies, the less is the aperture through which the star is seen; and consequently the fewer rays it admits into the eye. Now, since the stars appear less in a telescope which magnifies 200 times, than they do to the bare eye, inasmuch that they seem to be only indivisible points, it proves at once that the stars are at immense distances from us, and that they shine by their own proper light. If they shone by borrowed light, they would be as invisible without telescopes as the satellites of Jupiter are; for these satellites appear bigger when viewed with a good telescope than the largest fixed stars do.

The number of stars discoverable in either hemisphere, by the naked eye, is not above a thousand. This at first may appear incredible, because they seem to be without number: but the deception arises from our looking confusedly upon them, without reducing them into order. For, look but steadfastly upon a pretty large portion of the sky, and count the number of stars in it, and you will be surpris'd to find them so few. Or, if one considers how seldom the moon meets with any stars in her way, although there are as many about her path as in other parts of the heavens, he will soon be convinced that the stars are much thinner sown than he was aware of. The British catalogue, which, besides the stars visible to the bare eye, includes a great number which cannot be seen without the assistance of a telescope, contains no more than 3000, in both hemispheres.

198
Small number visible to the naked eye.

As we have incomparably more light from the moon than from all the stars together, it were the greatest absurdity to imagine that the stars were made for no other purpose than to cast a faint light upon the earth;

5 K

especially

especially since many more require the assistance of a good telescope to find them out than are visible without that instrument. Our sun is surrounded by a system of planets and comets; all which would be invisible from the nearest fixed star. And from what we already know of the immense distance of the stars, the nearest may be computed at 32,000,000,000,000 miles from us, which is farther than a cannon-bullet would fly in 7,000,000 years. Hence it is easy to prove, that the sun, from such a distance, would appear no bigger than a star of the first magnitude. From all this it is highly probable, that each star is a sun to a system of worlds moving round it, tho' unseen by us; especially as the doctrine of a plurality of worlds is rational, and greatly manifests the power, wisdom, and goodness, of the great Creator. See n^o 66.

261
Telescopic stars.

262
Unformed stars.

263
Uses of their division into constellations.

The stars, on account of their apparently various magnitudes, have been distributed into several classes, or orders. Those which appear largest are called *stars of the first magnitude*; the next to them in lustre, *stars of the second magnitude*; and so on to the *sixth*, which are the smallest that are visible to the bare eye. This distribution having been made long before the invention of telescopes, the stars which cannot be seen without the assistance of these instruments are distinguished by the name of *telescopic stars*.

The ancients divided the starry sphere into particular constellations, or systems of stars, according as they lay near one another, so as to occupy those spaces which the figures of different sorts of animals or things would take up, if they were there delineated. And those stars which could not be brought into any particular constellation were called *unformed stars*.

This division of the stars into different constellations, or asterisms, serves to distinguish them from one another, so that any particular star may be readily found in the heavens by means of a celestial globe; on which the constellations are so delineated, as to put the most remarkable stars into such parts of the figures as are most easily distinguished. The number of the ancient constellations is 48, and upon our present globes about 70. On Senex's globes are inserted Bayer's letters; the first in the Greek alphabet being put to the biggest star in each constellation, the second to the next, and

so on: by which means, every star is as easily found as if a name were given to it. Thus, if the star γ in the constellation of the ram be mentioned, every astronomer knows as well what star is meant as if it were pointed out to him in the heavens.

There is also a division of the heavens into three parts. 1. The zodiac (*zōdiacus*), from *zōdion*, *zodion*, an animal, because most of the constellations in it, which are twelve in number, have the names of animals: As *Aries* the ram, *Taurus* the bull, *Gemini* the twins, *Cancer* the crab, *Libra* the balance, *Scorpio* the scorpion, *Sagittarius* the archer, *Capricornus* the goat, *Aquarius* the water-bearer, and *Pisces* the fishes. The zodiac goes quite round the heavens: it is about 16 degrees broad, so that it takes in the orbits of all the planets, and likewise the orbit of the moon. Along the middle of this zone or belt is the ecliptic, or circle which the earth describes annually as seen from the sun, and which the sun appears to describe as seen from the earth. 2. All that region of the heavens which is on the north side of the zodiac, containing 21 constellations. And, 3. That on the south side, containing 15.

264
Division of the heavens. 4th and 5th Pl. XII. fig. 1.

The ancients divided the zodiac into the above 12 constellations or signs in the following manner. They took a vessel with a small hole in the bottom, and having filled it with water, suffered the same to distil drop by drop into another vessel set beneath to receive it; beginning at the moment when some star rose, and continuing till it rose the next following night. The water falling down into the receiver they divided into twelve equal parts; and having two other small vessels in readiness, each of them fit to contain one part, they again poured all the water into the upper vessel; and, observing the rising of some star in the zodiac, they at the same time suffered the water to drop into one of the small vessels; and as soon as it was full, they shifted it, and set an empty one in its place. When each vessel was full, they took notice what star of the zodiac rose; and tho' this could not be done in one night, yet in many they observed the rising of 12 stars or points, by which they divided the zodiac into 12 parts.

265
Zodiac how divided.

The names of the constellations, and the number of stars observed in each of them by different astronomers, are as follow.

Some of the stars, particularly Arcturus, have been observed to change their places above a minute of a degree with respect to others. But whether this be owing to any real motion in the stars themselves, must require the observations of many ages to determine. If our solar system changeth its place with regard to ab-

solute space, this must in process of time occasion an apparent change in the distances of the stars from each other: and in such a case, the places of the nearest stars to us being more affected than those which are very remote, their relative positions must seem to alter, tho' the stars themselves were really immoveable. On the

5 K 2 other

(P) To the conjectures mentioned n^o 65.—70. concerning the disappearance of some stars, we may add that of Mr Maupertuis, who, in his Dissertation on the figures of the celestial bodies (p. 61.—63.), is of opinion, that some stars, by their prodigious quick rotations on their axes, may not only assume the figures of oblate spheroids, but that, by the great centrifugal force arising from such rotations, they may become of the figures of mill-stones; or be reduced to flat circular planes, so thin as to be quite invisible when their edges are turned towards us; as Saturn's ring is in such positions. But when very excentric planets or comets go round any flat star, in orbits much inclined to its equator, the attraction of the planets or comets in their perihelions must alter the inclination of the axis of that star; on which account it will appear more or less large and luminous, as its broad side is more or less turned towards us. And thus he imagines we may account for the apparent changes of magnitude and lustre in those stars, and likewise for their appearing and disappearing.

207
Change of
places in the
stars.

other hand, if our own system be at rest, and any of the stars in real motion, this must vary their positions; and the more so, the nearer they are to us, or swifter their motions are, or the more proper the direction of their motions is for our perception. See note on n° 89.

208
Change in the obliquity of the ecliptic.

The obliquity of the ecliptic to the equinoctial is found at present to be above the third part of a degree less than Ptolemy found it. And most of the observers after him found it to decrease gradually down to Tycho's time. If it be objected, that we cannot depend on the observations of the ancients, because of the incorrectness of their instruments; we have to answer, that both Tycho and Flamsteed are allowed to have been very good observers; and yet we find that Flamsteed makes this obliquity 2 $\frac{1}{2}$ minutes of a degree less than Tycho did about 100 years before him: and as Ptolemy was 1324 years before Tycho, so the gradual decrease answers nearly to the difference of time between these three astronomers. If we consider, that the earth is not a perfect sphere, but an oblate spheroid, having its axis shorter than its equatorial diameter; and that the sun and moon are constantly acting obliquely upon the greater quantity of matter about the equator, pulling it, as it were, towards a nearer and nearer coincidence with the ecliptic; it will not appear improbable that these actions should gradually diminish the angle between those planes. Nor is it less probable that the mutual attractions of all the planets should have a tendency to bring their orbits to a coincidence: but this change is too small to become sensible in many ages.

Sect. IX. *Of calculating the periodical Times, Places, &c. of the Sun, Moon, and Planets; Delimitation of the Phases of the Moon for any particular time; and the Construction of Astronomical Tables.*

This title includes almost all of what may be called the *Practical part of Astronomy*; and as it is by far the most difficult and abstruse, so the thorough investigation of it would necessarily lead us into very deep geometrical demonstrations. The great labours of former astronomers have left little for succeeding ones to do in this respect: but the motions of all the celestial bodies have been made long ago, the periodical times, excentricities, &c. of the planets determined; and as we suppose few will desire to repeat these laborious operations, we shall here content ourselves with giving some general hints of the methods by which these things have been originally accomplished, that so the operations of the young astronomer who makes use of tables already formed to his hand may not be merely mechanical.

* N° 174.

It hath been already observed*, that the foundation of all astronomical operations was the drawing a meridian line. This being done, the next thing is to find out the latitude of the place where the observations are to be made, and for which the meridian line is drawn. From what hath been said n° 3. it will easily be understood that the latitude of a place must always be equal to the elevation either of the north or south pole above the horizon; because when we are exactly on the equator, both poles appear in the horizon. There is, however, no star exactly in either of the celestial poles; therefore, to find the altitude of that invisible point called the *Pole of the Heavens*, we must choose some star

209
Latitude of any place how found.

near it which does not set; and having by several observations, according to the directions given n° 177, found its greatest and least altitudes, divide their difference by 2; and half that difference added to the least, or subtracted from the greatest, altitude of the star, gives the exact altitude of the pole or latitude of the place. Thus, suppose the greatest altitude of the star observed is 60°, and its least 50°, we then know that the latitude of the place where the observation was made is exactly 55°.

The latitude being once found, the obliquity of the ecliptic, or the angle made by the sun's annual path with the earth's equator, is easily obtained by the following method. Observe, about the summer solstice, the sun's meridian distance from the zenith, which is easily done by a quadrant with a moveable index furnished with sights; if this distance is subtracted from the latitude of the place, provided the sun is nearer the equator than the place of observation, the remainder will be the obliquity of the ecliptic. But if the place of observation is nearer the equator than the sun at that time, the zenith distance must be added. By this method, the obliquity of the ecliptic hath been determined to be 23° 29'.

210
Obliquity of the ecliptic found.

By the same method the declination of the sun from the equator for any day may be found; and thus a table of his declination for every day in the year might be constructed: thus also the declination of the stars might be found.

211
Sun's declination.

Having the declination of the sun, his right ascension and place in the ecliptic may be geometrically found by the solution of a case in spherical trigonometry. For let EQ represent the celestial equator, y the sun, and yX the ecliptic; then, in the right-angled spherical triangle ECy, we have the side EY, equal to the sun's declination: the angle ECy is always 23° 29', being the angle of the ecliptic with the equator; and the angle yEC is 90°, or a right angle. From these data we can find the side EC the right ascension; and Cy the sun's place in the ecliptic, or his distance from the equinoctial point; and thus a table of the sun's place for every day in the year, answerable to his declination, may be formed.

212
His place in the ecliptic how found. Pl. XLIII. fig. 6.

Having the sun's place in the ecliptic, the right ascension of the stars may be found by the help of it and a good pendulum clock: For which purpose the motion of the clock must be so adjusted, that the hand may run thro' the 24 hours in the same time that a star leaving the meridian will arrive at it again; which time is somewhat shorter than the natural day, because of the space the sun moves through in the mean time eastward. The clock being thus adjusted, when the sun is in the meridian, fix the hand to the point from whence we are to begin to reckon our time; and then observe when the star comes to the meridian, and mark the hour and minute that the hand then shews: The hours and minutes described by the index, turned into degrees and minutes of the equator, will give the difference between the right ascension of the sun and stars; which difference, being added to the right ascension of the sun, will give the right ascension of the star. Now, if we know the right ascension of any one star, we may from it find the right ascensions of all the others which we see, by marking the time upon the clock between the arrival of the star, whose right ascension we know, to the meridian, and another star, whose ascension is

213
To find the right ascension of the stars.

to be found. This time converted into hours and minutes of the equator, will give the difference of right ascensions; from whence, by addition, we collect the right ascension of the star which was to be found out.

214
Their longitudes and latitudes found.

The right ascension and declination of a star being known, its longitude, and latitude, or distance from the first star of Aries, and north or south from the ecliptic, may thence be easily found, from the solution of a case in spherical trigonometry, similar to that already mentioned concerning the sun's place; and the places of the fixed stars being all marked in a catalogue according to their longitudes and latitudes, it may thence be conceived how the longitude and latitude of a planet or comet may be found for any particular time by comparing its distance from them, and its apparent path may thus be traced; and thus the paths of Mercury and Venus were traced by M. Cassini, though Mr Ferguson made use of an orrery for that purpose.

215
To find the periodical times of the planets.

With regard to the planets, the first thing to be done is to find out their periodical times, which is done by observing when they have no latitude. At that time the planet is in the ecliptic, and consequently in one of its nodes; so that, by waiting till it returns to the same node again, and keeping an exact account of the time, the periodical time of its revolution round the sun may be known pretty exactly. By the same observations, from the theory of the earth's motion we can find the position of the line of the nodes; and when once the position of this line is found, the angle of inclination of that planet's orbit to the earth may also be known.

216
Excentricity of the earth's orbit how determined.

The excentricity of the earth's orbit may be determined by observing the apparent diameters of the sun at different times: when the sun's diameter is least, the earth is at the greatest distance; and when this diameter is greatest, the earth is at its least distance from him. But as this method must necessarily be precarious, another is recommended by Dr Keil, by observing the velocity of the earth in its orbit, or the apparent velocity of the sun, which is demonstrated to be always reciprocally as the square of the distance.

217
Of the other planets.

The excentricities of the orbits of the other planets may be likewise found by observing their velocities at different times; for all of them observe the same proportions with regard to the increase or decrease of their velocity that the earth does; only, in this case, care must be taken to observe the real, not the apparent, velocities of the planets, the last depending on the motion of the earth at the same time. Their apheha, or points of their orbits where they are farthest from the sun, may be known by making several observations of their distances from him, and thus perceiving when these distances cease to increase.

218
To find their places in their orbits.

The position of the apheha being determined, the planet's distance from it at any time may also be found by observation, which is called its *true* or *coequated* anomaly; and by supposing the motion of the planet to be regular and uniform, tables of that motion may easily be constructed. From thence the planet's mean place in its orbit may be found for any moment of time; and one of these moments being fixed upon as an epocha or beginning of the table, it is easy to understand, that from thence tables of the planet's place in its orbit for any number of years either preceding or consequent to that period may be constructed. These tables are to be constructed according to the meridian

of equal time, and not true or apparent time, because of the inequalities of the earth's motion as well as of that of the planet, and equations must be made to be added to or subtracted from the mean motion of the planet, as occasion requires; which will be readily understood from what we have already mentioned concerning the unequal motion of the earth in its orbit. When all the necessary tables are constructed by this or similar methods, the calculating of the planetary places becomes a mere matter of mechanism, and consists only in the proper additions and subtractions according to the directions always given along with such tables.

219
Inaccuracies from the mutual attraction of the planets.

It must be observed, however, that the accidental interference of the planets with one another by their mutual attractions render it impossible to construct any tables that shall remain equally perfect; and therefore frequent actual observations and corrections of the tables will be necessary. This disturbance, however, is inconsiderable, except in the planets Jupiter and Saturn, and they are in conjunction only once in 800 years.

220
Difficulties with regard to the moon.

What hath been already mentioned with regard to the planets, is also applicable to the moon; but with more difficulty, on account of the greater inequalities of her motions. She indeed moves in an ellipse as the rest do, and its excentricity may be better computed from observing her diameter at different times than that of the earth's orbit; but that excentricity is not always the same. The reason of this, and indeed of all the other lunar inequalities, is, that the sun has a sensible effect upon her by his attraction, as well as the earth. Consequently, when the earth is at its least distance from the sun, her orbit is dilated, and she moves more slowly; and, on the contrary, when the earth is in its apheha, her orbit contracts, and she moves more swiftly. The excentricity is always greatest when the line of the apides coincides with that of the syzygies, and the earth at its least distance from the sun. When the moon is in her syzygies, *i. e.* in the line that joins the centres of the earth and sun, which is either in her conjunction or opposition, she moves swifter, *ceteris paribus*, than in the quadratures. According to the different distances of the moon from the syzygies, she changes her motion: from the conjunction to her first quadrature, she moves somewhat slower; but recovers her velocity in the second quarter. In the third quarter she again loses, and in the last again recovers it. The apogee of the moon is also irregular; being found to move forward when it coincides with the line of the syzygies, and backwards when it cuts that line at right angles. Nor is this motion in any degree equal: in the conjunction or opposition, it goes briskly forwards; and, in the quadratures, moves either slowly forwards, stands still, or goes backward. The motion of the nodes has been already taken notice of*; but this motion is not uniform more than the rest; for when the line of the nodes coincides with that of the syzygies, they stand still; when their line cuts that at right angles, they go backwards, with the velocity, as Sir Isaac Newton hath shewn, of 16", 10", 24" an hour. The only equable motion the moon has, is her revolution on her axis, which she always performs exactly in the space of time in which she moves round the earth. From hence arises what is called the *Moon's libration*; for as the motion round her axis is equable, and that in her orbit unequal, it follows, that when the moon

221
Moves equably on her axis.

* No 179.

is in her perigee, where she moves swiftest, that part of her surface, which on account of the motion in her orbit would be turned from the earth, is not so, by reason of the motion on her axis. Thus some parts in the limb or margin of the moon sometimes recede from, and sometimes approach towards, the centre of the disk. Yet this equable rotation produces an apparent irregularity; for the axis of the moon, not being perpendicular, but a little inclined to its orbit, and this axis maintaining its parallelism round the earth, it must necessarily change its situation with respect to an observer on the earth, to whom sometimes the one and sometimes the other pole of the moon becomes visible; whence it appears to have a kind of wavering or vacillatory motion.

112
Lunar irregularities accounted for by Sir Isaac Newton.

From all these irregularities it may well be concluded, that the calculation of the moon's place in her orbit is a very difficult matter; and indeed, before Sir Isaac Newton, astronomers in vain laboured to subject the lunar irregularities to any rule. By his labours, however, and those of other astronomers, these difficulties are in a great measure overcome; and calculations with regard to this luminary may be made with as great certainty as concerning any other. Her periodical time may be determined from the observation of two lunar eclipses, at as great a distance from one another as possible; for in the middle of every lunar eclipse, the moon is exactly in opposition to the sun. Compute the time between these two eclipses or oppositions, and divide this by the number of lunations that have intervened, and the quotient will be the synodical month, or time the moon takes to pass from one conjunction to another, or from one opposition to another. Compute the sun's mean motion in the time of the synodical month, and add this to the entire circle described by the moon. Then, As that sum is to 360°, so is the quantity of the synodical month to the periodical, or time that the moon takes to move from one point of her orbit to the same point again. Thus, Copernicus in the year 1500, November 6th, at 2 hours 20 minutes, observed an eclipse of the moon at Rome; and August 1st 1523, at 4 hours 25 minutes, another at Cracow: hence the quantity of the synodical month is thus determined

	Y.	D.	H.	M.
Observ. 2 ^d	1523	237	4	25
Observ. 1 st	1500	210	2	20
Interval of time Add the intercalary } days for leap years. }	22	292	2	5
Exact interval	22	297	2	5,011991005'

This interval divided by 282, the number of months elapsed in that time, gives 29 days 12 hours 41 minutes for the length of the synodical month. But from the observations of two other eclipses, the same author more accurately determined the quantity of the synodical month to be 29 degrees 11 hours 45 minutes 3 seconds; from whence the mean periodical time of the moon comes to be 27 degrees 7 hours 43 minutes 5 seconds, which exactly agrees with the observations of later astronomers.

114
Her diurnal and horary motion.

The quantity of the periodical month being given, by the Rule of Three we may find the moon's diurnal and horary motion; and thus may tables of the moon's

mean motion be constructed; and if from the moon's mean diurnal motion that of the sun be subtracted, the remainder will be the moon's mean diurnal motion from the sun.

Having the moon's distance from the sun, her phasis for that time may be easily delineated by the following method laid down by Dr Keil. "Let the circle COBP represent the disk of the moon, which is turned towards the earth; and let OP be the line in which the femicircle OMP is projected, which suppose to be cut by the diameter BC, at right angles; and, making LP the radius, take LF equal to the cosine of the elongation of the moon from the sun: And then upon BC, as the great axis, and LF the lesser axis, describe the semi-ellipse BFC. This ellipse will cut off from the disk of the moon the portion BFCP of the illuminated face, which is visible to us from the earth."

5th Plate
XLII. fig.
2. 3.
115
Her phasis delineated.

Since in the middle of a total eclipse the moon is exactly in the node, if the sun's place be found for that time, and six signs added to it, if the eclipse is a lunar one the sun will give the place of the node, or if the eclipse observed is a solar one, the place of the node and of the sun are the same. From comparing two eclipses together, the mean motion of the nodes will thus be found out. The apogee of the moon may be known from her apparent diameter, as already observed; and by comparing her place when in the apogee at different times, the motion of the apogee itself may also be determined.

116
Place of the nodes how found.

These short hints will be sufficient to give a general knowledge of the methods used for the solution of some of the most difficult problems in astronomy. As for the proper equations to be added or subtracted, in order to find out the true motion and place of the moon, together with the particular methods of constructing tables for calculating eclipses, they are given from Mr Ferguson, in the following section.

Sect. X. Of Eclipses: With Tables for their Calculation; the method of constructing them; rules for calculation, and directions for the delineation, of Solar and Lunar Eclipses.

EVERY planet and satellite is illuminated by the sun; and casts a shadow towards that point of the heavens which is opposite to the sun. This shadow is nothing but a privation of light in the space hid from the sun by the opaque body that intercepts his rays.

When the sun's light is so intercepted by the moon, that to any place of the earth the sun appears partly or wholly covered, he is said to undergo an eclipse; though, properly speaking, it is only an eclipse of that part of the earth where the moon's shadow or penumbra falls. When the earth comes between the sun and moon, the moon falls into the earth's shadow; and, having no light of her own, she suffers a real eclipse from the interception of the sun's rays. When the sun is eclipsed to us, the moon's inhabitants, on the side next the earth, see her shadow like a dark spot travelling over the earth, about twice as fast as its equatorial parts move, and the same way as they move. When the moon is in an eclipse, the sun appears eclipsed to her, total to all those parts on which the earth's shadow falls, and of as long continuance as they are in the shadow.

227
Eclipse defined.

That

218
Figure of
the earth
spherical.

That the earth is spherical (for the hills take off no more from the roundness of the earth, than grains of dust do from the roundness of a common globe) is evident from the figure of its shadow on the moon; which is always bounded by a circular line, although the earth is incessantly turning its different sides to the moon, and very seldom shews the same side to her in different eclipses, because they seldom happen at the same hours. Were the earth shaped like a round flat plate, its shadow would only be circular when either of its sides directly faced the moon, and more or less elliptical as the earth happened to be turned more or less obliquely towards the moon when she is eclipsed. The moon's different phases prove her to be round; for, as she keeps still the same side towards the earth, if that side were flat, as it appears to be, she would never be visible from the third quarter to the first; and from the first quarter to the third, she would appear as round as when we say *she is full*; because, at the end of her first quarter, the sun's light would come as suddenly on all her side next the earth, as it does on a flat wall, and go off as abruptly at the end of her third quarter.

219
Moon's fi-
gure the
same.

If the earth and sun were equally large, the earth's shadow would be infinitely extended, and all of the same bulk; and the planet Mars, in either of its nodes and opposite to the sun, would be eclipsed in the earth's shadow. Were the earth larger than the sun, its shadow would increase in bulk the farther it extended, and would eclipse the great planets Jupiter and Saturn, with all their moons, when they were opposite to the sun. But as Mars, in opposition, never falls into the earth's shadow, altho' he is not then above 42,000,000 miles from the earth, it is plain that the earth is much less than the sun; for otherwise its shadow could not end in a point at so small a distance. If the sun and moon were equally large, the moon's shadow would go on to the earth with an equal breadth, and cover a portion of the earth's surface more than 2000 miles broad, even if it fell directly against the earth's centre, as seen from the moon; and much more if it fell obliquely on the earth: But the moon's shadow is seldom 150 miles broad at the earth, unless when it falls very obliquely on the earth, in total eclipses of the sun. In annular eclipses, the moon's real shadow ends in a point at some distance from the earth. The moon's small distance from the earth, and the shortness of her shadow, prove her to be less than the sun. And, as the earth's shadow is large enough to cover the moon, if her diameter were three times as large as it is (which is evident from her long continuance in the shadow when she goes through its centre), it is plain, that the earth is much bigger than the moon.

220
Shadows of
the earth
and moon
conical.

Though all opaque bodies, on which the sun shines, have their shadows, yet such is the bulk of the sun, and the distances of the planets, that the primary planets can never eclipse one another. A primary can eclipse only its secondary, or be eclipsed by it; and never but when in opposition or conjunction with the sun. The primary planets are very seldom in these positions, but the sun and moon are so every month: Whence one may imagine, that these two luminaries should be eclipsed every month. But there are few eclipses in respect of the number of new and full moons; the reason of which we shall now explain.

If the moon's orbit were coincident with the plane

of the ecliptic, in which the earth always moves and the sun appears to move, the moon's shadow would fall upon the earth at every change, and eclipse the sun to some parts of the earth. In like manner, the moon would go through the middle of the earth's shadow, and be eclipsed at every full; but with this difference, that she would be totally darkened for above an hour and an half; whereas the sun never was above four minutes totally eclipsed by the interposition of the moon. But one half of the moon's orbit is elevated 5 $\frac{1}{2}$ degrees above the ecliptic, and the other half as much depressed below it; consequently, the moon's orbit intersects the ecliptic in two opposite points called the *moon's nodes*, as has been already taken notice of. When these points are in a right line with the centre of the sun at new or full moon, the sun, moon, and earth, are all in a right line; and if the moon be then new, her shadow falls upon the earth; if full, the earth's shadow falls upon her. When the sun and moon are more than 17 degrees from either of the nodes at the time of conjunction, the moon is then generally too high or too low in her orbit to cast any part of her shadow upon the earth; when the sun is more than 12 degrees from either of the nodes at the time of full moon, the moon is generally too high or too low in her orbit to go through any part of the earth's shadow: and in both these cases there will be no eclipse. But when the moon is less than 17 degrees from either node at the time of conjunction, her shadow or penumbra falls more or less upon the earth, as she is more or less within this limit. And when she is less than 12 degrees from either node at the time of opposition, she goes through a greater or less portion of the earth's shadow, as she is more or less within this limit. Her orbit contains 360 degrees; of which 17, the limit of solar eclipses on either side of the nodes, and 12, the limit of lunar eclipses, are but small portions: And as the sun commonly passes by the nodes but twice in a year, it is no wonder that we have so many new and full moons without eclipses.

To illustrate this, (Plate L. fig. 1.) let ABCD be the ecliptic, RSTU a circle lying in the same plane with the ecliptic, and VXYZ the moon's orbit, all thrown into an oblique view, which gives them an elliptical shape to the eye. One half of the moon's orbit, as VWX, is always below the ecliptic, and the other half XYV above it. The points V and X, where the moon's orbit intersects the circle RSTU, which lies even with the ecliptic, are the moon's nodes; and a right line, as XEV, drawn from one to the other, through the earth's centre, is the line of the nodes, which is carried almost parallel to itself round the sun in a year.

If the moon moved round the earth in the orbit RSTU, which is coincident with the plane of the ecliptic, her shadow would fall upon the earth every time she is in conjunction with the sun, and at every opposition she would go through the earth's shadow. Were this the case, the sun would be eclipsed at every change, and the moon at every full, as already mentioned.

But although the moon's shadow N must fall upon the earth at *a*, when the earth is at E, and the moon in conjunction with the sun at *i*, because she is then very near one of her nodes; and at her opposition *n* she must go through the earth's shadow I, because she is then near the other node; yet, in the time that she goes round:

221
Why there
are so few
eclipses.

round the earth to her next change, according to the order of the letters XYVV, the earth advances from E to ϵ , according to the order of the letters EFGH; and the line of the nodes VEX, being carried nearly parallel to itself, brings the point f of the moon's orbit in conjunction with the sun at that next change; and then the moon being at f , is too high above the ecliptic to cast her shadow on the earth: and as the earth is still moving forward, the moon at her next opposition will be at g , too far below the ecliptic to go through any part of the earth's shadow; for by that time the point g will be at a considerable distance from the earth as seen from the sun.

When the earth comes to F, the moon in conjunction with the sun Z is not at k in a plane coincident with the ecliptic, but above it at Y in the highest part of her orbit; and then the point b of her shadow O goes far above the earth (as in fig. 2. which is an edge view of fig. 1). The moon at her next opposition, is not at o (fig. 1.), but at W, where the earth's shadow goes far above her (as in fig. 2). In both these cases the line of the nodes VEX (fig. 1) is about ninety degrees from the sun, and both luminaries are as far as possible from the limits of the eclipses.

When the earth has gone half round the ecliptic from E to G, the line of the nodes VGX is nearly, if not exactly, directed towards the sun at Z; and then the new-moon l casts her shadow P on the earth G; and the full moon p goes through the earth's shadow L; which brings on eclipses again, as when the earth was at E.

When the earth comes to H, the new moon falls not at m in a plane coincident with the ecliptic CD, but at W in her orbit below it; and then her shadow Q (see fig. 2.) goes far below the earth. At the next full she is not at q (fig. 1.) but at Y in her orbit $5\frac{1}{2}$ degrees above g , and at her greatest height above the ecliptic CD; being then as far as possible, at any opposition, from the earth's shadow M, as in fig. 2.

So, when the earth is at E and G, the moon is about her nodes at new and full, and in her greatest north and south declination (or latitude as it is generally called) from the ecliptic at her quarters; but when the earth is at F or H, the moon is in her greatest north and south declination from the ecliptic at new and full, and in the nodes about her quarters.

The point X, where the moon's orbit crosses the ecliptic, is called the *ascending node*, because the moon ascends from it above the ecliptic; and the opposite point of intersection V is called the *descending node*, because the moon descends from it below the ecliptic. When the moon is at Y in the highest point of her orbit, she is in her greatest north latitude; and when she is at W in the lowest point of her orbit, she is in her greatest south latitude.

If the line of the nodes, like the earth's axis, was carried parallel to itself round the sun, there would be just half a year between the conjunctions of the sun and nodes. But the nodes shift backwards, or contrary to the earth's annual motion, $19\frac{1}{2}$ deg. every year; and therefore the same node comes round the sun 19 days sooner every year than on the year before. Consequently, from the time that the ascending node X (when the earth is at E) passes by the sun as seen from the earth, it is only 173 days (not half a year) till the

descending node V passes by him. Therefore in whatever time of the year we have eclipses of the luminaries about either node, we may be sure that in 173 days afterward we shall have eclipses about the other node. And when at any time of the year the line of the nodes is in the situation VGX, at the same time next year it will be in the situation rGX ; the ascending node having gone backward, that is, contrary to the order of signs, from X to r , and the descending node from V to r ; each $19\frac{1}{2}$ deg. At this rate, the nodes shift through all the signs and degrees of the ecliptic in 18 years and 225 days; in which time there would always be a regular period of eclipses, if any complete number of lunations were finished without a fraction. But this never happens: for if both the sun and moon should start from a line of conjunction with either of the nodes in any point of the ecliptic, the sun would perform 18 annual revolutions and 222 degrees over and above, and the moon 230 lunations and 85 degrees of the 231^{st} , by the time the node came round to the same point of the ecliptic again; so that the sun would then be 138 degrees from the node, and the moon 85 degrees from the sun.

But, in 223 mean lunations, after the sun, moon, and nodes, have been once in a line of conjunction, they return so nearly to the same state again, as that the same node, which was in conjunction with the sun and moon at the beginning of the first of these lunations, will be within $28' 12''$ of a degree of a line of conjunction with the sun and moon again, when the last of these lunations is completed. And therefore in that time there will be a regular period of eclipses, or return of the same eclipse, for many ages.—In this period (which was first discovered by the Chaldeans) there are 18 Julian years 11 days 7 hours 43 minutes 20 seconds, when the last day of February in leap-years is four times included; but when it is five times included, the period consists of only 18 years 10 days 7 hours 43 minutes 20 seconds. Consequently, if to the mean time of any eclipse, either of the sun or moon, you add 18 Julian years 11 days 7 hours 43 minutes 20 seconds, when the last day of February in leap-years comes in four times, or a day less when it comes in five times, you will have the mean time of the return of the same eclipse.

But the falling back of the line of conjunctions or oppositions of the sun and moon $28' 12''$ with respect to the line of the nodes in every period, will wear it out in process of time; and after that, it will not return again in less than 12,492 years.—These eclipses of the sun, which happen about the ascending node, and begin to come in at the north pole of the earth, will go a little southerly at each return, till they go quite off the earth at the south pole; and those which happen about the descending node, and begin to come in at the south pole of the earth, will go a little northerly at each return, till at last they quite leave the earth at the north pole.

To exemplify this matter, we shall first consider the sun's eclipse, (March 21st old style, April 1st new style), A. D. 1764, according to its mean revolutions, without equating the times, or the sun's distance from the node; and then according to its true equated times.

This eclipse fell in open space at each return, quite clear of the earth, ever since the creation, till A. D.

1295, June 13th old style, at 12 h. 52 m. 59 sec. *post meridiem*, when the moon's shadow first touched the earth at the north pole; the sun being then 17° 48' 27" from the ascending node. In each period since that time, the sun has come 28' 12" nearer and nearer the same node, and the moon's shadow has therefore gone more and more southerly.—In the year 1962, July 18th old style, at 10 h. 36 m. 21 sec. *p. m.* when the same eclipse will have returned 38 times, the sun will be only 24' 45" from the ascending node, and the centre of the moon's shadow will fall a little northward of the earth's centre.—At the end of the next following period, A. D. 1980, July 28th old style, at 18 h. 19 m. 41 sec. *p. m.* the sun will have receded back 3' 27" from the ascending node, and the moon will have a very small degree of southern latitude, which will cause the centre of her shadow to pass a very small matter south of the earth's centre.—After which, in every following period, the sun will be 28' 12" farther back from the ascending node than in the period last before; and the moon's shadow will go still farther and farther southward, until September 12th old style, at 23 h. 46 m. 22 sec. *p. m.* A. D. 2665; when the eclipse will have completed its 77th periodical return, and will go quite off the earth at the south pole (the sun being then 17° 55' 22" back from the node), and cannot come in at the north pole, so as to begin the same course over again, in less than 12,492 years afterwards.—And such will be the case of every other eclipse of the sun: For, as there is about 18 degrees on each side of the node within which there is a possibility of eclipses, their whole revolution goes through 36 degrees about that node, which, taken from 360 degrees, leaves remaining 324 degrees for the eclipses to travel in *expansum*. And as this 36 degrees is not gone through in less than 77 periods, which takes up 1388 years, the remaining 324 degrees cannot be so gone through in less than 12,492 years. For, as 36 is to 1388, so is 324 to 12,492.

To illustrate this a little farther, we shall examine some of the most remarkable circumstances of the returns of the eclipse which happened July 14th 1748, about noon. This eclipse, after traversing the voids of space from the creation, at last began to enter the Terra Australis Incognita about 88 years after the conquest, which was the last of king Stephen's reign: every Chaldean period it has crept more northerly, but was still invisible in Britain before the year 1622; when, on the 30th of April, it began to touch the south parts of England about 2 in the afternoon; its central appearance rising in the American south seas, and traversing Peru and the Amazon's country, through the Atlantic ocean into Africa, and setting in the Æthiopian continent, not far from the beginning of the Red sea.

Its next visible period was, after three Chaldean revolutions, in 1676, on the first of June, rising central in the Atlantic ocean, passing us about 9 in the morning, with four digits eclipsed on the under limb, and setting in the gulf of CochinChina in the East Indies.

It being now near the solstice, this eclipse was visible the very next return in 1694, in the evening; and in two periods more, which was in 1730, on the 4th of July, was seen about half eclipsed just after sun-rise, and observed both at Wirtemberg in Germany, and Pekin

in China, soon after which it went off.

Eighteen years more afforded us the eclipse which fell on the 14th of July 1748.

The next visible return happened on July 25th 1766 in the evening, about four digits eclipsed; and, after two periods more, will happen on August 16th 1802, early in the morning, about five digits, the centre coming from the north frozen continent, by the capes of Norway, through Tartary, China, and Japan, to the Ladrone islands, where it goes off.

Again, in 1820, August 26th, between one and two, there will be another great eclipse at London, about 10 digits; but, happening so near the equinox, the centre will leave every part of Britain to the west, and enter Germany at Emden, passing by Venice, Naples, Grand Cairo, and set in the gulf of Baffora near that city.

It will be no more visible till 1874, when five digits will be obscured (the centre being now about to leave the earth) on September 28th. In 1892, the sun will go down eclipsed in London; and again, in 1928, the passage of the centre will be in the *expansum*, tho' there will be two digits eclipsed at London, October the 31st of that year, and about the year 2090 the whole penumbra will be wore off; whence no more returns of this eclipse can happen till after a revolution of 10,000 years.

From these remarks on the entire revolution of this eclipse, we may gather, that a thousand years more or less, (for there are some irregularities that may protract or lengthen this period 100 years), complete the whole terrestrial phenomena of any single eclipse: and since 20 periods of 54 years each, and about 33 days, comprehend the entire extent of their revolution, it is evident, that the times of the returns will pass thro' a circuit of one year and ten months, every Chaldean period being 10 or 11 days later, and of the equable appearances, about 32 or 33 days. Thus, though this eclipse happens about the middle of July, no other subsequent eclipse of this period will return till the middle of the same month again; but wear constantly each period 10 or 11 days forward, and at last appear in winter, but then it begins to cease from affecting us.

Another conclusion from this revolution may be drawn, that there will seldom be any more than two great eclipses of the sun in the interval of this period, and these follow sometimes next return, and often at greater distances. That of 1715 returned again in 1733 very great; but this present eclipse will not be great till the arrival of 1820, which is a revolution of four Chaldean periods; so that the irregularities of their circuits must undergo new computations to assign them exactly.

Nor do all eclipses come in at the south pole: that depends altogether on the position of the lunar nodes, which will bring in as many from the *expansum* one way as the other; and such eclipses will wear more southerly by degrees, contrary to what happens in the present case.

The eclipse, for example, of 1736 in September, had its centre in the *expansum*, and set about the middle of its obscurity in Britain; it will wear in at the north pole, and in the year 2600, or thereabouts, go off into the *expansum* on the south side of the earth.

The eclipses therefore which happened about the crea-

236
Period in which the phenomena of an eclipse are completed.

237
Eclipses come in by the north and south poles.

ation are little more than half way yet of their ethereal circuit; and will be 4000 years before they enter the earth any more. This grand revolution seems to have been entirely unknown to the ancients.

²³⁹
Very ancient eclipses cannot be calculated by our tables.

It is particularly to be noted, that eclipses which have happened many centuries ago will not be found by our present tables to agree exactly with ancient observations, by reason of the great anomalies in the lunar motions; which appears an incontestable demonstration of the non-eternity of the universe. For it seems confirmed by undeniable proofs, that the moon now finishes her period in less time than formerly, and will continue, by the centripetal law, to approach nearer and nearer the earth, and to go sooner and sooner round it: nor will the centrifugal power be sufficient to compensate the different gravitations of such an assemblage of bodies as constitute the solar system, which would come to ruin of itself, without some regulation and adjustment of their original motions. See N^o 89.

We are credibly informed from the testimony of the ancients, that there was a total eclipse of the sun predicted by Thales to happen in the fourth year of the 48th Olympiad, either at Sardis or Miletus in Asia, where Thales then resided. That year corresponds to the 585th year before Christ; when accordingly there happened a very signal eclipse of the sun, on the 28th of May, answering to the present 10th of that month, central through North America, the fourth parts of France, Italy, &c. as far as Athens, or the isles in the Ægean sea; which is the farthest that even the Caroline tables carry it; and consequently make it invisible to any part of Asia, in the total character; tho' there are good reasons to believe that it extended to Babylon, and went down central over that city. We are not however to imagine, that it was set before it past Sardis and the Asiatic towns, where the predictor lived; because an invisible eclipse could have been of no service to demonstrate his ability in astronomical sciences to his countrymen, as it could give no proof of its reality.

For a further illustration, Thucydides relates, That a solar eclipse happened on a summer's day, in the afternoon, in the first year of the Peloponnesian war, so great, that the stars appeared. Rhodius was victor in the Olympic games the fourth year of the said war, being also the fourth year of the 87th Olympiad, on the 428th year before Christ. So that the eclipse must have happened in the 431st year before Christ; and by computation it appears, that on the third of August there was a signal eclipse which would have past over Athens, central about 6 in the evening, but which our present tables bring no farther than the ancient Syrtes on the African coast, above 400 miles from Athens; which, suffering in that case but 9 digits, could by no means exhibit the remarkable darkness recited by this historian: the centre therefore seems to have past Athens about 6 in the evening, and probably might go down about Jerusalem, or near it, contrary to the construction of the present tables. These things are only mentioned by way of caution to the present astronomers, in recomputing ancient eclipses; and they may examine the eclipse of Nicias, so fatal to the Athenian fleet; that which overthrew the Macedonian army, &c.

²³⁹
Number of eclipses in a year. In any year, the number of eclipses of both luminaries cannot be less than two, nor more than seven;

the most usual number is four, and it is very rare to have more than six. For the sun passes by both the nodes but once a-year, unless he passes by one of them in the beginning of the year; and if he does, he will pass by the same node again a little before the year be finished; because, as these points move 19 $\frac{1}{2}$ degrees backwards every year, the sun will come to either of them 173 days after the other. And when either node is within 17 degrees of the sun at the time of new moon, the sun will be eclipsed. At the subsequent opposition, the moon will be eclipsed in the other node, and come round to the next conjunction again ere the former node be 17 degrees past the sun, and will therefore eclipse him again. When three eclipses fall about either node, the like number generally falls about the opposite; as the sun comes to it in 173 days afterward; and six lunations contain but four days more. Thus, there may be two eclipses of the sun and one of the moon about each of her nodes. But when the moon changes in either of the nodes, she cannot be near enough the other node at the next full to be eclipsed; and in six lunar months afterward she will change near the other node: in these cases, there can be but two eclipses in a year, and they are both of the sun.

A longer period than the above-mentioned, for comparing and examining eclipses which happen at long intervals of time, is 557 years, 21 days, 18 hours, 30 minutes, 11 seconds; in which time there are 6890 mean lunations; and the sun and node meet again so nearly as to be but 11 seconds distant; but then it is not the same eclipse that returns, as in the shorter period above-mentioned.

Eclipses of the sun are more frequent than of the moon's; yet we have more visible eclipses of the moon than of the sun, because eclipses of the moon are seen from all parts of that hemisphere of the earth which is next her, and are equally great to each of those parts; but the sun's eclipses are visible only to that small portion of the hemisphere next him whereon the moon's shadow falls.

The moon's orbit being elliptical, and the earth in one of its focuses, she is once at her least distance from the earth, and once at her greatest, in every lunation. When the moon changes at her least distance from the earth, and so near the node that her dark shadow falls upon the earth, she appears big enough to cover the whole disk of the sun from that part on which her shadow falls; and the sun appears totally eclipsed there for some minutes: but when the moon changes at her greatest distance from the earth, and so near the node that her dark shadow is directed towards the earth, her diameter subtends a less angle than the sun's; and therefore she cannot hide his whole disk from any part of the earth, nor does her shadow reach it at that time; and to the place over which the point of her shadow hangs, the eclipse is annular, the sun's edge appearing like a luminous ring all around the body of the moon. When the change happens within 17 degrees of the node, and the moon at her mean distance from the earth, the point of her shadow just touches the earth, and she eclipseth the sun totally to that small spot whereon her shadow falls; but the darkness is not of a moment's continuance.

The moon's apparent diameter, when largest, exceeds

²⁴⁰
Why more eclipses of the moon than of the sun are observed.

²⁴¹
Total and annular eclipses.

ceeds the sun's, when least, only 1 minute 38 seconds of a degree; and in the greatest eclipse of the sun that can happen at any time and place, the total darkness continues no longer than whilst the moon is going 1 minute 38 seconds from the sun in her orbit, which is about 3 minutes and 13 seconds of an hour.

the moon's
shadow and
penumbra.

The moon's dark shadow covers only a spot on the earth's surface about 180 English miles broad, when the moon's diameter appears largest, and the sun's least; and the total darkness can extend no farther than the dark shadow covers. Yet the moon's partial shadow or penumbra may then cover a circular space 4900 miles in diameter, within all which the sun is more or less eclipsed, as the places are less or more distant from the centre of the penumbra. When the moon changes exactly in the node, the penumbra is circular on the earth at the middle of the general eclipse; because at that time it falls perpendicularly on the earth's surface; but at every other moment it falls obliquely, and will therefore be elliptical; and the more so, as the time is longer before or after the middle of the general eclipse; and then much greater portions of the earth's surface are involved in the penumbra.

244
Beginning,
ending, &c.
of a solar
eclipse.

When the penumbra first touches the earth, the general eclipse begins; when it leaves the earth, the general eclipse ends: in some part of the earth or other. When the penumbra touches any place, the eclipse begins at that place, and ends when the penumbra leaves it. When the moon changes in the node, the penumbra goes over the centre of the earth's disk as seen from the moon; and consequently, by describing the longest line possible on the earth, continues the longest upon it; namely, at a mean rate, 5 hours 50 minutes; more, if the moon be at her greatest distance from the earth, because she then moves slowest; less, if she be at her least distance, because of her quicker motion.

To make several of the above and other phenomena plainer, (Plate L. fig. 3.), let S be the sun, E the earth, M the moon, and AMP the moon's orbit. Draw the right line *Wc* from the western side of the sun at *W*, touching the western side of the moon at *c*, and the earth at *e*: draw also the right line *Vd* from the eastern side of the sun at *V*, touching the eastern side of the moon at *d*, and the earth at *e*: the dark space *ced* included between those lines is the moon's shadow, ending in a point at *e*, where it touches the earth; because in this case the moon is supposed to change at M in the middle between A the apogee, or farthest point of her orbit from the earth, and P the perigee, or nearest point to it. For, had the point P been at M, the moon had been nearer the earth; and her dark shadow at *e* would have covered a space upon it about 180 miles broad, and the sun would have been totally darkened, with some continuance; but had the point A been at M, the moon would have been farther from the earth, and her shadow would have ended in a point a little above *e*, and therefore the sun would have appeared like a luminous ring all around the moon. Draw the right lines *WXdb* and *VXcg*, touching the contrary sides of the sun and moon, and ending on the earth at *a* and *b*: draw also the right line *SXM*, from the centre of the sun's disk, thro' the moon's centre, to the earth; and suppose the two former lines *WXdb* and *VXcg* to revolve on the

line *SXM* as an axis, and their points *a* and *b* will describe the limits of the penumbra TT on the earth's surface, including the large space *aba*; within which the sun appears more or less eclipsed, as the places are more or less distant from the verge of the penumbra *ab*.

Draw the right line *yt* across the sun's disk, perpendicular to *SXM* the axis of the penumbra: then divide the line *yt* into twelve equal parts, as in the figure, for the twelve digits or equal parts of the sun's diameter; and, at equal distances from the centre of the penumbra at *e* (on the earth's surface *YY*) to its edge *ab*, draw twelve concentric circles, marked with the numeral figures 1 2 3 4 &c. and remember that the moon's motion in her orbit AMP is from west to east, as from *s* to *t*. Then,

To an observer on the earth at *b*, the eastern limb of the moon at *d* seems to touch the western limb of the sun at *W*, when the moon is at M; and the sun's eclipse begins at *b*, appearing as at A in Plate LI. fig. 1. at the left hand; but, at the same moment of absolute time, to an observer at *a* in Plate L. fig. 3. the western edge of the moon at *c* leaves the eastern edge of the sun at *V*, and the eclipse ends, as at the right hand C, Plate LI. fig. 1. At the very same instant, to all those who live on the circle marked 1 on the earth E, in Plate L. fig. 3. the moon M cuts off or darkens a twelfth part of the sun S, and eclipses him one digit, as at 1 in Plate LI. fig. 1.: to those who live on the circle marked 2 in Plate L. fig. 3. the moon cuts off two twelfth parts of the sun, as at 2 in Plate LI. fig. 1.; to those on the circle 3, three parts; and so on to the centre at 12 in Plate L. fig. 3. where the sun is centrally eclipsed, as at B in the middle of fig. 1. Plate LI.; under which figure there is a scale of hours and minutes, to shew at a mean rate how long it is from the beginning to the end of a central eclipse of the sun on the parallel of London; and how many digits are eclipsed at any particular time from the beginning at A to the middle at B, or the end at C. Thus, in 16 minutes from the beginning, the sun is two digits eclipsed; in an hour and five minutes, eight digits; and in an hour and 37 minutes, 12 digits.

By Plate L. fig. 3. it is plain, that the sun is totally or centrally eclipsed but to a small part of the earth at any time, because the dark conical shadow *e* of the moon M falls but on a small part of the earth; and that the partial eclipse is confined at that time to the space included by the circle *ab*, of which only one half can be projected in the figure, the other half being supposed to be hid by the convexity of the earth E: and likewise, that no part of the sun is eclipsed to the large space *YY* of the earth, because the moon is not between the sun and any of that part of the earth; and therefore to all that part the eclipse is invisible. The earth turns eastward on its axis, as from *g* to *h*, which is the same way that the moon's shadow moves; but the moon's motion is much swifter in her orbit from *s* to *t*: and therefore, although eclipses of the sun are of longer duration on account of the earth's motion on its axis than they would be if that motion was stop, yet, in four minutes of time at most, the moon's swifter motion carries her dark shadow quite over any place that its centre touches at the time of
greatest

greatest obscuration. The motion of the shadow on the earth's disk is equal to the moon's motion from the sun, which is about $30\frac{1}{2}$ minutes of a degree every hour at a mean rate; but so much of the moon's orbit is equal to $30\frac{1}{2}$ degrees of a great circle on the earth; and therefore the moon's shadow goes $30\frac{1}{2}$ degrees, or 1830 geographical miles, on the earth in an hour, or 302 miles in a minute, which is almost four times as swift as the motion of a cannon-ball.

As seen from the sun or moon, the earth's axis appears differently inclined every day of the year, on account of keeping its parallelism throughout its annual course. In Plate LI. fig. 2. let EDON be the earth at the two equinoxes and the two solstices, NS its axis, N the north pole, S the south pole, $\mathcal{A}EQ$ the equator, T the tropic of Cancer, t the tropic of Capricorn, and ABC the circumference of the earth's enlightened disk as seen from the sun or new moon at these times. The earth's axis has the position NES at the vernal equinox, lying towards the right hand, as seen from the sun or new moon; its poles N and S being then in the circumference of the disk; and the equator and all its parallels seem to be straight lines, because their planes pass thro' the observer's eye looking down upon the earth from the sun or moon directly over E, where the ecliptic FG intersects the equator $\mathcal{A}E$. At the summer solstice, the earth's axis has the position NDS; and that part of the ecliptic FG, in which the moon is then new, touches the tropic of Cancer T at D. The north pole N at that time inclining $23\frac{1}{2}$ degrees towards the sun, falls so many degrees within the earth's enlightened disk, because the sun is then vertical to D $23\frac{1}{2}$ degrees north of the equator $\mathcal{A}EQ$; and the equator with all its parallels seem elliptic curves bending downward, or towards the south pole, as seen from the sun; which pole, together with $23\frac{1}{2}$ degrees all round it, is hid behind the disk in the dark hemisphere of the earth. At the autumnal equinox, the earth's axis has the position NOS, lying to the left hand as seen from the sun or new moon, which are then vertical to O, where the ecliptic cuts the equator $\mathcal{A}EQ$. Both poles now lie in the circumference of the disk, the north pole just going to disappear behind it, and the south pole just entering into it; and the equator, with all its parallels, seem to be straight lines, because their planes pass thro' the observer's eye, as seen from the sun, and very nearly so as seen from the moon. At the winter solstice, the earth's axis has the position NNS, when its south pole S inclining $23\frac{1}{2}$ degrees towards the sun, falls $23\frac{1}{2}$ degrees within the enlightened disk, as seen from the sun or new moon, which are then vertical to the tropic of Capricorn t , $23\frac{1}{2}$ degrees south of the equator $\mathcal{A}EQ$: and the equator, with all its parallels, seem elliptic curves bending upward; the north pole being as far hid behind the disk in the dark hemisphere, as the south pole is come into the light. The nearer that any time of the year is to the equinoxes or solstices, the more it partakes of the phenomena relating to them.

Thus it appears, that from the vernal equinox to the autumnal, the north pole is enlightened; and the equator and all its parallels appear elliptical as seen from the sun, more or less curved as the time is nearer to, or farther from, the summer solstice; and bending downwards, or towards the south pole; the reverse of

which happens from the autumnal equinox to the vernal. A little consideration will be sufficient to convince the reader, that the earth's axis inclines towards the sun at the summer solstice; from the sun at the winter solstice; and sideways to the sun at the equinoxes; but towards the right hand, as seen from the sun at the vernal equinox; and towards the left hand at the autumnal. From the winter to the summer solstice, the earth's axis inclines more or less to the right hand, as seen from the sun; and the contrary from the summer to the winter solstice.

The different positions of the earth's axis, as seen from the sun at different times of the year, affect solar eclipses greatly with regard to particular places; yea, so far as would make central eclipses which fall at one time of the year invisible if they fell at another, even though the moon should always change in the nodes, and at the same hour of the day; of which indefinitely various affections, we shall only give examples for the times of the equinoxes and solstices.

In the same diagram, (Plate LI. fig. 2.), let FG be part of the ecliptic, and IK, ik , ik , part of the moon's orbit; both seen edgewise, and therefore projected into right lines; and let the intersections NODE be one and the same node at the above times, when the earth has the forementioned different positions; and let the spaces included by the circles Pppp be the penumbra at these times, as its centre is passing over the centre of the earth's disk. At the winter solstice, when the earth's axis has the position NNS, the centre of the penumbra P touches the tropic of Capricorn t in N at the middle of the general eclipse; but no part of the penumbra touches the tropic of Cancer T. At the summer solstice, when the earth's axis has the position NDS (iDk being then part of the moon's orbit whose node is at D), the penumbra p has its centre at D, on the tropic of Cancer T, at the middle of the general eclipse, and then no part of it touches the tropic of Capricorn t . At the autumnal equinox, the earth's axis has the position NOS, (iOk being then part of the moon's orbit), and the penumbra equally includes part of both tropics T and t at the middle of the general eclipse: at the vernal equinox it does the same, because the earth's axis has the position NES; but, in the former of these two last cases, the penumbra enters the earth at A, north of the tropic of Cancer T, and leaves it at m , south of the tropic of Capricorn t ; having gone over the earth obliquely southward, as its centre described the line AOm : whereas, in the latter case, the penumbra touches the earth at n , south of the equator $\mathcal{A}EQ$, and describing the line nEq (similar to the former line AOm in open space), goes obliquely northward over the earth, and leaves it at q , north of the equator.

In all these circumstances, the moon has been supposed to change at noon in her descending node: Had she changed in her ascending node, the phenomena would have been as various the contrary way, with respect to the penumbras going northward or southward over the earth. But because the moon changes at all hours, as often in one node as in the other, and at all distances from them both at different times as it happens, the variety of the phases of eclipses are almost innumerable, even at the same places; considering also how variously the same places are situated on the

244
Eclipses affected by the position of the earth's axis.

enlightened disk of the earth, with respect to the penumbra's motion, at the different hours when eclipses happen.

When the moon changes 17 degrees short of her descending node, the penumbra P18 just touches the northern part of the earth's disk, near the north pole N; and as seen from that place, the moon appears to touch the sun, but hides no part of him from sight. Had the change been as far short of the ascending node, the penumbra would have touched the southern part of the disk near the south pole S. When the moon changes 12 degrees short of the descending node, more than a third part of the penumbra P12 falls on the northern parts of the earth at the middle of the general eclipse: Had she changed as far past the same node, as much of the other side of the penumbra about P would have fallen on the southern part of the earth; all the rest in the expanse, or open space. When the moon changes 6 degrees from the node, almost the whole penumbra P6 falls on the earth at the middle of the general eclipse. And lastly, when the moon changes in the node at N, the penumbra PN takes the longest course possible on the earth's disk; its centre falling on the middle thereof, at the middle of the general eclipse. The farther the moon changes from either node, within 17 degrees of it, the shorter is the penumbra's continuance on the earth, because it goes over a less portion of the disk, as is evident by the figure.

The nearer that the penumbra's centre is to the equator at the middle of the general eclipse, the longer is the duration of the eclipse at all those places where it is central; because, the nearer that any place is to the equator, the greater is the circle it describes by the earth's motion on its axis: and so, the place moving quicker, keeps longer in the penumbra, whose motion is the same way with that of the place, though faster, as has been already mentioned. Thus (see the earth at D and the penumbra at 12) whilst the point *b* in the polar circle *abcd* is carried from *b* to *c* by the earth's diurnal motion, the point *d* on the tropic of Cancer T is carried a much greater length from *d* to D; and therefore, if the penumbra's centre goes one time over *c* and another time over D, the penumbra will be longer in passing over the moving place *d* than it was in passing over the moving place *b*. Consequently, central eclipses about the poles are of the shortest duration; and about the equator, of the longest.

In the middle of summer, the whole frigid zone, included by the polar circle *abcd*, is enlightened; and if it then happens that the penumbra's centre goes over the north pole, the sun will be eclipsed much the same number of digits at *a* as at *c*; but whilst the penumbra moves eastward over *c*, it moves westward over *a*; because, with respect to the penumbra, the motions of *a* and *c* are contrary: for *c* moves the same way with the penumbra towards *d*, but *a* moves the contrary way towards *b*; and therefore the eclipse will be of longer duration at *c* than at *a*. At *a* the eclipse begins on the sun's eastern limb, but at *c* on his western: at all places lying without the polar circles, the sun's eclipses begin on his western limb, or near it, and end on or near his eastern. At those places where the penumbra touches the earth, the eclipse begins with the rising sun, on the top of his western or uppermost edge;

and at those places where the penumbra leaves the earth, the eclipse ends with the setting sun, on the top of his eastern edge, which is then the uppermost, just at its disappearing in the horizon.

If the moon were surrounded by an atmosphere of any considerable density, it would seem to touch the sun a little before the moon made her appulse to his edge, and we should see a little faintness on that edge before it were eclipsed by the moon: but as no such faintness has been observed, it seems plain, that the moon has no such atmosphere as that of the earth. The faint ring of light surrounding the sun in total eclipses, called by Cassini *la chevelure du soleil*, is said to be the atmosphere of the sun; because it has been observed to move equally with the sun, not with the moon. See n^o 43.

Having been so prolix concerning eclipses of the sun, we shall drop that subject at present, and proceed to the doctrine of lunar eclipses; which, being more simple, may be explained in less time.

That the moon can never be eclipsed but at the time of her being full, and the reason why she is not eclipsed at every full, has been shewn already. In Plate L. fig. 3, let S be the sun, E the earth, RR the earth's shadow, and B the moon in opposition to the sun: In this situation the earth intercepts the sun's light in its way to the moon; and when the moon touches the earth's shadow at *e*, she begins to be eclipsed on her eastern limb *x*, and continues eclipsed until her western limb *y* leaves the shadow at *w*: at B she is in the middle of the shadow, and consequently in the middle of the eclipse.

The moon, when totally eclipsed, is not invisible if she be above the horizon and the sky be clear; but appears generally of a dusky colour, like tarnished copper, which some have thought to be the moon's native light*. But the true cause of her being visible is the scattered beams of the sun, bent into the earth's shadow by going through the atmosphere; which, being more or less dense near the earth than at considerable heights above it, refracts or bends the sun's rays more inward, the nearer they are passing by the earth's surface, than those rays which go through higher parts of the atmosphere, where it is less dense according to its height, until it be so thin or rare as to lose its refractive power. Let the circle *fg h i*, concentric to the earth, include the atmosphere whose refractive power vanishes at the heights *f* and *i*; so that the rays *Wf w* and *Viv* go on straight without suffering the least refraction: but all those rays which enter the atmosphere between *f* and *k*, and between *i* and *l*, on opposite sides of the earth, are gradually more bent inward as they go thro' a greater portion of the atmosphere, until the rays *Wk* and *Vl* touching the earth at *m* and *n*, are bent so much as to meet at *q*, a little short of the moon; and therefore the dark shadow of the earth is contained in the space *moqn*, where none of the sun's rays can enter: all the rest R R, being mixed by the scattered rays which are refracted as above, is in some measure enlightened by them; and some of those rays falling on the moon, give her the colour of tarnished copper, or of iron almost red hot. So that if the earth had no atmosphere, the moon would be as invisible in total eclipses as she is when new. If the moon were so near the earth as to go into its dark shadow, suppose about *po*, she would be invisible during her.

²⁴⁶ Lunar eclipses explained.

²⁴⁷ Why the moon is visible when eclipsed.

* See n^o 43.

²⁴⁵ Duration of eclipses in different parts of the earth.

her stay in it; but visible before and after in the fainter shadow RR.

When the moon goes thro' the centre of the earth's shadow, she is directly opposite to the sun: yet the moon has been often seen totally eclipsed in the horizon when the sun was also visible in the opposite part of it: for, the horizontal refraction being almost 34 minutes of a degree, and the diameter of the sun and moon being each at a mean state but 32 minutes, the refraction causes both luminaries to appear above the horizon when they are really below it.

When the moon is full at 12 degrees from either of her nodes, she just touches the earth's shadow, but enters not into it. In Plate LI. fig. 2. let GH be the ecliptic, *ef* the moon's orbit where she is 12 degrees from the node at her full; *cd* her orbit where she is 6 degrees from the node, *ab* her orbit where she is full in the node, A B the earth's shadow, and M the moon. When the moon describes the line *ef*, she just touches the shadow, but does not enter into it; when she describes the line *cd*, she is totally, tho' not centrally, immersed in the shadow; and when she describes the line *ab*, she passes by the node at M in the centre of the shadow, and takes the longest line possible, which is a diameter, through it: and such an eclipse being both total and central is of the longest duration, namely, 3 hours 57 minutes 6 seconds from the beginning to the end, if the moon be at her greatest distance from the earth; and 3 hours 37 minutes 26 seconds, if she be at her least distance. The reason of this difference is, that when the moon is farthest from the earth, she moves slowest; and when nearest to it, quickest.

The moon's diameter, as well as the sun's, is supposed to be divided into 12 equal parts, called *digits*; and so many of these parts as are darkened by the earth's shadow, so many digits is the moon eclipsed. All that the moon is eclipsed above 12 digits, shews how far the shadow of the earth is over the body of the moon, on that edge to which she is nearest at the middle of the eclipse.

It is difficult to observe exactly either the beginning or ending of a lunar eclipse, even with a good telescope, because the earth's shadow is so faint and ill defined about the edges, that when the moon is either just touching or leaving it, the obscuration of her limb is scarce sensible; and therefore the nicest observers can hardly be certain to four or five seconds of time. But both the beginning and ending of solar eclipses are visibly instantaneous; for the moment that the edge of the moon's disk touches the sun's, his roundness seems a little broke on that part; and the moment she leaves it, he appears perfectly round again.

In astronomy, eclipses of the moon are of great use for ascertaining the periods of her motions; especially such eclipses as are observed to be alike in all her circumstances, and have long intervals of time between them. In geography, the longitudes of places are found by eclipses: but for this purpose eclipses of the moon are more useful than those of the sun, because they are more frequently visible, and the same lunar eclipse is of equal largeness and duration at all places where it is seen. In chronology, both solar and lunar eclipses serve to determine exactly the time of any past event: for there are so many particulars observable in every eclipse, with respect to its quantity, the places

where it is visible (if of the sun), and the time of the day or night, that it is impossible there can be two solar eclipses in the course of many ages which are alike in all circumstances.

From the above explanation of the doctrine of eclipses, it is evident, that the darknets at our Saviour's crucifixion was supernatural. For he suffered on the day on which the passover was eaten by the Jews, on which day it was impossible that the moon's shadow could fall on the earth; for the Jews kept the passover at the time of full moon: nor does the darknets in total eclipses of the sun last above four minutes in any place; whereas the darknets at the crucifixion lasted three hours, Matth. xxviii. 15. and overspread at least all the land of Judea.

The theory of eclipses being now, we hope, pretty plainly laid down, the construction of tables for their calculation will be understood from the following considerations.

The motions of the sun and moon are observed to be continually accelerated from the apogee to the perigee, and as gradually retarded from the perigee to the apogee; being slowest of all when the mean anomaly is nothing, and swiftest of all when it is six signs.

When the luminary is in its apogee or perigee, its place is the same as it would be if its motion were equable in all parts of its orbit. The supposed equable motions are called *mean*; the unequable are justly called the *true*.

The mean place of the sun or moon is always forwarder than the true place, whilst the luminary is moving from its apogee to its perigee; and the true place is always forwarder than the mean, whilst the luminary is moving from its perigee to its apogee. In the former case, the anomaly is always less than six signs; and in the latter case, more.

It has been found, by a long series of observations, that the sun goes through the ecliptic, from the vernal equinox to the same equinox again, in 365 days 5 hours 48 minutes 55 seconds; from the first star of Aries to the same star again, in 365 days six hours nine minutes 24 seconds; and from his apogee to the same again, in 365 days six hours 14 minutes 0 seconds.—The first of these is called the *solar year*; the second, the *sidereal year*; and the third, the *anomalous year*. So that the solar year is 20 minutes 29 seconds shorter than the sidereal; and the sidereal year is 4 minutes 36 seconds shorter than the anomalous. Hence it appears, that the equinoctial point, or intersection of the ecliptic and equator at the beginning of Aries, goes backward with respect to the fixed stars, and that the sun's apogee goes forward.

It is also observed, that the moon goes through her orbit, from any given fixed star to the same star again, in 27 days 7 hours 43 minutes 4 seconds at a mean rate; from her apogee to her apogee again, in 27 days 13 hours 18 minutes 43 seconds; and from the sun to the sun again, in 29 days 12 hours 44 minutes $3\frac{1}{2}$ seconds. This shews, that the moon's apogee moves forward in the ecliptic, and that at a much quicker rate than the sun's apogee does; since the moon is five hours 55 minutes 39 seconds longer in revolving from her apogee to her apogee again, than from any star to the same star again.

The moon's orbit crosses the ecliptic in two opposite

250

Construction of tables for calculating eclipses.

248
Lunar eclipses difficultly observed.

249
Eclipses useful in determining longitudes, &c.

site points, which are called her *Nodes*: and it is observed, that the revolves sooner from any node to the node again, than from any star to the star again, by 2 hours 38 minutes 27 seconds; which shews, that her nodes move backward, or contrary to the order of signs, in the ecliptic.

The time in which the moon revolves from the sun to the sun again (or from change to change) is called a *Lunation*; which, according to Dr Pound's mean measures, would always consist of 29 days 12 hours 44 minutes 3 seconds 2 thirds 58 fourths, if the motions of the sun and moon were always equable. Hence, 12 mean lunations contain 354 days 8 hours 48 minutes 36 seconds 35 thirds 40 fourths, which is 10 days 21 hours 11 minutes 23 seconds 24 thirds 20 fourths less than the length of a common Julian year, consisting of 365 days 6 hours: and 13 mean lunations contain 383 days 21 hours 32 minutes 39 seconds 38 thirds 38 fourths, which exceeds the length of a common Julian year, by 18 days 15 hours 32 minutes 39 seconds 38 thirds 38 fourths.

The mean time of new moon being found for any given year and month, as supposé for March 1700, old stile, if this mean new moon falls later than the 11th day of March, then 12 mean lunations added to the time of this mean new moon will give the time of the mean new moon in March 1701, after having thrown off 365 days. But when the mean new moon happens to be before the 11th of March, we must add 13 mean lunations, in order to have the time of mean new moon in March the year following; always taking care to subtract 365 days in common years, and 366 days in leap-years, from the sum of this addition.

Thus, A. D. 1700, old stile, the time of mean new moon in March was the 8th day, at 16 hours 11 minutes 25 seconds after the noon of that day (viz. at 11 minutes 25 seconds past four in the morning of the 9th day, according to common reckoning). To this we must add 13 mean lunations, or 383 days 21 hours 32 minutes 39 seconds 38 thirds 38 fourths, and the sum will be 392 days 13 hours 44 minutes 4 seconds 38 thirds 38 fourths: from which subtract 365 days, because the year 1701 is a common year, and there will remain 27 days 13 hours 44 minutes 4 seconds 38 thirds 38 fourths for the time of mean new moon in March, A. D. 1701.

Carrying on this addition and subtraction till A. D. 1703, we find the time of mean new moon in March that year to be on the 6th day, at 7 hours 21 minutes 17 seconds 49 thirds 46 fourths past noon; to which add 13 mean lunations, and the sum will be 390 days 4 hours 53 minutes 57 seconds 28 thirds 20 fourths; from which subtract 366 days, because the year 1704 is a leap-year, and there will remain 24 days 4 hours 53 minutes 57 seconds 28 thirds 20 fourths, for the time of mean new moon in March, A. D. 1704.

In this manner was the first of the following tables constructed to seconds, thirds, and fourths; and then wrote out to the nearest seconds.—The reason why we chose to begin the year with March, was to avoid the inconvenience of adding a day to the tabular time in leap-years after February, or subtracting a day therefrom in January and February in those years; to which all tables of this kind are subject, which begin the year with January, in calculating the times of new or full

moons.

The mean anomalies of the sun and moon, and the sun's mean motion from the ascending node of the moon's orbit, are set down in Table III. from 1 to 13 mean lunations.—These numbers, for 13 lunations, being added to the radical anomalies of the sun and moon, and to the sun's mean distance from the ascending node, at the time of mean new moon in March 1700 (Table I.), will give their mean anomalies, and the sun's mean distance from the node, at the time of mean new moon in March 1701; and being added for 12 lunations to those for 1701, give them for the time of mean new moon in March 1702. And so on, as far as you please to continue the table (which is here carried on to the year 1800), always throwing off 12 signs when their sum exceeds 12, and setting down the remainder as the proper quantity.

If the numbers belonging to A. D. 1700 (in Table I.) be subtracted from those belonging to 1800, we shall have their whole differences in 100 complete Julian years; which accordingly we find to be 4 days 8 hours 10 minutes 52 seconds 15 thirds 40 fourths, with respect to the time of mean new moon.—These being added together 60 times (always taking care to throw off a whole lunation when the days exceed 29 $\frac{1}{2}$), make up 60 centuries, or 6000 years, as in Table VI. which was carried on to seconds, thirds, and fourths; and then wrote out to the nearest seconds. In the same manner were the respective anomalies and the sun's distance from the node found, for these centurial years; and then (for want of room) wrote out only to the nearest minutes, which is sufficient in whole centuries. By means of these two tables, we may find the time of any mean new moon in March, together with the anomalies of the sun and moon, and the sun's distance from the node, at these times, within the limits of 6000 years, either before or after any given year in the 18th century; and the mean time of any new or full moon in any given month after March, by means of the third and fourth tables, within the same limits, as shewn in the precepts for calculation.

Thus it would be a very easy matter to calculate the time of any new or full moon, if the sun and moon moved equably in all parts of their orbits.—But we have already shewn, that their places are never the same as they would be by equable motions, except when they are in apogee or perigee; which is, when their mean anomalies are either nothing, or six signs: and that their mean places are always forwarder than their true places, whilst the anomaly is less than six signs; and their true places are forwarder than the mean, whilst the anomaly is more.

Hence it is evident, that whilst the sun's anomaly is less than six signs, the moon will overtake him, or be opposite to him, sooner than she could if his motion were equable; and later whilst his anomaly is more than six signs.—The greatest difference that can possibly happen between the mean and true time of new or full moon, on account of the inequality of the sun's motion, is 3 hours 48 minutes 28 seconds: and that is, when the sun's anomaly is either 3 signs 1 degree, or 8 signs 29 degrees; sooner in the first case, and later in the last.—In all other signs and degrees of anomaly, the difference is gradually less, and vanishes when the anomaly is either nothing or six signs.

The sun is in his apogee on the 30th of June, and in his perigee on the 30th of December, in the present age: so that he is nearer the earth in our winter than in our summer.—The proportional difference of distance, deduced from the difference of the sun's apparent diameter at these times, is as 983 to 1017.

The moon's orbit is dilated in winter, and contracted in summer; therefore the lunations are longer in winter than in summer. The greatest difference is found to be 22 minutes 29 seconds; the lunations increasing gradually in length whilst the sun is moving from his apogee to his perigee, and decreasing in length whilst he is moving from his perigee to his apogee.—On this account, the moon will be later every time in coming to her conjunction with the sun, or being in opposition to him, from December till June, and sooner from June till December, than if her orbit had continued of the same size all the year round.

As both these differences depend on the sun's anomaly, they may be fitly put together into one table, and called *The annual or first equation of the mean to the true syzygy*, (see Table VII.) This equational difference is to be subtracted from the time of the mean syzygy when the sun's anomaly is less than six signs, and added when the anomaly is more.—At the greatest it is 4 hours 10 minutes 57 seconds, viz. 3 hours 48 minutes 28 seconds, on account of the sun's unequal motion, and 22 minutes 29 seconds, on account of the dilatation of the moon's orbit.

This compound equation would be sufficient for reducing the mean time of new or full moon to the true time thereof, if the moon's orbit were of a circular form, and her motion quite equable in it. But the moon's orbit is more elliptical than the sun's, and her motion in it so much the more unequal. The difference is so great, that she is sometimes in conjunction with the sun, or in opposition to him, sooner by 9 hours 47 minutes 54 seconds, than she would be if her motion were equable; and at other times as much later. The former happens when her mean anomaly is 9 signs 4 degrees, and the latter when it is 2 signs 26 degrees. See Table IX.

At different distances of the sun from the moon's apogee, the figure of the moon's orbit becomes different. It is longest of all, or most excentric, when the sun is in the same sign and degree either with the moon's apogee or perigee; shortest of all, or least excentric, when the sun's distance from the moon's apogee is either three signs or nine signs; and at a mean state when the distance is either 1 sign 15 degrees, 4 signs 15 degrees, 7 signs 15 degrees, or 10 signs 15 degrees. When the moon's orbit is at its greatest excentricity, her apogeeal distance from the earth's centre is to her perigeeal distance therefrom, as 1067 is to 933; when least excentric, as 1043 is to 957; and when at the mean state, as 1055 is to 945.

But the sun's distance from the moon's apogee is equal to the quantity of the moon's mean anomaly at the time of new moon, and by the addition of six signs it becomes equal in quantity to the moon's mean anomaly at the time of full moon. Therefore, a table may be constructed so as to answer to all the various inequalities depending on the different excentricities of the moon's orbit, in the syzygies; and called *The second equation of the mean to the true syzygy* (See Ta-

ble IX.); and the moon's anomaly, when equated by Table VIII. may be made the proper argument for taking out this second equation of time; which must be added to the former equated time, when the moon's anomaly is less than six signs, and subtracted when the anomaly is more.

There are several other inequalities in the moon's motion, which sometimes bring on the true syzygy a little sooner, and at other times keep it back a little later, than it would otherwise be: but they are so small, that they may be all omitted except two; the former of which (see Table X.) depends on the difference between the anomalies of the sun and moon in the syzygies, and the latter (see table XI.) depends on the sun's distance from the moon's nodes at these times.—The greatest difference arising from the former is 4 minutes 58 seconds; and from the latter, 1 minute 34 seconds.

The tables here inserted being calculated by Mr Ferguson according to the methods already given, he gives the following directions for their use.

252
Directions
for the use
of those
tables.

To calculate the true time of New or full Moon.

PRECEPT I. If the required time be within the limits of the 18th century, write out the mean time of new moon in March, for the proposed year, from Table I. in the old file, or from Table II. in the new; together with the mean anomalies of the sun and moon, and the sun's mean distance from the moon's ascending node. If you want the time of full moon in March, add the half lunation at the foot of Table III. with its anomalies, &c. to the former numbers, if the new moon falls before the 15th of March; but if it falls after, subtract the half lunation, with the anomalies, &c. belonging to it, from the former numbers, and write down the respective sums or remainders.

II. In these additions or subtractions, observe, that 60 seconds make a minute, 60 minutes make a degree, 30 degrees make a sign, and 12 signs make a circle. When you exceed 12 signs in addition, reject 12, and set down the remainder. When the number of signs to be subtracted is greater than the number you subtract from, add 12 signs to the lesser number, and then you will have a remainder to set down. In the tables signs are marked thus °, degrees thus °, minutes thus ', and seconds thus ''.

III. When the required new or full moon is in any given month after March, write out as many lunations with their anomalies, and the sun's distance from the node from Table III. as the given month is after March, setting them in order below the numbers taken out for March.

VI. Add all these together, and they will give the mean time of the required new or full moon, with the mean anomalies and sun's mean distance from the ascending node, which are the arguments for finding the proper equations.

V. With the number of days added together, enter Table IV. under the given month; and against that number you have the day of mean new or full moon in the left-hand column, which set before the hours, minutes, and seconds, already found.

But (as it will sometimes happen) if the said number of days falls short of any in the column under the given month, add one lunation and its anomalies, &c. (from Table III.) to the foresaid sums, and then you

will

will have a new sum of days wherewith to enter Table IV. under the given month, where you are sure to find it the second time, if the first falls short.

VI. With the signs and degrees of the sun's anomaly, enter Table VII. and therewith take out the annual or first equation for reducing the mean syzygy to the true; taking care to make proportions in the table for the odd minutes and seconds of anomaly, as the table gives the equation only to whole degrees.

Observe, in this and every other case of finding equations, that if the signs are at the head of the table, their degrees are at the left hand, and are reckoned downwards; but if the signs are at the foot of the table, their degrees are at the right hand, and are counted upward; the equation being in the body of the table, under or over the signs, in a collateral line with the degrees. The titles *Add* or *Subtract* at the head or foot of the tables where the signs are found, shew whether the equation is to be added to the mean time of new or full moon, or to be subtracted from it. In this table, the equation is to be subtracted, if the signs of the sun's anomaly are found at the head of the table; but it is to be added, if the signs are at the foot.

VII. With the signs and degrees of the sun's mean anomaly, enter Table VIII. and take out the equation of the moon's mean anomaly; subtract this equation from her mean anomaly, if the signs of the sun's anomaly be at the head of the table, but add it if they are at the foot; the result will be the moon's equated anomaly, with which enter Table IX. and take out the second equation for reducing the mean to the true time of new or full moon; adding this equation, if the signs of the moon's anomaly are at the head of the

table, but subtracting it if they are at the foot; and the result will give you the mean time of the required new or full moon twice equated, which will be sufficiently near for common almanacs.—But when you want to calculate an eclipse, the following equations must be used: thus,

VIII. Subtract the moon's equated anomaly from the sun's mean anomaly, and with the remainder in signs and degrees, enter Table X. and take out the third equation, applying it to the former equated time, as the titles, *Add* or *Subtract*, do direct.

IX. With the sun's mean distance from the ascending node enter Table XI. and take out the equation answering to that argument, adding it to, or subtracting it from, the former equated time, as the titles direct, and the result will give the time of new or full moon, agreeing with well regulated clocks or watches, very near the truth. But, to make it agree with the solar, or apparent time, you must apply the equation of natural days, taken from an equation table, as it is leap-year, or the first, second, or third after. This, however, unless in very nice calculations, needs not be regarded, as the difference between true and apparent time is never very considerable.

The method of calculating the time of any new or full moon without the limits of the 18th century, will be shewn further on. And a few examples compared with the precepts, will make the whole work plain.

N. B. The tables begin the day at noon, and reckon forward from thence to the noon following.—Thus, March the 31st, at 22 h. 30 min. 25 sec. of tabular time, is April 1st (in common reckoning) at 30 min. 25 sec. after 10 o'clock in the morning.

E X A M P L E I.

Required the true time of New Moon in April 1764, New Style?

253 To calculate the time of New and Full Moon in a given year and month of any particular century, between the Christian era and the 18th century.

PRECEPT I. Find a year of the same number in the 18th century with that of the year in the century proposed, and take out the mean time of new moon in March, old style, for that year, with the mean anomalies and sun's mean distance from the node at that time, as already taught.

II. Take as many complete centuries of years from Table VI. as, when subtracted from the above said year in the 18th century, will answer to the given year; and take out the first mean new moon and its anomalies, &c.

belonging to the said centuries, and set them below those taken out for March in the 18th century.

III. Subtract the numbers belonging to these centuries, from those of the 18th century, and the remainders will be the mean time and anomalies, &c. of new moon, in March, in the given year of the century proposed.—Then, work in all respects for the true time of new or full moon, as shewn in the above precepts and examples.

IV. If the days annexed to these centuries exceed the number of days from the beginning of March taken out in the 18th century, add a lunation and its anomalies, &c. from Table III. to the time and anomalies of new moon in March, and then proceed in all respects as above.—This circumstance happens in Example V.

E X A M P L E III.

Required the true time of Full Moon in April, *Old Style*, A. D. 30.

From 1730 subtract 1700 (or 17 centuries) and there remains 30.

By the Precepts.

	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s.	o	'	"	s	o	'	"	s	o	'	"
March 1730,	7	12	34	16	8	18	4	31	9	0	32	17	1	23	17	16
Add $\frac{1}{2}$ Lunation,	14	18	22	2	0	14	33	10	6	12	54	30	0	15	20	7
Full Moon,	22	6	56	18	9	2	37	41	3	13	26	47	2	8	37	23

Time thrice equated,	6	8	26	37												
Fourth Equation,	—	1	33													
True Full Moon, April,	6	8	25	4												

254

To calculate the true time of New or Full Moon in any given year and month before the Christian era.

PRECEPT I. Find a year in the 18th century, which being added to the given number of years before Christ diminished by one, shall make a number of complete centuries.

II. Find this number of centuries in Table VI. and

E X A M P L E IV.

Required the true time of New Moon in May, Old Stile, the year before Christ 585?

The years 584 added to 1716, make 2300, or 23 centuries.

By the Precepts.

	New moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s	o	'	"	s	o	'	"	s	o	'	"
March 1716, 2300 years subtraçt.	11	17	33	29	8	22	50	39	4	4	14	2	4	27	17	5
	11	5	57	53	11	19	47	0	1	5	59	0	7	25	27	0
March before Christ 585, Add 3 Lunations,	0	11	35	36	9	3	3	39	2	28	15	2	9	1	50	5
	88	14	12	9	2	27	18	58	2	17	27	1	3	2	0	42
May before Christ 585, First Equation,	28	1	47	45	0	0	22	37	5	15	42	3	0	3	50	47
			—	1	37			17			—	46				
Time once equated, Second Equation,	28	1	46	8	6	14	41	20	5	15	41	17	Sun from Node, and Arg. fourth equation.			
	+	2	15	1	Arg. 3 ^d equation.				Arg. 2 ^d equation.							
Time twice equated, Third Equation,	28	4	1	9												
	+	1	9													
Time thrice equated, Fourth Equation,	28	4	2	18												
			+	12												
True new moon,	28	4	2	30												

So the true time was May 28th, at 2 minutes 30 seconds past four in the afternoon.

255

These Tables are calculated for the meridian of London; but they will serve for any other place, by subtracting four minutes from the tabular time, for every

degree that the meridian of the given place is westward of London, or adding four minutes for every degree that the meridian of the given place is eastward: as in

E X A M P L E V.

Required the true time of Full Moon at Alexandria in Egypt in September, Old Stile, the year before Christ 201?

The years 200 added to 1800, make 2000, or 20 centuries.

By the Precepts.

	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s	o	'	"	s	o	'	"	s	o	'	"
March 1800, Add 1 lunation,	13	0	22	17	8	23	19	55	10	7	52	36	11	3	58	24
	29	12	44	3	0	29	6	19	0	25	49	0	1	0	40	14
From the sum, Subtraçt 2000 years,	42	13	6	20	9	22	26	14	11	3	41	36	0	4	38	38
	27	18	9	19	0	8	50	0	0	15	42	0	6	27	45	0
N. M. bef. Chr. 201, Add { 6 lunations, half lunations,	14	18	57	1	9	13	36	14	10	17	59	36	5	6	53	38
	177	4	24	18	5	24	37	56	5	4	54	3	6	4	1	24
	14	18	22	2	0	14	33	10	6	12	54	30	0	15	20	7
Full Moon, September, First equation,	22	17	43	21	3	22	47	20	10	5	48	9	11	26	15	9
			—	3	52	6	10	4	19	53	—	1	28	14	Sun from Node, and Argument fourth equation.	
Time once equated, Second equation,	22	13	51	15	5	18	27	25	10	4	19	55				
			—	8	25	4	Arg. 3 ^d equation.				Arg. 2 ^d equation.					
Time twice equated, Third equation,	22	5	26	11												
			—	58												
Time thrice equated, Fourth equation,	22	5	25	13												
			—	12												
True time at London, Add for Alexandria,	22	5	25	1												
				2	1	27										
True time there,	22	7	26	28												

Thus it appears, that the true time of Full Moon at Alexandria, in September, old stile, the year before Christ 201, was the 22^d day, at 26 minutes 28 seconds after seven in the evening.

EXAMPLE VI.

Required the true time of Full Moon at Babylon in October, Old Stile, the 4008 year before the first year of Christ, or 4007 before the year of his birth?

The years 4007 added to 1793, make 5800, or 58 centuries.

By the Precepts.

	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.					
	D.	H.	M.	S.	s	o	'	"	s	o	'	"	s	o	'	"		
March 1793,	30	9	13	55	9	10	16	11	8	7	37	58	7	6	18	26		
Subtract 5800 years,	15	12	38	7	10	21	35	0	6	24	43	0	9	13	1	0		
N. M. bef. Chr. 4007,	14	20	35	48	10	18	41	11	1	12	54	58	9	23	17	26		
Add { 7 lunations,	206	17	8	21	6	23	44	15	6	0	43	3	7	4	41	38

Second Equation,	+	8	29	21	Arg. 3 ^d equation.				Arg. 2 ^d equation.				fourth equation.					
Time twice equated,	22	16	22	6														
Third Equation,			—	4	10													
Time thrice equated,	22	16	17	56														
Fourth equation,				—	51													
Full Moon at London,	22	16	17	5														
Add for Babylon,				2	25	41												
True time there,	22	18	42	46														

So that, on the meridian of London, the true time was October 23^d, at 17 minutes 5 seconds past four in the morning; but at Babylon, the true time was October 23^d, at 42 minutes 46 seconds past six in the morning.—This is supposed by some to have been the year of the creation.

256 To calculate the true time of new or full moon in any given year and month after the 18th century.

PRECEPT I. Find a year of the same number in the 18th century with that of the year proposed, and take out the mean time and anomalies, &c. of new moon in March, old stile, for that year, in Table I.

II. Take so many years from Table VI. as when added to the abovementioned year in the 18th century

will answer to the given year in which the new or full moon is required; and take out the first new moon, with its anomalies for these complete centuries.

III. Add all these together, and then work in all respects as above shewn, only remember to subtract a lunation and its anomalies, when the above said addition carries the new moon beyond the 31st of March; as in the following example.

EXAMPLE VII.

Required the true time of New Moon in July, Old Stile, A. D. 2180?

Four centuries (or 400 years) added to A. D. 1780, make 2180.

By the Precepts.

True time, July,	8	6	22	55													

True time, July 8th, at 22 minutes 55 seconds past six in the evening.

In keeping by the old stile, we are always sure to be right, by adding or subtracting whole hundreds of years to or from any given year in the 18th century. But in the new stile we may be very apt to make mistakes, on account of the leap-year's not coming in regularly every fourth year: and therefore, when we go without the limits of the 18th century, we had best keep to the old stile, and at the end of the calculation reduce the time to the new. Thus, in the 22^d century, there will be fourteen days difference between the stiles; and therefore, the true time of new moon in this last example being reduced to the new stile, will be the 22^d of July, at 22 minutes 55 seconds past six in the evening.

257 To calculate the true place of the Sun for any given moment of time.

PRECEPT I. In Table XII. find the next lesser year in number to that in which the sun's place is sought, and write out his mean longitude and anomaly answering thereto: to which add his mean motion and

So that in the meridian of London, the sun was then just entering the sign $\underline{\text{Libra}}$, and consequently was upon the point of the autumnal equinox.

If to the above time of the autumnal equinox at London, we add 2 hours, 25 minutes 41 seconds for the longitude of Babylon, we shall have for the time of the same equinox, at that place, October 23^d, at 19 hours 22 minutes 41 seconds; which, in the common way of reckoning, is October 24th, at 22 minutes 41 seconds past seven in the morning.

And it appears by Example VI. that in the same year, the true time of full moon at Babylon was October 23^d, at 42 minutes 46 seconds after six in the morning; so that the autumnal equinox was on the day next after the day of full moon.—The dominical letter for that year was G, and consequently the 24th of October was on a Wednesday.

grees, shews that the sun must then be eclipsed.

And now we shall shew how to project this, or any other eclipse, either of the sun or moon.

To project an Eclipse of the Sun.

In order to this, we must find the ten following elements, by means of the tables.

1. The true time of conjunction of the sun and moon; and at that time.
2. The semidiameter of the earth's disk, as seen from the moon, which is equal to the moon's horizontal parallax.
3. The sun's distance from the solstitial colure to which he is then nearest.
4. The sun's declination.
5. The angle of the moon's visible path with the ecliptic.
6. The moon's latitude.
7. The moon's true horary motion from the sun.
8. The sun's semidiameter.
9. The moon's.
10. The semidiameter of the penumbra.

We shall now proceed to find these elements for the sun's eclipse in April 1764.

To find the true time of new moon. This, by Example I. p. 829, is found to be on the first day of the said month, at 30 minutes 25 seconds after ten in the morning.

To find the moon's horizontal parallax, or semidiameter of the earth's disk, as seen from the moon. Enter Table XVII. with the signs and degrees of the moon's anomaly (making proportions, because the anomaly is in the table only to every 6th degree), and thereby take out the moon's horizontal parallax; which for the above time, answering to the anomaly 11s 9° 24' 21", is 54' 53".

To find the sun's distance from the nearest solstice, viz. the beginning of Cancer, which is 38 or 90° from the beginning of Aries. It appears by Example I. on p. 833, (where the sun's place is calculated to the above time of new moon) that the sun's longitude from the beginning of Aries is then 08 12° 10' 12": that is, the sun's place at that time is ♉ 8° 10' 12".

	8	0	0	0
Therefore from	-	-	3	0
Subtract the sun's longitude or place	0	12	10	12

Remains the sun's distance from the solstice $\overline{=}$ 2 17 49 48 Or 77° 49' 48"; each sign containing 30 degrees.

To find the sun's declination. Enter Table XIV. with the signs and degrees of the sun's true place, viz. 08 12°, and making proportions for the 10' 12", take out the sun's declination answering to his true place, and it will be found to be 4° 49' north.

To find the moon's latitude. This depends on her distance from her ascending node, which is the same as the sun's distance from it at the time of new moon; and is thereby found in Table XVI.

But we have already found, that the sun's equated distance from the ascending node, at the time of new moon in April 1764, is 08 7° 42' 14". See above.

Therefore, enter Table XVI. with 0 signs at the top, and 7 and 8 degrees at the left hand, and take out 36' and 39", the latitude for 7°; and 41' 51", the latitude for 8°: and by making proportions between these latitudes for the 42' 14", by which the moon's distance from the node exceeds 7 degrees; her true latitude will be found to be 40' 18" north ascending.

To find the moon's true horary motion from the sun.

To find the sun's distance from the moon's ascending node, at the time of any given new or full moon; and consequently, to know whether there is an eclipse at that time, or not.

The sun's distance from the moon's ascending node is the argument for finding the moon's fourth equation in the syzygies, and therefore it is taken into all the foregoing examples in finding the times thereof. Thus, at the time of mean new moon in April 1764, the sun's mean distance from the ascending node, is 05° 35' 2". See Example I. p. 829.

The descending node is opposite to the ascending one, and they are just six signs distant from each other.

When the sun is within 17 degrees of either of the nodes at the time of new moon, he will be eclipsed at that time; and when he is within 12 degrees of either of the nodes at the time of full moon, the moon will be then eclipsed. Thus we find, that there will be an eclipse of the sun at the time of new moon in April 1764.

But the true time of that new moon comes out by the equations to be 50 minutes 46 seconds later than the mean time thereof, by comparing these times in the above example; and therefore, we must add the sun's motion from the node during that interval, to the above mean distance 05° 35' 2", which motion is found in Table XII. for 50 minutes 46 seconds, to be 2' 12". And to this we must apply the equation of the sun's mean distance from the node, in Table XV. found by the sun's anomaly, which, at the mean time of new moon in Example I. is 03 1° 26' 19"; and then we shall have the sun's true distance from the node, at the true time of new moon, as follows:

	Sun from Node.
	8 0 ' "
At the mean time of new moon in ?	0 5 35 2
April 1764	} 2 10 2

With the moon's anomaly, viz. $11^{\circ} 9' 24'' 11''$, enter Table XVII. and take out the moon's horary motion; which, by making proportions in that table, will be found to be $3' 22''$. Then, with the sun's anomaly, $9^{\circ} 1' 16' 19''$, take out his horary motion $2' 28''$ from the same table: and subtracting the latter from the former, there will remain $27' 54''$ for the moon's true horary motion from the sun.

266 7. To find the angle of the moon's visible path with the ecliptic. This, in the projection of eclipses, may be always rated at $5^{\circ} 35'$, without any sensible error.

267 8, 9. To find the semidiameters of the sun and moon. These are found in the same table, and by the same arguments, as their horary motions. In the present case, the sun's anomaly gives his semidiameter $16' 6''$, and the moon's anomaly gives her semidiameter $14' 57''$.

268 10. To find the semidiameter of the penumbra. Add the moon's semidiameter to the sun's, and their sum will be the semidiameter of the penumbra, viz. $31' 3''$.

Now collect these elements, that they may be found the more readily when they are wanted in the construction of this eclipse.

To project an eclipse of the sun geometrically.

269 Plate L. 1. Make a scale of any convenient length, as AC, and divide it into as many equal parts as the earth's semidisk contains minutes of a degree; which, at the time of the eclipse in April 1764, is $54^{\circ} 53''$. Then, with the whole length of the scale as a radius, describe the semicircle AMB upon the centre C; which semicircle shall represent the northern half of the earth's enlightened disk, as seen from the sun.

Upon the centre C raise the straight line CH, perpendicular to the diameter ACB; fo' ACB shall be a part of the ecliptic, and CH its axis.

Being provided with a good sector, open it to the radius CA in the line of chords; and taking from thence the chord of $23\frac{1}{2}$ degrees in your compasses, set it off both ways from H, to g and to h, in the periphery of the semidisk; and draw the straight line gVh, in which the north pole of the disk will always be found.

When the sun is in Aries, Taurus, Gemini, Cancer, Leo, and Virgo, the north pole of the earth is enlightened by the sun: but whilst the sun is in the other six signs, the fourth pole is enlightened, and the north pole is in the dark.

And when the sun is in Capricorn, Aquarius, Pifces, Aries, Taurus, and Gemini, the northern half of the earth's axis C XII P lies to the right hand of the axis of the ecliptic, as seen from the sun; and to the

left hand, whilst the sun is in the other six signs.

Open the sector till the radius (or distance of two 90's) of the fines be equal to the length of VA, and take the sine of the sun's distance from the solstice ($77^{\circ} 49' 48''$) as nearly as you can guess, in your compasses, from the line of fines, and set off that distance from V to P in the line gVh, because the earth's axis lies to the right hand of the axis of the ecliptic in this case, the sun being in Aries; and draw the straight line C XII P for the earth's axis, of which P is the north pole. If the earth's axis had lain to the left hand from the axis of the ecliptic, the distance VP would have been set off from V towards g.

To draw the parallel of latitude of any given place, as suppos'd London, or the path of that place on the earth's enlightened disk as seen from the sun, from sunrise till sun-set, take the following method.

Subtract the latitude of London, $51^{\circ} \frac{1}{2}$ from 90° , and the remainder $38^{\circ} \frac{1}{2}$ will be the co-latitude, which take in your compasses from the line of chords, making CA or CB the radius, and set it from b (where the earth's axis meets the periphery of the disk) to VI and VI, and draw the occult or dotted line VI K VI. Then, from the points where this line meets the earth's disk, set off the chord of the sun's declination $4^{\circ} 49'$ to D and F, and to E and G, and connect these points by the two occult lines F XII G and DLE.

Bisect LK XII in K, and through the point K draw the black line VI K VI. Then making CB the radius of a line of fines on the sector, take the co-latitude of London $38^{\circ} \frac{1}{2}$ from the fines in your compasses, and set it both ways from K, to VI and VI.—These hours will be just in the edge of the disk at the equinoxes, but at no other time in the whole year.

With the extent K VI taken into your compasses, set one foot in K (in the black line below the occult one) as a centre, and with the other foot describe the semicircle VI 7 8 9 10, &c. and divide it into 12 equal parts. Then, from these points of division, draw the occult lines 7p, 8o, 9n, &c. parallel to the earth's axis C XII P.

With the small extent K XII as a radius, describe the quadrantal arc XII; and divide it into six equal parts, as XII a, ab, bc, cd, de, and ef; and through the division-points a, b, c, d, e draw the occult lines VII e V, VIII d IV, IX c III, X b II, and XI a I, all parallel to VI K VI, and meeting the former occult lines 7p, 8o, &c. in the points VII VIII IX X XI, V IV III II and I: which points shall mark the several situations of London on the earth's disk, at these hours respectively, as seen from the sun; and the elliptic curve VI VII VIII, &c. being drawn through these points, shall represent the parallel of latitude, or path of London on the disk, as seen from the sun, from its rising to its setting.

N. B. If the sun's declination had been south, the diurnal path of London would have been on the upper side of the line VI K VI, and would have touched the line DLE in L. It is requisite to divide the horary spaces into quarters (as some are in the figure), and, if possible, into minutes also.

Make CB the radius of a line of chords on the sector, and taking therefrom the chord of $5^{\circ} 35'$, the angle of the moon's visible path with the ecliptic, set it off from H to M on the left hand of CH, the axis

of the ecliptic, because the moon's latitude is north ascending. Then draw CM for the axis of the moon's orbit, and bisect the angle MCH by the right line Cz. If the moon's latitude had been north descending, the axis of her orbit would have been on the right hand from the axis of the ecliptic.—N. B. The axis of the moon's orbit lies the same way when her latitude is south ascending, as when it is north ascending; and the same way when south descending, as when north descending.

Take the moon's latitude $40^{\circ} 18'$ from the scale CA in your compasses, and set it from *i* to *x* in the bisecting line Cz, making *ix* parallel to Cy: and thro' *x*, at right angles to the axis of the moon's orbit CM, draw the straight line N *wxyS* for the path of the penumbra's centre over the earth's disk.—The point *w*, in the axis of the moon's orbit, is that where the penumbra's centre approaches nearest to the centre of the earth's disk, and consequently is the middle of the general eclipse: the point *x* is that where the conjunction of the sun and moon falls, according to equal time by the tables; and the point *y* is the ecliptical conjunction of the sun and moon.

Take the moon's true horary motion from the sun, $27' 54''$, in your compasses, from the scale CA (every division of which is a minute of a degree), and with that extent make marks along the path of the penumbra's centre; and divide each space from mark to mark into sixty equal parts or horary minutes, by dots; and set the hours to every 60th minute in such a manner, that the dot signifying the instant of new moon by the tables, may fall into the point *x*, half way between the axis of the moon's orbit and the axis of the ecliptic; and then, the rest of the dots will shew the points of the earth's disk, where the penumbra's centre is at the instants denoted by them, in its transit over the earth.

Apply one side of a square to the line of the penumbra's path, and move the square backwards and forwards until the other side of it cuts the same hour and minute (as at *m* and *n*) both in the path of London, and in the path of the penumbra's centre; and the particular minute or instant which the square cuts at the same time in both paths, shall be the instant of the visible conjunction of the sun and moon, or greatest obscuration of the sun, at the place for which the construction is made, namely London, in the present example; and this instant is at $47\frac{1}{2}$ minutes past ten o'clock in the morning; which is 17 minutes five seconds later than the tabular time of true conjunction.

Take the sun's semidiameter, $16' 6''$, in your compasses, from the scale CA, and setting one foot in the path of London, at *m*, namely at $47\frac{1}{2}$ minutes past ten, with the other foot describe the circle UY, which shall represent the sun's disk as seen from London at the greatest obscuration.—Then take the moon's semidiameter, $14' 57''$, in your compasses from the same scale; and setting one foot in the path of the penumbra's centre at *m*, in the $47\frac{1}{2}$ minute after ten, with the other foot describe the circle TY for the moon's disk, as seen from London, at the time when the eclipse is at the greatest, and the portion of the sun's disk which is hid or cut off by the moon's, will shew the quantity of the eclipse at that time; which quantity may be

measured on a line equal to the sun's diameter, and divided into 12 equal parts for digits.

Lastly, take the semidiameter of the penumbra, $31' 3''$, from the scale CA in your compasses; and setting one foot in the line of the penumbra's central path, on the left hand from the axis of the ecliptic, direct the other foot toward the path of London; and carry that extent backwards and forwards, till both the points of the compasses fall into the same instants in both the paths: and these instants will denote the time when the eclipse begins at London.—Then, do the like on the right hand of the axis of the ecliptic; and where the points of the compasses fall into the same instants in both the paths, they will shew at what time the eclipse ends at London.

These trials give 20 minutes after nine in the morning for the beginning of the eclipse at London, at the points N and O; $47\frac{1}{2}$ minutes after ten, at the points *m* and *n*, for the time of greatest obscuration; and 18 minutes after twelve, at R and S, for the time when the eclipse ends; according to mean or equal time.

From these times we must subtract the equation of natural days, viz. three minutes 48 seconds, in leap-year April 1, and we shall have the apparent times; namely, nine hours 16 minutes 12 seconds for the beginning of the eclipse, ten hours 43 minutes 42 seconds for the time of greatest obscuration, and 12 hours 14 minutes 12 seconds for the time when the eclipse ends.—But the best way is to apply this equation to the true equal time of new moon, before the projection be begun; as is done in example I. For the motion or position of places on the earth's disk answer to apparent or solar time.

In this construction it is supposed, that the angle under which the moon's disk is seen, during the whole time of the eclipse, continues invariably the same; and that the moon's motion is uniform and rectilineal during that time. But these suppositions do not exactly agree with the truth; and therefore, supposing the elements given by the tables to be accurate, yet the times and phases of the eclipse, deduced from its construction, will not answer exactly to what passeth in the heavens; but may be at least two or three minutes wrong, though done with the greatest care. Moreover, the paths of all places of considerable latitudes, are nearer the centre of the earth's disk, as seen from the sun, than those constructions make them: because the disk is projected as if the earth were a perfect sphere although it is known to be a spheroid. Consequently, the moon's shadow will go farther northward in all places of northern latitude, and farther southward in all places of southern latitude, than it is shewn to do in these projections.—According to Meyer's Tables, this eclipse was about a quarter of an hour sooner than either these tables, or Mr Flamsteed's, or Dr Halley's make it; and was not annular at London. But M. de la Caille's make it almost central.

The projection of lunar eclipses.

When the moon is within 12 degrees of either of her nodes at the time when she is full, she will be eclipsed, otherwise not.

We find by example second, page 830, that at the time of mean full moon in May 1762, the sun's distance from the ascending node was only $4^{\circ} 49' 35''$; and

and the moon being then oppofite to the fun, muft have been juft as near her defcending node, and was there fore eclipfed.

The elements for conftituting an eclipfe of the moon, are eight in number, as follow:

1. The true time of full moon; and at that time,
2. The moon's horizontal parallax.
3. The fun's femidiameter.
4. The moon's.
5. The femidiameter of the earth's fhadow at the moon.
6. The moon's latitude.
7. The angle of the moon's vifible path with the ecliptic.
8. The moon's true horary motion from the fun.—Therefore,

1. To find the true time of new or full moon. Work as already taught in the precepts.—Thus we have the true time of full moon in May 1762 (fee example II. page 830) on the 8th day, at 50 minutes 50 feconds paft three o'clock in the morning.

2. To find the moon's horizontal parallax. Enter Table XVII. with the moon's mean anomaly (at the above full) 9° 2' 42' 42", and thereby take out her horizontal parallax; which by making the requifite proportions, will be found to be 57' 23".

3, 4. To find the femidiameters of the fun and moon. Enter Table XVII. with their refpective anomalies, the fun's being 10° 7' 27' 45" (by the above example) and the moon's 9° 2' 42' 42"; and thereby take out their refpective femidiameters; the fun's 15' 56", and the moon's 15' 38".

5. To find the femidiameter of the earth's fhadow at the moon. Add the fun's horizontal parallax, which is always 10", to the moon's which in the prefent cafe is 57' 23", the fum will be 57' 33", from which fubtract the fun's femidiameter 15' 56", and there will remain 41' 37" for the femidiameter of that part of the earth's fhadow which the moon then paffes through.

6. To find the moon's latitude. Find the fun's true diftance from the afcending node (as already taught in page 834) at the true time of full moon; and this diftance increafed by fix figns, will be the moon's true diftance from the fame node; and confequently the argument for finding her true latitude, as fhewn in page 834.

Thus, in example II. the fun's mean diftance from the afcending node was 0° 4' 49' 35", at the time of mean full moon: but it appears by the example, that the true time thereof was fix hours 33 minutes 38 feconds fooner than the mean time; and therefore we muft fubtract the fun's motion from the node (found in Table XII.) during this interval, from the above mean diftance 0° 4' 49' 35", in order to have his mean diftance from it at the true time of full moon. Then to this apply the equation of his mean diftance from the node, found in Table XV. by his mean anomaly 10° 7' 27' 45"; and laftly add fix figns: fo fhall the moon's true diftance from the afcending node be found as follows:

Sun from node at mean full moon	0	4	49	35
His motion from it in	}	6 hours	15	35
		33 minutes	1	26
		38 feconds		2
Sum, fubtract from the uppermoft line			17	3
Remains his mean diftance at true full moon	}	0	4	32 32

VOL. II.

Equation of his mean diftance, add	5	0	1	00
			1	38 00
Sun's true diftance from the node	0	6	10	32
To which add	6	0	0	00
And the fum will be	6	6	10	32

Which is the moon's true diftance from her afcending node at the true time of her being full; and confequently the argument for finding her true latitude at that time.—Therefore, with this argument, enter Table XVI. making proportions between the latitudes belonging to the 6th and 7th degree of the argument at the left hand (the figns being at top) for the 10' 32" and it will give 32' 21" for the moon's true latitude, which appears by the table to be fourth defcending.

7. To find the angle of the moon's vifible path with the ecliptic. This may be flated at 5° 35', without any error of confequence in the projection of the eclipfe.

8. To find the moon's true horary motion from the fun. With their refpective anomalies take out their horary motions from Table XVII. and the fun's horary motion fubtracted from the moon's, leaves remaining the moon's true horary motion from the fun: in the prefent cafe 30' 52".

Now collect thefe elements together for ufe.

	D.	H.	M.	S.
1. True time of full moon in } May, 1762	8	3	50	50
2. Moon's horizontal parallax	0	57	23	"
3. Sun's femidiameter	0	15	56	"
4. Moon's femidiameter	0	15	38	"
5. Semidiameter of the earth's fhadow } at the moon	0	41	37	"
6. Moon's true latitude, fouth defcending	0	32	21	"
7. Angle of her vifible path with the } ecliptic	5	35	0	"
8. Her true horary motion from the fun	0	30	52	"

Thefe elements being found for the conftituting of the moon's eclipfe in May, 1762, proceed as follows:

Make a fcale of any convenient length, as W X, Plate L. and divide it into 60 equal parts, each part ftanding for a minute of a degree.

Draw the right line ACB (fig. 4.) for part of the ecliptic, and CD perpendicular thereto for the fourth part of its axis; the moon having fouth latitude.

Add the femidiameters of the moon and earth's fhadow together, which, in this eclipfe, will make 57' 15"; and take this from the fcale in your compaffes, and fetting one foot in the point C as a centre, with the other foot defcribe the femicircle ADB; in one point of which the moon's centre will be at the beginning of the eclipfe, and in another at the end thereof.

Take the femidiameter of the earth's fhadow, 41' 37", in your compaffes from the fcale, and fetting one foot in the centre C, with the other foot defcribe the femicircle KLM for the fouthern half of the earth's fhadow, becaufe the moon's latitude is fouth in this eclipfe.

5 N

Make

Make CD equal to the radius of a line of chords on the sector, and set off the angle of the moon's visible path with the ecliptic, $5^{\circ} 35'$, from D to E, and draw the right line CFE for the southern half of the axis of the moon's orbit, lying to the right hand from the axis of the ecliptic CD, because the moon's latitude is south descending.—It would have been the same way (on the other side of the ecliptic) if her latitude had been north descending; but contrary in both cases, if her latitude had been either north ascending or south ascending.

Bisect the angle DCE by the right line Cg; in which line the true equal time of opposition of the sun and moon falls, as given by the tables.

Take the moon's latitude, $32^{\circ} 21'$, from the scale with your compasses, and set it from C to G, in the line CG; and through the point G, at right angles to CFE, draw the right line PHGFN for the path of the moon's centre. Then, F shall be the point in the earth's shadow, where the moon's centre is at the middle of the eclipse; G, the point where her centre is at the tabular time of her being full; and H, the point where her centre is at the instant of her ecliptical opposition.

Take the moon's horary motion from the sun, $30^{\circ} 52'$, in your compasses from the scale; and with that extent make marks along the line of the moon's path PGN: then divide each space from mark to mark, into 60 equal parts, or horary minutes, and set the hours to the proper dots in such a manner, that the dot signifying the instant of full moon (viz. 50 minutes 50 seconds after III in the morning) may be in the point G, where the line of the moon's path cuts the line that bisects the angle DCE.

Take the moon's semidiameter, $15^{\circ} 38'$, in your compasses from the scale, and with that extent, as a radius, upon the points N, F, and P, as centres, describe the circle Q for the moon at the beginning of the eclipse, when she touches the earth's shadow at V; the circle R for the moon at the middle of the eclipse; and the circle S for the moon at the end of the eclipse, just leaving the earth's shadow at W.

The point N denotes the instant when the eclipse began, namely, at 15 minutes 10 seconds after II in the morning; the point F the middle of the eclipse at 47 minutes 44 seconds past III; and the point P the end of the eclipse, at 18 minutes after V.—At the greatest obscuration the moon was 10 digits eclipsed.

Sect. XI. *The method of finding the Longitude by the Eclipses of Jupiter's Satellites; The amazing Velocity of Light demonstrated by these Eclipses; and of Cometary Eclipses.*

In the former section, having explained at great length, how eclipses of the sun and moon happen at certain times, it must be evident, that similar eclipses will be observed by the inhabitants of Jupiter and Saturn, which are attended by so many moons. These eclipses indeed very frequently happen to the satellites of Jupiter; and as they are of the greatest service in determining the longitudes of places on this earth, astronomers have been at great pains to calculate tables for the eclipses of these satellites by their primary, for the satellites themselves have never been observed to eclipse one another. The construction of such tables

is indeed much easier for these satellites than of any other celestial bodies, as their motions are much more regular.

The English tables are calculated for the meridian of Greenwich, and by these it is very easy to find how many degrees of longitude any place is distant either east or west from Greenwich; for, let an observer, who has these tables, with a good telescope and a well-regulated clock at any other place of the earth, observe the beginning or ending of an eclipse of one of Jupiter's satellites, and note the precise moment of time that he saw the satellite either immerge into, or emerge out of the shadow, and compare that time with the time shewn by the tables for Greenwich; then 15 degrees difference of longitude being allowed for every hour's difference of time, will give the longitude of that place from Greenwich; and if there be any odd minutes of time, for every minute a quarter of a degree, east or west, must be allowed, as the time of observation is later or earlier than the time shewn by the tables. Such eclipses are very convenient for this purpose at land, because they happen almost every day; but are of no use at sea, because the rolling of the ship hinders all nice telescopical observations.

To explain this by a figure, in Plate XLVI. fig. 1. let J be Jupiter, K, L, M, N his four satellites in their respective orbits, 1, 2, 3, 4; and let the earth be at F (suppose in November, altho' that month is no otherwise material than to find the earth readily in this scheme, where it is shewn in eight different parts of the orbit). Let Q be a place on the meridian of Greenwich, and R a place on some other meridian eastward from Greenwich. Let a person at R observe the instantaneous vanishing of the first satellite K into Jupiter's shadow, suppose at three o'clock in the morning; but by the tables he finds the immersion of that satellite to be at midnight at Greenwich; he then can immediately determine, that as there are three hours difference of time between Q and R, and that R is three hours forwarder in reckoning than Q, it must be 45 degrees of east longitude from the meridian of Q. Were this method as practicable at sea as at land, any sailor might almost as easily, and with equal certainty, find the longitude as the latitude.

Whilst the earth is going from C to F in its orbit, only the immersions of Jupiter's satellites into his shadow are generally seen; and their emersions out of it while the earth goes from G to B. Indeed, both these appearances may be seen of the second, third, and fourth satellite when eclipsed, whilst the earth is between D and E, or between G and A; but never of the first satellite, on account of the smallness of its orbit and the bulk of Jupiter, except only when Jupiter is directly opposite to the sun, that is, when the earth is at G; and even then, strictly speaking, we cannot see either the immersions or emersions of any of his satellites, because his body being directly between us and his conical shadow, his satellites are hid by his body a few moments before they touch his shadow; and are quite emerg'd from thence before we can see them, as it were just dropping from him. And when the earth is at C, the sun, being between it and Jupiter, hides both him and his moons from us.

In this diagram, the orbits of Jupiter's moons are drawn

drawn in true proportion to his diameter; but in proportion to the earth's orbit, they are drawn vastly too large.

In whatever month of the year Jupiter is in conjunction with the sun, or in opposition to him, in the next year it will be a month later at least. For whilst the earth goes once round the sun, Jupiter describes a twelfth part of his orbit. And therefore, when the earth has finished its annual period, from being in a line with the sun and Jupiter, it must go as much forward as Jupiter has moved in that time, to overtake him again; just like the minute hand of a watch, which must, from any conjunction with the hour-hand, go once round the dial-plate and somewhat above a twelfth part more, to overtake the hour-hand again.

284
Velocity of light.

It is found by observation, that when the earth is between the sun and Jupiter, as at G, his satellites are eclipsed about 8 minutes sooner than they should be according to the tables; and when the earth is at B or C, these eclipses happen about 8 minutes later than the tables predict them. Hence it is undeniably certain, that the motion of light is not instantaneous, since it takes about 16½ minutes of time to go through a space equal to the diameter of the earth's orbit, which is 180,000,000 of miles in length; and consequently the particles of light fly almost 200,000 miles every second of time, which is above a million of times swifter than the motion of a cannon bullet. And as light is 16½ minutes in travelling across the earth's orbit, it must be 8½ minutes in coming from the sun to us: therefore if the sun were annihilated, we should see him for 8½ minutes after; and if he were again created, he would be 8½ minutes old before we could see him.

To illustrate this progressive motion of light, (Plate XLVI. fig. 2.) let A and B be the earth in two different parts of its orbit, whose distance from each other is 95,000,000 of miles, equal to the earth's distance from the sun S. It is plain, that if the motion of light were instantaneous, the satellite I would appear to enter into Jupiter's shadow FF at the same moment of time to a spectator in A, as to another in B. But by many years observations it has been found, that the immersion of the satellite into the shadow is seen 8½ minutes sooner when the earth is at B, than when it is at A. And so, as Mr Romer first discovered, the motion of light is thereby proved to be progressive, and not instantaneous, as was formerly believed. It is easy to compute in what time the earth moves from A to B; for the chord of 60 degrees of any circle is equal to the semidiameter of that circle; and as the earth goes through all the 360 degrees of its orbit in a year, it goes through 60 of those degrees in about 61 days. Therefore, if on any given day, suppose the first of June, the earth is at A, on the first of August it will be at B; the chord, or straight line AB, being equal to DS the radius of the earth's orbit, the same with AS its distance from the sun.

As the earth moves from D to C, through the side AB of its orbit, it is constantly meeting the light of Jupiter's satellites sooner, which occasions an apparent acceleration of their eclipses; and as it moves through the other half H of its orbit, from C to D, it is receding from their light, which occasions an apparent retardation of their eclipses, because their light is then

longer before it overtakes the earth.

That these accelerations of the immersions of Jupiter's satellites into his shadow, as the earth approaches towards Jupiter, and the retardations of their emersions out of his shadow, as the earth is going from him, are not occasioned by any inequality arising from the motions of the satellites in excentric orbits, is plain, because it affects them all alike, in whatever parts of their orbits they are eclipsed. Besides, they go often round their orbits every year, and their motions are no way commensurate to the earth's. Therefore, a phenomenon not to be accounted for from the real motions of the satellites, but so easily deducible from the earth's motion, and so answerable thereto, must be allowed to result from it. This affords one very good proof of the earth's annual motion.

285
Acceleration of the eclipses not owing to any inequality in the motions of the satellites.

From what we have said in general concerning eclipses, it is plain that secondary planets are not the only bodies that may occasion them. The primary planets would eclipse one another, were it not for their great distances; but as the comets are not subject to the same laws with the planets, it is possible they may sometimes approach so near to the primary planets, as to cause an eclipse of the sun to those planets; and as the body of a comet bears a much larger proportion to the bulk of a primary planet than any secondary, it is plain that a cometary eclipse would both be of much longer continuance, and attended with much greater darkness, than that occasioned by a secondary planet. This behoved to be the case at any rate: but if we suppose the primary planet and comet to be moving both the same way, the duration of such an eclipse would be prodigiously lengthened; and thus, instead of four minutes, the sun might be totally darkened to the inhabitants of certain places for as many hours. Hence we may account for that prodigious darkness which we sometimes read of in history at times when no eclipse of the sun by the moon could possibly happen (see N^o 12). It is remarkable, however, that no comet hath ever been observed passing over the disk of the sun like a spot, as Venus and Mercury are; yet this must certainly happen, when the comet is in its perihelion, and the earth on the same side of its annual orbit. Such a phenomenon well deserves the watchful attention of astronomers, as it would be a greater confirmation of the planetary nature of comets, than any thing hitherto observed.

286
Eclipses by comets.

Scct. XII. *Of the Division of Time. A perpetual Table of New Moons. The Times of the Birth and Death of CHRIST. A Table of remarkable Eras or Events.*

THE parts of time are *Seconds, Minutes, Hours, Days, Years, Cycles, Ages, and Periods.* 287

The original standard, or integral measure of time, is a year; which is determined by the revolution of some celestial body in its orbit, viz. the sun or moon. 288

The time measured by the sun's revolution in the ecliptic, from any equinox or solstice to the same again, is called the *Solar or Tropical Year*, which contains 365 days, 5 hours, 48 minutes, 57 seconds; and is the only proper or natural year, because it always keeps the same seasons to the same months. 289

The quantity of time measured by the sun's revolution, 290

tion, as from any fixed star to the same star again, is called the *sidereal year*; which contains 365 days 6 hours 9 minutes $14\frac{1}{2}$ seconds; and is 20 minutes $17\frac{1}{2}$ seconds longer than the true solar year.

291 The time measured by 12 revolutions of the moon, from the sun to the sun again, is called the *lunar year*: it contains 354 days 8 hours 48 minutes 36 seconds; and is therefore 10 days 21 hours 0 minutes 21 seconds shorter than the solar year. This is the foundation of the *epact*.

292 Civil year. The *civil year* is that which is in common use among the different nations of the world; of which, some reckon by the lunar, but most by the solar. The civil solar year contains 365 days, for three years running, which are called *common years*; and then comes in what is called the *bisextile* or *leap-year*, which contains 366 days. This is also called the *Julian year*, on account of Julius Cæsar, who appointed the intercalary day every fourth year, thinking thereby to make the civil and solar year keep pace together. And this day, being added to the 23^d of February, which in the Roman calendar was the sixth of the kalends of March, that sixth day was twice reckoned, or the 23^d and 24th were reckoned as one day, and was called *bis sextus dies*; and thence came the name *bisextile* for that year. But in our common almanacs this day is added at the end of February.

293 Civil lunar year. The *civil lunar year* is also common or intercalary. The common year consists of 12 lunations, which contain 354 days; at the end of which, the year begins again. The *intercalary*, or *embolismic year* is that wherein a month was added, to adjust the lunar year to the solar. This method was used by the Jews, who kept their account by the lunar motions. But by intercalating no more than a month of 30 days, which they called *Ve-Adar*, every third year, they fell $3\frac{1}{4}$ days short of the solar year in that time.

The Romans also used the lunar embolismic year at first, as it was settled by Romulus their first king, who made it to consist only of 10 months or lunations, which fell 61 days short of the solar year, and so their year became quite vague and unfixed; for which reason, they were forced to have a table published by the high-priest, to inform them when the spring and other seasons began. But Julius Cæsar, as already mentioned, taking this troublesome affair into consideration, reformed the calendar, by making the year to consist of 365 days 6 hours.

294 Calendar reformed by Julius Cæsar. The year thus settled, is what we still make use of in Britain; but as it is somewhat more than 11 minutes longer than the solar tropical year, the times of the equinoxes go backward, and fall earlier by one

day in about 130 years. In the time of the Nicene council, (A. D. 325), which was 1444 years ago, the vernal equinox fell on the 21st of march; and if we divide 1444 by 130 it will quote 11, which is the number of days which the equinox has fallen back since the council of Nice. This causing great disturbances, by unfixing the times of the celebration of Easter, and consequently of all the other moveable feasts, Pope Gregory XIII. in the year 1582, ordered ten days to be at once struck out of that year; and the next day after the 4th of October was called the 15th. By this means the vernal equinox was restored to the 21st of March; and it was endeavoured, by the omission of three intercalary days in 400 years, to make the civil or political year keep pace with the solar for time to come. This new form of the year is called the *Gregorian account*, or *new stile*; which is received in all countries where the pope's authority is acknowledged, and ought to be in all places where truth is regarded.

295 By Pope Gregory. The principal division of the year is into *months*, which are of two sorts, namely, *astronomical* and *civil*. The astronomical month is the time in which the moon runs through the zodiac, and is either *periodical* or *synodical*. The periodical month is the time spent by the moon in making one complete revolution from any point of the zodiac to the same again; which is 27^d 7^h 43^m. The synodical month, called a *lunation*, is the time contained between the moon's parting with the sun at a conjunction, and returning to him again, which is 29^d 12^h 44^m. The civil months are those which are framed for the uses of civil life; and are different as to their names, number of days, and times of beginning, in several different countries. The first month of the Jewish year fell according to the moon in our August and September, old stile; the second in September and October, and so on. The first month of the Egyptian year began on the 29th of our August. The first month of the Arabic and Turkish year began the 16th of July. The first month of the Grecian year fell according to the moon in June and July, the second in July and August, and so on, as in the following table.

297 Weeks. A month is divided into four parts called *weeks*, and a week into seven parts called *days*; so that in a Julian year there are 13 such months, or 52 weeks, and one day over. The Gentiles gave the names of the sun, moon, and planets, to the days of the week. To the first, the name of the *Sun*; to the second, of the *Moon*; to the third, of *Mars*; to the fourth, of *Mercury*; to the fifth, of *Jupiter*; to the sixth, of *Venus*; and to the seventh, of *Saturn*.

Days in the year			354	Days in the year			354
The Arabians add 11 days at the end of every year, which keep the ſame months to the ſame ſeaſons.							

A day is either natural or artificial. The natural day contains 24 hours; the artificial the time from ſun-riſe to ſun-ſet. The natural day is either *aſtronomical* or *civil*. The *aſtronomical* day begins at noon, becauſe the increaſe and decreaſe of days terminated by the horizon are very unequal among themſelves; which inequality is likewiſe augmented by the inconfancy of the horizontal refractions, and therefore the aſtronomer takes the meridian for the limit of diurnal revolutions, reckoning noon, that is, the inſtant when the ſun's centre is on the meridian, for the beginning of the day. The Britiſh, French, Dutch, Germans, Spaniards, Portugueſe, and Egyptians, begin the civil day at midnight; the ancient Greeks, Jews, Bohemian's, Sileſians, with the modern Italians, and Chineſe, begin it at ſun-ſetting; and the ancient Babylo- nians, Perſians, Syrians, with the modern Greeks, at ſun-riſing.

An hour is a certain determinate part of the day, and is either equal or unequal. An equal hour is the 24th part of a mean natural day, as ſhewn by well regulated clocks and watches: but theſe hours are not quite equal as meaſured by the returns of the ſun to the meridian, becauſe of the obliquity of the ecliptic and ſun's

unequal motion in it. Unequal hours are thoſe by which the artificial day is divided into twelve parts, and the night into as many.

An hour is divided into 60 equal parts called *minutes*, and theſe again into 60 equal parts called *ſeconds*, and theſe again into 60 equal parts called *thirds*. The Jews, Chaldeans, and Arabians, divide the hour into 1080 equal parts called *ſcruples*; which number contains 18 times 60, fo that one minute contains 18 ſcruples.

A cycle is a perpetual round, or circulation of the ſame parts of time of any ſort. The *cycle of the ſun* is a revolution of 28 years, in which time the days of the months return again to the ſame days of the week; the ſun's place to the ſame ſigns and degrees of the ecliptic on the ſame months and days, ſo as not to differ one degree in 100 years; and the leap-years begin the ſame courſe over again with reſpect to the days of the week on which the days of the months fall. The *cycle of the moon*, commonly called the *golden number*, is a revolution of 19 years; in which time, the conjunctions, oppoſitions, and other aſpects of the moon, are within an hour and half of being the ſame as they were on the ſame days of the months 19 years before. The *in- diction*

distion is a revolution of 15 years, used only by the Romans for indicating the times of certain payments made by the subjects to the republic: It was established by Constantine, A. D. 312.

The year of our Saviour's birth, according to the vulgar æra, was the 9th year of the solar cycle, the first year of the lunar cycle, and the 312th year after his birth was the first year of the Roman indiction. Therefore, to find the year of the solar cycle, add 9 to any given year of Christ, and divide the sum by 28, the quotient is the number of cycles elapsed since his birth, and the remainder is the cycle for the given year: If nothing remains, the cycle is 28. To find the lunar cycle, add 1 to the given year of Christ, and divide the sum by 19; the quotient is the number of cycles elapsed in the interval, and the remainder is the cycle for the given year: If nothing remains, the cycle is 19. Lastly, subtract 312 from the given year of Christ, and divide the remainder by 15; and what remains after this division is the indiction for the given year: If nothing remains, the indiction is 15.

Although the above deficiency in the lunar circle of an hour and an half every 19 years be but small, yet in time it becomes so sensible as to make a whole natural day in 310 years. So that, although this cycle be of use, when the golden numbers are rightly placed against the days of the months in the calendar, as in the Common Prayer Books, for finding the days of the mean conjunctions or oppositions of the sun and moon, and consequently the time of Easter; it will only serve for 310 years, old file. For as the new and full moons anticipate a day in that time, the golden numbers ought to be placed one day earlier in the calendar for the next 310 years to come. These numbers were rightly placed against the days of new moon in the calendar, by the council of Nice, A. D. 325; but the anticipation, which has been neglected ever since, is now grown almost into 5 days: And therefore, all the golden numbers ought now to be placed 5 days higher in the calendar for the old file than they were at the time of the said council; or 6 days lower for the new file, because at present it differs 11 days from the old.

In the following table the golden numbers under the months stand against the days of new moon in the left-hand column, for the new file; adapted chiefly to the second year after leap-year, as being the nearest mean for all the four; and will serve till the year 1900. Therefore, to find the day of new moon in any month of a given year till that time, look for the golden number of that year under the desired month, and against it you have the day of new moon in the left-hand column. Thus, suppose it were required to find the day of new moon in September 1769; the golden number for that year is 3, which I look for under September, and right against it in the left-hand column you will find 30, which is the day of new moon in that month. *N. B.* If all the golden numbers, except 17 and 6, were set one day lower in the table, it would serve from the beginning of the year 1900 till the end of the year 2199. The table at the end of this section shews the golden number for 4000 years after the birth of Christ, by looking for the even hundreds of any given year at the left hand, and for the rest to make up that year at the head of the table; and where the columns meet, you have the golden number (which is the same both

in old and new file) for the given year. Thus, suppose the golden number was wanted for the year 1769; look for 1700 at the left hand of the table, and for 69 at the top of it; then guiding your eye downward from 69 to over-against 1700, you will find 3, which is the golden number for that year.

But because the lunar cycle of 19 years sometimes includes five leap-years, and at other times only four, this table will sometimes vary a day from the truth in leap-years after February. And it is impossible to have one more correct, unless we extend it to four times 19 or 76 years; in which there are 19 leap-years without a remainder. But even then to have it of perpetual use, it must be adapted to the old file; because, in every centurial year not divisible by 4, the regular course of leap-years is interrupted in the new; as will be the case in the year 1800.

The cycle of Easter, also called the *Dionysian period*, is a revolution of 532 years, found by multiplying the solar cycle 28 by the lunar cycle 19. If the new moons did not anticipate upon this cycle, Easter-day would always be the Sunday next after the first full moon, which follows the 21st of March. But, on account of the above anticipation, to which no proper regard was had before the late alteration of the file, the ecclesiastic Easter has several times been a week different from the true Easter within this last century: which inconvenience is now remedied by making the table, which used to find Easter for ever, in the Common Prayer Book, of no longer use than the lunar difference from the new file will admit of.

The earliest Easter possible is the 22^d of March, the latest the 25th of April. Within these limits are 35 days, and the number belonging to each of them is called the *number of direction*; because thereby the time of Easter is found for any given year.

The first seven letters of the alphabet are commonly placed in the annual almanacs, to shew on what days of the week the days of the months fall throughout the year. And because one of those seven letters must necessarily stand against Sunday, it is printed in a capital form, and called the *dominical letter*; the other six being inserted in small characters, to denote the other six days of the week. Now, since a common Julian year contains 365 days, if this number be divided by 7 (the number of days in a week) there will remain one day. If there had been no remainder, it is plain the year would constantly begin on the same day of the week; but since one remains, it is plain, that the year must begin and end on the same day of the week; and therefore the next year will begin on the day following. Hence, when January begins on Sunday, A is the dominical or Sunday letter for that year: Then, because the next year begins on Monday, the Sunday will fall on the seventh day, to which is annexed the seventh letter G, which therefore will be the dominical letter for all that year: and as the third year will begin on Tuesday, the Sunday will fall on the sixth day; therefore F will be the Sunday letter for that year. Whence it is evident, that the Sunday letters will go annually in a retrograde order thus, G, F, E, D, C, B, A. And, in the course of seven years, if they were all common ones, the same days of the week and dominical letters would return to the same days of the months. But because there are 366 days in a leap-year, if this num-

Dionysian period, cycle of 532 years.

309

310
Dominical letter.

ber

ber be divided by 7, there will remain two days over and above the 52 weeks of which the year consists. And therefore, if the leap-year begins on Sunday, it will end on Monday; and the next year will begin on Tuesday, the first Sunday whereof must fall on the sixth of January, to which is annexed the letter F, and not G, as in common years. By this means, the leap-year returning every fourth year, the order of the dominical letters is interrupted; and the series cannot return to its first state till after four times seven, or 28 years; and then the same days of the months return in order to the same days of the week as before.

(for no later could all the three cycles begin together), and it is not yet completed: And therefore it includes all other cycles, periods, and eras. There is but one year in the whole period that has the same numbers for the three cycles of which it is made up: And therefore, if historians had remarked in their writings the cycles of each year, there had been no dispute about the time of any action recorded by them.

The Dionysian or vulgar era of Christ's birth was about the end of the year of the Julian period 4713; and consequently the first year of his age, according to that account, was the 4714th year of the said period. Therefore, if to the current year of Christ we add 4713, the sum will be the year of the Julian period. So the year 1769 will be found to be the 6482^d year of that period. Or, to find the year of the Julian period answering to any given year before the first year of Christ, subtract the number of that given year from 4714, and the remainder will be the year of the Julian period. Thus, the year 585 before the first year of Christ (which was the 584th before his birth) was the 4129th year of the said period. Lastly, to find the cycles of the sun, moon, and indiction for any given year of this period, divide the given year by 28, 19, and 15; the three remainders will be the cycles sought, and the quotients the numbers of cycles run since the beginning of the period. So in the above 4714th year of the Julian period, the cycle of the sun was 10, the cycle of the moon 2, and the cycle of indiction 4; the solar cycle having run through 168 courses, the lunar 248, and the indiction 314.

The vulgar era of Christ's birth was never settled till the year 527, when Dionysius Exiguus, a Roman abbot, fixed it to the end of the 4713th year of the Julian period, which was four years too late. For our Saviour was born before the death of Herod, who sought to kill him as soon as he heard of his birth. And, according to the testimony of Josephus (*B. xvii. ch. 8.*) there was an eclipse of the moon in the time of Herod's last illness; which eclipse appears by our astronomical tables to have been in the year of the Julian period 4710, March 13^h, at 3 hours past midnight, at Jerusalem. Now, as our Saviour must have been born some months before Herod's death, since in the interval he was carried into Egypt, the latest time in which we can fix the true era of his birth is about the end of the 4709th year of the Julian period.

As there are certain fixed points in the heavens from which astronomers begin their computations, so there are certain points of time from which historians begin to reckon; and these points or roots of time are called *eras* or *epochs*. The most remarkable eras are, those of the Creation, the Greek Olympiads, the building of Rome, the era of Nabonassar, the death of Alexander, the birth of Christ, the Arabian Hegira, and the Persian Jsedegird: All which, together with several others of less note, have their beginnings in the following table fixed to the years of the Julian period, to the age of the world at those times, and to the years before and after the year of Christ's birth.

Days.	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.

From the multiplication of the solar cycle of 28 years into the lunar cycle of 19 years, and the Roman indiction of 15 years, arises the great Julian period, consisting of 7980 years, which had its beginning 764 years before Strauchius's supposed year of the creation

³¹³ To find the year of the Julian period.

In fixing the year of the creation to the 706th year of the Julian period, which was the 400th year before the year of Christ's birth, we have followed Mr Bedford in his scripture chronology, printed A. D. 1730, and Mr Kennedy in a work of the same kind, printed A. D. 1762.—Mr Bedford takes it only for granted that the world was created at the time of the autumnal equinox: But Mr Kennedy affirms, that the

faid equinox was at the noon of the fourth day of the creation-week, and that the moon was then 24 hours past her opposition to the sun.—If Moses had told us the same things, we should have had sufficient data for fixing the era of the creation: But as he has been silent on these points, we must consider the best accounts of chronologers as entirely hypothetical and uncertain.

TABLE, shewing the Golden Number, (which is the same both in the Old and New Stile) from the Christian Era, to A. D. 4000.

Seçt. XIII. A Description of the Astronomical Machinery serving to explain and illustrate the foregoing part of this Treatise.

The ORRERY, (Plate LI. fig. 3.) This machine shews the motions of the sun, Mercury, Venus, earth, and moon; and occasionally the superior planets, Mars, Jupiter, and Saturn, may be put on; Jupiter's four satellites are moved round him in their proper times by a small winch; and Saturn has his five satellites, and his ring which keeps its parallelism to the sun; and by a lamp put in the sun's place, the ring shews all its various phases already described.

In the centre, N^o 1. represents the sun, supported by its axis, inclining almost 8 degrees from the axis of the ecliptic, and turning round in 25 $\frac{1}{2}$ days on its axis, of which the north pole inclines toward the eighth degree of Pices in the great ecliptic, (N^o 11.), where-on the months and days are engraven over the signs and degrees in which the sun appears, as seen from the earth, on the different days of the year.

The nearest planet (N^o 2.) to the sun is Mercury, which goes round him in 87 days 23 hours, or 87 $\frac{1}{2}$ diurnal rotations of the earth; but has no motion round its axis in the machine, because the time of its diurnal motion in the heavens is not known to us.

The next planet in order is Venus, (N^o 3.), which performs her annual course in 224 days 17 hours, and turns round her axis in 24 days 8 hours, or in 24 $\frac{1}{2}$ diurnal rotations of the earth. Her axis inclines 75 degrees from the axis of the ecliptic, and her north pole inclines towards the 20th degree of Aquarius, according to the observations of Bianchini. She shews all the phenomena described in Sect. ii.

Next, without the orbit of Venus, is the earth, (N^o 4.), which turns round its axis, to any fixed point at a great distance, in 23 hours 56 minutes four seconds of mean solar time; but from the sun to the sun again, in 24 hours of the same time. N^o 6. is a sidereal dial-plate under the earth, and N^o 7. a solar dial-plate on the cover of the machine. The index of the former shews sidereal, and of the later, solar time; and hence the former index gains one entire revolution on the latter every year, as 365 solar or natural days contain 366 sidereal days, or apparent revolutions of the stars. In the time that the earth makes 365 $\frac{1}{2}$ diurnal rotations on its axis, it goes once round the sun in the plane of the ecliptic; and always keeps opposite to a moving index (N^o 10.) which shews the sun's daily change of place, and also the days of the months.

The earth is half covered with a black cap, for dividing the apparently enlightened half next the sun from the other half, which, when turned away from him, is in the dark. The edge of the cap represents the circle bounding light and darkness, and shews at what time the sun rises and sets to all places throughout the year. The earth's axis inclines 23 $\frac{1}{2}$ degrees from the axis of the ecliptic; the north pole inclines toward the beginning of Cancer, and keeps its parallelism throughout its annual course; so that in summer the northern parts of the earth incline towards the sun, and in winter from him: by which means, the different lengths of days and nights, and the cause of the various seasons, are demonstrated to sight.

There is a broad horizon, to the upper side of which is fixed a meridian femicircle in the north and south points, graduated on both sides from the horizon to 90° in the zenith or vertical point. The edge of the horizon is graduated from the east and west to the south and north points, and within these divisions are the points of the compass. From the lower side of this thin horizontal plate stand out four small wires, to which is fixed a twilight-circle 18 degrees from the graduated side of the horizon all round. This horizon may be put upon the earth, (when the cap is taken away), and rectified to the latitude of any place; and then by a small wire called the *solar ray*, which may be put on so as to proceed directly from the sun's centre towards the earth's, but to come no farther than almost to touch the horizon. The beginning of twilight, time of sun-rising, with his amplitude, meridian altitude, time of setting, amplitude then, and end of twilight, are shewn for every day of the year, at that place to which the horizon is rectified.

The moon (N^o 5.) goes round the earth, from between it and any fixed point at a great distance, in 27 days 7 hours 43 minutes, or through all the signs and degrees of her orbit, which is called her *periodical revolution*; but she goes round from the sun to the sun again, or from change to change, in 29 days 12 hours 45 minutes, which is her *synodical revolution*; and in

that time she exhibits all the phases already described.

When the abovementioned horizon is rectified to the latitude of any given place, the times of the moon's rising and setting, together with her amplitude, are shewn to that place as well as the sun's; and all the various phenomena of the harvest-moon are made obvious to sight.

The moon's orbit (N^o 9.) is inclined to the ecliptic (N^o 11.), one half being above, and the other below it. The nodes, or points at 0 and o, lie in the plane of the ecliptic, as before described, and shift backward through all its signs and degrees in 18 $\frac{1}{2}$ years. The degrees of the moon's latitude to the highest at NL (north latitude) and lowest at SL (south latitude), are engraven both ways from her nodes at o and o, and as the moon rises and falls in her orbit according to its inclination, her latitude and distance from her nodes are shewn for every day, having first rectified her orbit so as to set the nodes to their proper places in the ecliptic; and then as they come about at different and almost opposite times of the year, and then point towards the sun, all the eclipses may be shewn for hundreds of years, (without any new rectification), by turning the machinery backward for time past, or forward for time to come. At 17 degrees distance from each node, on both sides is engraved a small sun; and at 12 degrees distance, a small moon, which shew the limits of solar and lunar eclipses; and when, at any change the moon falls between either of these suns and the node, the sun will be eclipsed on the day pointed to by the annual index, (N^o 10.); and as the moon has then north or south latitude, one may easily judge whether that eclipse will be visible in the northern or southern hemisphere: especially as the earth's axis inclines toward the sun or from him at that time. And when at any full, the moon falls between either of the little moon's and node, she will be eclipsed, and the annual index shews the day of that eclipse. There is a circle of 29 $\frac{1}{2}$ equal parts (N^o 8.) on the cover of the machine, on which an index shews the days of the moon's age.

There are two femicircles (Plate LII. fig. 1.) fixed to an elliptical ring, which being put like a cap upon the earth, and the forked part F upon the moon, shews the tides as the earth turns round within them, and they are led round it by the moon. When the different places come to the femicircle A, E, B, they have tides of flood; and when they come to the femicircle C, E, D, they have tides of ebb; the index on the hour circle (N^o 7. Plate LI.) shewing the times of these phenomena.

There is a jointed wire, of which one end being put into a hole in the upright stem that holds the earth's cap, and the wire laid into a small forked piece which may be occasionally put upon Venus or Mercury, shews the direct and retrograde motions of these two planets, with their stationary times and places, as seen from the earth.

The whole machinery is turned by a winch or handle (N^o 12.), and is so easily moved, that a clock might turn it without any danger of stopping.

To give a plate of the wheel-work of this machine, would answer no purpose, because many of the wheels lie so behind others as to hide them from sight in any view whatever.

THE COMETARIUM, (Plate LII. fig. 2.) This curious machine shews the motion of a comet or excentric body moving round the sun, describing equal areas in equal times, and may be so contrived as to shew such a motion for any degree of excentricity. It was invented by the late Dr Defaguliers.

The dark elliptical groove round the letters *abdefghi* *klm* is the orbit of the comet Y; this comet is carried round in the groove according to the order of letters, by the wire W fixed in the sun S, and slides in the wire as it approaches nearer to or recedes farther from the sun, being nearest of all in the perihelion *a*, and farthest in the aphelion *g*. The areas, *aSb*, *bSc*, *cSd*, &c. or contents of these several triangles, are all equal; and in every turn of the winch N, the comet Y is carried over one of these areas; consequently, in as much time as it moves from *f* to *g*, or from *g* to *h*, it moves from *m* to *a*, or from *a* to *b*; and so of the rest, being quickest of all at *a*, and slowest at *g*. Thus the comet's velocity in its orbit continually decreases from the perihelion *a* to the aphelion *g*; and increases in the same proportion from *g* to *a*.

The elliptic orbit is divided into 12 equal parts or signs, with their respective degrees, and so is the circle *mnoprstu*, which represents a great circle in the heavens, and to which the comet's motion is referred by a small knob on the point of the wire W. Whilst the comet moves from *f* to *g* in its orbit, it appears to move only about five degrees in this circle, as is shewn by the small knob on the end of the wire W; but in as short time as the comet moves from *m* to *a*, or from *a* to *b*, it appears to describe the large space *tn* or *no* in the heavens, either of which spaces contains 120 degrees, or four signs. Were the excentricity of its orbit greater, the greater still would be the difference of its motion, and *vice versa*.

ABCDEFGHIKLMA is a circular orbit for shewing the equable motion of a body round the sun S, describing equal areas ASB, BSC, &c. in equal times with those of the body Y in its elliptical orbit above mentioned; but with this difference, that the circular motion describes the equal arcs AB, BC, &c. in the same equal times that the elliptical motion describes the unequal arcs, *ab*, *bc*, &c.

Now, suppose the two bodies Y and I to start from the points *a* and A at the same moment of time, and, each having gone round its respective orbit, to arrive at these points again at the same instant, the body Y will be forwarder in its orbit than the body I all the way from *a* to *g*, and from A to G; but I will be forwarder than Y through all the other half of the orbit; and its difference is equal to the equation of the body Y in its orbit. At the points *aA*, and *gG*, that is, that in the perihelion and aphelion, they will be equal; and then the equation vanishes. This shews why the equation of a body moving in an elliptic orbit, is added to the mean or supposed circular motion from the perihelion to the aphelion, and subtracted from the aphelion to the perihelion, in bodies moving round the sun, or from the perigee to the apogee, and from the apogee to the perigee in the moon's motion round the earth.

This motion is performed in the following manner by the machine, (Plate LII. fig. 3.) ABC is a wooden bar, (in the box containing the wheel-work), above which are the wheels D and E, and below it the

elliptic plates FF and GG; each plate being fixed on an axis in one of its foci, at E and K; and the wheel E is fixed on the same axis with the plate FF. These plates have grooves round their edges precisely of equal diameters to one another, and in these grooves is the cat-gut string *gg*, *gg* crossing between the plates at *b*. On H, the axis of the handle or winch N in fig. 2. is an endless screw in fig. 4. working in the wheels D and E, whose numbers of teeth being equal, and should be equal to the number of lines *aS*, *bS*, *cS*, &c. in fig. 2. they turn round their axes in equal times to one another, and to the motion of the elliptic plates. For, the wheels D and E having equal numbers of teeth, the plate FF being fixed on the same axis with the wheel E, and the plate II turning the equally big plate GG by a cat-gut string round them both, they must all go round their axes in as many turns of the handle N as either of the wheels has teeth.

It is easy to see, that the end of *b* of the elliptical plate FF being farther from its axis E than the opposite end I is, must describe a circle so much the larger in proportion, and therefore move through so much more space in the same time; and for that reason the end *b* moves so much faster than the end I, although it goes no sooner round the centre E. But then the quick-moving end *b* of the plate FF leads about the short end *bK* of the plate GG with the same velocity; and the slow-moving end I of the plate FF coming half round as to B, must then lead the long end *k* of the plate GG as slowly about: so that the elliptical plate FF and its axis E move uniformly and equally quick in every part of its revolution; but the elliptical plate GG, together with its axis K, must move very unequally in different parts of its revolution; the difference being always inversely as the distance of any point of the circumference of GG from its axis at K: or in other words, to instance in two points, if the distance *Kk* be four, five, or six times as great as the distance *Kb*, the point *b* will move in that position four, five, or six times as fast as the point *k* does, when the plate GG has gone half round; and so on for any other excentricity or difference of the distances *Kk* and *Kb*. The tooth I on the plate FF falls in between the two teeth at *k* on the plate GG, by which means the revolution of the latter is so adjusted to that of the former, that they can never vary from one another.

On the top of the axis of the equally-moving wheel D in fig. 3. is the sun S in fig. 2.; which sun, by the wire fixed to it, carries the ball I round the circle ABCD, &c. with an equable motion, according to the order of the letters: and on the top of the axis K of the unequally-moving ellipsis GG, in fig. 3. is the sun S in fig. 2. carrying the ball Y unequally round in the elliptical groove *abcd*, &c. N. B. This elliptical groove must be precisely equal and similar to the verge of the plate GG, which is also equal to that of FF.

In this manner machines may be made to shew the true motion of the moon about the earth, or of any planet about the sun, by making the elliptical plates of the same excentricities, in proportion to the radius, as the orbits of the planets are, whose motions they represent; and so their different equations in different parts of their orbits may be made plain to sight, and clearer ideas of these motions and equations acquired in half an hour, than could be gained from reading half

a day about such motions and equations.

The IMPROVED CELESTIAL GLOBE, (Pl. XLVIII. fig. 2.) On the north pole of the axis, above the hour-circle, is fixed an arch MKH of $23\frac{1}{2}$ degrees; and at the end H is fixed an upright pin HG, which stands directly over the north pole of the ecliptic, and perpendicular to that part of the surface of the globe. On this pin are two moveable collets at D and I, to which are fixed the quadrant wires N and O, having two little balls on their ends for the sun and moon, as in the figure. The collet D is fixed to the circular plate F, whereon the $29\frac{1}{2}$ days of the moon's age are engraven, beginning jult under the sun's wire N; and as this wire is moved round the globe, the plate F turns round with it. These wires are easily turned, if the screw G be slackened: and when they are set to their proper places, the screw serves to fix them there so as in turning the ball of the globe, the wires with the sun and moon go round with it; and these two little balls rise and set at the same times, and on the same points of the horizon, for the day to which they are rectified, as the sun and moon do in the heavens.

Because the moon keeps not her course in the ecliptic, (as the sun appears to do), but has a declination of $5\frac{1}{2}$ degrees on each side from it in every lunation, her ball may be screwed as many degrees to either side of the ecliptic as her latitude or declination from the ecliptic amounts to at any given time; and for this purpose S, Plate LV. fig. 1. is a small piece of pasteboard, of which the curved edge at S, is to be set upon the globe at right angles to the ecliptic, and the dark line over S to stand upright upon it. From this line, on the convex edge, are drawn the $5\frac{1}{2}$ degrees of the moon's latitude on both sides of the ecliptic; and when this piece is set upright on the globe, its graduated edge reaches to the moon on the wire O, by which means she is easily adjusted to her latitude found by an ephemeris.

The horizon is supported by two semicircular arches, because pillars would stop the progress of the balls when they go below the horizon in an oblique sphere.

To rectify this globe. Elevate the pole to the latitude of the place; then bring the sun's place in the ecliptic for the given day to the brazen meridian, and set the hour index to 12 at noon, that is to the upper 12 on the hour circle; keeping the globe in that situation, slacken the screw G, and set the fun directly over his place on the meridian; which done set the moon's wire under the number that expresses her age for that day on the plate F, and the will then stand over her place in the ecliptic, and shew what constellation she is in. Lastly, fasten the screw G, and laying the curved edge of the pasteboard S over the ecliptic below the moon, adjust the moon to her latitude over the graduated edge of the pasteboard; and the globe will be rectified.

Having thus rectified the globe, turn it round, and observe on what points of the horizon the sun and moon balls rise and set, for these agree with the points of the compass on which the sun and moon rise and set in the heavens on the given day: and the hour index shews the times of their rising and setting; and likewise the time of the moon's passing over the meridian.

This simple apparatus shews all the varieties that can happen in the rising and setting of the sun and moon: and makes the forementioned phenomena of

the harvest moon plain to the eye. It is also very useful in reading lectures on the globes, because a large company can see this sun and moon go round, rising above and setting below the horizon at different times according to the seasons of the year; and making their appulses to different fixed stars. But in the usual way, where there is only the places of the sun and moon in the ecliptic to keep the eye upon, they are easily lost sight of, unless they be covered with patches.

The PLANETARY GLOBE, (Plate LIII. fig. 1.) In this machine, a terrestrial globe is fixed on its axis standing upright on the pedestal CDE, on which is an hour-circle, having its index fixed on the axis, which turns somewhat tightly in the pedestal, so that the globe may not be liable to shake; to prevent which, the pedestal is about two inches thick, and the axis goes quite through it, bearing on a shoulder. The globe is hung in a graduated brazen meridian, much in the usual way; and the thin plate N, NE, E is a moveable horizon graduated round the outer edge, for shewing the bearings and amplitudes of the sun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a slender semicircle of brass, the ends of which are fixed to the horizon in its north and south points; this semicircle slides in the groove as the horizon is moved in rectifying it for different latitudes. To the middle of this semicircle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude q turns; the lower-end of which, in all positions touches the horizon as it is moved round the same.

This quadrant is divided into 90 degrees from the horizon to the zenithal pin on which it is turned, at 90. The great flat circle or plate AB is the ecliptic, on the outer edge of which the signs and degrees are laid down: and every fifth degree is drawn through the rest of the surface of this plate towards its centre. On this plate are seven grooves, to which seven little balls are adjusted by sliding wires, so that they are easily moved in the grooves, without danger of starting them. The ball next the terrestrial globe is the moon, the next without it is Mercury, the next Venus, the next the sun, then Mars, then Jupiter, and lastly Saturn. This plate or ecliptic, is supported by four strong wires, having their lower ends fixed into the pedestal, at C, D, E, the fourth being hid by the globe. The ecliptic is inclined $23\frac{1}{2}$ degrees to the pedestal, and is therefore properly inclined to the axis of the globe which stands upright on the pedestal.

To rectify this machine. Set the sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris; then set the north point of the horizon to the latitude of your place on the brazen meridian, and the quadrant of altitude to the south point of the horizon; which done, turn the globe with its furniture till the quadrant of altitude comes right against the sun, viz. to his place in the ecliptic: and keeping it there, set the hour index to the XII next the letter C; and the machine will be rectified, not only for the following problems, but for several others which the artist may easily find out.

PROBLEM. I. To find the amplitudes, meridian altitudes, and times of rising, culminating, and setting of the sun, moon, and planets.

Turn the globe round eastward, or according to the order of signs; and as the eastern edge of the horizon comes right against the sun, moon, or any planet, the hour index will shew the time of its rising; and the inner edge of the ecliptic will cut its rising amplitude in the horizon. Turn on, and as the quadrant of altitude comes right against the sun, moon, or planets, the ecliptic cuts their meridian altitudes in the quadrant, and the hour index shews the times of their coming to the meridian. Continue turning, and as the western edge of the horizon comes right against the sun, moon, or planets, their setting amplitudes are cut in the horizon by the ecliptic; and the times of their setting are shewn by the index on the hour-circle.

322 **PROB. II.** *To find the altitude and azimuth of the sun, moon, and planets, at any time of their being above the horizon.*

Turn the globe till the index comes to the given time in the hour-circle, then keep the globe steady, and moving the quadrant of altitude to each planet respectively, the edge of the ecliptic will cut the planet's mean altitude on the quadrant, and the quadrant will cut the planet's azimuth, or point of bearing on the horizon.

323 **PROB. III.** *The sun's altitude being given at any time either before or after noon, to find the hour of the day, and variation of the compass, in any known latitude.*

With one hand hold the edge of the quadrant right against the sun; and with the other hand, turn the globe westward, if it be in the forenoon, or eastward if it be in the afternoon, until the sun's place at the inner edge of the ecliptic cuts the quadrant in the sun's observed altitude; and then the hour-index will point out the time of the day, and the quadrant will cut the true azimuth, or bearing of the sun for that time: the difference between which, and the bearing shewn by the azimuth compass, shews the variation of the compass in that place of the earth.

324 **THE TRAJECTORIUM LUNARE, Plate LIII. fig. 2.** This machine is for delineating the paths of the earth and moon, shewing what sort of curves they make in the ethereal regions. S is the sun, and E the earth, whose centres are 95 inches distant from each other; every inch answering to 1,000,000 of miles. M is the moon, whose centre is $\frac{2}{3}$ parts of an inch from the earth's in this machine, this being in just proportion to the moon's distance from the earth. A A is a bar of wood, to be moved by hand round the axis *g* which is fixed in the wheel Y. The circumference of this wheel is to the circumference of the small wheel L (below the other end of the bar) as $365\frac{1}{4}$ days is to $29\frac{1}{2}$, or as a year is to a lunation. The wheels are grooved round their edges, and in the grooves is the cat-gut string GG crossing between the wheels at X. On the axis of the wheel L is the index F, in which is fixed the moon's axis M for carrying her round the earth E (fixed on the axis of the wheel L) in the time that the index goes round a circle of $29\frac{1}{2}$ equal parts, which are the days of the moon's age. The wheel Y has the months and days of the year all round its limb; and in the bar A A is fixed the index I, which points out the days of the months answering to the days of

the moon's age, shewn by the index F, in the circle of $29\frac{1}{2}$ equal parts at the other end of the bar. On the axis of the wheel L is put the piece D, below the cock C, in which this axis turns round; and in D are put the pencils *e* and *m*, directly under the earth E and moon M; so that *m* is carried round *e*, as M is round E.

Lay the machine on an even floor, pressing gently on the wheel Y, to caufe its spiked feet (of which two appear at P and P, the third being supposed to be hid from sight by the wheel) enter a little into the floor to secure the wheel from turning. Then lay a paper about four feet long under the pencils *e* and *m*, cross-wise to the bar; which done, move the bar slowly round the axis *g* of the wheel Y; and as the earth E goes round the sun S, the moon M will go round the earth with a duly proportioned velocity; and the friction wheel W running on the floor, will keep the bar from bearing too heavily on the pencils *e* and *m*, which will delineate the paths of the earth and moon. As the index I points out the days of the months, the index F shews the moon's age on these days, in the circle of $29\frac{1}{2}$ equal parts. And as this last index points to the different days in its circle, the like numeral figures may be set to those parts of the curves of the earth's path and moon's, where the pencils *e* and *m* are at those times respectively, to shew the places of the earth and moon. If the pencil *e* be pushed a very little off, as if from the pencil *m*, to about $\frac{1}{10}$ part of their distance, and the pencil *m* pushed as much towards *e*, to bring them to the same distances again, though not to the same points of space; then, as *m* goes round *e*, *e* will go as it were round the centre of gravity between the earth *e* and moon *m*; but this motion will not sensibly alter the figure of the earth's path or the moon's.

If a pin, as *p*, be put through the pencil *m*, with its head towards that of the pin *q* in the pencil *e*, its head will always keep thereto as *m* goes round *e*, or as the same side of the moon is still obverted to the earth. But the pin *p*, which may be considered as an equatorial diameter of the moon, will turn quite round the point *m*, making all possible angles with the line of its progress, or line of the moon's path. This is an ocular proof of the moon's turning round her axis.

325 **THE TIDE-DIAL, Plate LIV. fig. 1.** The outside parts of this machine consist of, 1. An eight-sided box, on the top of which at the corners is shewn the phases of the moon at the octants, quarters, and full. Within these is a circle of $29\frac{1}{2}$ equal parts, which are the days of the moon's age accounted from the sun at new moon, round to the sun again. Within this circle is one of 24 hours divided into their respective halves and quarters. 2. A moving elliptical plate, painted blue, to represent the rising of the tides under and opposite to the moon; and has the words, *high water, tide falling, low water, tide rising*, marked upon it. To one end of this plate is fixed the moon M by the wire W, and goes along with it. 3. Above this elliptical plate is a round one, with the points of the compass upon it, and also the names of above 200 places in the large machine (but only 32 in the figure, to avoid confusion) set over those points in which the moon bears when she raises the tides to the greatest heights at these places twice in every lunar day: And to the north and south points of this plate are fixed two indexes

indexes I and K, which shew the times of high water, in the hour circle, at all these places. 4. Below the elliptical plate are four small plates, two of which project out from below its ends at new and full moon; and so, by lengthening the ellipse, shew the spring-tides, which are then raised to the greatest heights by the united attractions of the sun and moon. The other two of these small plates appear at low water when the moon is in her quadratures, or at the sides of the elliptical plate, to shew the neap-tides; the sun and moon then acting cross-wise to each other. When any two of these small plates appear, the other two are hid; and when the moon is in her octants, they all disappear, their being neither spring nor neap tides at those times. Within the box are a few wheels for performing these motions by the handle or winch H.

Turn the handle until the moon M comes to any given day of her age in the circle of $29\frac{1}{2}$ equal parts, and the moon's wire W will cut the time of her coming to the meridian on that day, in the hour circle; the XII under the sun being mid-day, and the opposite XII mid-night: Then looking for the name of any given place on the round plate (which makes $29\frac{1}{2}$ rotations whilst the moon M makes only one revolution from the sun to the sun again), turn the handle till that place comes to the word *high water* under the moon, and the index which falls among the forenoon hours will shew the time of high water at that place in the forenoon of the given day: then turn the plate half round, till the same place comes to the opposite high-water mark, and the index will shew the time of high water in the afternoon at that place. And thus, as all the different places come successively under and opposite to the moon, the indexes shew the times of high water at them in both parts of the day: and, when

the same places come to the low-water marks, the indexes shew the times of low water. For about three days before and after the times of new and full moon, the two small plates come out a little way from below the high-water marks on the elliptical plate, to shew that the tides rise still higher about these times: and about the quarters, the other two plates come out a little from under the low-water mark, towards the sun, and on the opposite side, shewing that the tides of flood rise not then so high, nor do the tides of ebb fall so low, as at other times.

By pulling the handle a little way outward, it is disengaged from the wheel-work, and then the upper plate may be turned round quickly by hand, so as the moon may be brought to any given day of her age in about a quarter of a minute; and by pushing in the handle, it takes hold of the wheel-work again.

On AB, (fig. 2.) the axis of the handle H, is an endless screw C, which turns the wheel FED of 24 teeth round in 24 revolutions of the handle: this wheel turns another ONG of 48 teeth, and on its axis is the pinion PQ of four leaves, which turns the wheel LKI of 59 teeth round in $29\frac{1}{2}$ turnings or rotations of the wheel FED, or in 708 revolutions of the handle, which is the number of hours in a synodical revolution of the moon. The round plate, with the names of places upon it, is fixed on the axis of the wheel FED; and the elliptical or tide-plate with the moon fixed to it, is upon the axis of the wheel LKI; consequently, the former makes $29\frac{1}{2}$ revolutions in the time that the latter makes one. The whole wheel FED, with the endless screw C, and dotted part of the axis of the handle AB, together with the dotted part of the wheel ONG, lie hid below the large wheel LKI.

A S T

ASTROP-WELLS, in Northamptonshire, were recommended by the physicians Willis and Clever, for the cure of the scurvy, asthma, &c.

ASTROSCOPE, a kind of astronomical instrument, composed of two cones, on whose surface the constellations, with their stars, are delineated, by means whereof the stars may easily be known. The astroscope is the invention of William Schukhard, formerly professor of mathematics at Tubingen, who published a treatise expressly on it, in 1698.

ASTRUC (John), a celebrated physician, was born in the year 1684, at the little town of Savoy, in the province of Languedoc. His father, who was a protestant clergyman, bestowed particular pains upon the earliest part of his education. After which he went to the university of Montpellier, where he was created master of arts in the year 1700. He then began the study of medicine; and, in two years, obtained the degree of bachelor, having, upon that occasion, written a dissertation on the cause of fermentation, which he defended in a very spirited manner. On the 25th of January 1703, he was created doctor of physic; after which, before arriving at extensive practice, he applied to the study of medical authors, both ancient and modern, with uncommon assiduity. The good effects of his study soon appeared; for, in the year 1710, he published a treatise concerning muscular

A S T

motion, from which he acquired very high reputation. In the year 1717, he was appointed to teach medicine at Montpellier; which he did with such perspicuity and eloquence, that it was universally said, he had been born to be a professor. His fame soon rose to such a height, that the king assigned him an annual salary; and he was, at the same time, appointed to superintend the mineral waters in the province of Languedoc.

But, as Montpellier did not afford sufficient scope for his aspiring genius, he went to Paris with a great flock of manuscripts, which he intended to publish, after subjecting them to the examination of the learned. Soon after, however, he left it, having in the year 1729 accepted the office of first physician to the king of Poland, which was then offered to him. His stay in Poland, however, was but of short duration, and he again returned to Paris.

Upon the death of the celebrated Geoffroy, in the year 1731, he was appointed Regius Professor of medicine at Paris. The duties of this office he discharged in such a manner, as to answer even the most sanguine expectations. He taught the practice of physic with so great applause, as to draw from other universities to that of Paris, a great concourse of medical students, foreigners as well as natives of France. At the same time he was not more celebrated as a professor than a practitioner. And, even at an advanced age, he per-

fitted with unwearied assiduity in that intense study which first raised his reputation. Hence it is, that he has been enabled to transmit to posterity so many valuable monuments of his medical erudition. He died, universally regretted, on the 15th of May, 1766, in the 82^d year of his age.

ASTURIA, an ancient kingdom of Spain, subdued by Augustus emperor of Rome.—The inhabitants of this country, along with those of Cantabria, asserted their liberty long after the rest of Spain had received the Roman yoke. So great was their desire of liberty, that, after being closely shut up by the Roman army, they endured the most terrible calamities of famine, even to the devouring of one another, rather than submit to the enemy. At length, however, the Asturians were for surrendering; but the Cantabrians opposed this measure, maintaining that they ought all to die sword in hand like brave men. Upon this the two nations quarrelled, notwithstanding their desperate situation; and a battle ensuing, 10,000 of the Asturians were driven to the intrenchments of the Romans, whom they begged in the most moving manner to receive them on any terms they pleased. But Tiberius the emperor's son-in-law refusing to admit them into the camp, some of these unhappy people put an end to their lives by falling upon their own swords; others lighting great fires threw themselves into them, while some poisoned themselves by drinking the juice of a venomous herb.

The campaign being put an end to by winter, the next year the Asturians summoned all their strength and resolution against the Romans; but, notwithstanding their utmost efforts of valour and despair, they were entirely defeated in a most bloody battle which lasted two days, and for that time entirely subdued. A few years afterwards they rebelled, in conjunction with the Cantabrians; but were soon reduced by the Romans, who massacred most of the young men that were capable of bearing arms. This did not prevent them from revolting anew in a short time afterwards; but without success, being obliged to submit to the Roman power, till the subversion of that empire by the Goths.

ASTURIAS, anciently the kingdom of Asturia, is now a principality of modern Spain, bounded by Biscay on the east, Galicia on the west, Castile and Old Leon on the south, and the sea on the north. Its greatest length is about 110 miles, and its breadth 54. On the south it is separated from Castile and Old Leon by high mountains covered with woods. The province is tolerably fertile; but thinly inhabited. The inhabitants value themselves much on being descended from the ancient Goths. Even the poor peasants, who are fain to go to seek work in other provinces, call themselves *illustrious Goths* and *Mountaineers*, thinking it ignominious to marry even with great and rich families of another race. This pride is flattered by the respect paid them by the rest of the nation, and the privileges bestowed upon them by the government. The hereditary prince of Spain is stiled prince of the Asturias. The most remarkable places in this principality are Oviedo, Gyon, Santillana, and St Andero. See these articles.

ASTYAGES, son of Cyaxares, the last king of the Medes. He dreamed that from the womb of his daughter Mandane, married to Cambyses king of Persia, there sprung a vine that spread itself over all Asia. She

being with child, he resolved to kill the infant as soon as born. Its name was Cyrus; and Harpagus, being sent to destroy it, preserved it: which Astyages after a long time hearing of, he caused Harpagus to eat his own son. Harpagus called in Cyrus, who dethroned his grandfather, and thereby ended the monarchy of the Medes. See **MEDIA** and **PERSIA**.

ASTYANAX, the only son of Hector and Andromache: after the taking of Troy, he was thrown from the top of a tower by Ulysses's orders.

ASTYNOMI, in Grecian antiquity, magistrates in Athens, corresponding to the ædiles of the Romans; they were ten in number. See **ÆDILE**.

ASYLUM, a sanctuary, or place of refuge, where criminals shelter themselves from the hands of justice. The asyls of altars and temples were very ancient; and likewise those of tombs, statues, and other monuments of considerable personages: Thus, the temple of Diana at Ephesus was a refuge for debtors, the tomb of Thearkus for slaves. The Jews had their asyls; the most remarkable of which were, the six cities of refuge, the temple, and the altar of burnt-offerings.

ASYMMETRY, the want of proportion between the parts of any thing, being the contrary of symmetry.

ASYMPTOTE, in geometry, a line which continually approaches nearer to another; but, though continued infinitely, will never meet with it: Of these are many kinds. In strictness, however, the term *asymptotes* is appropriated to right lines, which approach nearer and nearer to some curves of which they are said to be *asymptotes*; but if they and their curve are indefinitely continued, they will never meet*.

ASYNDETON, in grammar, a figure which omits the conjunctions in a sentence; as in *veni, vidi, vici*, ET is left out. * See Conic Sections.

ATABULUS, in physiology, a provincial wind in Apulia, of a dry pinching quality, and very noxious in its effects. The ancient naturalists speak of the Atabulus in terms of horror, on account of the ravage it made among the fruits of the earth, which it scorched or withered up.

ATABYRIS, a very high mountain in the island of Rhodes, on which, according to Strabo and Diodorus Siculus, there stood a temple of Jupiter Atrabyrius, whose worship a colony of Rhodians carried into Sicily, where a temple was built to the same deity at Agrigentum.

ATARGATIS FANUM, the temple of a goddess worshipped by the Syrians and Parthians, having the face of a woman, and tail of a fish, and called *Derceto* by the Greeks. Her temple stood in the city Bambyce, called afterwards *Hierapolis*. It was extremely rich, inasmuch that Crassus, in his march against the Parthians, spent several days in weighing the treasure. Vossius makes the name of this goddess *Phanician*, from *Addir-dag*, the great fish.

ATALANTA, an island in the Euripus of Eubœa, near the Locri Opuntii, said to have been originally a city of the Locri, but torn from the continent in the time of an earthquake, and during an eruption of mount Ætna. This happened in the fourth year of the 93^d Olympiad, in the reign of Artaxerxes Mneumon, (Pliny, Orosius).

ATALANTIS, **ATLANTICA**, or **ATLANTIS**. See **ATLANTIS**.

ATARAXY,

Ataraxy
||
Atelle.

ATARAXY, a term used by the stoics and sceptics, to denote that calmness of mind which secures us from all emotions arising from vanity and self-conceit.

ATARNEA, an ancient town of Myſia, ſituated between Adramyttium and Pitane, remarkable for the marriage of Ariſtotele with the ſiſter or concubine of the tyrant Hermias; alſo for the dotage of that philoſopher.

ATAXY, in a general ſenſe, the want of order: With phyſicians, it ſignifies irregularity of criſes and paroxyſms of fevers.

ATCHE, in commerce, a ſmall ſilver coin uſed in Turkey, and worth only one third of the Engliſh penny.

ATCIEVEMENT, in heraldry, denotes the arms of a perſon, or family, together with all the exterior ornaments of the ſhield; as helmet, mantle, creſt, ſcrolls, and motto, together with ſuch quarterings as may have been acquired by alliances, all maſſed in order.

ATCIEVE. This term is derived from the French *achever*, i. e. to finiſh or make an end of; but ſignifies, in heraldry, to perform great actions or exploits.

ATE, the goddeſs of miſchief, in the Pagan theology. She was daughter of Jupiter, and caſt down from heaven at the birth of Hercules. For Juno having deceived Jupiter, in cauſing Eurithus to be born before Hercules, Jupiter expreſſed his reſentment on Ate, as the author of that miſchief; and threw her headlong from heaven to earth, ſwearing he ſhould never return thither again, (*Homeri Il. xix. 125.*) The name of this goddeſs comes from *αττα*, *nocce*, to hurt. Her being the daughter of Jupiter means, according to mythologiſts, that no evil happens to us but by the permiſſion of providence; and her baniſhment to earth denotes the terrible effects of divine juſtice among men.

ATEGUA, or **ATTEGUA**, an ancient town of Spain, placed by ſome in the road from Antiquara, now Antequera, to Hiſpaliſ, or Seville; by others near Alcala Real; which laſt is the more probable ſituation, becauſe the flumen ſalum, now the Salado, was in its neighbourhood. Now *Tebala Vieja*, or *Tevola*.

ATELLA, an ancient town of Campania in Italy, between Capua and Neapolis. From this town the *Atellana fabule*, or *Atellani ludj*, took their name. Theſe were alſo called *Oſci*, from their inventor, in whoſe territory Atella lay. They were generally a ſpecies of farce, interlarded with much ribaldry and buffoonery; and ſometimes were exordia or interludes preſented between the acts of other plays. The actors in theſe farces were not reckoned among the common players, nor deemed infamous; but retained the rights of their tribe, and might be liſted for ſoldiers, the privilege only of free men. The ruins of this town are ſtill to be ſeen about 11 miles from the modern Aversa, which was built out of its materials.

A TEMPO GIUSTO, in muſic, ſignifies to ſing or play in an equal, true, and juſt time.

ATERNUM, a town of Lucania in Italy, now *Aterni*, (*Cluvenus*): Alſo a town in the territory of the Piceni, now *Pescara*, a port-town of Naples, ſituated on the Adriatic. E. Long. 15. 25. N. Lat. 42. 30.

ATESTE, a town in the territory of Venice in Italy, now called *Eſte*. E. Long. 12. 6. N. Lat. 45. 25.

ATHAMADULET, the prime miniſter of the Perſian empire, as the grand vizer is of the Turkiſh empire. He is great chancellor of the kingdom, preſident of the council, ſuperintendent of the finances, and is charged with all foreign affairs.

ATHAMANTA, **SPIGNEL**; a genus of the diſynymia order, belonging to the pentandria claſs of plants. Of this genus Linnæus enumerates nine ſpecies; but none of them merit particular notice except the cretaſis, otherwiſe called *daucus creticus*. This is an umbelliferous plant growing wild in the Levant and the warmer parts of Europe. The leaves are irregularly diſpoſed, and formed like thoſe of fennel. The flower-ſtalk riſes about two feet high, ſending out many branches, terminated at the top by compound umbels, compoſed of near 20 ſmall ones. Theſe have white flowers with five petals, which are ſucceeded by oblong, hairy, channelled fruit, divided into two parts, containing one oblong hairy ſeed. The ſeeds have a warm biting taſte, with an agreeable aromatic ſmell. They are kept in the ſhops as a medicine, are carminative, and ſaid to be diuretic; but are little uſed in practice. The plant may be propagated from ſeeds, which ſhould be ſown on an open bed of light dry ground; the following autumn the plants ſhould be taken up, and planted at about a foot diſtance in a bed of light ſandy earth, where the roots will continue ſeveral years.

ATHANASIA, **GOLDBLOCKS**; a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants. Of this genus, Dr Linnæus mentions 11

Species; of which the following fix are by Mr Miller reckoned worthy of a place in thoſe gardens where there are conveniencies for preſerving tender plants, as none of theſe ſpecies will outlive the winters of this country. 1. The *dentata* grows naturally at the Cape of Good Hope. It riſes three or four feet high, ſending out many ſide-branches, garniſhed with pretty long narrow leaves, having ſome reſemblance to thoſe of buckthorn plantain. The branches are generally terminated by yellow flowers formed into a kind of umbel. Theſe flowers appear early in ſummer, and the ſeeds ripen in autumn. 2. The *trifurcata* is alſo a native of Africa, as are the three following ſorts. It is a ſhrubby plant, about the height of the former, ſending out ſeveral weak ſhoots, garniſhed with awl-shaped triſid leaves ſet cloſe to them, of a pale ſilvery colour. The flowers are yellow, and terminate the branches in a corymbus. They appear in Auguſt, and the ſeeds ripen in October. 3. The *crithmifolia* riſes with a ſtrong ſhrubby ſtalk to the height of fix or eight feet, ſending out many ligneous branches garniſhed with long narrow leaves terminating in four or five parts like thoſe of ſampſhire. The flowers are like thoſe of the former, and appear in July and Auguſt, being ſucceeded by ſeeds which ripen in October. 4. The *puberſens* hath ſtrong woody ſtalks four or five feet high, covered with a woolly bark, as are alſo the branches, which are cloſely garniſhed with entire, ſpearſhaped, woolly leaves, and are terminated by yellow flowers having a long foot-ſtalk, and are ſometimes ſucceeded by ſeeds that ripen in the autumn. 5. The annual is a low annual plant, ſeldom riſing above a foot high, and ſending forth two or three ſlender branches garniſhed with wing-pointed leaves: the ſtalks are terminated

minated by bright yellow flowers growing in umbels, which appear in August and September; but unless the season is very favourable, the seeds do not ripen in this country. 6. The maritima, or sea cudweed, grows naturally on the coasts of the Mediterranean, as also in Wales, and some other parts of Britain; notwithstanding which, Mr Miller says it must be put under a glass-frame in winter, and rarely perfects good seeds in Britain. It rises two or three feet high, sending out a few weak branches, garnished with white spear-shaped leaves terminated by a single flower upon each foot-stalk. The first four of these sorts may be propagated either by seeds or cuttings; and their culture is not materially different from that of the common hot-bed plants.

ATHANASIAN CREED; a formulary, or confession of faith, long supposed to have been drawn up by Athanasius bishop of Alexandria, in the fourth century, to justify himself against the calumnies of his Arian enemies. But it is now generally allowed among the learned not to have been his. Dr Waterland ascribes it to Hilary bishop of Arles, for the following among other reasons: 1. Because Honoratus of Marcellis, the writer of his life, tells us, that he composed an *Exposition of the Creed*; a proper title for the *Athanasian*, than that of *Creed* simply which it now bears. 2. Hilary was a great admirer and follower of St Austin; and the whole composition of this creed is in a manner upon St Austin's plan, both with respect to the trinity and incarnation. 3. It is agreeable to the style of Hilary, as far as we can judge from the little that is left of his works. Upon the whole, he concludes, that Hilary bishop of Arles, about the year 430, composed the *The Exposition of Faith*, which now bears the name of the *Athanasian Creed*, for the use of the Gallican clergy, and particularly those of the diocese of Arles: That, about the year 570, it became famous enough to be commented upon; but that, all this while, and for several years lower, it had not yet acquired the name of *Athanasian*, but was simply styled *The Catholic Faith*: That, before 670, Athanasius's admired name came in to recommend and adorn it, being in itself an excellent system of the Athanasian principles of the trinity and incarnation, in opposition chiefly to the Arians, Macedonians, and Apollinarians. This is the hypothesis of the learned author of the *Critical History of the Athanasian Creed*.

As to the reception of this creed in the Christian churches, we find, that it obtained in France in the time of Hincmar, or about 850; that it was received in Spain about 100 years later than in France, and in Germany much about the same time. As to our own country, we have clear and positive proofs of this creed being sung alternately in our churches in the tenth century. It was in common use in some parts of Italy, particularly in the diocese of Verona, about the year 960, and was received at Rome about the year 1014. As to the Greek and oriental churches, it has been questioned, whether any of them ever received this creed at all; tho' some very considerable writers are of a contrary persuasion. It appears then, that the reception of this creed has been both general and ancient; and may vie with any, in that respect, except the Nicene, or Constantinopolitan, the only general creed common to all the churches.

As to the matter of this creed, it is given as a summary of the true orthodox faith, and a condemnation of all heresies ancient and modern. Unhappily, however, it has proved a fruitful source of unprofitable controversy and unchristian animosity even down to the present time.

ATHANASIUS (St), bishop of Alexandria, and one of the greatest defenders of the faith against the Arians, was born in Egypt. He followed St Alexander to the council of Nice, in 325, where he disputed against Arius, and the following year was made bishop of Alexandria; but, in 335, was deposed by the council of Tyre: when, having recourse to the emperor Constantine, the Arian deputies accused him of having hindered the exportation of corn from Alexandria to Constantinople; on which the emperor, without suffering him to make his defence, banished him to Treves. The emperor, two years after, gave orders that he should be restored to his bishopric: but, on his return to Alexandria, his enemies brought fresh accusations against him, and chose Gregory of Cappadocia to his see; which obliged Athanasius to go to Rome to reclaim it of pope Julius. He was there declared innocent, in a council held in 342, and in that of Sardica in 347, and two years after was restored to his see by order of the emperor Constantine; but after the death of that prince, he was again banished by the emperor Constantius, which obliged him to retire into the deserts. The Arians then elected one George in his room; who being killed in a popular sedition under Julian, in 360, St Athanasius returned to Alexandria, but was again banished under Julian, and restored to his see under Jovian. He addressed to that emperor a letter, in which he proposed that the Nicene creed should be the standard of the orthodox faith, and condemned those who denied the divinity of the Holy Ghost. He was also banished by Valens in 367, and afterwards recalled. St Athanasius died on the 2^d of May, 373.

His works principally contain a defence of the mystery of the Trinity, and of the incarnation and divinity of the Word and Holy Spirit. There are three editions of his works which are esteemed; that of Commelin, printed in 1600; that of Peter Nannius, in 1627; and that of father Montfaucon. As to the creed which bears his name, see the preceding article.

ATHANATI, in Persian antiquity, a body of cavalry, consisting of 10,000 men, always complete. They were called *athanati*, (a word originally Greek, and signifying *immortal*), because, when one of them happened to die, another was immediately appointed to succeed him.

ATHANOR. Chemists have distinguished by this name a furnace so constructed that it can always maintain an equal heat, and which shall last a long time without addition of fresh fuel.

The body of the athanor has nothing in it particular, and is constructed like ordinary furnaces. But at one of its sides, or its middle, there is an upright hollow tower, which communicates with the fire-place by one or more sloping openings. This tower ought to have a lid which exactly closes its upper opening.

When the athanor is to be used, as much lighted coal is put in the fire-place as is judged necessary, and the tower is filled to the top with unlighted fuel. The

Athor
||
Atheing.

Athelan
||
Athens.

tower is then to be exactly closed with its lid. As fast as the coal in the fire-place is consumed, that in the tower falls down and supplies its place. As the coal contained in the tower has no free communication with the external air, it cannot burn till it falls into the fire-place.

The athor being much celebrated and used by ancient chemists, it has been particularly described by many authors, and was formerly found in all laboratories. At present this furnace is much less employed, and is even neglected. The reason of this is, that all the ancient chemists were in search of the art of making gold; and being excited by this powerful desire, and confidence of success, they spared no trouble nor expense to accomplish this design. They undertook, without hesitation, operations which required great length of time and unremitting heat. Whereas now, these alluring hopes having vanished, the cultivators of chemistry have no other view than to extend and perfect the theory of this essential part of natural philosophy. This motive, altho' undoubtedly much nobler than the former, seems however to be less powerful over most men. For now, all long and laborious operations where chemistry might receive great advantages, are neglected, as being tiresome and disgusting. There is, in fact, a considerable difference betwixt the hope of explaining a philosophical phenomenon, and that of obtaining an ingot of gold capable of producing many others. Hence the instruments employed in long operations, and particularly the athor, are now much neglected; and also because the fuel in the tower is apt to stick there or fall down at once in too great quantity. The lamp-furnace, which is a true athor, may be successfully employed in operations which do not require much heat*.

* See Chemi-
stry, n^o 98, a.

ATHEISM, the disbelief of a deity. See ATHEIST.

ATHEIST, a person who does not believe the existence of a Deity. Many people, both ancient and modern, have pretended to atheism, or have been reckoned atheists by the world; but it is justly questioned whether any man seriously adopted such a principle. These pretensions, therefore, must be founded on pride or affectation.

Atheism, as absurd and unreasonable as it is, has had its martyrs. Lucilio Vanini, an Italian, native of Naples, publicly taught atheism in France, about the beginning of the seventeenth century; and, being convicted of it at Toulouse, was condemned to death. Being pressed to make public acknowledgement of his crime, and to ask pardon of God, the king, and justice, he answered, he did not believe there was a God; that he never offended the king; and, as for justice, he wished it to the devil. He confessed that he was one of twelve, who parted in company from Naples, to spread their doctrine in all parts of Europe. His tongue was first cut out, and then his body burnt, April 9. 1619.

ATHELING, ADELING, EDLING, ETHLING, or ETHELING, among the Anglo-Saxons, was a title of honour properly belonging to the heir apparent, or presumptive, to the crown. This honourable appellation was first conferred by king Edward the Confessor on Edgar, to whom he was great uncle, when, being without any issue of his own, he intended to make him his heir.

ATHELSTAN, a Saxon king of England, natural son of Edward the elder, and grandson of the great Alfred. He succeeded to the crown in 925, and reigned 16 years. There was a remarkable law passed by this prince, which shews his just sentiments of the advantages of commerce, as well as the early attention to it in this country: it declared, that any merchant who made three voyages on his own account beyond the British channel or narrow seas, should be entitled to the privileges of a thane, or gentleman.

ATHENEA, in antiquity, a feast celebrated by the ancient Greeks in honour of Minerva, who was called *Athene*.

ATHENÆUM, in antiquity, a public place where in the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their performances. These places, of which there were a great number at Athens, were built in the manner of amphitheatres, encompassed with seats, called *cunei*. The three most celebrated Athenæa were those at Athens, at Rome, and at Lyons, the second of which was built by the emperor Adrian.

ATHENÆUS, a physician, born in Cilicia, cotemporary with Pliny, and founder of the pneumatic sect. He taught that the fire, air, water, and earth, are not the true elements, but that their qualities are, *viz.* heat, cold, moisture, and dryness; and to these he added a fifth element, which he called *spirit*, whence his sect had its name.

ATHENÆUS, a Greek grammarian, born at Naucratis in Egypt in the 3^d century, one of the most learned men of his time. Of all his works we have none extant but his *Deipnosophis*, i. e. the *sophists at table*; there is an infinity of facts and quotations in this work which render it very agreeable to admirers of antiquity.

There was also a mathematician of this name, who wrote a treatise on mechanics, which is inserted in the works of the ancient mathematicians, printed at Paris in 1693, in folio, in Greek and Latin.

ATHENAGORAS, an Athenian philosopher, flourished about the middle of the 2^d century; and was remarkable for his zeal for Christianity, and his great learning, as appears from the apology which he addressed to the emperors Marcus Aurelius Antoninus and Lucius Commodus.

ATHENODORUS, a famous stoic philosopher, born at Tarsus, went to the court of Augustus, and was made by him tutor to Tiberius. Augustus had a great esteem for him, and found him by experience a man of virtue and probity. He used to speak very freely to the emperor. He, before he left the court to return home, warned the emperor not to give himself up to anger, but, whenever he should be in a passion, to rehearse the 24 letters of the alphabet before he resolved to say or do any thing. He did not live to see his bad success in the education of Tiberius.

ATHENOPOLIS, a town of the Massiliens, an ancient nation of Gaul. It is conjectured by Harduin to be the same with *Telo Martius*, now *Toulon*; by others to be the same with *Antipolis* or *Antibes*.

ATHENREE, a town of Ireland in the county of Galway, and province of Connaught. W. Long. 8. 5. N. Lat. 53. 14.

ATHENS, a celebrated city of Greece, and capital

Athens.

tal of the ancient kingdom of Attica, situated in E. Long. 53. N. Lat. 38. 5. See ATTICA.

In early times, that which was afterwards called the *citadel* was the whole city; and went under the name of *Cecropia*, from its founder Cecrops, whom the Athenians in after times affirmed to have been the first builder of cities, and called this therefore by way of eminence *Polis*, i. e. the city. In the reign of Erichthonius it lost the name of *Cecropia*, and acquired that of *Athens*, on what account is not certain; the most probable is, that it was so named in respect to the goddess Minerva, whom the Greeks call *Athene*, who was also esteemed its protectress. This old city was seated on the top of a rock in the middle of a large and pleasant plain, which, as the number of inhabitants increased, became full of buildings, which induced the distinction of Acro and Catapolis, i. e. of the upper and lower city. The extent of the citadel was 60 stadia; it was surrounded by olive trees, and fortified, as some say, with a strong palisade; in succeeding times it was encompassed with a strong wall, in which there were nine gates, one very large one, and the rest small. The inside of the citadel was adorned with innumerable edifices. The most remarkable of which were, 1. The magnificent temple of Minerva, styled *parthenion*, because that goddess was a virgin. The Persians destroyed it; but it was rebuilt with still greater splendour, by the famous Pericles, all of the finest marble, with such skill and strength, that, in spite of the rage of time and barbarous nations, it remains perhaps the first antiquity in the world, and stands a witness to the truth of what ancient writers have recorded of the prodigious magnificence of Athens in her flourishing state. 2. The temple of Neptune and of Minerva; for it was divided into two parts: one sacred to the god, in which was the salt fountain said to have sprung upon the stroke of his trident; the other to the goddess protectress of Athens, wherein was the sacred olive which she produced, and her image which fell down from heaven in the reign of Erichthonius. At the back of Minerva's temple was the public treasury, which was burnt to the ground through the knavery of the treasurers, who, having misapplied the revenues of the state, took this short method of making up accounts. The lower city comprehended all the buildings surrounding the citadel, the fort Munychia, and the havens Phalerum and Piræus, the latter of which was joined to the city by walls five miles in length; that on the north was built by Pericles, but that on the south by Themistocles; but by degrees the turrets which were at first erected on these walls were turned into dwelling-houses for the accommodation of the Athenians, whose large city was now become too small for them. The city, or rather the lower city, had 13 great gates, with the names of which it is not necessary to trouble the reader. Among the principal edifices which adorned it, we may reckon, 1. The temple of Theseus, erected by Conon, near its centre. Adjacent thereto, the young people performed their exercises. It was also a sanctuary for distressed persons, slaves or free. 2. The Olympian temple erected in honour of Jupiter, the honour of Athens, and of all Greece. The foundation of it was laid by Pisistratus: it was carried on but slowly in succeeding times, 700 years elapsing before it was finished, which happened under the reign

of Adrian, who was particularly kind to Athens: this was the first building in which the Athenians beheld pillars. 3. The pantheon, dedicated to all the gods; a most noble structure, supported by 120 marble pillars, and having over its great gate two horses carved by Praxiteles: it is yet remaining, as we shall have occasion to shew hereafter when we come to speak of the present state of this famous city. In several parts of it were *staoi* or portico's, wherein people walked in rainy weather, and from whence a sect of philosophers were denominated stoics, because their master Zeno taught in those portico's.

There were at Athens two places called *Ceramicus*, from Ceramus the son of Bacchus and Ariadne; one within the city, containing a multitude of buildings of all sorts; the other in the suburbs, in which was the academy, and other edifices. The Gymnasia of Athens were many; but the most remarkable were the Lyceum, Academia, and Cynosarges. The Lyceum stood on the banks of Ilissus; some say it was built by Pisistratus, others by Pericles, others by Lycurgus. Here Aristotle taught philosophy, instructing such as came to hear him as they walked, whence his disciples are generally thought to derive the name of peripatetics. The ceramicus without the city was the distance of six stadia from its walls. The academy made part thereof; as to the name of which there is some dispute. Some affirm that it was so called from Academus, an ancient hero, who, when Helen was stolen by Theseus, discovered the place where she lay hid, to Castor and Pollux: for which reason the Lacedæmonians, when they invaded Attica, always spared this place. Dicaearchus writes, that Castor and Pollux had two Arcadians in their army, the one named *Echeademus*, the other *Marrothus*; from the former of these he says this place took its name, and that the borough of Marathon was so called from the other. It was a marshy unwholesome place, till Cimon was at great pains to have it drained; and then it became extremely pleasant and delightful, being adorned with shady walks, where Plato read his lectures, and from thence his scholars were styled *academics*. The Cynosarges was a place in the suburbs not far from the Lyceum: it was famous on many accounts; but particularly for a noble gymnasium erected there, appointed for the special use of such as were Athenians only by one side. In after times Themistocles derived to himself ill-will, by carrying many of the nobility to exercise with him here, because, being but of the half blood, he could exercise no where else but in this gymnasium. Antisthenes instituted a sect of philosophers, who from the name of this district, as many think, were styled *Cynics*.

The havens of Athens were three. First the Pyræus, which was distant about 35 or 40 stadia from the city, till joined thereto by the long walls beforementioned, after which it became the principal harbour of the city. It had three docks; Cantharos, Aphrodisium, and Zea: the first was so called from an ancient hero, the second from the goddess Venus who had there two temples, and the third from bread-corn. There were in this port five portico's, which joining together formed one great one called from thence *Macra Stoa*, or the grand portico. There were likewise two great markets or fora; one near the long portico, the other near the city. The second port was Munichia, a promontory

Athens.

By whom founded.

Remarkable buildings.

Ceramicus,

Cynosarges,

Havens.

Athens.

not far distant from Pyræus; a place very strong by nature, and afterwards rendered far stronger by art. It was of this that Epimenides said, if the Athenians foreswear what mischief it would one day produce to them, they would eat it away with their teeth. The third was Phalerum, distant from the city, according to Thucydides, 35 stadia, but according to Pausanias only 20. This was the most ancient harbour of Athens, as Pyræus was the most capacious.

6
Present
state.

Of this city, as it stands at present, we have the following account by Dr Chandler. "It is now called *Athini*; and is not inconsiderable, either in extent or the number of inhabitants. It enjoys a fine temperature, and a serene sky. The air is clear and wholesome, though not so delicately soft as in Ionia. The town stands beneath the Acropolis or citadel; not encompassing the rock, as formerly; but spreading into the plain, chiefly on the west and north-west. Corsairs infesting it, the avenues were secured, and in 1676 the gates were regularly shut after sunset. It is now open again; but several of the gateways remain, and a guard of Turks patrols at midnight. Some masses of brick-work, standing separate, without the town, belonged perhaps to the ancient wall, of which other traces also appear. The houses are mostly mean, and straggling; many with large areas or courts before them. In the lanes, the high walls on each side, which are commonly white-washed, reflect strongly the heat of the sun. The streets are very irregular; and anciently were neither uniform nor handsome. They have water conveyed in channels from mount Hymettus, and in the bazar or market-place is a large fountain. The Turks have several mosques and public baths. The Greeks have convents for men and women; with many churches, in which service is regularly performed; and besides these, they have numerous oratories or chapels, some in ruins or consisting of bare walls, frequented only on the anniversaries of the saints to whom they are dedicated. A portrait of the owner on a board is placed in them at that occasion, and removed when the solemnity of the day is over.

7
Citadel, or
city of Ce-
crops.

"The city of Cecrops is now a fortress with a thick irregular wall, standing on the brink of precipices, and inclosing a large area about twice as long as broad. Some portions of the ancient wall may be discovered on the outside, particularly at the two extreme angles; and in many places it is patched with pieces of columns, and with marbles taken from the ruins. A considerable sum had been recently expended on the side next Hymettus, which was finished before we arrived. The scaffolding had been removed to the end toward Pentele; but money was wanting, and the workmen were withdrawn. The garrison consists of a few Turks, who reside there with their families, and are called by the Greeks *Gabriani*, or the soldiers of the castle. The rock is lofty, abrupt, and inaccessible, except the front, which is toward the Piræus; and on that quarter is a mountainous ridge, within cannon-shot. It is destitute of water fit for drinking; and supplies are daily carried up in earthen jars, on horses and asses, from one of the conduits in the town.

"The acropolis furnished a very ample field to the ancient virtuosi. It was filled with monuments of Athenian glory, and exhibited an amazing display of beauty, of opulence, and of art; each contending, as it

Athens.

was, for the superiority. It appeared as one entire offering to the Deity, surpassing in excellence, and astonishing in richness. Heliodorus, named Periegetes *the guide*, had employed on it 15 books. The curiosities of various kinds, with the pictures, statues, and pieces of sculpture, were so many and so remarkable, as to supply Polemo Periegetes with matter for four volumes; and Strabo affirms, that as many would be required in treating of other portions of Athens and of Attica. In particular, the number of statues was prodigious. Tiberius Nero, who was fond of images, plundered the acropolis, as well as Delphi and Olympia; yet Athens, and each of these places, had not fewer than 3000 remaining in the time of Pliny. Even Pausanias seems here to be distressed by the multiplicity of his subject. But this banquet, as it were, of the senses has long been withdrawn; and is now become like the tale of a vision. The spectator views with concern the marble ruins intermixed with mean flat-roofed cottages, and extant amid rubbish; the sad memorials of a nobler people; which, however, as visible from the sea, should have introduced modern Athens to more early notice. They who reported it was only a small village, must, it has been surmised, have beheld the acropolis through the wrong end of their telescopes.

"The acropolis has now, as formerly, only one entrance, which fronts the Piræus. The ascent is by traverses and rude fortifications furnished with cannon, but without carriages, and neglected. By the second gate is the station of the guard, who fits cross-legged under cover, much at his ease, smoking his pipe, or drinking coffee, with his companions about him in like attitudes. Over this gateway is an inscription in large characters on a stone turned upside down, and black from the fires made below. It records a present of a pair of gates.

8
Propylæa

"Going farther up, you come to the ruins of the propylæa, an edifice which graced the entrance into the citadel. This was one of the structures of Pericles, who began it when Euthymenes was archon, 435 years before Christ. It was completed in five years, at the expense of 2012 talents. It was of marble, of the Doric order, and had five doors to afford an easy passage to the multitudes which resorted on business or devotion to the acropolis.

"While this fabric was building, the architect Mnesicles, whose activity equalled his skill, was hurt by a fall, and the physicians despaired of his life; but Minerva, who was propitious to the undertaking, appeared, it was said, to Pericles, and prescribed a remedy, by which he was speedily and easily cured. It was a plant or herb growing round about the acropolis, and called afterwards *parthenium*.

9
Temple
Victory.

"The right wing of the propylæa was a temple of victory. They related that Ægeus had stood there, viewing the sea, and anxious for the return of his son Theseus, who was gone to Crete with the tributary children to be delivered to the Minotaur. The vessel which carried them had black sails suiting the occasion of its voyage; and it was agreed, that, if Theseus overcame the enemy, their colour should be changed to white. The neglect of this signal was fatal to Ægeus, who, on seeing the sails unaltered, threw himself down headlong from the rock, and perished. The idol was named

Athens. named *Victory without wings*; it was said, because the news of the success of Theseus did not arrive, but with the conqueror. It had a pomegranate in the right hand, and an helmet in the left. As the statue was without pinions, it was hoped the goddess would remain for ever on the spot.

“ On the left wing of the propylæa, and fronting the temple of Victory, was a building decorated with paintings by Polygnotus, of which an account is given by Pausanias. This edifice, as well as the temple, was of the Doric order, the columns fluted, and without bases. Both contributed alike to the uniformity and grandeur of the design; and the whole fabric, when finished, was deemed equally magnificent and ornamental. The interval between Pericles and Pausanias consists of several centuries. The propylæa remained entire in the time of this topographer, and, as will be shown, continued nearly so to a much later period. It had then a roof of white marble, which was unsurpassed either in the size of the stones, or in the beauty of their arrangement; and before each wing was an equestrian statue.

“ The propylæa have ceased to be the entrance of the acropolis. The passage, which was between the columns in the centre, is walled up almost to their capitals, and above is a battery of cannon. The way now winds before the front of the ancient structure; and, turning to the left hand among rubbish and mean walls, you come to the back part, and to the five doorways. The soil without is risen higher than the top of the two smaller. There, under the vault and cannon, lies an heap of large stones, the ruin of the roof.

“ The temple of Victory, standing on an abrupt rock, has its back and one side unencumbered with the modern ramparts. The columns in the front being walled up, you enter it by a breach in the side, within the propylæa. It was used by the Turks as a magazine for powder, until about the year 1656; when a sudden explosion, occasioned by lightning, carried away the roof, with a house erected on it, belonging to the officer who commanded in the acropolis, whose family, except a girl, perished. The women of the Aga continued to inhabit in this quarter, but it is now abandoned and in ruins.

“ The cell of the temple of Victory, which is of white marble, very thick, and strongly cemented, sufficiently witnesses the great violence it has undergone; the stones in many places being disjointed, as it were, and forced from their original position. Two of these making an acute angle, the exterior edges touching, without a crevice; and the light abroad being much stronger than in the room, which has a modern roof and is dark; the portion in contact becoming pellucid, had illumined the vacant space with a dim colour resembling that of amber. We were desirous to examine this extraordinary appearance, which the Greeks regarded as a standing miracle, and which the Turks, who could not confute them, beheld with equal astonishment. We found in the gape some coals, which had been brought on a bit of earthen ware for the purpose of burning incense, as we supposed, and also a piece of wax-taper, which probably had been lighted in honour of the faint and author of the wonder; but our Swiss unfortunately carrying his own candle too far in, the smoke blackened the marble, and de-

froyed the phenomenon.

“ The building opposite to the temple has served as a foundation for a square lofty tower of ordinary masonry. The columns of the front are walled up, and the entrance is by a low iron gate in the side. It is now used as a place of confinement for delinquents; but in 1676 was a powder-magazine. In the wall of a rampart near it are some fragments of exquisite sculpture, representing the Athenians fighting with the Amazons. These belong to the frieze, which was then standing. In the second century, when Pausanias lived, much of the painting was impaired by age, but some remained, and the subjects were chiefly taken from the Trojan story. The traces are since vanished.

“ The pediment of the temple of Victory, with that of the opposite wing, is described as remaining in 1676; but on each building a square tower had been erected. One of the steps in the front of the propylæa was entire, with the four columns, their entablature and the pediment. The portico, to which the five doorways belonged, consisted of a large square room, roofed with slabs of marble, which were laid on two great marble beams, and sustained by four beautiful columns. These were Ionic, the proportions of this order best suited that purpose, as taller than the Doric; the reason it was likewise preferred in the pronaos of the temple of Victory. The roof of the propylæa, after standing above 2000 years, was probably destroyed, with all the pediments, by the Venetians in 1687, when they battered the castle in front, firing red-hot bullets, and took it, but were compelled to resign it again to the Turks in the following year. The exterior walls, and, in particular, a side of the temple of Victory, retain many marks of their hostilities.

“ The chief ornament of the acropolis was the parthenon or great temple of Minerva, a most superb and magnificent fabric. The Persians had burned the edifice, which before occupied the site, and was called *hecatompedon*, from its being 100 feet square. The zeal of Pericles and of all the Athenians was exerted in providing a far more ample and glorious residence for their favourite goddess. The architects were Callicrates and Ictinus; and a treatise on the building was written by the latter and Carion. It was of white marble, of the Doric order, the columns fluted and without bases, the number in front eight; and adorned with admirable sculpture. The story of the birth of Minerva was carved in the front pediment; and in the back, her contest with Neptune for the country. The beasts of burden, which had conveyed up the materials, were regarded as sacred, and recompensed with pastures; and one, which had voluntarily headed the train, was maintained during life, without labour, at the public expence.

“ The statue of Minerva, made for this temple by Phidias, was of ivory, 26 cubits or 39 feet high. It was decked with pure gold to the amount of 44 talents, so disposed by the advice of Pericles as to be taken off and weighed, if required. The goddess was represented standing, with her vestment reaching to her feet. Her helmet had a sphinx for the crest, and on the sides were griffins. The head of Medusa was on her breast-plate. In one hand she held her spear, and in the other supported an image of Victory about four cubits high. The battle of the Centaurs and

Lapithe

to
Roof carried off by an explosion.

11
Temple of Minerva.

12
Her statue.

Athens.

Lapithæ was carved on her sandals; and on her shield, which lay at her feet, the war of the gods and giants, and the battle of the Athenians and Amazons. By her spear was a serpent, in allusion to the story of Erichthonius; and on the pedestal, the birth of Pandora. The Sphinx, the Victory, and Serpent, were accounted eminently wonderful. This image was placed in the temple in the first year of the 87th Olympiad, in which the Peloponnesian war began. The gold was stripped off by the tyrant Lachares, when Demetrius Poliorettes compelled him to fly. The same plunderer plucked down the golden shields in the acropolis, and carried away the golden Victories, with the precious vessels and ornaments provided for the Panathenæan festival.

“The parthenon remained entire for many ages after it was deprived of the goddess. The Christians converted it into a church, and the Mahometans into a mosque. It is mentioned in the letters of Crusius, and miscalled the *pantheon*, and the *temple of the unknown God*. The Venetians under Koningmark, when they besieged the acropolis in 1687, threw a bomb, which demolished the roof, and setting fire to some powder, did much damage to the fabric. The floor, which is indented, still witnesses the place of its fall. This was the sad forerunner of farther destruction; the Turks breaking the stones, and applying them to the building of a new mosque, which stands within the ruin, or to the repairing of their houses and the walls of the fortrefs. The vast pile of ponderous materials, which lay ready, is greatly diminished; and the whole structure will gradually be consumed and disappear.

13
Temple converted into a mosque.

The temple of Minerva in 1676 was, as Wheeler and Spon assert, the finest mosque in the world, without comparison. The Greeks had adapted the fabric to their ceremonial by constructing at one end a semicircular recess for the holy tables, with a window: for before it was enlightened only by the door, obscurity being preferred under the heathen ritual, except on festivals, when it yielded to splendid illuminations; the reason, it has been surmised, why temples are commonly found simple and unadorned on the insides. In the wall beneath the window were inserted two pieces of the stone called *phengites*, a species of marble discovered in Cappadocia in the time of Nero; and so transparent, that he erected with it a temple to Fortune, which was luminous within, when the door was shut. These pieces were perforated, and the light which entered was tinged with a reddish or yellowish hue. The picture of the Panagia or Virgin Mary, in Mosaic, on the ceiling of the recess, remained; with two Jasper columns belonging to the ikreen, which had separated that part from the nave; and within, a canopy supported by four pillars of porphyry, with Corinthian capitals of white marble, under which the table had been placed; and behind it, beneath the window, a marble chair for the archbishop; and also a pulpit, standing on four small pillars in the middle aisle. The Turks had white-washed the walls, to obliterate the portraits of saints, and the other paintings, with which the Greeks decorate their places of worship; and had erected a pulpit on the right hand for their iman or reader. The roof was disposed in square compartments; the stones massive; and some had fal-

len in. It had been sustained in the pronaos by six columns; but the place of one was then supplied by a large pile of rude masonry, the Turks not having been able to fill up the gap more worthily. The roof of the naos was supported by colonnades ranging with the door, and on each side; consisting of 22 pillars below, and of 23 above. The odd one was over the entrance, which by that disposition was left wide and unembarrassed. In the portico were suspended a few lamps, to be used in the mosque at the seasons when the musfelmans assemble before day-break, or to be lighted up round the minaret, as is the custom during their Ramadan or Lent.

“It is not easy to conceive a more striking object than the parthenon, though now a mere ruin. The columns within the naos have all been removed: but on the floor may be seen the circles which directed the workmen in placing them; and at the farther end is a groove across it, as for one of the partitions of the cell. The recess erected by the Christians is demolished; and from the rubbish of the ceiling the Turkish boys collect bits of the Mosaic, of different colours, which composed the picture. We were told at Smyrna, that this substance had taken a polish, and been set in buckles. This cell is about half demolished; and in the columns, which surrounded it, is a large gap near the middle. On the walls are some traces of the paintings. Before the portico is a reservoir sunk in the rock, to supply the Turks with water for the purifications customary on entering their mosques. In it, on the left-hand, is the rubbish of the pile erected to supply the place of a column; and on the right, a staircase, which leads out on the architrave, and has a marble or two with inscriptions, but worn so as not to be legible. It belonged to the minaret, which has been destroyed.

74
Magnificent ruin.

“The travellers, to whom we are indebted for an account of the mosque, have likewise given a description of the sculpture then remaining in the front. In the middle of the pediment was seen a bearded Jupiter, with a majestic countenance, standing, and naked; the right arm broken. The thunder-bolt, it has been supposed, was placed in that hand, and the eagle between his feet. On his right was a figure, it is conjectured, of Victory, clothed to the mid-leg; the head and arms gone. This was leading on the horses of a car, in which Minerva sat, young and unarmed; her head-dress, instead of a helmet, resembling that of a Venus. The generous ardour and lively spirit visible in this pair of celestial steeds, was such as bespoke the hand of a master, bold and delicate, of a Phidias or Praxiteles. Behind Minerva was a female figure, without a head, sitting, with an infant in her lap; and in this angle of the pediment was the emperor Hadrian with his arm round Sabina, both reclining, and seeming to regard Minerva with pleasure. On the left side of Jupiter were five or six other trunks to complete the assembly of deities, into which he received her. These figures were all wonderfully carved, and appeared as big as life. Hadrian and his consort, it is likely, were complimented by the Athenians with places among the marble gods in the pediment, as benefactors. Both of them may be considered as intruders on the original company; and possibly their heads were placed on trunks, which before had other owners. They

75
Sculpture.

still

Athens.

still possess their corner, and are easy to be recognized, though not unimpaired. The rest of the statues are defaced, removed, or fallen. Morosini was ambitious to enrich Venice with the spoils of Athens; and by an attempt to take down the principal group, hastened their ruin. In the other pediment is a head or two of sea-horses finely executed, with some mutilated figures; and on the architrave beneath them are marks of the fixtures of votive offerings, perhaps of the golden shields, or of festoons suspended on solemn occasions, when the temple was dressed out to receive the votaries of the goddesses.

16

Erechtheum.

“ Neptune and Minerva, once rival deities, were joint and amicable tenants of the Erechtheum, in which was an altar of Oblivion. The building was double, a partition-wall dividing it into two temples, which fronted different ways. One was the temple of Neptune Erechtheus, the other of Minerva Polias. The latter was entered by a square portico connected with a marble screen, which fronts towards the propylæa. The door of the cell was on the left hand; and at the farther end of the passage was a door leading down into the Pandrosæum, which was contiguous.

17

temple of Neptune E. crechtheus.

“ Before the temple of Neptune Erechtheus was an altar of Jupiter the *supreme*, on which no living thing was sacrificed, but they offered cakes without wine. Within it was the altar of Neptune and Erechtheus; and two, belonging to Vulcan and a hero named *Buteus*, who had transmitted the priesthood to his posterity, which were called *Butade*. On the walls were paintings of this illustrious family, from which the priestesses of Minerva Polias was also taken. It was asserted that Neptune had ordained the well of salt water, and the figure of a trident in the rock, to be memorials of his contending for the country. The former, Pausanias remarks, was no great wonder, for other wells of a similar nature were found inland; but this, when the fourth wind blew, afforded the sound of waves.

19

of Minerva Polias.

“ The temple of Minerva Polias was dedicated by all Attica, and possessed the most ancient statue of the goddesses. The demi or towns had other deities, but their zeal for her suffered no diminution. The image, which they placed in the acropolis, then the city, was in after ages not only reputed consummately holy, but believed to have fallen down from heaven in the reign of Erichthonius. It was guarded by a large serpent, which was regularly served with offerings of honied cakes for his food. This divine reptile was of great sagacity, and attained to an extraordinary age. He wisely withdrew from the temple, when in danger from the Medes; and, it is said, was living in the second century. Before this statue was an owl; and a golden lamp. This continued burning day and night. It was contrived by a curious artist, named *Callimachus*, and did not require to be replenished with oil oftener than once a-year. A brazen palm-tree, reaching to the roof, received its smoke. Aristion had let the holy flame expire while Sylla besieged him, and was abhorred for his impiety. The original olive-tree, said to have been produced by Minerva, was kept in this temple. When the Medes set fire to the acropolis, it was consumed; but, they asserted, on the following day, was found to have shot up again as much as a cubit. It grew low and crooked, but was esteemed very holy. The priestesses of Minerva was not allowed

Athens.

to eat of the new cheefe of Attica; and, among her perquisites, was a measure of wheat, and one of barley, for every birth and burial. This temple was again burned when Callias was archon, 24 years after the death of Pericles. Near it was the tomb of Cecrops, and within it Erechtheus was buried.

“ The ruin of the Erechtheum is of white marble; the architectural ornaments of very exquisite workmanship, and uncommonly curious. The columns of the front of the temple of Neptune are standing with the architrave; and also the screen and portico of Minerva Polias, with a portion of the cell retaining traces of the partition-wall. The order is Ionic. An edifice revered by ancient Attica, as holy in the highest degree, was in 1676 the dwelling of a Turkish family, and is now deserted and neglected; but many ponderous stones and much rubbish must be removed before the well and trident would appear. The former, at least, might probably be discovered. The portico is used as a powder-magazine; but we obtained permission to dig and to examine the outside. The door-way of the vestibule is walled up, and the soil risen nearly to the top of the door-way of the Pandrosæum. By the portico is a battery commanding the town, from which ascends an amusing hum. The Turks fire from it, to give notice of the commencement of Ramazan or of their Lent, and of bairam or the holy-days, and on other public occasions.

“ The pandrosæum is a small, but very particular building, of which no satisfactory idea can be communicated by description. The tabernacle is supported by women called *Caryatides*. Their story is thus related. The Greeks, victorious in the Persian war, jointly destroyed Carya, a city of the Peloponnesus, which had favoured the common enemy. They cut off the males, and carried into captivity the women, whom they compelled to retain their former dress and ornaments, though in a state of servitude. The architects of those times, to perpetuate the memory of their punishment, represented them, as in this instance, each with a burden on her head, one hand uplifted to it, and the other hanging down by her side. The images were in number six, all looking toward the parthenon. The four in front, with that next to the propylæa, remain, but mutilated, and their faces besmeared with paint. The soil is risen almost to the top of the basement on which they are placed. This temple was open or latticed between the statues; and in it also was a stunted olive-tree, with an altar of Jupiter Hercæus standing under it. The propylæa are nearly in a line with the space dividing it from the parthenon; which disposition, besides its other effects, occasioned the front and flank of the latter edifice to be seen at once by those who approached it from the entrance of the acropolis.

“ The ruin of the temple of Jupiter Olympius consists of prodigious columns, tall and beautiful, of the Corinthian order, fluted; some single, some supporting their architraves; with a few massive marbles beneath; the remnant of a vast heap, which only many ages could have consumed and reduced into so scanty a compass. The columns are of very extraordinary dimensions, being about six feet in diameter, and near sixty in height. The number without the cell was 116 or 120. Seventeen were standing in 1676; but a few years before we arrived,

19
of Jupiter Olympius.

ved,

Athens.

ved, one was overturned with much difficulty, and applied to the building a new mosque in the bazar or market-place. This violence was avenged by the bashaw of Negropont, who made it a pretext for extorting from the waiwode or governor 15 purses; the pillar being, he alleged, the property of their master the Grand Signior. It was an angular column, and of consequence in determining the dimensions of the fabric. We regretted that the fall of this mighty mass had not been postponed until we came, as it would have afforded an opportunity of inspecting and measuring some members which we found far too lofty to be attempted. On a piece of the architrave, supported by a couple of columns, are two parallel walls, of modern masonry, arched about the middle, and again near the top. You are told it has been the habitation of a hermit, doublets of a Stylites; but of whatever building it has been part, and for whatever purpose designed, it must have been erected thus high in air, while the immense ruin of this huge structure was yet scarcely diminished, and the heap inclined so as to render it accessible. It was remarked that two stones of a step in the front had coalesced at the extremity, so that no juncture could be perceived; and the like was discovered also in a step of the parthenon. In both instances it may be attributed to a concretionary fluid, which pervades the marble in the quarry. Some portion remaining in the pieces, when taken green as it were, and placed in mutual contact, it excluded and united them by a process similar to that in a bone of an animal when broken and properly set.

20
Detached
pieces of an-
tique sculp-
ture, &c.

“ Besides the more stable antiquities, many detached pieces are found in the town, by the fountains, in the streets, the walls, the houses, and churches. Among these are fragments of sculpture; a marble chair or two, which probably belonged to the Gymnasium or theatres; a fun-dial at the catholicon or cathedral, inscribed with the name of the maker; and, at the archiepiscopal house close by, a very curious vessel of marble, used as a cistern to receive water, but once serving, it is likely, as a public standard or measure. Many columns occur; with some maimed statues; and pedestals, several with inscriptions, and almost buried in earth. A custom has prevailed, as at Chios, of fixing in the wall, over the gateways and doors of the houses, carved stones, most of which exhibit the funeral supper. In the courts of the houses lie many round stela, or pillars, once placed on the graves of the Athenians; and a great number are still to be seen applied to the same use in the Turkish burying grounds before the acropolis. These generally have concise inscriptions containing the name of the person, and of the town and tribe, to which the deceased belonged. Demetrius the Phalerean, who endeavoured to restrain sepulchral luxury, enacted, that no person should have more than one, and that the height should not exceed three cubits. Another species, which resembles our modern head-stones, is sometimes adorned with sculpture, and has an epitaph in verse. We saw a few mutilated Hermæ. These were built on long quadrangular bases, the heads frequently of brass, invented by the Athenians. At first they were made to represent only Hermes or Mercury, and designed as guardians of the sepulchres in which they were lodged; but afterwards the houses, streets, and

Athens.

Athens.

porticoes of Athens, were adorned with them, and rendered venerable by a multitude of portraits of illustrious men and women, of heroes and of gods: and, it is related, Hipparchus, son of Pisistratus, erected them in the demi or borough-towns, and by the road side, inscribed with moral apophthegms in elegiac verse; thus making them vehicles of instruction.”

ATHERINA, in ichthyology, a genus of fishes of the order of abdominales. The characters of this genus are these: The upper jaw is plain: the rays of the branchiosteege membrane are six; and the side-belt or line shines like silver. The species are two, viz. 1. The hepsetus, with about 12 rays in the fin next the anus. It is found in the Mediterranean. It is also very common in the sea near Southampton, where it is called a *finelt*. The highest season is from March to the latter end of May, or beginning of June; in which month it spawns. It never deserts the place; and is constantly taken except in hard frost. It is also found on other coasts of our island. The length is above four inches $\frac{1}{2}$, and the tail is much forked. The fish is semipellucid, covered with scales; the colour silvery, tinged with yellow: beneath the side-line is a row of small black spots. 2. The menidea, with 24 rays in the fin next the anus. This is a very small pellucid fish, with many black points interperled; it has many teeth in the lips, but none in the tongue or jaws. It is found in the fresh waters of Carolina, and spawns in April.

ATHEROMA, in surgery, a tumour without pain or discoloration of the skin, containing, in a membranous bag, matter resembling pap, intermixed with hard and stony particles. These tumours are easily cured by incision.

ATHERTON, or ATHERSTON, a town of Warwickshire in England, situated on the river Stour, in W. Long. 1. 30. N. Lat. 52. 40. It is a considerable town, and had formerly a monastery; but now is best known by its fair, which is the greatest in England for cheese.

ATHLETÆ, in antiquity, persons of strength and agility, disciplined to perform in the public games. The word is originally Greek, ἀθλητής; formed from ἀθλος, certamen, combat; whence also ἀθλον, the prize or reward adjudged the victor. Under athlete were comprehended wrestlers, boxers, runners, leapers, throwers of the disk, and those practised in other exercises exhibited in the Olympic, Pythian, and other solemn sports; for the conquerors wherein there were established prizes.

ATHLETIC HABIT, denotes a strong hale constitution of body. Anciently it signified a full fleshy corpulent state, such as the athlete endeavoured to arrive at. The athletic habit is esteemed the highest pitch of health: yet is it dangerous, and the next door to disease; since, when the body is no longer capable of being improved, the next alteration must be for the worse. The chief object of the athletic diet, was to obtain a firm, bulky, weighty body; by force of which, more than art and agility, they frequently overpowered their antagonist: hence they fed altogether on dry, solid, and viscous meats. In the earlier days, their chief food was dry figs, and cheese, which was called *arida saginatio*, ἄριστα τροφῆς, and Ἀκκίαις διαίτην ἰσχυροῦν. Orbalus, or, as others say, Pythagoras, first brought
this

Athlone
||
Athos.

this in difuse, and fubftituted flefh in lieu thereof. They had a peculiar bread called *κροτωνια*: They exercifed, eat, and drank, without ceafing: they were not allowed to leave off eating when fatiated, but were obliged to cram on till they could hold no more; by which means they at length acquired a degree of voracity which to us feems incredible, and a ftrength proportional. Witnefs what Pausanias relates of the four celebrated athletes, Polydamas the Theffalian, Milo the Crotonian, Theagenes the Thalian, and Euthymus the Locrian *: The fecond is faid to have carried a bull on his back a confiderable way, then to have knocked him down with a blow of his fist, and laftly, as fome add, devoured him at a meal.

ATHLONE, a town of Weftmeath in Ireland, fituated on the river Shannon, in W. Long. 8. o. N. Lat. 53. 20. It is pretty large, and divided into two parts by the river, over which there is a ftone bridge. Both divifions are well fortified, but it was taken by king William in 1691. Below this town the country is low, flat, and marfhy; and on the bank of the Shannon there is a great bog, the foil of which is good for nothing but to make turf. This bog extends 50 miles in length, and in fome places is two or three miles broad.

ATHOL, the moft northern diftrict of Perthshire in Scotland, extending in length forty-three miles, and in breadth thirty. It is bordered on the north by Badenoch, on the weft by Lochaber, on the eaft and fouth-eaft by Mar and Gowrie, on the fouth by Strathern and Perth Proper, and on the fouth-weft by Braidalbane. The country is very rough and mountainous, and contains part of the ancient Caledonian foreft, but thefe mountains are interperfed with fruitful valleys. Here are feveral villages, but no towns of any confideration. The moft noted place is Blair Caftle, feated on the river Tilt, near its influx into the Gurry, a pleafant limpid ftream, that falls into the Tay. This caftle belongs to the duke of Athol, who derives his title from this diftrict, and lives here with great magnificence. In the fame neighbourhood we fee the pafs of Gillicranky, rendered memorable by the battle fought here in the beginning of king William's reign, between that monarch's general McKay, and the Highlanders adhering to king James. See GILLICRANKY.

ATHOS, a celebrated mountain of Chalcidia in Macedonia, fituated E. Long. 26. 20. N. Lat. 40. 10. The ancients entertained extravagant notions concerning its height. Mela affirmed it to be fo high as to reach above the clouds; and Martianus Capellinus, that it was fix miles high. It was a received opinion, that the fummit of mount Athos was above the middle region of the air, and that it never rained there; becaufe the afhes left on the altars erected near its fummit were always found as they were left, dry and unfcattered. But if on many accounts it was famous among the ancients, it is no lefs fo among the moderns. The Greeks, ftuck with its fingular fituation and the venerable appearance of its towering afcent, erected fo many churches, monafteries, hermitages, &c. upon it, that it became in a manner inhabited by devotees, and from thence received the name of the *Holy Mountain*; which name it ftill retains, though many of thofe conſecrated works are now decayed. According to the accounts of modern travellers, this mountain advances into the Archipelago, being joined to the continent by

Vol. II.

an ifthmus about half a league in breadth. It is about 30 miles in circumference, and two in perpendicular height. It may be travelled over in about three days, and may be feen 90 miles off. There is a fine profpect from the top; but, like all other high mountains, the cold on its fummit is exceffive. It abounds with many different kinds of plants and trees, particularly the pine and fir. In the valleys grows a plant called *elogia*, whose branches ferve to make pens for writing. In ſhort, this mountain is faid to be adorned with variety of herbage and evergreens, a multitude of fprings and ftreams, and woods growing near the ſhore, fo as to be one of the moft agreeable places in the world.

It is now inhabited by Caloyers, a fort of Greek monks, of the order of St Baſil, who never marry; though others of that church do. They abſtain from flefh, and fare very hardly, their ordinary meal being olives pickled when they are ripe. They are about 6000 in all, and inhabit feveral parts of the mountain, on which are 24 large old monafteries, furrrounded with high walls for a defence againſt banditti. They are fo reſpected, that the Turks themſelves will often fend them alms. Theſe monks are not idle like others; but labour with the ax, fpade, and ſickle, dreſſing themſelves like hermits. Formerly they had fine Greek manuſcripts; but are now become fo illiterate, that they can ſcarce read or write.

Through this mountain, or rather through the iſthmus behind it, Xerxes king of Perſia is ſaid to have cut a paſſage for his fleet when about to invade Greece. In this work he ſpent three whole years, and employed in it all the forces on board the fleet. He is alſo ſaid, before the work was begun, to have written the following inſolent and ridiculous letter to the mountain: "Athos, thou proud and aſpiring mountain, that liſteſt up thy head to the very ſkies, I adviſe thee not to be ſo audacious as to put rocks and ſtones, that cannot be cut, in the way of my workmen. If thou makeſt that oppoſition, I will cut thee entirely down, and throw thee headlong into the ſea." The directors of this enterpriſe are ſaid to have been Bubaris the ſon of Megabyzus, and Artacheus the ſon of Arbeus, both Perſians; but as no traces of ſuch a great work remain, the truth of the whole relation has juſtly been called in queſtion.

ATHY, a town of Ireland in the county of Kildare, not far from the borders of Queen's county. W. Long. 7. o. N. Lat. 53. o.

ATIGNY, an ancient town of Champagne in France, where ſeveral of the kings of France had their reſidence. It is ſeated on the river Arſne, in E. Long. 4. 47. N. Lat. 49. 30.

ATKINS (Sir Robert), lord chief baron of the exchequer, was born in 1621, and educated at the univerſity of Oxford, from whence he removed to the inns of court, and became eminent in the law. He was made knight of the Bath, with many other perſons of the firſt diſtinction, at the coronation of king Charles II. In 1672, he was appointed one of the judges of Common Pleas; in which honourable ſtation he continued till 1679, when, foreſeeing the troubles that ſoon after enſued, he thought fit to reſign, and retire into the country. In 1689, he was made by king William lord chief baron of the exchequer; and about the ſame time executed the office of ſpeaker to

Athos
||

Atkins
Atlantis.

the house of lords, which had been previously refused by the marquis of Halifax. He distinguished himself by an unshaken zeal for the laws and liberties of his country. He wrote several pieces, which have been collected into one volume 8vo, under the title of *Parliamentary and Political Tracts*. The authors of the *Biographia Britannica* remark, that whoever inclines to be thoroughly informed of the true constitution of his country, of the grounds and reasons of the revolution, and of the danger of suffering prerogative to jostle law, cannot read a better or plainer book than those tracts of Sir Robert Atkins. He died in 1709, aged 88.

ATKINS (Sir Robert), son of the preceding, was born in 1646, and was eminent for all the virtues that could adorn an English gentleman. He wrote the ancient and present state of Gloucestershire, in one large volume in folio; and died October 29, 1711.

ATKINS (Richard), was descended from a good family, and was born at Tuffleigh, in Gloucestershire, in the year 1615. He was educated at Oxford, from whence he removed to Lincoln's Inn, and afterwards distinguished himself by his loyalty to king Charles I. for whom he raised a troop of horse at his own expense. At the Restoration he was made one of the deputy lieutenants of Gloucestershire, and distinguished himself by his attachment to the government. But at length being committed prisoner to the Marshalsea in Southwark for debt, he died there on the 14th of September 1677. He wrote several pieces, particularly a treatise on the original and growth of Printing.

ATLANTIC OCEAN, that bounded by Europe and Africa on the east, and by America on the west.

ATLANTICA. See ATLANTIS.

ATLANTIDES, in astronomy, a denomination given to the Pleiades, or seven stars, sometimes also called *Vergilæ*. They are thus called, as being supposed by the poets to have been the daughters either of Atlas, or his brother Hesperus, who were translated into heaven.

ATLANTIS, ATALANTIS, or ATLANTICA, an island mentioned by Plato, and some others of the ancients, concerning the real existence of which many disputes have been raised. Homer, Horace, and the other poets, make two Atlanticas, calling them *Hesperides*, and *Elysian fields*, making them the habitations of the blessed. The most distinct account of this island we have in Plato's *Timæus*, of which Mr Chambers gives the following abridgement. "The Atlantis was a large island in the western ocean, situated before or opposite to the straits of Gades. Out of this island there was an easy passage into some others, which lay near a large continent exceeding in bigness all Europe and Asia. Neptune settled in this island (from whose son Atlas its name was derived), and divided it among his ten sons. To the youngest fell the extremity of the island called *Gadir*, which, in the language of the country, signifies *fertile*, or *abundant in sheep*. The descendants of Neptune reigned here from father to son for a great number of generations in the order of primogeniture, during the space of 9000 years. They also possessed several other islands; and, passing into Europe and Africa, subdued all Libya as far as Egypt, and all Europe to Asia Minor. At length the island sunk under

water; and for a long time afterwards the sea thereabouts was full of rocks and shelves."

Many of the moderns, also, are of opinion that the existence of the Atlantis is not to be looked upon as entirely fabulous. Some take it to have been America; and from thence, as well as from a passage in Seneca's *Medea*, and some other obscure hints*, they imagine that the new world was not unknown to the ancients. But allowing this to be the case, the above-mentioned continent which was said to lie beyond Atlantis would seem rather to have been the continent of America than Atlantis itself. The learned Rudbeck, professor in the university of Upsal, in a work entitled *Atlantica sive Manheim*, endeavours to prove that Sweden and Norway are the Atlantis of the ancients; but this its situation will by no means allow us to believe. By Kircher it is supposed to have been an island extending from the Canaries quite to the Azores; that it was really swallowed up by the ocean as Plato asserts; and that these small islands are the shattered remains of it which were left standing.

ATLAS, king of Mauritania, a great astronomer, contemporary with Moses. From his taking observations of the stars from a mountain, the poets feigned him to have been turned into a mountain, and to sustain the heavens on his shoulders. Being an excellent astronomer, and the first who taught the doctrine of the sphere, they tell us that his daughters were turned into stars; seven of them forming the Pleiades, and other seven the Hyades.

ATLAS, a chain of mountains in Africa, lying between the 20th and 25th degree of north latitude, and supposed almost to divide the continent from east to west*. They are said to have derived their name from Atlas king of Mauritania, who was a great astronomer. They are greatly celebrated by the ancients on account of their height, inasmuch that the above-mentioned king, who is said to have been transformed into a mountain, was feigned to bear up the heavens on his shoulders. We are assured, however, by Dr Shaw, that the part of this chain of mountains which fell under his observation, could not stand in competition either with the Alps or Apennines. He tells us, that if we conceive a number of hills, usually of the perpendicular height of 400, 500, or 600 yards, with an easy ascent, and several groves of fruit or forest trees, rising up in a succession of ranges above one another; and that if to this prospect we add now and then a rocky precipice, and on the summit of each imagine a miserable mud-walled village; we shall then have a just idea of the mountains of Atlas.

ATLAS, in matters of literature, denotes a book of universal geography, containing maps of all the known parts of the world.

ATLAS, in commerce, a silk-satin, manufactured in the East Indies. There are some plain, some striped, and some flowered, the flowers of which are either gold or only silk. There are atlases of all colours; but most of them false, especially the red and the crimson. The manufacture of them is admirable; the gold and silk being worked together after such a manner as no workmen in Europe can imitate; yet they are very far from having that fine gloss and lustre which the French know how to give to their silk stuffs. In the Chinese manufactures of this sort, they gild paper on

Atla

* See Africa, 107.

* See Africa.

Atmo-
sphere.Atmo-
sphere.

one side with leaf-gold; then cut it in long slips, and weave it into their silks; which makes them, with very little cost, look very rich and fine. The same long slips are twisted or turned about silk-threads, fo artificially, as to look finer than gold thread, though it be of no great value.

ATMOSPHERE, is most generally understood to signify the whole extent of air diffused around this earth, the sun, moon, or any other great body in the universe.

1
Component
parts of our
atmosphere.

With regard to the component parts of the air we breathe, Dr Priestley hath by undoubted experiments proved them to be the nitrous acid, earth, and phlogiston. To these we may certainly add water, of which the substances he made use of in producing air could never be perfectly free; and as the Doctor inclines to think that the electric fluid may be the phlogiston itself, we will thus have the subtle fluid of electricity as a capital ingredient in the composition of the atmosphere of the earth.

Indeed, whether this fluid is admitted by the Doctor or not as an ingredient in the air he distills, we are absolutely certain that it enters in no small quantity into the composition of the air we breathe. It is also certain, that the higher up we go in the atmospherical regions, the quantity of electrical fluid is apparently greater; neither hath any means been as yet suggested, by which we can determine where this electrical power begins to diminish, much less where it ceases altogether. Hence some have imagined, that though the atmosphere of the earth, as consisting of an heterogeneous mixture of a great number of fluids, extends but for a little way, yet that the electrical part of it may extend to the moon, or farther, and be the cause of the revolutions of that luminary; and that a similar affection of the solar atmosphere may occasion the revolutions of planets and comets*.

See A. 170.
102.2
Methods of
ascertaining
the height.

The first-rate geometricians of modern times have been very solicitous to find out the height of the atmosphere; but the high degree of electricity always existing in the upper parts of it being but very lately, and even yet imperfectly, discovered, it was necessarily overlooked by them, so that their calculations were made without any regard to it, or without suspecting the existence of any such thing. The first attempts that were made with this view were soon after the weight of the atmosphere was found out. It having been discovered, that a column of air whose base was an inch square, and the height of it that of the whole atmosphere, weighed 15 lb, and that the weight of air was to Mercury as 1 to 10,800, it thence followed, that if the weight of the atmosphere was sufficient to raise a column of Mercury to the height of 30 inches, the height of the aerial column itself behaved to be 10,800 times as much, or a little more than five miles high. But as the air hath also a very great elastic power, by which it expands itself when the pressure of the rest is taken off from any part of it, it is impossible the foregoing calculation can be just. Another method therefore behaved to be followed. It being found by repeated experiments in different countries, that the spaces which any portion of air takes up are reciprocally proportional to the weights with which it is compressed, allowances for the gradual decrease of weight behaved to be made in calculating the height of the

atmosphere. If we suppose the height of the whole atmosphere divided into innumerable equal parts, the density of each of which is as its quantity, and the weight of the whole incumbent atmosphere being also as its quantity, it is evident, that the weight of the incumbent air is every where as the quantity contained in the subjacent part; which makes a difference between the weight of each two contiguous parts of air. By a theorem in geometry, where the differences of magnitudes are geometrically proportional to the magnitudes themselves, those magnitudes are in continual arithmetical proportion; therefore, if, according to the supposition, the altitude of the air by the addition of new parts into which it is divided, do continually increase in arithmetical proportion, its density will be diminished, or, which is the same thing, its gravity decreased, in continual geometrical proportion.

From such a series it is easy, by making two or three barometrical observations, and determining the rarity of the air at two or three different stations, to determine its rarity at any assignable height. Calculations accordingly were made upon this plan; but it having been found that the barometrical observations by no means corresponded with the density which by other experiments the air ought to have had, it was suspected that the upper parts of the atmospherical regions were not subject to the same laws with the lower ones. Another method therefore was had recourse to, namely, by calculating the height from which the light of the sun was refracted so as to become visible to us before the sun himself arose. Thus, it was determined, that at the height of 45 miles the atmosphere had no power of refracting light; and therefore, that, if it extended beyond that distance, it behaved to be the next thing to a perfect vacuum, and not to be regarded.

3
Found in-
sufficient.

This theory being extremely plausible, very soon became general; and the height of the atmosphere was commonly spoken of as familiarly as the height of a mountain, and reckoned to be as certainly, if not more certainly, calculated than the heights of mountains are. Some appearances, however, seemed to form insuperable objections. The most remarkable were those globes of fire called *meteors*, which sometimes appear, and are found to move at vast heights above the earth. A very remarkable one of this kind was seen by Sir Hans Sloane, and the account communicated to Dr Halley, who seems to have been greatly embarrassed by the phenomena attending it. The account given by Sir Hans Sloane is as follows: That "on Tuesday, March 19th 17th 5, about eight in the evening, passing eastward by the north-east corner of Southampton street in Bloomsbury Square, London, he saw of a sudden a very great light much surpassing that of the moon, which shone then very bright. Upon turning to observe it, he saw a long stream of very bright fire, branched in the middle; but at last it came to be pear-shaped, tapering upwards, and afterwards spherical, though not so big as the full moon. The colour of it was whitish, with a shade of blue, of a most vivid dazzling lustre, which seemed in brightness very nearly to resemble, if not to surpass, that of the body of the sun in a clear day. In about half a minute or less, it seemed to move over about 20° of the heavens, and to go out as much above the horizon, leaving a visible track behind it." All the other observers of this phe-

of meteors.

Atmo-
sphere.

nomenon agreed, that the splendour of this meteor was very little inferior to that of the sun; that within doors the candles scarce gave any light; and in the streets, not only the stars disappeared, but the moon, though then nine days old, and very near the meridian, could scarcely be seen, at least the east no visible shade even where the beams of the meteor were intercepted by the houses; so that for a few seconds, in all respects it resembled perfect day.

6
Height and
magnitude
of a meteor
calculated
by Dr Hal-
ley.

Sir Hans Sloane, at London, observed this meteor about the Pleiades, descending a little beyond and below the stars in the belt of Orion. At Oxford, from the track it had left in the sky, it was found to have passed about $1\frac{1}{2}$ above the preceding shoulder of Orion, and about $3\frac{1}{2}$ above the middle of his belt, where there appeared a luminous nebula of reddish light, being a dilatation of the tract, seeming to have been occasioned by some explosion there; and there the observer was informed it first broke out. From this it proceeded, as to sense, in the arch of a great circle, and passing in the middle between the tail of Lepus (γ Bayero) and β in the forefoot of Canis Major, it terminated about $\frac{1}{2}$ in the breast of the same; and at the place of its extinction there remained a large whitish nebula, much broader and of a stronger light than the rest of the track, by which a very strong explosion was thought to be indicated. At Worcester it was observed to have left all Orion and Canis Major to the westward, and divided the distance between Sirius and Procyon, so as to be almost twice as far from Procyon as from Sirius.

From these observations, the distances of the three cities London, Oxford, and Worcester being known, as also the sun's place at that time, and the altitudes of the stars among which it passed, Dr Halley computes the height of the meteor to have been between 69 and $73\frac{1}{2}$ English miles from the surface of the earth, its diameter to have been 2800 yards, upwards of an English mile and an half, and its velocity more than 350 miles in a minute.

7
Difficult to
be account-
ed for.

The perplexing circumstances here are, that, at such an height, the atmosphere of the earth ought to have no density sufficient to sustain flame of any kind, much less such an intensely dazzling one, and of such magnitude, as this meteor was. Add to this, that, without air, no sound could possibly have attended its explosion, nor indeed could any explosion have taken place; yet all accounts from Devonshire and Cornwall agreed that there was heard there a report as of a very great cannon, or rather a broadside at some distance, followed by a rattling noise, as if some small arms had been promiscuously discharged. The same was heard at London and in Sussex; nor was it known how far it extended, as we have certain accounts that it was heard beyond the city of Aberdeen in the north of Scotland. What was peculiar to this found was, that it was accompanied with an uncommon tremor in the air, so as to shake the glass-windows and doors, and, according to some, even the houses themselves, much beyond the usual effect of cannon though near. The learned Dr Halley acknowledges himself unable to reconcile these circumstances with the received theory of the height of the atmosphere; as in the regions in which this meteor moved, the air ought to have been 300,000 times rarer than what we breathe, and the next thing to a perfect

8
Dr Halley's
conjecture.

vacuum. He offers a kind of dubious conjecture indeed, that the extreme magnitude of the meteor might have compensated for the fineness of the medium. But this we think will hardly account for all the phenomena. According to this supposition, the explosion of a globe of fire 2800 yards in diameter in such a medium ought to be equivalent to the explosion of one 300,000 times less in the denser regions of our atmosphere. But globes are to one another as the cubes of their diameters; therefore, dividing 2800 by the cube-root of 300,000, we have the diameter of a sphere of fire, which ought to produce as extensive effects as this meteor, supposing it to explode at the surface of the earth, or in any part of the atmosphere of nearly the same density. The diameter of such a globe behoved to be almost 42 yards, or 126 feet; and though we must acknowledge the effects of such an explosion to be prodigious in those places that were in its neighbourhood, it is scarce probable that it could extend in such a manner over the whole island of Britain. The truth is, however, that here we have very few data to go upon; the largest flashes of lightning, or meteors that have been observed in the lower regions of the atmosphere, bearing but a very small proportion to a globe of 42 yards diameter.

The greatest difficulty, however, is to account for the brightness of the light. The appearance of meteors of this kind, and indeed of all kinds, are now attributed to electricity; but still the difficulty remains. We know that the electrical fluid pervades the vacuum of the air-pump with the utmost facility; but then it appears in long streams resembling the aurora borealis, not in small bright and concentrated sparks, as when drawn from a conductor, or discharged from a vial in the open air. To make this fluid exhibit a very bright vivid flash, the presence of the gross atmosphere seems necessary; and where that is taken off, the electric spark always diffuses itself over a large surface, and therefore becomes proportionably less bright. Experience shews, that though an electrified bottle will discharge itself through a great space of vacuum, yet the spark diverges and loses its force and brightness; whereas this meteor, which at first was long and branched, collected itself afterwards into a lesser compass; which is a very strong presumption of the pressure of a denser fluid; not to mention, that an explosion can be only made by a rare fluid forcing through a dense one. Thus gun-powder fired in the open air explodes, because the flame forces violently against the dense air; but though heated ever so much *in vacuo*, no such explosion is produced.

Inflances have been known of balls of fire similar to this meteor, though vastly inferior in size and brightness, travelling along the surface of the ground, or along the sea, and afterwards bursting with an explosion. A very remarkable one of this kind is mentioned by Dr Priestley in his history of electricity. The substance of the account is, that as the observer (Mr Chalmers) was endeavouring to find the latitude, on board the Montague, Nov. 4th 1749, in Lat. $42^{\circ} 48'$, about 10 minutes before 12, he was desired by one of the quarter-masters to look to the windward. Upon which he observed a large ball of blue fire rolling on the surface of the water at about three miles distance from them. They immediately lowered their top-sails; but before

kable fire
rolling on
the sea.

Atmo-
sphere.

before they could raise their main tack, it was advanced within 40 or 50 yards of the main chains. It now appeared as big as a large millstone; and, rising perpendicularly, went off with an explosion as if hundreds of cannon had been fired at once. The noise lasted about half a second; after which they found their maintop-mast shattered to pieces, and their main-mast rent quite down to the keel; five men were knocked down, and one greatly burnt, &c.

11
How the
gravity of
the air may
be dimini-
sh'd, without
affecting its
density.

Now, though we can by no means pretend to give a reason why such large bodies of electric fire should thus be found travelling as it were in quest of adventures; yet as it seems indisputable that they actually do move in this unaccountable manner, both on the surface of the earth and at the height of 30, 40, 50, or 70 miles above it, it seems to some extremely probable, that, excepting the mere want of aqueous vapours, the atmosphere even at that great height is not much different in density from what we breathe. To those who consider the effects of the electric fluid upon light bodies on earth, the decrease of gravity in the superior regions of the atmosphere will be no argument of its want of density. We know, that it is the nature of any electrified substance to attract light bodies; and that, by proper management, they may even be suspended in the air, without either moving up or down, for a considerable time. If this is the case with light terrestrial bodies, it cannot be thought very improbable that the aerial particles themselves should be thus affected in those regions where electricity is so abundant. It is possible, therefore, that where the air is in a highly electrified state, its tendency towards the earth or its gravity may be very much diminished, without its density being at all affected; and if this is the case, it will no doubt occasion great difficulties in assigning the true height of the atmosphere, by rendering every barometrical observation exceedingly precarious.

12
Uncertainty
of barome-
trical obser-
vations.

From these considerations, and many others that will naturally occur to every one who attends to this subject, it must appear that the height of our atmosphere is yet very far from being determined. At first the sinking of the barometer was thought to be a certain method of determining the degree of the atmospherical density on the tops of mountains, and in some of these it was even said that the air became too subtle for breathing; but this is now found to be a mistake. The French mathematicians, when on the top of one of the Andes, and above the common region of clouds, made no complaint of this kind. On the top of mount *Ætna*, where the smoke of the mountain sinks instead of rising, Mr Brydone found no inconvenience in this respect. Sir William Hamilton indeed says he did; but besides the conjecture mentioned under the article *Ætna*, we apprehend that the respiration may be affected on the top of a volcano, from so many different causes, that nothing can be concluded from thence. With regard to the barometer, M. De Luc hath been at incredible pains to ascertain and reduce to rule the irregularities of it, which he found to arise from the different temperature of the air; and it is to be hoped that by his labours the mensuration of altitudes by this instrument will be greatly facilitated, and the conclusions rendered much more certain than before, though whether the difficulties are entirely removed can only be determined by future experience. (See *BAROMETER*).

sphere
||
Atomical.

13
Pressure of
the atmo-
sphere.

As all bodies which are immerged in the atmosphere of our earth must sustain its pressure, which is various at various times, it is plain, that this variation must occasion very considerable changes in these bodies. We have already mentioned, that the pressure of the atmosphere upon every square inch of the earth's surface is equivalent to 15 pounds. Hence, Dr Cotes hath computed that the pressure of the whole ambient fluid upon the earth's surface is equivalent to that of a globe of lead 60 miles in diameter. From this it also appears, that the pressure upon the human body must be very considerable; for, as every square inch of surface sustains a pressure of 15 pounds, every square foot, as containing 144 square inches, must sustain a pressure of 2160; and therefore, if a man's body contains 15 square feet of surface, which is pretty near the truth, he must sustain a weight of $2160 \times 15 = 32,400$ pounds, or sixteen tun, for his ordinary load, which, by the diminution or increase of the gravity of the atmosphere, may become heavier or lighter by near a whole tun. By this enormous pressure we should certainly be crushed to pieces in a moment, were not all parts of our bodies filled either with air, or with some other elastic fluid, the spring of which is sufficient to counterbalance the weight of the atmosphere. Whatever this fluid is, we are sure that it is just able to counterbalance the atmospherical gravity, and no more; for if any considerable pressure is superadded to that of the air, as by going into deep water, &c. it is always severely felt, let it be ever so equable. If the pressure is taken off from any part of the body, as by putting the hand upon the mouth of an open receiver which is afterwards exhausted, the weight of the atmosphere then discovers itself, and we imagine the hand is strongly sucked down into the glass. See *PNEUMATICS*.

14
Why we are
not crushed
by it.

To the above-mentioned changes in gravity of the atmosphere, we owe the prognostications of the weather by the barometer; but these changes seem to take place mostly in such places as are at a distance from the equator. In the torrid zone, though frequent and very great changes of weather happen, the barometer stands commonly at the same height, or with little variation. See *BAROMETER*.

For the causes of the elasticity of the atmosphere, see the article *ELASTICITY*; for the formation and ascent of vapour, see *EVAPORATION*; and for the other natural operations, see *CONGELATION*, *COLD*, *RAIN*, *HAIL*, *SNOW*, *METEORS*, &c.

ATOCK, the capital of a province of the same name in the dominions of the Great Mogul. It is seated on a point of land where two large rivers meet, and is one of the best fortresses the Mogul has; but formerly nobody was permitted to enter it without a passport from the Mogul himself. E. Long. 72. 10. N. Lat. 32. 20.

ATOM, in philosophy, a particle of matter, so minute, as to admit of no division. Atoms are the *minima natura*, and are conceived as the first principles or component parts of all physical magnitude.

ATOMICAL PHILOSOPHY, or the doctrine of atoms, a system which, from the hypothesis that atoms are endued with gravity and motion, accounted for the origin and formation of things. This philosophy was first broached by Mofchus, some time before the Trojan war; but was much cultivated and improved by

Epi-

Attonement

Atractylis.

Epicurus, whence it is denominated the *Epicurean phiblophy*. See EPICUREAN.

ATONEMENT. See EXPIATION.

ATONY, in medicine, a defect of tone or tension, or a laxity or debility of the solids of the body.

ATRA BILIS, BLACK BILE, or MELANCHOLY. According to the ancients it hath a twofold origin: 1st, From the grosser parts of the blood, and this they called the *melancholy humour*. 2^d, From yellow bile being highly concocted. Dr Percival, in his *Essays Med. and Exp.* suggests, that it is the gall rendered acrid by a stagnation in the gall-bladder, and rendered viscid by the absorption of its fluid parts. Bile in this state discharged into the duodenum, occasions universal disturbance and disorder, until it is evacuated; it occasions violent vomiting, or purging, or both; and previous to this the pulse is quick, the head aches, a delirium comes on, a hicough, intense thirst, inward heat, and a fetid breath. Some describe this kind of bile as being acid, harsh, corroding, and, when poured on the ground, bubbling up, and raising the earth after the manner of a ferment. Dr Percival says, that by the use of the *infus. fene limoniet.* warmed with the *inct. columb.* he had checked the vomitings occasioned by this matter.

ATRA DIES, in antiquity, denotes a *fatal day*, whereon the Romans received some memorable defeat. The word literally imports a *black day*; a denomination taken from the colour, which is the emblem of death and mourning. Whence the Thracians had a custom of marking all their happy days with white stones or calculi, and their unhappy days with black ones; which they cast, at the close of each day, into an urn. At the person's death, the stones were taken out; and from a comparison of the numbers of each completion, a judgment was made of the felicity or infelicity of his course of life. The *dies atrae*, or *atri*, were afterwards denominated *mesalli*, and *posteri*. Such, in particular, was the day when the tribes were defeated by the Gauls, at the river Allia, and lost the city; also that whereon the battle of Cannæ was fought; and several others marked in the Roman calendar as *atrae* or unfortunate.

ATRACYLLIS, DISTAFF THISTLE; a genus of the polygamia æqualis order, belonging to the syngenesia class of plants.

Species. 1. The cancellata, or small cnicus, is an annual plant rising about eight or nine inches high, with a slender stem, garnished with hoary leaves, having spines on their edges. At the top of these branches are sent out two or three slender stalks, each terminated by a head of flowers like those of the thistle. The empalement is curiously netted over, and is narrow at the top, but swelling below; and contains many florets of a purplish colour. These are each succeeded by a single downy seed, which in cold years do not ripen in this country. 2. The humilis, or purple prickly cnicus, rises about a foot high, with indented leaves, having small spines on their edges. The upper part of the stalk is divided into two or three slender branches, each supporting a head of purple flowers, having rays inclosed in a scaly empalement. The flowers appear in June; but unless the season is warm, the seeds will not ripen in this country. 3. The gummifera, or prickly gum-bearing cnicus, known among physicians by the

name of *carline thistle*. This sends out many narrow leaves, which are deeply serrated, and armed with spines on their edges. These lie close on the ground; and between them the flower is situated, without a stalk, and having many florets inclosed in a prickly empalement. Those on the border are white; but such as compose the disk are of a yellowish colour. It flowers in July, but never perfects seeds in Britain.

Culture. All these plants are natives of the warm parts of Europe, as Spain, Sicily, and the Archipelago islands, from whence their seeds must be procured. They must be sown upon an open bed of light earth, where the plants are to remain; and when the plants come up, they should be thinned, so as to leave them three or four inches asunder. The roots of the second will last two or three years, and the third is a perennial plant.

Medicinal Uses. The root of the third sort was formerly used as a warm diaphoretic and alexipharmic; but it never came much into use in Britain, and the present practice has entirely rejected it. The root is about an inch thick, externally of a pale rusty brown colour, corroded as it were in the surface; and perforated with numerous small holes, so as to appear worm-eaten when cut. It has a strong smell, and a subacid, bitterish, and weakly aromatic taste. Frederic Hoffman the Elder, relates, that he has observed a decoction of it in broth to occasion vomiting.

ATRÆTI, in medicine, infants having no perforation in the anus, or persons imperforated in the vagina or urethra.

ATRAPHAXIS, a genus of the digynia order, belonging to the hexandria class of plants, for which there is no English name. There are two species, both natives of warm countries; but their properties are too trifling to merit any particular description.

ATREUS, in fabulous history, the son of Pelops and Hippodamia, and the father of Agamemnon and Menelaus, is supposed to have been king of Mycenæ and Argos about 1228 years before the Christian æra. He drove his brother Thyestes from court, for having a criminal commerce with Ærope his wife; but understanding that he had had two children by her, he sent for him again, and made him eat them; at which horrid action, the sun, it is said, withdrew his light.

ATRI, a town of Italy, in the farther Abruzzo in the kingdom of Naples, with the title of a duchy; it is the see of a bishop, and is seated on a craggy mountain, four miles from the Adriatic Sea. E. Long. 13. 8. N. Lat. 42. 45.

ATRIPLEX, ORACH, or ARACH; a genus of the monocæia order, belonging to the polygamia class of plants.

Species. 1. The hortensis, or garden orach, was formerly cultivated in gardens, and used as a substitute for spinach, to which it is still preferred by some, tho' in general it is disliked by the English; however, it still maintains its credit in France, as also in the northern parts of England. There are three or four varieties of this plant, whose only difference is their colour; one is a deep green, another a dark purple, and a third with green leaves and purple borders. 2. The halimus, or broad-leaved orach, was formerly cultivated in gardens as a shrub, by some formed into hedges, and constantly sheared to keep them thick: but this is a purpose

Atraphax
||
Atriplex

pose to which it is by no means adapted, as the shoots grow so vigorous, that it is impossible to keep the hedge in any tolerable order; and what is worse, in severe winters the plants are often destroyed. 3. The *petalocoides*, or shrubby sea-orach, grows wild by the sea-side in many places of Britain. It is a low under-shrub, seldom rising above two feet and an half, or at most three feet high; but becomes very bushy. This may have a place in gardens among other low shrubs, where it will make a pretty diversity. Besides these, nine other species are enumerated by botanical writers, but the above-mentioned are the most remarkable.

Culture, &c. The first sort is annual, so must be propagated by seeds. These are to be sown at Michaelmas, soon after the seeds are ripe. The plants require no other culture than to be kept free from weeds, to hoe them when they are about an inch high, and to cut them down when they are too thick, so as to leave them about four inches asunder. When these plants are sown in a rich soil, and allowed a good distance from each other, the leaves will grow very large, and in this their goodness consists. This must be eaten whilst it is young; for when old, the leaves become tough, and are good for nothing. This species is an article of the *materia medica*; a decoction of the leaves is recommended in costiveness, where the patient is of a hot bilious disposition.—The second sort may be propagated by cuttings. These are to be planted in any of the summer-months, in a shady border; where they will soon take root, and be fit against the following Michaelmas to transplant into those places where they are to remain.—The third sort requires very little culture. It may be also propagated from cuttings, and is to be planted in a poor gravelly soil.

ATROPA, DEADLY NIGHT-SHADE; a genus of the monogynia order, belonging to the pentandria class of plants.

Species. Of this genus there are five species enumerated by the botanists; the three following are the most remarkable. 1. The *belladonna* grows wild in many parts of Britain. It hath a perennial root, which sends out strong herbaceous stalks of a purplish colour, which rise to the height of four or five feet, garnished with entire oblong leaves, which towards autumn change to a purplish colour. The flowers are large, and come out singly between the leaves, upon long foot-stalks; bell shaped, and of a dusky colour on the outside, but purplish within. After the flower is past, the germen turns to a large round berry a little flattened at the top. It is first green; but, when ripe, turns to a shining black, sits close upon the empalement, and contains a purple juice of a nauseous sweet taste, and full of small kidney-shaped seeds. 2. The *frutescens* is a native of Spain, and rises with a shrubby stem to the height of six or eight feet; dividing into many branches garnished with round leaves, in shape like those of the storax tree: these are placed alternately on the branches. The flowers come out between the leaves on short foot-stalks, shaped like those of the former, but much less; of a dirty yellowish colour, with a few brown stripes: but these are never succeeded by berries in Britain. 3. The *herbacea*, with an herbaceous stalk, is a native of Cambrachy. This hath a perennial root, which puts forth several channelled herbaceous stalks rising about two

feet; and towards the top they divide into two or three small branches garnished with oval leaves four inches long and three broad, having several prominent transverse ribs on their under side. The flowers come out from between the leaves on short foot-stalks; they are white, and shaped like those of the common sort, but smaller. It flowers in July and August, but seldom ripens its fruit in Britain.

Culture. The first species, which is remarkable for its poisonous qualities, is very seldom admitted in gardens, nor should it ever be cultivated or allowed to grow in those places to which children have access. The other kinds are propagated by seeds, and placed in a stove, as is requisite for the more tender plants.

Poisonous Qualities, &c. The first species, as we have already observed, is a strong poison. Mr Ray gives a good account of the symptoms that follow the taking of it inwardly, by what happened to a mendicant friar upon his drinking a glass of mallow wine in which the herb was infused. In a short time he became delirious, and soon after was seized with a grinning laughter; then with several irregular motions, and at last with a real madness, and such a stupidity as those have who are foolishly drunk; but after all, he was cured by a draught of vinegar. Buchanan also gives an account of the destruction of the army of Sweno the Dane, when he invaded Scotland, by mixing a quantity of the *belladonna* berries with the drink which the Scots were, according to a treaty of truce, to supply them with. This so intoxicated the Danes, that the Scots fell upon them in their sleep, and killed the greatest part of them, so that there were scarcely men enough left to carry off their king. There have also been many instances in Britain of children being killed by eating berries of a fine black colour, and about the size of a small cherry, which are no other than those of *belladonna*. Notwithstanding this violent quality, however, some have prescribed it as a cure for cancers; but whatever may be pretended from some instances, it seems very unlikely that this terrible disease should be cured, or even alleviated in the least, by any such means.

ATROPHY, in medicine, a disease, wherein the body, or some of its parts, do not receive the necessary nutriment, but waste and decay incessantly*.

ATROPOS, in fabulous history, the name of the third of the Paræci, or Fates, whose business it was to cut the thread of life.

ATTACHMENT, in the law of England, implies the taking or apprehending a person by virtue of a writ or precept. It is distinguished from an *arrest*, by proceeding out of a higher court by precept or writ; whereas the latter proceeds out of an inferior court by precept only. An arrest lies only on the body of a man; whereas an attachment lies often on the goods only, and sometimes on the body and goods. An attachment by writ differs from *distress*, in not extending to lands, as the latter does; nor does a distress touch the body, as an attachment does.

ATTACHMENT *out of the Chancery*, is obtained upon an affidavit made, that the defendant was served with a subpoena, and made no appearance; or it issues upon not performing some order or decree. Upon the return of this attachment by the sheriff, *quod non est inventus in balliva sua*, another attachment, with a proclamation, issues; and if he still refuses to appear, a com-

* See the Index sub-joined to Medicine.

Attach-
ment
||
Attainder.

commission of rebellion.

ATTACHMENT of the Forest, is one of the three courts held in the forest. The lowest court is called the *court of attachment*, or *wood-mote court*; the mean, *swan-mote*; and the highest, the *justice in eyre's seat*. The court of attachments has its name from the verdurers of the forest having no other authority in it, but to receive the attachments of offenders against vert and venison taken by the foresters, and to enroll them, that they may be presented or punished at the next justice in eyre's seat. This attachment is by three means: by goods and chattels; by body, pledges, or main-prize; or by the body only. This court is held every 40 days throughout the year; and is thence called *forty-days court*.

Foreign ATTACHMENT is an attachment of money or goods found within a liberty or city, to satisfy some creditor within such liberty or city. By the custom of London, and several other places, a man can attach money or goods in the hands of a stranger, to satisfy himself.

ATTACK, a violent attempt upon any person or thing, an assault, or the act of beginning a combat or dispute.

ATTACK, in the military art, is an effort made to force a post, break a body of troops, &c.

ATTACK of a Siege, is a furious assault made by the besiegers with trenches, covers, mines, &c. in order to make themselves masters of a fortress, by storming one of its sides. If there are two or three attacks made at the same time, there should be a communication betwixt them. See **SIEGE**.

ATTAINDER, in law. When sentence of death, the most terrible and highest judgment in our laws, is pronounced, the immediate inseparable consequence by the common law is attainder. For when it is now clear beyond all dispute, that the criminal is no longer fit to live upon the earth, but is to be exterminated as a monster and a bane to human society, the law sets a note of infamy upon him, puts him out of its protection, and takes no farther care of him than barely to see him executed. He is then called *attainted*, *attindius*, *stained*, or *blackened*. He is no longer of any credit or reputation; he cannot be a witness in any court; neither is he capable of performing the functions of another man: for, by an anticipation of his punishment, he is already dead in law. This is after judgment: for there is great difference between a man *convicted*, and *attainted*; though they are frequently through inaccuracy confounded together. After conviction only, a man is liable to none of these disabilities: for there is still in contemplation of law a possibility of his innocence. Something may be offered in arrest of judgment: the indictment may be erroneous, which will render his guilt uncertain, and thereupon the present conviction may be quashed: he may obtain a pardon, or be allowed the benefit of clergy; both which suppose some latent sparks of merit, which plead in extenuation of his fault. But when judgment is once pronounced, both law and fact conspire to prove him completely guilty; and there is not the remotest possibility left of any thing to be said in his favour. Upon judgment therefore of death, and not before, the attainder of a criminal commences: or upon such circumstances as are equivalent to judgment of death; as judgment of

outlawry on a capital crime, pronounced for absconding or fleeing from justice, which tacitly confesses the guilt: And therefore, upon judgment either of outlawry, or of death, for treason or felony, a man shall be said to be attained.

A person attainted of high treason forfeits all his lands, tenements, and hereditaments; his blood is corrupted, and he and his posterity rendered base; and this corruption of blood cannot be taken off but by act of parliament*.

Attainders may be reversed or falsified, (i. e. proved to be false) by writ of error, or by plea. If by writ of error, it must be by the king's leave, &c.; and when by plea, it may be by denying the treason, pleading a pardon by act of parliament, &c.

Persons may be attainted by act of parliament.—Acts of attainder of criminals have been passed in several reigns, on the discovery of plots and rebellions, from the reign of king Charles II. when an act was made for the attainder of several persons guilty of the murder of king Charles I. Among acts of this nature, that for attainting Sir John Fenwick, for conspiring against king William, is the most remarkable; it being made to attain and convict him of high treason on the oath of one witness, just after a law had been enacted, "That no person should be tried or attainted of high treason where corruption of blood is incurred, but by the oath of two lawful witnesses, unless the party confess, stand mute, &c." Stat. 7 and 8 W. 3. cap. 3. But in the case of Sir John Fenwick, there was something extraordinary; for he was indicted of treason on the oaths of two witnesses, though but only one could be produced against him on his trial.

ATTAINT, is a writ that lies after judgment against a jury of twelve men that have given false verdict in any court of record, in an action real or personal, where the debt or damages amount to above 40 s. Stat. 5 and 34 Ed. III. c. 7. It is called *attaint*, because the party that obtains it endeavours thereby to stain or taint the credit of the jury with perjury, by whose verdict he is grieved.

The jury who are to try this false verdict must be twenty-four, and are called the *grand jury*; for the law will not that the oath of one jury of twelve men should be attained or set aside by an equal number, nor by less indeed than double the former. And he that brings the attaint can give no other evidence to the grand jury, than what was originally given to the petit. For as their verdict is now trying, and the question is whether or no they did right upon the evidence that appeared to them, the law adjudged it the highest absurdity to produce any subsequent proof upon such trial, and to condemn the prior jurisdiction for not believing evidence which they never knew. But those against whom it is brought are allowed, in the affirmation of the first verdict, to produce new matter: because the petit jury may have formed their verdict upon evidence of their own knowledge, which never appeared in court; and because very terrible was the judgment which the common law inflicted upon them, if the grand jury found their verdict a false one. The judgment was, 1. That they should lose their *liberam legem*, and become ever infamous. 2. That they should forfeit all their goods and chattels. 3. That their lands and tenements

* See article on
Fines and
Corruption
of Blood.

tenements should be seized into the kings hands. 4. That their wives and children should be thrown out of doors. 5. That their houses should be rased and thrown down. 6. That their trees should be rooted up. 7. That their meadows should be ploughed. 8. That their bodies should be cast into jail. 9. That the party should be restored to all that he lost by reason of the unjust verdict. But as the severity of this punishment had its usual effect, in preventing the law from being executed, therefore by the statute 11 Hen. VII. c. 24. revived by 23 Hen. VIII. c. 3. and made perpetual by 13 Eliz. c. 25. it is allowed to be brought after the death of the party, and a more moderate punishment was inflicted upon attainted jurors; viz. perpetual infamy, and if the cause of action were above 40*l.* value, a forfeiture of 20*l.* apiece by the jurors; or, if under 40*l.* then 5*l.* apiece; to be divided between the king and the party injured. So that a man may now bring an attaint either upon the statute or at common law, at his election; and in both of them may reverse the former judgment. But the practice of setting aside verdicts upon motion, and granting new trials, has so superseded the use of both sorts of attaints, that there is hardly any instance of an attaint later than the 16th century.

ATTAINT, among farriers, a knock or hurt in a horse's leg, proceeding either from a blow with another horse's foot, or from an over-reach in frosty weather, when a horse, being rough-shod, or having shoes with long caulkers, strikes his hinder feet against his fore-leg.

ATTAINTEED, in law, is applied to a person's being under attainder. See **ATTAINDER**.

ATTALUS, the name of several kings of Pergamus. See **PERGAMUS**.

ATTELABUS, in zoology, a genus of insects belonging to the order of coleoptera or beetle-kind. It has four wings, of which the superior are crustaceous, and serve as a sheath or cover to the inferior, which are membranous. The head tapers behind, and is inclined; the feelers turn thicker towards the apex. The species are 13; viz. 1. The coryli is black, with red elytra or crustaceous wings. 2. The avellana is black, with the breast, feet, and elytra red. 3. The curculionoides is black, with red elytra and breast. The above three species frequent the leaves of the hazel and filbert nut-trees. 4. The surinamensis has a double indentation (or two teeth) in the top of the elytra. It is a native of Surinam. 5. The pensilvanicus is black, with red elytra, a black belt round the middle, and another towards the apex of the elytra. It is a native of Philadelphia. 6. The melanurus is black, with testaceous elytra, black at the apex. It is a native of Sweden. 7. The betula has saltatory or springy legs, and the whole body is of a dark-red colour. It frequents the leaves of the birch-tree. 8. The formicarius is black, with red elytra, and a double white belt towards the base. It is a native of Europe. 9. The sphyllus is green, with a hairy breast, and a double yellow belt upon the elytra. 10. The apiaris

Vol. II.

is bluish, with red elytra, and three black belts. It is a native of Germany. 11. The mollis is yellowish and hairy, with pale elytra, and three belts. It is a native of Europe. 12. The ceramboides is of a blackish red colour, and the elytra is furrowed. It frequents the spongy boletus, a species of mushroom. 13. The bu-prestoides is of a dark-red colour, with a globular breast, and nervous elytra. It is a native of Europe.

ATTENUANTS, medicines which relieve the viscosity of the humours; and thereby promoting their circulation, as well as the discharge of all noxious or extraneous matter.

ATTENTION, is that state of mind which prepares one to receive impressions. According to the degree of attention, objects make a stronger or weaker impression (A). Attention is requisite even to the simple act of seeing: the eye can take in a considerable field at one look; but no object in the field is seen distinctly, but that singly which fixes the attention: in a profound reverie that totally occupies the attention, we scarce see what is directly before us. In a train of perceptions, no particular object makes such a figure as it would do singly and apart; for when the attention is divided among many objects, no particular object is intitled to a large share. Hence, the stillness of night contributes to terror, there being nothing to divert the attention:

Horror ubique animos, simul ipsa silentia terrent. *Æneid. ii.*

Zoro. Silence and solitude are ev'ry where!
 'Trough all the gloomy ways and iron doors
 That hinder lead, nor human face nor voice
 Is seen or heard. A dreadful din was wont
 To grate the sense, when enter'd here, from groans
 And howls of slaves condemn'd, from clink of chains,
 And crash of rusty bars and creaking hinges;
 And ever and anon the fight was dash'd
 With frightful faces, and the meagre look
 Of grim and ghastly executioners.
 Yet more this illfulness terrifies my soul
 Than did that scene of complicated horrors.

Mourning Bride, act 5. sc. 8.

In matters of slight importance, attention is mostly directed by will; and for that reason, it is our own fault if trifling objects make any deep impression. Had we power equally to with-hold our attention from matters of importance, we might be proof against any deep impression. But our power fails us here: an interesting object seizes and fixes the attention beyond the possibility of control; and while our attention is thus forcibly attached to one object, others may solicit for admittance; but in vain, for they will not be regarded. Thus a small misfortune is scarce felt in presence of a greater:

Lear. Thou think't 'tis much, that this contentious storm
 Invades us to the skin; so 'tis to thee;
 But where the greater malady is fix'd,
 The lesser is scarce felt. Thou'ldst thou a bear;
 But if thy sight lay toward the roaring sea,
 Thou'ldst meet the bear i' th' mouth. When the mind's free,
 The body's delicate: the tempest in my mind
 Doth from my senses take all feeling else,
 Save what beats there. *King Lear, act 3. sc. 5.*

ATTERBURY (Dr Francis), son of Dr Lewis Atterbury,

(A) Bacon, in his natural history, makes the following observations. " Sounds are meliorated by the intention of the sense, where the common sense is collected most to the particular sense of hearing, and the sight suspended. " Therefore sounds are sweeter, as well as greater, in the night than in the day; and I suppose they are sweeter to blind men than to others: and it is manifest, that between sleeping and waking, when all the senses are bound and suspended, music is far sweeter than when one is fully waking."

Atterbury. Atterbury, was born at Milton in Buckinghamshire, 1662; educated at Westminster; and from thence elected to Christ-Church in Oxford, where he distinguished himself early by his fine genius and turn for polite literature. The year he was made M. A. 1687, he exerted himself in the controversy with the Papists, vindicated Luther in the strongest manner, and shewed an uncommon fund of learning, enlivened with great vivacity: he was indeed seldom disengaged from literary disputes, either religious or political; and was thought to have had no inconsiderable part in the famous controversy between Mr Boyle and Dr Bentley, about the genuineness of Phalaris's epistles. Q. ANNE, upon her accession to the throne, appointed him her chaplain. In September following, he was presented to the deanry of Carlisle. A funeral sermon of his engaged him in a dispute with Mr Hoadly, afterward bishop of Winchester, concerning the advantages of virtue with regard to the present life. His Latin sermon to the clergy of London at Zion-College, upon Rom. xiii. 1. published by him in 1708, engaged him in another dispute with Hoadly about passive obedience. In 1710 he was supposed to have been very assiduous to Dr Sacheverel. The same year he was chosen prolocutor in the convocation of the clergy of the province of Canterbury; and the management of affairs in the lower house was principally directed by him. In 1713 he was promoted to the see of Rochester; and had a considerable interest in the ministry at that time. During the rebellion in Scotland, when the Pretender's declaration was dispersed, the archbishop of Canterbury, and the bishops in and near London, had published a *Declaration of their Abhorrence of the present Rebellion, and an Exhortation to the clergy and people to be zealous in the discharge of their duties to his Majesty King George*: but the bishop of Rochester refused to sign it, and engaged bishop Smalridge in the same refusal, on account of some reflections it contained against the high-church party. He appeared generally among the protestors against the measures of the ministry under the king, and drew up the reasons of the protests with his own hand. In 1722 he was committed prisoner to the tower of London for high treason. What share he is said to have had in the conspiracy appears from the *Report of the Secret Committee of the House of Commons*; which occasioned a resolution in that house, March 11, 1723, 'That Francis lord bishop of Rochester was principally concerned in forming, directing, and carrying on, a wicked and detestable conspiracy, for invading these kingdoms with a foreign force, and for raising insurrections and a rebellion at home, in order to subvert our happy establishment in church and state, by placing a popish pretender on the throne.' In consequence of this, a bill was brought in to inflict pains and penalties upon him, which received the royal assent, May 27. To mitigate the sentence of banishment, his daughter was permitted to attend him. He softened the rigour of his exile by study, and conversation with men of letters. It is said he translated *Virgil's Georgics* into English, and wrote an *Harmonia Evangelica*. He also wrote a vindication of himself, bishop Smalridge, and Dr Aldrich, from a charge brought against them by Mr Oldmixon, of altering and interpolating the lord Clarendon's history of the

rebellion. He died at Paris, Feb. 15th, 1731; and his body was brought to England, and interred in Westminster abbey. Though his character is differently represented by different parties, it is universally allowed that he had uncommon abilities, was a fine writer, and a most excellent preacher. His sermons are printed in four volumes 8^{vo}.

ATTESTATION, the act of affirming or witnessing the truth of something, more especially in writing.

ATTIC, any thing relating to Attica, or to the city of Athens: thus ATTIC salt, in philology, is a delicate poignant sort of wit and humour peculiar to the Athenian writers; ATTIC witness, a witness incapable of corruption, &c.

ATTIC Order. See ARCHITECTURE, n^o 58.

ATTIC Base, a peculiar kind of base used by the ancient architects in the Ionic order; and by Palladio, and some others, in the Doric.

ATTIC Story, in architecture; a story in the upper part of a house, where the windows are usually square.

ATTICA, an ancient kingdom of Greece, situated along the north coast of the gulph of Saroo, bounded on the west by Megara, mount Cithæron, and part of Bœotia; on the north by the gulph of Euripus, now *Stretto di negro ponte*, and the rest of Bœotia; and on the east by the Eurapius. It extended in length from north-west to south-east about 60 miles; its breadth from north to south was 56, decreasing as it approached the sea.

The soil of this country was naturally barren and craggy, though by the industry of its inhabitants it produced all the necessaries of life. On this account Attica was less exposed to invasions than other more fertile countries; and hence it preserved its ancient inhabitants beyond all the other kingdoms in its neighbourhood; so that they were reputed to be the spontaneous productions of the soil; and as a badge of this, Thucydides tells us, they wore golden grasshoppers in their hair.

The chief cities in the kingdom of Attica were Athens the capital; next to it, Eleusis, situated on the same gulph, near the coasts of Megara; and next to that, Rhamnus, famed for the temple of Amphiaræus and the statue of the goddess Nemesis.

The first king of this country, of whom we have any distinct account, was Cecrops. Others indeed are said to have reigned before him, particularly one Actæus, whose daughter Cecrops married, and in her right laid the foundation of his new monarchy. Cecrops is said to have been the first who deified Jupiter, set up altars and idols, and instituted marriage among the Greeks. He is likewise affirmed to have taught his subjects navigation, and for the better administration of justice, and promoting intercourse among them, to have divided them into the first four tribes called *Cecropiæ, Autochthon, Actæa, and Paralîa*; and he is also by some said to be the founder of the Areopagus. From this monarch the Athenians affected to call themselves *Cecropiæ* till the reign of Erechtheus their sixth king, after whom they took the name of *Erechthidæ*.

Cecrops dying after a reign of 50 years, left three daughters, by marrying one of which, probably, Crœneus a wealthy citizen ascended the throne. He enjoyed his crown peaceably for ten years; till, having married one of his daughters, named *Attis*, to Amphic-

Crœneus.

tyon the son of Deucalion, he was by him dethroned, and forced to lead a private life to the last. From this daughter, the country which before had been called *Alcæa*, took the name of *Attica*.

After a reign of ten or 12 years, Amphictyon was himself depoted by Erichonius, said to be the son of Vulcan and Tethys: Being lame of both his feet, he is said to have invented coaches, or, as others will have it, instituted horse and chariot races in honour of Minerva. He is also reported to have been the first who stamped silver coin. He reigned 50 years, and was succeeded by his son Pandion the father of Progne and Philomela; whose hard fate, so famous among the poets, is supposed to have broke his heart, after a reign of about 40 years. In his time Triptolemus taught the Athenians agriculture, which he had learned from Ceres.

Pandion was succeeded by his son Erechtheus, who being reckoned the most powerful prince of his time, Boreas king of Thrace demanded his daughter Orithia in marriage, and on being refused carried her off by force. After a reign of 50 years, Erechtheus being killed in a battle with the Eleusians, was succeeded by his son Cecrops II. who is generally allowed to have been the first who gathered the people into towns; they having till then lived in houses and cottages scattered here and there, without order or regular distance. After a reign of 40 years he was driven out by his brethren Metion and Pandorus, who forced him to fly into *Ægialea*, where he died.

Cecrops II. was succeeded by his son Pandion II. and he was likewise driven out by Metion, who assumed the government. Pandion in the mean time fled into Megara, where he married Pelia the daughter of Pylas king of that place, and was appointed successor to the kingdom. Here he had four sons, who returning to Athens, whether with or without their father is uncertain, expelled the sons of Metion, and after the decease of Pandion their father, divided the government among themselves; notwithstanding which, the royal dignity did in effect remain with *Ægeus* the eldest.

Ægeus, when he ascended the throne, finding himself despised by his subjects because he had no sons, and sometimes insulted by his brother Pallas who had no less than fifty, consulted the oracle of Apollo at Delphi. Receiving here, as was commonly the case, an answer which could not be understood without a commentator, he applied to Pittheus king of Troezen, famous for his skill in expounding oracles. This prince easily prevailed with him to lie with his daughter *Æthra*, who proved with child; and as none but these three were privy to the secret, *Ægeus*, before his return to Athens, hid a sword and a pair of shoes under a stone, leaving orders with the princess, that if the child proved a boy, she should send him to Athens with these tokens, as soon as he was able to lift up that stone. He charged her moreover to use all imaginable secrecy, lest the sons of his brother Pallas should way-lay and murder him.

Æthra being delivered of a son, Pittheus gave out that Neptune was the father of it. This child was named *Theſeus*, and proved one of the most famous heroes of antiquity. Being arrived at the age of 16, his mother brought him to the stone above-mentioned; and he having lifted it with ease, was desired to take

up the sword and shoes, and prepare himself to go to his father. He was advised to go by sea rather than by land, as, ever since the departure of Hercules, the roads had been exceedingly infested by banditti. *Theſeus*, however, who had already begun to discover marks of uncommon strength and courage, no sooner heard the name of Hercules mentioned, than he became desirous of imitating so great a pattern, and after performing a number of glorious exploits, for which see the article *THEſſUS*, he arrived safe at his father's capital.

The great achievements of our young hero procured him a welcome reception at the court of *Ægeus*, though his birth was unknown to all except Medea, to whom the king had lately been married. This queen being a forcerel, it is not to be supposed any thing could be concealed from her: she therefore, by her diabolical penetration, quickly found out that *Theſeus* was the king's son; after which he became so jealous of him on account of his valour, that he persuaded her old husband to invite the young stranger to a banquet, and poison him in a glass of wine. The poison was accordingly prepared, and *Theſeus* invited; but the prince suddenly drawing his sword, it was immediately recognized by *Ægeus* to be the same he had formerly buried below the stone. Upon this, he stepped forward to *Theſeus*, throwing down the poisoned draught in his way, and, embracing him with much tenderness, owned him for his son before all the court.

At this time the king of Athens had great occasion for such a champion as *Theſeus*. The sons of Pallas, who had all along behaved with great insolence, upon *Theſeus* being discovered to be the king's son, and heir apparent to the crown, broke out in open rebellion. They were soon discomfited; but *Ægeus* and the whole country of Attica were still in great distress on the following account. Some years before, *Androgeus*, the son of Minos king of Crete, came to Athens to be present at one of their feasts. During this visit he contracted such an intimacy with the fifty sons of Pallas, that *Ægeus*, fearing some fatal consequences, caused him to be privately murdered. According to others, *Androgeus* having undertaken to encounter the Marathonian bull, was killed by it. Be this as it will, Minos having received news of his son's death, imputed it to the people of Attica; and therefore, after several unsuccessful attempts to revenge his own quarrel, prayed to the gods to do it for him. The Athenians, in consequence of this prayer, were visited with earthquakes, famine, and pestilence, on account of which they applied to the oracle. Here they were informed, that no relief was to be had till they were reconciled to the Cretan king. Minos resolving to make them pay dear for their delivrance, imposed upon them a tribute of seven young men, and as many virgins, whom he condemned to be devoured by the *Minotaur*, a monster feigned by the poets to have been half man and half bull. This bloody tribute had been twice paid, and Minos had already sent his messengers the third time, when *Theſeus* willingly offered himself to be one of the unhappy victims, and embarking with them in one ship, he gave the pilot two sails, the one black to sail with, and the other white to be hoisted up at his return in case he came off victorious. Our hero had all the success he could wish; he killed the

Attica.
16
Death of
Ægeus.

Minotaur, prevailed with Minos to remit the tribute, and his daughter Ariadne to run away with him; but her he left with child in the isle of Naxos. Unfortunately, however, for Ægeus, the joy of Theseus and his company was so great, that at their return they forgot to hoist the white flag in token of their victory: upon which the old king, taking for granted that his son was killed, threw himself into the sea, which ever since has from him been called the *Ægean* Sea.

17
Theseus
king of Attica.

18
New-models the government.

Theseus, being thus left in possession of the kingdom of Attica, began immediately to think of indulging his warlike genius, and rendering the civil affairs of his kingdom as little troublesome as possible. To accomplish this purpose, he began with gathering most of the people of Attica into the old and new town, which he incorporated into one city. After this he divested himself of all his regal power, except the title of king, the command of the army, and the guardianship of the laws. The rest he committed to proper magistrates chosen out of three different orders of the people, whom he divided into nobles, husbandmen, and artificers. The first he invested with the power of interpreting and executing the laws, and regulating whatever related to religion. The other two chose their inferior magistrates from among themselves, to take care of whatever related to their separate orders: so that the kingdom was in some measure reduced to a commonwealth, in which the king had the greatest post; the nobles were next to him in honour and authority; the husbandmen had the greatest profit; and the artists exceeded them in number. He likewise abolished all their distinct courts of judicature, and built one common council hall called *prytaneum*, which stood for many ages afterwards.

Having thus new-modelled the government, his next care was to join to his dominions the kingdom of Megara, in right of his grandfather Pandion II. who had married the daughter of Pylas, as abovementioned. On this occasion he erected the famous pillar in the isthmus, which shewed the limits of the two countries that met there. On the one side of this pillar was inscribed, "This is not Peloponnesus, but Ionia;" and on the other, "This is Peloponnesus, not Ionia." After this he undertook an expedition against the Amazons, whom he overcame, took their queen Hippolyta, and afterwards married her. Soon after this, Theseus contracted an intimacy with Pirithous the son of Ixion, and being invited to his nuptials, assisted him in killing a number of Centaurs, or rather Thessalian horsemen, (who in their cups had offered violence to their female guests); and drove the rest out of the country. Our two associates then proceeded to Sparta, where Theseus fell in love with the famed Helena, at that time not above nine years old, while he himself was upwards of fifty. Her they carried off; and of the rape there are various accounts; but the following one, which is given by Plutarch, is generally allowed to be the most authentic.

According to that historian, they stole this beauty, the greatest in the world at that time, out of the temple of Diana Orta, where Helena happened to be dancing. They were pursued as far as Tegea, but made their escape out of Peloponnesus; and thinking themselves now secure of their prey, they agreed to cast lots for her, upon condition that he to whose lot she fell should assist the other in procuring some celebrated

beauty. Fortune having declared for Theseus, he assisted his companion in the like attempt upon Proserpina daughter of Aidonius king of the Molossi in Epirus, who, being the next beauty to Helena, was guarded by the dog Cerberus, which had three heads, and was consequently a very formidable enemy. Her father, however, understanding that they designed to steal away his daughter, threw Pirithous to be torn in pieces by Cerberus, and put Theseus in prison, from whence he was afterwards relieved at the intercession of Hercules.

After this misfortune, Theseus at length returned to Athens, but found himself very coolly received by his subjects. Mneftheus, the son of Peteus, and great-grandson of Erectheus, had made use of the king's absence to ingratiate himself with the people; and, upon the commencement of a war with Castor and Pollux, the two brothers of Helena, he persuaded the people of Athens to open their gates to the two brothers. Upon this, Theseus was under the necessity of conveying away himself and family with all possible privacy. This he luckily accomplished; and designed to have sailed to Crete, to have obtained assistance from Deucalion son of Minos, and now brother-in-law to Theseus himself, he having lately married Phædra sister to Deucalioa. Unfortunately, however, our hero was shipwrecked on the island of Scyros. Here he was at first kindly received by Lycomedes the king of that island; but was soon after killed by a fall from a high rock, over which some say he was pushed by Lycomedes himself, who had been prevailed upon to destroy Theseus in that manner by Mneftheus, that he might with the more security enjoy the kingdom of Athens.

Mneftheus reigned 24 years, but lost his life at the siege of Troy; and was succeeded by Demophon one of the sons of Theseus by Phædra, who was likewise at the siege of Troy, but had the good fortune to return in safety. In his reign was erected the famous court of the Ephete; consisting originally of 50 Athenians and as many Argives, for trying of wilful murders. By this court the king himself afterwards submitted to be tried for having accidentally killed one of his subjects. He reigned 33 years, and was succeeded by his son, according to some, or according to others his brother, Oxyntes, who reigned 12 years. Oxyntes was succeeded by his son Aphydas, who was murdered by Thymætes the bastard son of Oxyntes.

This king discovered many base qualities unworthy of his dignity; and at last was deposed by his subjects on the following occasion. Xanthus king of Bœotia had a contest with the Athenians about one of their frontier towns. He offered to decide the matter by single combat with the king; but this was declined by Thymætes. It happened, that at that time one Melanthus a Messenian, who had been driven out of his country by the Heraclidæ, was come to Athens; who accepted the king of Bœotia's challenge. At the first onset, Melanthus asked his adversary, why he had, contrary to the articles, brought a second into the field with him? and as Xanthus immediately looked about to see who was behind him, Melanthus run hin thro' with his lance. This victory, though it did little honour to him who gained it, was so agreeable to the Athenians, that they deposed their cowardly king Thymætes, after he had reigned 8 years; and appointed Melanthus in his stead, who after a reign of 37 years left the kingdom

dom to his son Codrus.

This prince reigned about 21 years; during which time the Doræ and Heraclidæ had regained all Peloponnesus, and were upon the point of entering into Attica. Codrus, being informed that the oracle had promised them victory provided they did not kill the king of the Athenians, came immediately to a resolution of dying for his country. Disguising himself, therefore, like a peasant, he went into the enemy's camp, and quarrelling with some of the soldiers, was killed by them. On the morrow, the Athenians knowing what was done, sent to demand the body of their king; at which the invaders were so terrified, that they decamped without striking a blow.

Upon the death of Codrus, a dispute which happened among his sons concerning the succession, furnished the Athenians with a pretence for ridding themselves of their kings altogether, and changing the monarchical form of government into a republican one. It was improbable, they said, that they should ever have so good a king as Codrus; and to prevent their having a worse, they resolved to have no king but Jupiter. That they might not, however, seem ungrateful to the family of Codrus, they made his son Medon their supreme magistrate, with the title of *archon*. They afterwards rendered that office decennial, but continued it still in the family of Codrus. The extinction of the Medontidæ at last left them without restraint; upon which they not only made this office annual, but created nine archons. By the latter invention they provided against the too great power of a single person, as by the former they took away all apprehension of the archons having time to establish themselves, so as to change the constitution. In a word, they now attained what they had long sought, viz. the making the supreme magistrates dependent on the people.

We have a list of these archons, for upwards of 600 years, beginning with Creon, who lived about 684 years before Christ, to Herodes, who lived only 60 years before that time. The first archon of whom we hear any thing worth notice, is named *Draco*. He reigned in the second, or, as others say, in the last year of the 39th Olympiad, when, it is supposed, he published his laws: but though his name is very frequently mentioned in history, yet no connected account can be found either of him, or his institutions; only, in general, his laws were exceedingly severe, inflicting death for the smallest faults; which gave occasion to one Demades an orator to observe, that the laws of Draco were written with blood, and not with ink. For this extraordinary severity he gave no other reason, than that small faults seemed to him to be worthy of death, and he could find no higher punishment for the greatest. He was far advanced in years when he gave laws to Athens; and to give his institutions the greater weight, he would not suffer them to be called *nomoi*, or laws, but *thesmoi*, or sanctions proceeding from more than human wisdom. The extreme severity of these laws, however, soon made the Athenians weary both of them and the author of them; upon which Draco was obliged to retire to Ægina. Here he was received with the highest honours: but the favour of the inhabitants of this place proved more fatal to him than the hatred of the Athenians; for coming one day into the theatre, the audience, to shew their regard, threw, as the custom

then was, their cloaks upon him; and the multitude of these being very great, they stifled the old man, who was too weak to disengage himself from their load.

After the expulsion of Draco, nothing remarkable happened at Athens till the year before Christ 606, when we find the republic engaged in a war with the Mitylenians about the city Sigæum, situated near the mouth of the river Scamander. The Athenian army was commanded by Phrynon, a person equally remarkable for the comeliness of his person and the generosity of his mind. The Mitylenians were commanded by Pittacus, one of the celebrated sages of Greece. As these commanders looked upon the honour of their respective countries to be concerned, they exerted themselves to the utmost. At last they met in single combat: where Phrynon depended on his valour only; but Pittacus concealed behind his shield a net, wherewith he suddenly entangled his antagonist, and easily slew him. This, however, not putting an end to the war, Pericles tyrant of Corinth interposed; and both parties having submitted to his arbitration, he decreed that Sigæum should belong to the Athenians.

About seven years after this war, a conspiracy was formed by Cylon son-in-law to Theagenes tyrant of Megara, who, having by his assable behaviour procured many friends, formed a design of seizing the sovereignty of Athens. Having consulted the oracle as to the most proper time, he was directed to make the attempt when the citizens of Athens were employed in celebrating their highest feast to Jupiter. When many of the citizens therefore were gone to the Olympic games, Cylon and his associates made themselves masters of the citadel. Here they were instantly besieged by Megacles at that time archon, and soon reduced to great distress for want of water. The chief together with his brother found means to make their escape, but the meaner sort were left to thirst for themselves. In this extremity they fled to the temple of Minerva, from whence Megacles with much ado prevailed upon them to come down and submit themselves to the mercy of their country. Having at last assented to this, they tied a cord to the image of the goddess, and carried the clue with them, to demonstrate that though they were out of the temple they were still under Minerva's protection. Unfortunately for them, however, as they passed the temple of the furies, the line snapt of itself; which Megacles construing into a renunciation by the goddess, caused his men fall upon them and dispatch as many as they could find. Such as were without the temple, were immediately massacred, and those who fled thither again were murdered in their sanctuary. In short, none escaped but such as bribed the wives of the officers of justice. This carnage, however, did not put an end to the sedition. The remains of Cylon's faction created great disturbances, by insinuating that the violation of Minerva's sanctuary had drawn down the anger of the gods; and these discourses had such an effect, that Megacles and his officers were styled *execrable*, and held to be persons under the displeasure of Heaven.

During the time of this confusion, the Megarensians attacked Nisea, which they took, as well as Salamis; and so completely routed the Athenians in every attempt to recover the latter, that a law was at last passed by which it should be capital for any one to propose the recovery of Salamis. About the same time the

the city was disturbed by reports of frightful appearances, and filled with superstitious fears; the oracle at Delphi was therefore consulted, and an answer returned that the city behoved to be expiated. Upon this, Epimenides the Phestian was sent for from Crete, to perform the necessary ceremonies, he being reputed an holy man, and one that was deeply skilled in all the mysteries of religion. His expiation consisted in taking some black, and some white sheep, turning them all loose, and directing some persons to follow them to those places where they couched, and there to sacrifice them to the local deity. He caused also many temples and chapels to be erected, two of which have been particularly noted, viz. the chapel of *Contumely*, and that of *Impudence*. This man is said to have looked wistfully on the port of Munychia for a long time, and then to have spoke as follows to those that were near him. "How blind is man to future things? for did the Athenians know what mischief will one day be derived to them from this place, they would eat it with their teeth." This prediction was thought to be accomplished 270 years after, when Antipater constrained the Athenians to admit a Macedonian garrison into that place.

36
Epimenides's expiation and prophecy.

37
Solon the wife legislator.

About 597 years before Christ, Solon the famed Athenian legislator began to shew himself to his countrymen. He is said to have been lineally descended from Codrus; but left by his father in circumstances rather necessitous, which obliged him to apply to merchandize: it is plain, however, both from his words and writings, that he was a disinterested patriot. The shameful decree, that none under pain of death should propose the recovery of Salamis, grieved him so much, that having composed an elegy of 100 verses, such as he thought would be most proper to inflame the minds of the people, he ran into the market-place as if he had been mad, with his night-cap on his head, repeating his elegy. A crowd being gathered round the pretended madman, his kinsman Pisistratus mingled among the rest, and observing the people moved with Solon's words, he also seconded him with all the eloquence he was master of, and between them they prevailed so far as to have the law repealed, and a war was immediately commenced against the people of Megara. Who was commander in this expedition is not certain; but the city was recovered, according to the most general account, by the following stratagem. Solon coming with Pisistratus to Colias, and finding there the women busy in celebrating, according to custom, the feast of Ceres, sent a confidant of his to Salamis, who pretended to be no friend to the people of Attica, telling the inhabitants of Salamis, that if they had a mind to seize the fairest of the Athenian ladies, they might now do it by passing over to Colias. The Megarensians giving easy credit to what the man said, immediately fitted out a ship; which Solon perceiving from the opposite shore, dismissed the women, and having dressed a number of beardless youths in female habits, under which they concealed every one a dagger, he sent them to the sea-side to dance and divert themselves as the women were wont to do. When those who came from Salamis saw these young persons skipping up and down, they strove who should be first on shore; but were every one of them killed, and their vessel seized; aboard which the Athenians embarking, sailed immediately to Sa-

39
Salamis recovered by his means.

lams, and took it.

On the return of Solon to Athens, he was greatly honoured by the people, to whom another occasion of admiring his wisdom was quickly afforded. The inhabitants of Cirrha, a town situated in the bay of Corinth, after having by repeated incursions wasted the territory of Delphi, at last besieged the capital itself, with a view of making themselves masters of the treasures contained in the temple of Apollo. Advice of this intended sacrilege being sent to the Amphictyons, who were the states-general of Greece, Solon advised that the matter should be universally referred, and that all the states should join in punishing the Cirrheans, and saving the Delphic oracle. This advice was complied with, and a general war against Cirrha declared. Clisthenes, tyrant of Sicyon, commanded in chief, and Alcmaeon was general of the Athenian quota. Solon went as assistant or counsellor to Clisthenes, and by following his advice the war was conducted to a prosperous issue. For when the Greek army had besieged Cirrha for some time without any appearance of success, the oracle at Delphi was consulted, from whence the following answer was returned:

"In vain you hope to take the place before

"The sea's blue waves roll o'er the hallow'd shore."

This answer struck the whole army with surprize, till Solon advised Clisthenes to consecrate solemnly the whole territory of Cirrha to the Delphic Apollo; so, as that was a maritime country, the sea must then wash the sacred coast. According to Pausanias, the city was reduced by the following stratagem, likewise invented by Solon. He caused the river Plutius, which run through Cirrha, to be turned into another channel, hoping thereby to have distressed the inhabitants for want of water; but finding they had many wells within the city, and were not to be reduced by that means, he caused a vast quantity of roots of hellebore to be thrown into the river, which was then suffered to return into its former bed. The inhabitants, overjoyed at the sight of running water, came in troops to drink of it; whereupon an epidemic flux ensued, and the citizens being no longer able to defend the walls, the town was easily taken.

On the return of Solon to Athens he found things again in the utmost confusion. The remnant of Cylon's faction gave out, that all sorts of misfortunes had befallen the republic on account of the impiety of Megacles and his followers, which clamour was heightened by the retaking of Salamis about this time by the Megarensians. Solon interposed, and persuaded those who were styled *execrable* to abide a trial, and 300 persons were chosen to judge them. The event was, that 300 of Megacles's party who were alive were sent into perpetual banishment, and the bones of such as were dead were dug up and sent without the limits of their country.

Though this decision restored the public quiet for the present, it was not long before the people were divided into three factions contending about the proper form of government. These were called the *Diacrii*, *Pedici*, and *Parali*: the first of these were the inhabitants of the hilly country, who declared positively for democracy; the second, dwelling in the lower parts, and who were far more opulent than the former, declared for an oligarchy, as supposing the government would

fall mostly into their hands; the third party, who lived on the sea-coast, were people of moderate principles, and therefore were for a mixed government. Besides the disturbances raised on this account, others were occasioned by the rich oppressing the poor. According to Plutarch, the poor being indebted to the rich, either tilled their grounds, and paid them the sixth part of the produce, or engaged their bodies for their debts, so that many were made slaves at home, and many sold into other countries; nay, some were obliged to sell their children to pay their debts, and others in despair quitted Attica altogether. The greatest part, however, were for throwing off the yoke, and began to look about for a leader, openly declaring that they intended to change the form of government, and make a repartition of lands. In this extremity, the eyes of all the citizens were cast upon Solon. The most prudent were for offering him the sovereignty; but he perceiving their intentions, behaved in such a manner as to cheat both parties, and shewed a spirit of patriotism perhaps never equalled. He refused the sovereignty as far as it might have benefited himself; and yet took upon himself all the care and trouble of a prince, for the sake of his people.

He was chosen archon without having recourse to lots, and after his election disappointed the hopes of both parties. It was Solon's fundamental maxim, That those laws will be best observed which power and justice equally support. Wherever, therefore, he found the old constitution consonant to justice in any tolerable degree, he refused to make any alteration at all, and was at extraordinary pains to shew the reason of the changes he did make. In short, being a perfect judge of human nature, he sought to rule, only by shewing his subjects that it was their interest to obey, and not by forcing upon them what he himself esteemed best. Therefore, to a person who asked whether he had given the Athenians the best laws in his power, he replied, "I have established the best they could receive."

As to the main cause of sedition, viz. the oppressed state of the meaner sort, Solon removed it by a contrivance which he called *sisachthia*, i. e. *discharge*; but what this was, authors are not agreed upon. Some say that he released all debts then in being, and prohibited the taking any man's person for payment of a debt for the future. According to others, the poor were eased, not by cancelling the debts, but by lowering the interest, and increasing the value of money; a mina, which before was made equal to 73 drachms only, being by him made equal to 100; which was of great advantage to the debtor, and did the creditor no hurt. It is, however, most probable that the *sisachthia* was a general remittance of all debts whatever, otherwise Solon could not have boasted in his verses that he had removed so many marks of mortgages (B) as were every where frequent; that he had freed from apprehension such as were driven to despair, &c.

But in the midst of all Solon's glory, an accident befel him, which, for a time, hurt his reputation, and had almost entirely ruined his schemes. He had consulted Conon, Clinias, and Hipponicus, his three friends, on an oration prepared with a view to engage

the people's consent to the discharge; and these three men, thus knowing there was to be a general discharge of debts, basely took the opportunity of borrowing vast sums before the law was promulgated, in consequence of which they were never obliged to return them.

This was thought at first to have been done with Solon's consent, and that he had shared in the money; but this assertion was quickly wiped off when it appeared that the lawgiver himself was a very considerable loser by his own law. His friends, however, could never recover their credit, but were ever afterwards stigmatized with the opprobrious appellation of *chreocopides*, or *debt-sinkers*.

The Athenians were as little pleased with Solon's management as with their former condition; the rich thinking he had done too much in cancelling the money-debts due to them, and the poor that he had done too little because he had not divided the lands of Attica equally. In a short time, however, they acquiesced in the new institutions, and gave a more public token of their repentance than they had before shewn of their displeasure, instituting a solemn sacrifice under the name of *Sisachthia*, at the same time that Solon was unanimously elected legislator of Athens, with full power to make laws, and alter or new model the constitution as he thought fit.

Solon being now invested with unlimited authority, set about the arduous task of compiling new laws for the turbulent people of Attica; which having at last completed in the best manner he was able, or in the best manner the nature of the people would admit, he procured them to be ratified for 100 years. Such as related to private actions were preserved on parallelograms of wood, with cases which reached from the ground, and turned about upon a pin like a wheel. These were thence called *Axones*; and were placed first in the citadel, and afterwards in the prytaneum, that all the subjects might have access to them when they pleased. Such as concerned public institutions and sacrifices were contained in triangular tables of stone called *cyrbes*. The Athenian magistrates were sworn to observe both; and in process of time these monuments of Solon's wisdom became so famous, that all public acts were from them named *Axones* and *Cyrbes*.

After the promulgation of the laws, Solon found himself obliged to leave Athens, to prevent his being continually teased for explanations and alterations of them. He therefore pretended an inclination to merchandise, and obtained leave to absent himself for 10 years, during which time he hoped the laws would be grown familiar. From Athens Solon travelled into Egypt, where he conversed with Psenophis the Heliopolitan, and Sonchis the Saite, the most learned priests of that age. From these he learned the situation of the island Atlantis, of which he wrote an account in verse, which Plato afterwards continued. From Egypt he went to Cyprus, where he was extremely well received by one of the petty kings. This prince lived in a city called *Apeia*, built by Demophon the son of Theseus, on an eminence near the river Clarius, but in a soil craggy and barren. Solon observing a very pleasant plain below, engaged the king to remove thither; assisted in executing the scheme he had formed;

(B) The Athenians had a custom of hanging up billets to shew that houses were engaged for such and such sums of money.

46
Solon blamed at first, but afterwards applauded and chosen legislator.

formed; and succeeded so well, that a new city was formed which soon became populous, and out of gratitude to the Athenian legislator was called *Solos*.

49
Things fall
into dis-
order in his
absence.

But while Solon was thus travelling in quest of wisdom, and with a view to benefit those among whom he came, his countrymen, who seem to have resolved on being dissatisfied at all events, had again divided themselves into three factions. Lycurgus put himself at the head of the country people; Megacles the son of Alcemeon was at the head of those who lived on the sea-coast; and Pisistratus put himself at the head of the poorer sort, to protect them, as he pretended, from tyranny, but in reality to seize on the sovereignty for himself. All the factions pretended to have a vast regard for Solon and his laws, at the same time that they were very desirous of a change; but how they were to be bettered, none of them knew, or pretended to know.

50
He returns
to Athens,
but refuses
to resume
his office.

In the midst of this confusion the legislator returned. Each of the factions paid their court to him, and affected to receive him with the deepest reverence and respect; beseeching him to reassume his authority, and compose the disorders which they themselves kept up. This Solon declined on account of his age, which, he said, rendered him unable to speak and act for the good of his country as formerly: however, he sent for the chiefs of each party, beseeching them in the most pathetic manner not to ruin their common parent, but to prefer the public good to their own private interest.

Pisistratus, who of all the three had perhaps the least intention to follow Solon's advice, seemed to be the most affected with his discourses; but as Solon perceived he affected popularity by all possible methods, he easily penetrated into his designs of assuming the sovereign power. This he spoke of to Pisistratus himself, at first privately; but as he saw that his admonitions in this way had no effect, he then said the same things to others, that the public might be on their guard against him.

51
Pisistratus
assumes the
sovereign-
ty.

All the wise discourses of Solon, however, were lost upon the Athenians. Pisistratus had got the meaner sort entirely at his devotion, and therefore resolved to cheat them out of the liberty which they certainly deserved to lose. With this view he wounded himself, and, as Herodotus says, the mules that drew his chariot; then he drove into the market-place, and there shewed his bleeding body, imploring the protection of the people from those whom his kindness to them had rendered his implacable enemies. A concourse of people being instantly formed, Solon came among the rest, and, suspecting the deceit, openly taxed Pisistratus with his perfidious conduct; but to no purpose. A general assembly of the people was called, wherein it was moved by one Ariston, that Pisistratus should have a guard. Solon was the only person present who had resolution enough to oppose this measure; the richer Athenians, perceiving that the multitude implicitly followed Pisistratus, and applauded every thing he said, remaining silent through fear. Solon himself, when he saw he could prevail nothing, left the assembly, saying he was *wiser than some, and souter than others*. A guard of 400 men was now unanimously decreed to Pisistratus, as we are told by Solon himself. This inconsiderable body he made use of to enslave the people, but in what manner he accomplished his purpose is not agreed.

Certain it is, that with his sword he seized the citadel; but Polyænus hath given an account of a very singular method which he took to put it out of the power of the Athenians to defend themselves even against such a small number. He summoned an assembly to be held at the Anacium, and directed that the people should come thither armed. They accordingly came; and Pisistratus harangued them, but in a voice so low that they could not tell what he said. The people complaining of this, Pisistratus told them that they were hindered from hearing him by the clangor of their arms; but, if they would lay them down in the portico, he would then be heard distinctly. This they did; and while they listened very attentively to a long and eloquent oration, Pisistratus's guard conveyed away their arms, so that they found themselves deprived of all power of resistance. During the confusion which followed this event, another assembly was held, wherein Solon inveighed bitterly against the meanness of his countrymen, inviting them to take up arms in defence of their liberty. When he saw that nothing would do, he laid down his own arms, saying, that he had done his utmost for his country and his laws. According to Plutarch, he refused to quit the city; but the most probable opinion is, that he immediately retired from the dominions of Athens, and refused to return, even at the solicitation of Pisistratus himself.

Atties.

52
Solon leaves
Athens.

Pisistratus, having thus obtained the sovereignty, did not overturn the laws of Solon, but used his power with the greatest moderation. It is not to be expected, however, that so turbulent a people as the Athenians could be satisfied by any method of government he could lay down. At the beginning of his administration, Megacles and his family retired out of Athens to save their own lives, yet without despairing of being able some time or other to return. With this view Megacles and his associates entered into a treaty with Lycurgus; and having brought him and his party into a scheme for deposing Pisistratus, they concerted matters so well, that Pisistratus was soon obliged to seek for shelter somewhere else, and, on his departure, the Athenians ordered his goods to be sold. Nobody, however, except one person (*Callias*), would venture to buy any of them, from an apprehension, no doubt, that they would soon be restored to their proper owner, which accordingly happened in a very short time.

53
Pisistratus
governs
with great
moderation.54
Driven out
by Megacles.

As Megacles and his party had negotiated with Lycurgus to turn out Pisistratus, so they now entered into a treaty with Pisistratus to reinstate him in his principality, as soon as they found Lycurgus would not be implicitly governed by them. To accomplish this, they fell upon a very ridiculous project; which, however, was attended with the desired success. They found out a woman whose name was *Phya*, of a mean family and fortune, but of a great stature, and very handsome. Her they dressed in armour, placed her in a chariot, and having disposed things so as to make her appear with all possible advantage, they conducted her towards the city, sending heralds before, with orders to speak to the people in the following terms; "Give a kind reception, O Athenians, to Pisistratus, who is so much honoured by Minerva above all other men, that she herself condescends to bring him back to the citadel." The report being universally spread that Minerva was bringing home Pisistratus, and the ignorant multitude believing

second
ne.

Pisistratus did not long enjoy the kingdom to which he had been restored in so strange a manner. He had married the daughter of Megacles, as already observed; but having children by a former wife, and remembering that the whole family of Megacles was reprobed by the Athenians, he thought proper to let his new spouse remain in a state of perpetual widowhood. This she patiently bore for some time, but at last acquainted her mother. An affront so grievous could not fail to be highly resented. Megacles instantly entered into a treaty with the malcontents, of whom there were always great plenty at Athens whatever was the form of government. This Pisistratus being apprized of, and perceiving a new storm gathering, he voluntarily quitted Athens, and retired to Eretria. Here having consulted with his sons, it was resolved to reduce Athens by force. With this view he applied to several of the Greek states, who furnished him with the troops he desired, but the Thebans exceeded all the rest in their liberality; and with this army he returned to Attica, according to Herodotus, in the 11th year of his banishment. They first reduced Marathon, the inhabitants of which had taken no measures for their defence, tho' they knew that Pisistratus was preparing to attack them. The republican forces in the mean time marched out of Athens to attack him; but behaving in a secure and careless manner, they were surprised by Pisistratus, and totally routed. While they were endeavouring to make their escape, he caused his two sons ride before him with all speed, and tell those they came up with that nobody had any thing to fear, but that they might every one return to his own home. This stratagem so effectually dispersed the republican army, that it was impossible to rally them, and Pisistratus became a third time absolute master of Attica.

57
t returns
in an
ny.

Pisistratus being once more in possession of the sovereignty, took a method of establishing himself on the throne directly opposite to what Theseus had done. Instead of collecting the inhabitants from the country into cities, as Theseus had done, Pisistratus made them retire from the cities into the country, in order to apply themselves to agriculture. This prevented their meeting together, and caballing against him in such bodies as they had been accustomed to do. By this means also the territory of Athens was greatly meliorated, and great plantations of olives were made over all Attica, which had before not only been destitute of corn, but also bare of trees. He also commanded, that, in the city, men should wear a kind of sheep-skin vest, reaching to the knees; but so intolerable were the laws of Pisistratus to his subjects, that this kind of garment in succeeding times became proverbially the habit of slavery.

58
takes
the

59
s subjects
d discontented
notwithstanding
his motion.

As prince of Athens, Pisistratus received the tenth part of every man's revenues, and even of the fruits of the earth; and this also, though for the service of the state, seemed to the Athenians a most grievous burden. In short, though Pisistratus behaved in all respects as a most excellent prince, his subjects fancied

themselves oppressed by tyranny, and were perpetually grumbling from the time he first ascended the throne to the day of his death, which happened about 33 years after he had first assumed the sovereignty, of which time, according to Aristotle, he reigned 17 years.

Pisistratus left behind him two sons named Hipparchus and Hippias, both men of great abilities, who shared the government between them, and behaved with lenity and moderation. But though by the mildness of their government the family of the Pisistratide seemed to be fully established on the throne of Athens, a conspiracy was unexpectedly formed against both the brothers, by which Hipparchus was taken off, and Hippias narrowly escaped. The most material facts relating to this conspiracy are what follow.

60
Hipparchus
and Hip-
pias.

There were at that time in Athens two young men called *Harmodius* and *Aristogiton*; the former of these was exquisitely beautiful in his person, and on that account, according to the infamous custom of the Greeks, violently beloved of the other. This Harmodius was also beloved of Hipparchus; who, if we may believe Thucydides, forced him. This was grievously resented, and revenge determined on; to hasten which, another accident concurred. Hipparchus, finding that Harmodius endeavoured to avoid him, publicly affronted him, by not suffering his sister to carry the offering of Minerva, as if she was a person unworthy of that office. The two young men, not daring to shew any public signs of resentment, consulted privately with their friends; among whom it was resolved, that at the approaching festival of Panathenæa, when the citizens were allowed to appear in arms, they should attempt to restore Athens to its former liberty. In this they imagined that they should find themselves seconded by the whole body of the people. But when the day appointed was come, they perceived one of their number talking very familiarly with Hippias; and fearing that they were discovered, they immediately fell upon Hipparchus, and dispatched him with a multitude of wounds. In this exploit the people were so far from seconding them, as they expected, that they suffered Harmodius to be killed by Hipparchus's guards, and seizing Aristogiton themselves delivered him up to Hippias. Some time afterwards, however, the respect they paid to these two young men exceeded all bounds. They caused their praises to be sung at the Panathenæa, forbid any citizen to call a slave by either of their names, and erected brazen statues to them in the forum; which statues were afterwards carried into Persia by Xerxes, and sent back from thence by Alexander the Great, Antiochus, or Seleucus, for authors are not agreed by which. Several immunities and privileges were also granted to the descendants of these two patriots, and all possible means were taken to render their memory venerable and respected by posterity.

64
Cruelty of
Hippias.

Hippias being now sole master of Athens, and probably exasperated by the murder of his brother, began to alter his conduct greatly, and treat his subjects in an oppressive and cruel manner. He began with torturing Aristogiton, in order to make him confess his accomplices: but this proved fatal to his own friends: for Aristogiton impeaching such as he knew to be best affected to Hippias, they were immediately put to death; and when he had destroyed all those he knew, at last told Hippias, that now he knew of none that deserved

Attica. to suffer death except the tyrant himself. Hippias next vented his rage on a woman named *Leena*, who was kept by Aristogiton. She endured the torture as long as she could; but finding herself unable to bear it any longer, she at last bit off her tongue, that she might not have it in her power to make any discovery. To her the Athenians erected the statue of a lioness, alluding to her name, without a tongue, on which was engraved a suitable inscription.

After the conspiracy was, as Hippias thought, thoroughly quashed, he set himself about strengthening his government by all the means he could think of. He contracted leagues with foreign princes, increased his revenues by various methods, &c. But these precautions were of little avail: the lenity of Pisistratus's government had alone supported it; and Hippias pursuing contrary methods, was deprived of the sovereignty in less than four years after the death of his brother.

65
He is driven
out of A-
thens,

This revolution was likewise owing to the family of Megacles, who were styled *Alcæonidae*, and had settled at Liphdyrum. In times of discontent, which at Athens were very frequent, this family was the common refuge of all who fled from that city; and at last they thought of a method of expelling the Pisistratidæ altogether. The method they took to accomplish their purpose was as follows. They agreed with the Amphictyons to rebuild the temple at Delphi; and being possessed of immense riches, they performed their engagement in a much more magnificent manner than they were bound to do; for having agreed only to build the front of common stone, they built it of Parian marble. At the same time they corrupted the prophetess Pythia, engaging her to exhort all the Lacedæmonians that came to consult the oracle either in behalf of the state, or their own private affairs, to attempt the delivery of Athens. This had the desired effect: the Lacedæmonians, surpris'd at hearing this admonition incessantly repeated, at last resolv'd to obey the divine command, as they imagin'd it to be; and sent Anchimolius, a man of great quality, at the head of an army into Attica, though they were at that time in league with Hippias, and accounted by him his good friends and allies. Hippias demanding assistance from the Thessalians, they readily sent him 1000 horse, under the command of one of their princes named *Cineas*. The Lacedæmonians being landed, Hippias fell upon them so suddenly, that he defeated them with great slaughter, killed their general, and forced the shattered remains of their army to fly to their ships. The Spartans, incens'd at this unfortunate expedition, determin'd to send another army into Attica, which they accordingly did soon after under their king Cleomenes; and he having, at his entrance into the Athenian territories, defeated the Thessalian horse, oblig'd Hippias to shut himself up in the city of Athens, which he was soon after forced to abandon altogether. He was, however, in no want of a place of refuge; the Thessalian princes inviting him into their country, and the king of Macedon offering his family a city and territory, if they chose to retire into his dominions. But Hippias chose rather to go to the city of Sigeum, which Pisistratus had conquered, and left to his own family.

66
And retires
to Sigeum.

After the expulsion of the Pisistratidæ, the Athenians did not long enjoy the quiet they had propos'd to themselves. They were quickly divided into two fac-

tions; at the head of one was Clisthenes, one of the chief of the Alcæonidæ; and of the other, Isagoras, a man of great quality, and highly in favour with the Athenian nobility. Clisthenes applied himself to the people, and endeavour'd to gain their affection by increasing their power as much as possible. Isagoras perceiving that by this means his rival would get the better, apply'd to the Lacedæmonians for assistance, reviving at the same time the old story of Megacles's sacrilege, and insinuating that Clisthenes ought to be banish'd as being of the family of Megacles. Cleomenes king of Sparta readily came into his measures, and suddenly dispatched an herald to Athens with a declaration of war in case all the Alcæonidæ were not immediately banish'd. The Athenians did not hesitate to banish their benefactor Clisthenes, and all his relations; but this piece of ingratitude did not answer their purpose. Cleomenes enter'd Attica at the head of a Spartan army; and, arriving at Athens, condemn'd to banishment 700 families more than what had been sent into exile before. Not content with this, he would have dissolv'd the senate, and vest'd the government in 300 of the chief of Isagoras's faction. This the Athenians would by no means submit to; and therefore took up arms, and drove Cleomenes and his troops into the citadel, where they were besieged for two days. On the third day Cleomenes surrendered, on condition that all those who were in the citadel should retire unmoles'ted. This, though agreed to, was not performed by the Athenians. They fell upon such as were separated from the army, and put them to death without mercy. Among the number of those slain on this occasion was Timæsthenes the brother of Cleomenes himself.

69
But with-
out suc-
cess.

The Spartan king was no sooner withdrawn from Athens, than he form'd a strong combination in favour of Isagoras. He engag'd the Bœotians to attack Attica on the one side, and the Chalcidians on the other, while he at the head of a powerful Spartan army enter'd the territories of Eleusina. In this distress, the Athenians, not being able to cope with so many enemies at once, resolv'd to suffer their territories to be ravag'd by the Chalcidians and Bœotians, contenting themselves with opposing the army commanded by Cleomenes in person. But this powerful confederacy was quickly dissolv'd: the Corinthians, who were allied with Cleomenes, doubting the justice of their cause, return'd home; his other allies likewise beginning to waver, and his colleague Ariston, the other king of Sparta, differing in sentiments, Cleomenes was oblig'd to abandon the enterprise. The Spartans and their allies being withdrawn, the Athenians took a severe revenge of the Bœotians and Chalcidians, totally routing their forces, and carrying off a great number of prisoners. The prisoners taken in this war were put in irons, but afterwards set at liberty on paying a ransom of two minæ per head. Their fetters were, however, hung up in the citadel; and the Athenians consecrating the tenth of what they had received for ransom, purchased a statue representing a chariot and four horses, which they set up in the portico of the citadel, with a triumphant inscription in token of their victory.

70

Attica. their attention to the Bœotian war, the Æginetans landing a considerable army ravaged the coasts of Attica.

But while the Athenians were thus employed against the Bœotians and Æginetans, a jealousy sprung up on the part of Lacedæmon, which was never afterwards eradicated. Cleomenes, after his unsuccessful expedition against Attica, produced at Sparta certain oracles which he said he had found in the citadel of Athens while he was besieged therein: the purport of these oracles was, that Athens would in time become a rival to Sparta. At the same time it was discovered, that Clythemnes had bribed the priestesses of Apollo to cause the Lacedæmonians expell the Pisistratidæ from Athens; which was facinating their best friends to those whom interest obliged to be their enemies. This had such an effect, that the Spartans, repenting their folly in expelling Hippias, sent for him from Sigeum, in order to restore him to his principality: but this not being agreed to by the rest of the states, they were forced to abandon the enterprise, and Hippias returned to Sigeum as he came.

About this time too, Aristagoras the Milesian, having set on foot a revolt in Ionia against the Persian king, applied to the Spartans for assistance; but they declining to have any hand in the matter, he next applied to the Athenians, and was by them furnished with 20 ships under the command of Melanthus, a nobleman universally esteemed. This rash action cost the Greeks very dear, as it brought upon them the whole power of the Persian empire; for no sooner did the king of Persia hear of the assistance sent from Athens to his rebellious subjects, than he declared himself the sworn enemy of that city, and solemnly besought God that he might one day have it in his power to be revenged on them.

The Ionian war being ended, by the reduction of that country again under the Persian government, the king of Persia sent to demand earth and water as tokens of submission from the Greeks. Most of the islanders yielded to this command out of fear, and among the rest the people of Ægina; upon which the Athenians accused the inhabitants of this island of treachery towards Greece, and a war was carried on with them for a long time. How it ended we are not informed; but its continuance was fortunate for Greece in general, as, by insuring them to war, and sea-affairs in particular, it prevented the whole of the Grecian states from being swallowed up by the Persians who were now about to invade them.

Besides the displeasure which Darius had conceived against the Athenians on account of the assistance they had afforded the Ionians, he was farther urged to an expedition against Greece by the intrigues of Hippias. Immediately on his returning unsuccessfully from Lacedæmon, as above related, Hippias passed over into Asia, went to Artaphernes governor of the adjacent provinces belonging to the Persian king, and excited him to make war upon his country, promising to be obedient to the Persian monarch provided he was restored to the principality of Athens. Of this the Athenians being apprized, sent ambassadors to Artaphernes, desiring leave to enjoy their liberty in quiet: but that nobleman returned for answer, that if they would have peace with the great king, they must

immediately receive Hippias; upon which answer, the Athenians resolved to assist the enemies of Darius as much as possible. The consequence of this resolution was, that Darius commissioned Mardonius to revenge him of the insults he thought the Greeks had offered him. But Mardonius having met with a storm at sea, and other accidents, which rendered him unable to do any thing, Datis, and Artaphernes the son of Artaphernes abovementioned, were commissioned to do what he was to have done.

The Persian commanders, fearing again to attempt to double the promontory of Athos, where their fleet had formerly suffered, drew their forces into the plains of Cilicia; and passing from thence through the Cyclades to Eubœa, directed their course to Athens. Their charge from Darius was to destroy both Eretria and Athens; and to bring away the inhabitants, that they might be at his disposal. Their first attempt was on Eretria, the inhabitants of which sent to Athens for assistance on the first approach of the Persian fleet. The Athenians, with a magnanimity almost unparalleled at such a juncture, sent 4000 men to their assistance; but the Eretrians were so much divided among themselves, that nothing could be resolved on. One party among them was for receiving the Athenian succours into the city; another, for abandoning the city and retiring into the mountains of Eubœa; while a third sought to betray their country to the Persians for their own private interest. Seeing things in this situation, therefore, and that no good could possibly be done, one Æschines, a man of great authority among the Eretrians, generously informed the Athenian commanders that they might return home. They accordingly retired to Oropus; by which means they escaped destruction: for Eretria being soon after betrayed to the Persians, was pillaged, burnt, and its inhabitants sold for slaves.

On the news of this disaster the Athenians immediately drew together all the forces they were able, which after all amounted to no more than 9000 men. These, with 1000 Plataeans, who afterwards joined them, were commanded by ten general officers, who had equal power; among whom were Miltiades, Aristides, and Themistocles, men of distinguished valour and great abilities. But it being generally imagined that so small a body of troops would be unable to resist the formidable power of the Persians, a messenger was dispatched to Sparta to intreat the immediate assistance of that state. He communicated his business to the senate in the following terms. "Men of Lacedæmon, the Athenians desire you to assist them, and not to suffer the most ancient of all the Grecian cities to be enslaved by the barbarians. Eretria is already destroyed, and Greece consequently weakened by the loss of so considerable a place." The assistance was readily granted; but at the same time the succours arrived so slowly, that the Athenians were forced to fight without them. In this memorable engagement in the plains of Marathon, whither Hippias had conducted the Persians, the latter were defeated with the loss of 6300 men, while the Greeks lost only 192. The Persians being thus driven to their ships, endeavoured to double Cape Sunium, in order to surprize Athens itself, before the army could return: but in this they were prevented by Miltiades; who, leaving Aristides with 1000 men to guard the prisoners, returned so expeditiously

with the other 9000, that he was at the temple of Hercules, which was but a small way distant, before the barbarians could attack the city.

77
Integrity of
Aristides.

After the battle, Aristides discharged the trust reposed in him with the greatest integrity. Tho' there was much gold and silver in the Persian camp, and the tents and ships they had taken were filled with all sorts of riches, he not only forbore touching any thing himself, but to the utmost of his power prevented others from doing it. Some, however, found means to enrich themselves; among the rest, one Callias, counsellor-german to Aristides himself. This man being a torch-bearer, and, in virtue of his office, having a fillet on his head, one of the Persians took him for a king, and, falling down at his feet, discovered to him a vast quantity of gold hid in a well. Callias not only seized, and applied it to his own use, but had the cruelty to kill the poor man who discovered it to him, that he might not mention it to others; by which infamous action he entailed on his posterity the name of *Laccopluti*, or *enriched by the well*.

78
Miltiades
ungratefully
treated by
the Athenians.

After the battle of Marathon, all the inhabitants of Platæa were declared free citizens of Athens, and Miltiades, Themistocles, and Aristides, were treated with all possible marks of gratitude and respect. This, however, was but very short-lived; Miltiades proposed an expedition against the island of Paros, in which having been unsuccessful, through what cause is not well known, he was, on his return, accused, and condemned to pay 50 talents, the whole expence of the scheme; and being unable to pay the debt was thrown into prison, where he soon died of a wound received at Paros.

79
As likewise
Aristides.

If any thing can exceed the enormity of such a proceeding as this, it was the treatment Aristides next received. Miltiades had proposed an expedition which had not proved successful, and in which he might possibly have had bad designs; but against Aristides not so much as a shadow of guilt was pretended. On the contrary, his extraordinary virtue had procured him the title of *Just*, and he had never been found to swerve from the maxims of equity. His downfall was occasioned by the intrigues of Themistocles; who being a man of great abilities, and hating Aristides on account of the character he deservedly bore among his countrymen, took all opportunities of insinuating that his rival had in fact made himself master of Athens without the parade of guards and royalty. "He gives laws to the people," said he; "and what constitutes a tyrant, but giving laws?" In consequence of this strange argument, a strong party was formed against the virtuous Aristides, and it was resolved to banish him for 10 years by the Ostracism. In this case, the name of the person to be banished was written upon a shell by every one who desired his exile, and carried to a certain place within the forum inclosed with rails. If the number of shells so collected exceeded 6000, the sentence was inflicted; if not, it was otherwise. When the agents of Themistocles had sufficiently accomplished their purpose, on a sudden the people flocked to the forum desiring the ostracism. One of the clowns who had come from a borough in the country, bringing a shell to Aristides, said to him, "Write me Aristides upon this." Aristides, surprised, asked him if he knew any ill of that Athenian, or if he had ever done him any hurt. "Me hurt! (said the fellow), no,

I don't so much as know him; but I am weary and sick at heart on hearing him every where called *the just*." Aristides therefore took the shell, and wrote his own name upon it; and when informed that the ostracism fell upon him, modestly retired out of the forum, saying, "I beseech the gods that the Athenians may never see that day which shall force them to remember Aristides."

After the battle of Marathon, the war with Ægina was revived with great vigour; but the Æginetans generally had the superiority, on account of their great naval power. Themistocles observing this, was continually exhorting his countrymen to build a fleet, not only to make them an equal match for the Æginetans, but also because he was of opinion that the Persians would soon pay them another visit. At last, he had the boldness to propose, that the money produced by the silver mines, which the Athenians had hitherto divided among themselves, should be applied to the building of a fleet: which proposal being complied with, 100 galleys were immediately put upon the stocks; and this sudden increase of the maritime power proved the means of saving all Greece from slavery.

80
Themistocles
advises
the building
of a fleet.

About three years after the banishment of Aristides, Xerxes king of Persia sent to demand earth and water: but Themistocles desiring to make the breach with that monarch still wider, put to death the interpreter for publishing the decree of the king of Persia in the language of the Greeks; and having prevailed upon the several states to lay aside their animosities, and provide for their common safety, got himself elected general of the Athenian army.

81
Xerxes in-
vades
Greece.

When the news arrived that the Persians were advancing to invade Greece by the streights of Thermopylæ, and that they were for this purpose transporting their forces by sea, Themistocles advised his countrymen to quit the city, embark on board their galleys, and meet their enemies well yet at a distance. This they would by no means comply with; for which reason Themistocles put himself at the head of the army, and having joined the Lacedæmonians, marched towards Tempe. Here, having received advice that the straits of Thermopylæ were forced, and that both Bœotia and Thessaly had submitted to the Persians, the army returned without doing any thing.

In this distress the Athenians applied to the oracle at Delphi: from whence they received at first a very severe answer, threatening them with total destruction; but after much humiliation, a more favourable one was delivered, in which, probably by the direction of Themistocles, they were promised safety in *walls of wood*. This was by Themistocles and the greatest part of the citizens interpreted as a command to abandon Athens, and put all their hopes of safety in their fleet. Upon this, the opinion of Themistocles prevailing, the greatest part began to prepare for this embarkation; and had money distributed among them by the council of the Areopagus, to the amount of eight drachms per man; but this not proving sufficient, Themistocles gave out that somebody had stolen the shield of Minerva; under pretence of searching for which, he seized on all the money he could find. Some, however, there were who refused to embark with the rest, but raised to themselves fortifications of wood; understanding the oracle in its literal sense, and resolving to wait the arrival of the Persians,

The Persians having advanced to Athens soon after the inhabitants had deserted it, met with no opposition except from the few just now mentioned; who, as they would hearken to no terms of accommodation, were all cut in pieces, and the city utterly destroyed. Xerxes, however, being defeated in a sea-fight at Salamis, was forced to fly with prodigious loss. Themistocles was for pursuing him, and breaking down the bridge he had cast over the Hellespont; but this advice being rejected, he sent a trusty messenger to Xerxes, acquainting him that the Greeks intended to break down his bridge, and therefore desired him to make all the haste he could, lest by that means he should be shut up in Europe. According to Herodotus, he also advised the Athenians to quit the pursuit and return home, in order to build their ruined houses. This advice, tho' misinterpreted by some, was certainly a very prudent one, as Xerxes, though once defeated, was still at the head of an army capable of destroying all Greece; and had he been driven to despair by finding himself shut up, or warmly pursued, it was impossible to say what might have been the event. After this, Themistocles formed a scheme, for the aggrandizement of Athens indeed, but a most unjust and infamous one. It was, in short, to make Athens mistress of the sea by burning all the ships except those belonging to that republic. He told his countrymen that he had something to propose of great consequence, but which could not be spoken publicly: whereupon he was desired to communicate it to Aristides, by whom the proposal was rejected; and Aristides having informed the Athenians that what Themistocles had said was very advantageous but very unjust, they desired him to think no more of it.

⁸⁵
Themisto-

The fleet returned to Salamis, extraordinary honours were paid to Themistocles by the Lacedæmonians. On his entering that city, they decreed him a wreath of olive, as the prize of prudence; presented him with the most magnificent chariot in Sparta; and when he returned to Athens, he was escorted by 500 horse, an honour never paid to any stranger but himself. On his arrival at Athens, however, there were not wanting some who insinuated that the receiving such honours from the Lacedæmonians was injurious to the republic; but Themistocles confiding in his innocence, treated these clamours with contempt, and exhorted his countrymen to entertain no doubts of their allies, but rather endeavour to preserve the great reputation they had acquired throughout all Greece.

⁸⁷
Per-
and defeat-
at Platae-
at Mycale-
The defeat of Xerxes at Salamis made Mardonius, who was left to carry on the war by land, more ready to treat with the Athenians than to fight them; and with this view he sent Alexander king of Macedonia to Athens to make proposals of alliance with that republic, exclusively of all the other Grecian states. This proposal, however, was rejected; and the consequence was, that Athens was a second time destroyed, the Spartans sending assistance so slowly, that the Athenians were forced to retire to Salamis: but they were soon freed from all apprehensions by the total defeat and death of Mardonius at Platae; where Aristides, and

the body of troops under his command, distinguished themselves in a most extraordinary manner.

The same day that the battle of Platae was fought, the Persians were defeated in a sea-fight at Mycale in Ionia, wherein it was allowed that the Athenians who were there behaved better than any of the other Greeks; but when it was proposed to transport the Ionians into Europe, that they might be in perfect safety, and give them the territories of such Grecian states as had sided with the Persians, the Athenians refused to comply, fearing the Ionians would rival them in trade, or refuse the obedience they used to pay them: besides which, they would then lose the opportunity of plundering the Persians in case of any quarrel with Ionia. Before they returned home, however, the Athenians crossed over to the Chersonesus, and besieged Sestos. The siege was long and troublesome: but at last the garrison, being pressed with hunger, and having no hopes of relief, divided themselves into two bodies, and endeavoured to make their escape; but were pursued, and all either killed or taken. *Oibazus*, one of their commanders, was sacrificed to a Thracian god; and the other, called *Artyades*, impaled alive, and his son stoned before his face, because he had rifled the sepulchre of Proteilaus.

After the victories at Platae and Mycale, the Athenians returned without any apprehension, and began to rebuild their city in a more magnificent manner than before. Here they were no sooner arrived, than a dispute was ready to be commenced about the form of government. The commons, with Themistocles at their head, were for a democracy; to which Aristides, rather than hazard the raising disturbances, consented. It was therefore proposed, that every citizen should have an equal right to the government; and that the archons should be chosen out of the body of the people, without preference or distinction: and this proposal being agreed to, put an end to all dissenters for the present.

Themisto-
cles advises
to fortify
Athens,
and deceives
the Sparta-
nians who
oppose it.
At this time also Themistocles proposed that the city of Athens should be fortified in the best manner possible, that it might not be liable to be again destroyed, when the Persians should take it into their heads to invade Greece. At this proposal the Lacedæmonians were exceedingly alarmed; and therefore remonstrated, that should Athens once be strongly fortified, and the Persians become possessed of it, it would be impossible to get them out of it again. At last, seeing these arguments had no effect, they absolutely forbid the Athenians to carry their walls any higher. This command gave great offence; but Themistocles, considering the power of Sparta at that time, advised the Athenians to temporize; and to assure the ambassadors, that they should proceed no farther in their work, till, by an embassy of their own, satisfaction should be given to their allies. Being named ambassador at his own desire to Sparta, with some other Athenians, Themistocles set out alone, telling the senate that it would be for the interest of the state to delay sending the other ambassadors as long as possible. When arrived at Sparta, he put off from time to time receiving an audience, on account of his colleagues not being arrived: but in the mean time the walls of Athens were building with the utmost expedition; neither houses nor sepulchres being spared for materials; and men, women, children, strangers, citizens, and servants, working without intermission. Of this the Lacedæmonians having notice, and the rest of the

Attica. the Athenian ambassadors being arrived, Themistocles and his colleagues were summoned before the ephori, who immediately began to exclaim against the Athenians for their breach of promise. Themistocles denied the charge: he said his colleagues assured him of the contrary; that it did not become a great state to give heed to vague reports, but that deputies ought to be sent from Sparta to inquire into the truth of the matter, and that he himself would remain as a hostage, to be answerable for the event. This being agreed to, he engaged his associates to advise the Athenians to commit the Spartan ambassadors to safe custody, till he should be released; after which he publicly avowed the whole transaction, took the scheme upon himself, and told the Lacedæmonians that "all things are lawful for our country." The Spartans seeing no remedy, concealed their resentment, and sent Themistocles home in safety.

97
Makes the
Pyraeum the
port of A-
thens.

The next year, being the last of the 75th Olympiad, Themistocles observing the inconvenience of the port Phalerum, thought of making the *Pyraeum* the port of Athens. This he did not at first think proper to mention publicly; but having signified to the people that he had something of importance to communicate, they appointed Xanthippus and Aristides to judge of his proposal. They readily came into his measures, and told the people that what Themistocles proposed would be of the utmost advantage to the state, at the same time that it might be performed with ease. Upon this they were desired to lay the matter before the senate; who coming unanimously into their measure, ambassadors were dispatched to Sparta to insinuate there how proper it would be for the Greeks to have some great port, where a fleet might always watch the designs of the Persians; and thus having prevented any umbrage from their first undertakings, the work was set about with such expedition, that it was finished before the Lacedæmonians knew well what they were about.

98
Sovereignty
of the sea
transferred
to Athens.

At this time also the sovereignty of the sea was transferred from Sparta to Athens, through the haughty behaviour of Pausanias the Lacedæmonian. He had commanded at Plataea, and still enjoyed the supreme authority in the war which was all this time carrying on against the Persians; but being elated with his success at Plataea, and having entered into a treasonable correspondence with the enemy, he treated the captains under his command with the greatest haughtiness, giving the preference to the Spartans in such a manner that the rest of the Greeks could no longer bear his insolence. On the contrary, Aristides, and Cimon the son of Miltiades, who commanded the Athenians, by their obliging behaviour gained the favour of every body; so that the allies, having publicly affronted Pausanias, put themselves under the protection of the Athenian republic; and thenceforward the Athenians, and not the Lacedæmonians, had the supreme command.

99
Aristides
taxes Greece
with extra-
ordinary ap-
plause.

The Greeks being now sensible that they would always have occasion to be on their guard against the Persians, and that it was necessary to establish a fund by a common taxation of all the states, Aristides was pitched upon as the only person that could be trusted with the power of allotting to each of the states its proper quota. This difficult task he undertook, and executed in a manner unparalleled in the annals of history. All parties were pleased, and his taxation was

style the happy lot of Greece. The gross amount of it was 450 talents.

Attica

96
Themisto-
cles banis-
ed.

It now came to the turn of Themistocles to experience the gratitude of his countrymen. His services had been so essential, that the treatment he received may perhaps be a sufficient excuse for modern patriots when they connect their own interest with the service of their country. Themistocles had plainly saved the state from ruin by his advice; he had distinguished himself by his valour; had rendered Athens, by his policy, superior to the other states of Greece; and entirely subverted the Lacedæmonian scheme of power. Yet, notwithstanding all this, he was banished by the ostracism, without the smallest crime pretended, unless that he was hated by the Lacedæmonians, and that he had erected a temple, near his own house, dedicated to *Diana, the giver of the best counsel*; intimating that he himself had given the best counsel for the safety both of Athens and of all Greece, which was no more than the truth. Nay, he was not only driven out of Athens, but out of all Greece; so that he was forced to seek shelter from the king of Persia, against whom he had fought with so much valour. That monarch gave him a gracious reception; and he was never recalled, because the Greeks had no occasion for his services.

The war with Persia was not yet discontinued; the Greeks found their advantage in plundering and enriching themselves with the spoils of the king of Persia's subjects. For this reason, in the end of the 77th O-

95
Success of
Cimon against
the Persians.

lympiad, they equipped a navy, under a pretence of relieving such of the Greek cities in Asia as were subject to the Persians. Of this fleet Cimon, the son of Miltiades by the daughter of the king of Thrace, was appointed commander in chief. He had already tasted the justice and generosity of his countrymen, having been thrown into prison for his father's sine, from which he was released by *Callias*, whom his sister Elpinice married on account of his great wealth procured by no very honourable means. He accepted of the command, however; and gained such immense booty in this expedition, that the Athenians were thereby enabled to lay the foundation of those long extended walls which united the port to the city. The foundation was laid in a moorish ground; so that they were forced to sink it very deep, and at a great expence: but to this Cimon himself contributed out of his own share of the spoils, which was very considerable. He also adorned the forum with palm-trees, and beautified the academy with delightful walks and fountains.

The Persians having soon after this expedition invaded Chersonesus, and with the assistance of the Thracians made themselves masters of it, Cimon was sent against them in a great hurry. He had only four ships; but nevertheless with these he took 13 of the Persian galleys, and reduced the whole of the Chersonesus. After this he marched against the Thracians, who revolting against the Athenians, had made themselves masters of the gold mines lying between the rivers Nyssus and Strymon. The Thracians were quickly obliged to yield; after which the Athenians sent a great colony to Amphipolis a city of Thrace, which for some time made a considerable figure, but afterwards attempting to penetrate into the country of the *Edones*, great part of them were destroyed.

96
He subdues
the Cherso-
nesus.

Attica. Cimon also fell upon the following expedient to make Athens irrefragable at sea by the other states of Greece. Many of the Greek states, by virtue of Aristides's taxation, were bound to furnish men and galleys, as well as to pay the tax for their support. But when they saw themselves out of danger from the Persians, most of them were very unwilling to furnish their quota of men. This the Athenian generals being offended with, were for having recourse to force; but Cimon permitted such as were desirous of staying at home to do so, and accepted a sum of money in lieu of a galley completely manned. By this means he injured the Athenians, whom he took on board his galleys, to hardship and discipline; while the allies who remained at home became enervated through idleness, and from being confederates, dwindled into tributaries, and almost slaves. In the last year of the 77th Olympiad, Cimon was sent to assist the Lacedæmonians against their Helotes, who had revolted from them. In this he was attended with his usual success: but, some time after, the Lacedæmonians being engaged in the siege of Ithome, sent again to the Athenians for succour, and Cimon was a second time sent to their relief; but the Spartans having received a sufficient supply of troops from other quarters before the arrival of the Athenian general, he and his men were dismissed without doing any thing. This grievously offended the people of Athens, who thenceforward hated not only the Lacedæmonians, but all their own citizens who were thought to be friends to that state.

98
s ha-
ed.

It was not possible, however, that any person who had served the state should escape banishment at Athens. Cimon had gained great wealth both to the public and to himself. In his public character he had behaved with unimpeached honesty, and as a private citizen he dedicated his wealth to the most excellent purposes. He demolished the inclosures about his grounds and gardens, permitting every one to enter and take what fruits they pleased; he kept an open table, where both rich and poor were plentifully entertained. If he met a citizen in a tattered suit of cloaths, he made some of his attendants exchange with him; or if the quality of the person rendered that kindness unsuitable, he caused a sum of money to be privately given him. All this, however, was not sufficient: he did not concur with every measure of the commonalty; and therefore the popular party determined, not to banish him, but to put him to death. The crime laid to his charge was, that by presents from the Macedonians he was prevailed upon to let slip a manifest opportunity of enlarging his conquests, after taking from the Persians the gold mines of Thrace. To this accusation Cimon replied, that to the utmost of his power he had prosecuted the war against the Thracians and other enemies of the state of Athens; but that it was true he had not made any inroads into Macedonia, because he did not imagine he was to act as a public enemy of mankind, and because he was struck with respect for a nation modest in their carriage, just in their dealings, and strictly honourable in their behaviour towards him and the Athenians: that if his countrymen looked upon this as a crime, he must abide their judgment; but, for his part, he could never be brought to think such conduct amiss. Elpizice, Cimon's sister, used all her interest in his behalf,

and amongst others spoke to Pericles the celebrated statesman and orator. He was indeed Cimon's rival, and had no doubt assisted in stirring up the prosecution against him; but he did not desire his death: and therefore, though appointed to accuse him, Pericles spoke in such a manner that it plainly appeared he did not think him guilty; and, in consequence of this lenity, Cimon was only banished by the ostracism.

The Athenian power was now risen to such an height, that all the other states of Peloponnesus looked upon this republic with a jealous eye, and were continually watching every opportunity of making war upon it when the state was engaged in troublesome affairs, and seemed to be less able to resist. These attempts, however, so far from lessening, generally contributed to increase, the power of the Athenians; but in the year before Christ 458, the republic entered into a war with Sparta, which was scarce put an end to but by the destruction of the city of Athens. For this war, there was no recent provocation on the part of the Spartans. They had sent a great army to assist the Dorians against the Ploicians, and the Athenians took this opportunity to revenge themselves of former quarrels. Having therefore drawn in the Argives and Thebians to be their confederates, they posted themselves on the Isthmus, so that the Spartan army could not return without engaging them. The Athenians and their confederates amounted to 14,000, and the Spartans to 11,500. The Spartan general, however, not very willing to hazard a battle, turned aside to Tanagra, a city in Bœotia, where some of the Athenians who inclined to aristocracy entered into a correspondence with him. But before their designs were ripe for execution, the Athenian army marched with great expedition to Tanagra, so that a battle became inevitable. When the armies were drawing up in order of battle, Cimon presented himself before his countrymen in complete armour, and went to take post among those of his own tribe; but the popular party raised such a clamour against him, that he was forced to retire. Before he departed, however, he exhorted Euthippus and the rest of his friends to behave in such a manner that they might wipe off the aspersions thrown upon him, as if he had designed to betray his country's cause to the Lacedæmonians. Euthippus desired him to leave his armour, which he did; and a battle ensuing, the Athenians were defeated with great loss, and Euthippus with the rest of Cimon's friends were all killed in defence of his armour which they had surrounded. Another engagement soon followed, wherein both armies suffered so much, that they were glad to conclude a short truce, that each might have time to recruit their shattered forces.

100
Athens and
Sparta.

101
They gain
great advantages over
the Spartans.

The scale of fortune now seemed to turn in favour of the Athenians. The Thebans, who had been deprived of the command of Bœotia, on account of their having sided with Xerxes, were now restored to it by the Lacedæmonians. At this the Athenians were displeas'd, that they sent an army under Myronides the son of Callias into Bœotia to overturn all that had been done. That general was met by the Thebans and their allies, who composed a numerous and well disciplined army. Nevertheless, though the Athenian army was but an handful in comparison of their enemies, Myronides gained a complete victory over the allies, in some sense

Attica.

sense more glorious than either that of Marathon or Plataea. In these battles they had fought against effeminate and ill-disciplined Persians, but now they encountered and defeated a superior army composed of the bravest Greeks. After this victory, Myronides marched to Tanagra; which he took by storm, and razed to the ground: he then plundered Bœotia; defeated another army which the Bœotians had drawn together to oppose him; then fell upon the Locrians; and, having penetrated into Thessaly, chastised the inhabitants of that country for having revolted from the Athenians, and from thence returned to Athens laden with riches and glory.

The next year Tolmides the Athenian admiral invaded Laconia, where he made himself master of several places; and on the back of this, Pericles invaded Peloponnesus with great success, burning, spoiling, or taking, whatever places he attempted. On his return he found the people greatly out of humour on account of Cimon's banishment; so he was immediately recalled.

102
Cimon re-
called.

Cimon was no sooner returned, than he fell to his old employment of plundering the Persians; and, according to Plutarch, he had now nothing less in view than the conquest of the whole Persian empire. The Persian monarch finding he could have no rest, at last sent orders to Artabazus and Megabizus, his commanders, to conclude a treaty; which was done on the following conditions. 1. That the Greek cities in Asia should be free, and governed by their own laws. 2. That the Persians should send no army within three days journey of the sea. 3. That no Persian ship of war should sail between Thessaly and Cyrene, the former a city of Pamphylia, and the latter of Lycia.

103
His death.

While this treaty was carrying on Cimon died, whether of sickness, or of a wound he had received, is not known; and after his death the Athenian affairs began to fall into confusion. It was now the misfortune of this state to be alike hated by her enemies and allies; the consequence of which was, that the latter were perpetually revolting whenever they thought they had an opportunity of doing so with impunity. The Megarians, at this time, who had been long under the protection or dominion of Athens, thought proper for some reason or other to disclaim all dependance on their former protectors, and have recourse to Sparta, with which state they entered into a strict alliance. This the Athenians revenged by ravaging the country of the Megarians; which soon brought on a renewal of the Lacedæmonian war that had been for a little time suspended. Pericles, however, procured the return of the first Lacedæmonian army, without bloodshed, by bribing Chandrides the young king of Sparta's tutor. In the winter, Tolmides resolved to undertake an expedition into Bœotia with a small body of troops; which design he put in execution contrary to the advice of Pericles, and his rashness was soon punished by his own death and the total defeat of his army. Notwithstanding this misfortune, however, Pericles soon after invaded and reduced Eubœa; and the Lacedæmonians, finding it was not for their interest to carry on the war, concluded a truce with the Athenians for 30 years.

nians.

105
Crucely of
Pericles.

About this time Psammiticus, king of Egypt, sent by way of present to the people of Athens, 40,000 bushels of wheat; which proved a great misfortune to the city: for Pericles, out of spite to Cimon, who had

children by an Arcadian woman, had preferred a law whereby the Athenians of the half blood were disfranchised; and this law, on account of the distribution of the corn abovementioned, was prosecuted with such severity, that no less than 5000 persons, who till then had been considered as free-men, were sold for slaves. This piece of cruelty has been of great service to the critics, as by means of it we know exactly the number of Athenian citizens, which at this time amounted to no more than 14,040 persons, though Athens was now aiming at no less than erecting an universal monarchy.

nian citi-
zens.

Six years after the conclusion of the peace between Athens and Sparta, a war broke out between the Samians and Milesians about the city of Priene, seated under mount Mycale in Ionia. How this war came to affect the Athenians, is not certainly known: but, somehow or other, this republic was induced to take the part of the Milesians; and the island of Samos was reduced by Pericles, who established there a democracy, and left an Athenian garrison. He was no sooner gone, however, than the Samians, disliking their new form of government, drove out the garrison he had left; but Pericles quickly returning, besieged and took their city, demolished their walls, and fined them of the whole expence of the war, part of which he obliged them to pay down, and took hostages for the remainder. When Pericles returned, he procured himself to be appointed to pronounce the public oration in honour of those who fell; which he did with such eloquence, that when he came down from the pulpit, the women gathered about him, took him by the hand, and crowned him with garlands.

107
Samos re-
duced by
Pericles.

A little after this commenced the war between the Corcyrians and Corinthians, which by degrees brought the Athenians into those engagements that proved the ruin of their state. The causes of this war were the following. An intestine war breaking out in the little territory of Epidamnus, a city of Macedonia, founded by the Corcyrians, one party called in to their assistance the Illyrians, and the other the Corcyrians. The latter neglecting the matter, Corinth was applied to, as the Corcyrians were a colony from that place. The Corinthians, partly out of pity to the Epidamnians, and partly out of spleen to the Corcyrians, sent a very great fleet to the assistance of the former, by which means that party which had applied to Corinth was thoroughly established. This being retented by the Corcyrians, they sent a fleet to Epidamnus to support the exiles; and accordingly this fleet began to act offensively on its entering the port, the chief commanders having instructions to propose terms of accommodation, to which the Corinthians would by no means agree. The next year the Corcyrians defeated at sea the Corinthians and their allies, and took Epidamnus by storm; after which they wasted the territories of the allies of the Corinthians, which greatly exasperated the latter. At Corinth, therefore, they began to make great preparations for carrying on the war, and pressed their confederates to do the same, that they might be in a condition to retrieve the honour they had lost, and humble this ungrateful colony which had thus insulted her mother-city.

108
War be-
tween the
Corcyrian
and Corin-
thians.

The Corcyrians were no sooner acquainted with these proceedings, than they dispatched ambassadors to Athens concerning their complaints; and these were quickly followed

Attica. followed by others from Corinth on the same errand. At first the people of Athens inclined to favour the Corinthians; but they soon changed their minds, and took part with the Corcyrians: they contented themselves, however, with entering into a defensive alliance with that little state, whereby they promised to assist each other, in case either party should be attacked; and in consequence of this treaty they furnished the Corcyrians with ten galleys, under Lacedæmonius the son of Cimon, with whom were joined Diotenes and Proteus as colleagues.

As soon as the season of the year permitted, the Corinthians sailed for the coast of Corcyra with a fleet of 150 ships, under the command of Xenocides, assisted by four other Corinthian admirals; each squadron of their allies being commanded by a chief of their own. The Corcyrian and Athenian fleet amounted to 120, but the Athenians had orders to give as little assistance as possible. The action was very brisk for some time: the Corcyrian right wing broke the left of the Corinthian fleet; and forcing some of the ships on shore, landed, pillaged their camp, and made a great number of them prisoners: on the other hand, the Corinthian ships in their right wing beat the Corcyrian ships there, they being but very faintly assisted by the Athenians, till the latter were at last obliged to defend themselves, which they did so well, that the Corinthians were glad to retire. The next day preparations were made on both sides for another engagement; but 20 ships coming from Athens to the assistance of the Corcyrians, the Corinthians declined the combat.

As soon as the Corcyrian war broke out, the Athenians sent orders to the citizens of Potidæa to demolish a part of their wall, to send back the magistrates they had received from Corinth, and to give hostages for their own behaviour. Potidæa was a town in Macedonia, founded by the Corinthians, but at that time in alliance with the Athenians. Perdiccas king of Macedon, who hated the Athenians, took this opportunity to persuade the Potidæans to revolt. Accordingly they sent ambassadors to Athens to intreat the revocation of these orders; but at the same time sent deputies to Sparta, to join with the Corinthians and Megarians in their complaints against the Athenians. The Athenians upon this sent a considerable fleet against Potidæa under the command of Calias, a nobleman of great courage. The Corinthians on their part dispatched one Aristeus with a considerable body of troops to the assistance of that city. An engagement following, the Athenians were victors, but with the loss of their general. Phormio, who succeeded in the command, invested the city in form, and shut up its port with his fleet; but the Potidæans dreading to fall into the hands of the Athenians, made a most obstinate defence, while in the mean time they warmly solicited the Corinthians to perform their promises, and engage the rest of the states of Peloponnesus in their quarrel.

The Lacedæmonians having heard what the Corinthians and other little states of Greece had to say against the Athenians, sent ambassadors to the latter, demanding reparation for the injuries, with orders, in case of a refusal, to declare war. The terms demanded were, in the first place, the expulsion of those Athenians who were allied to the family of Megacles so of-

ten mentioned. This article was on account of Pericles; for he was the son of Xanthippus the Athenian commander at Mycale, by Agariste niece to the famous Clisthenes, who corrupted the priests of Apollo in order to procure the expulsion of the Pisistratide. They next insisted that the siege of Potidæa should be raised; thirdly, that the inhabitants of Ægina should be left free; and lastly, that a decree made against the Megarians, whereby they were forbid the ports and markets of Athens, should be revoked, and all the Grecian states under the dominion of Athens set at liberty.

These terms the Athenians were persuaded by Pericles to reject. The arguments used by him were in substance as follows: That whatever the Lacedæmonians might pretend as to the justice of the complaints of the allies, the true ground of this resentment was the prosperity of the Athenian republic, which the Spartans always hated, and now sought an opportunity of humbling; that it must be owing to the Athenians themselves if this design succeeded, because for many reasons Athens was better able to engage in a long and expensive war than the Peloponnesians. He then laid before the people an exact account of their circumstances; putting them in mind, that the treasure brought from Delos amounted to 10,000 talents; and that tho' 4000 of these had been expended on the stately gate of their citadel, yet that 6000 were still in hand; that they were also intitled to the subsidies paid by the confederate states; that the statues of their gods, the Persian spoils, &c. were worth immense sums; that private men were arrived at vast fortunes; and that, considering their trade by sea, they had a certain annual increase of wealth; that they had on foot an army of 12,000 men, and in their colonies and garrisons 17,000; that their fleet consisted of 300 sail; whereas the Peloponnesians had no such advantages. For these reasons he proposed as the most feasible, and likewise the most equitable satisfaction that could be given, that they would reverse their decree against Megara, if the Lacedæmonians would allow free egress and regress in their city to the Athenians and their allies; that they would leave all those states free who were free at the making of the last peace with Sparta, provided the Spartans would also leave all states free who were under their dominion; and that future disputes should be submitted to arbitration. In case these offers should be rejected, he advised them to hazard a war; telling them, that they should not think they ran that hazard for a trifle, or retain a scruple in their minds as if a small matter moved them to it, because on this small matter depended their safety, and the reputation of their constancy and resolution; whereas, if they yielded in this, the next demand of the Lacedæmonians would be of a higher nature; for having once discovered that the Athenians were subject to fear, they would thence conclude that nothing could be denied to Sparta, whereas a stiff denial in this case would teach them to treat Athens for the future on terms of equality. He enforced these reasons by shewing that their ancestors had always acted on the like principles, and in all cases preferred their glory to their ease, and their liberty to their possessions.

This was the origin of the Peloponnesian war, which makes so great a figure in ancient history. The

immediate preliminary to general hostilities was an attempt of the Thebans to surprize Platæa. With this view they sent Eurymachus with 300 Thebans to assist view of the Plataeans as they had drawn over to their interest, in making themselves masters of the place. In this design they succeeded very well at first, the Plataeans who had promised to open the gates keeping their words exactly, so that they were instantly in possession of the city. The other party, however, perceiving how small a number they had to contend with, unanimously rose upon them, killing a great many, and forcing the rest to surrender themselves prisoners of war. Another party came from Thebes to assist their countrymen; but they arrived too late: the Plataeans, however, foreseeing that they would waste their country, promised to release the prisoners if they would forbear to spoil their lands. On this the Thebans withdrew; and the Plataeans cruelly put to death all their prisoners, to the number of 180, with Eurymachus their chief, alleging that they had not promised their release but in case of peace. The Athenians, as soon as they had notice of this attempt of the Thebans, caused all the Bœotians in their territory to be arrested; and when they understood how the Plataeans had delivered themselves, they sent a great convoy of provisions to that city, and a numerous body of troops to escort their wives and children to Athens.

114
They are
massacred.

115
Account of
the allies on
both sides.

Both parties now prepared in earnest for war, both sent ambassadors to the Persians, and both sought to rouse their allies. Most of the Greek states inclined to favour the Spartans, because they acted on this occasion as the deliverers of Greece, and because they either had been, or feared that they would be, oppressed by the Athenians. With the Spartans joined all the Peloponnesians, except the Argives and part of the Achæans; without Peloponnesus, the Megarians, Phocians, Locrians, Bœotians, Ambraciots, Leucadians, and Anactorians, declared themselves on their side. On the other hand, the Chians, Lesbians, Platæans, Messenians, Acarnanians, Corcyrians, Zacynthians, Carians, Dorians, Thracians, most part of the islands, and all the Cyclades excepting Melos and Thera, with Eubœa and Samos, joined the Athenians.

116
First year of
the war.

The Peloponnesian war commenced 431 years before Christ. The Lacedæmonian army was assembled at the Isthmus, and consisted of no less than 60,000 men; but before Archidamus king of Sparta, who commanded in chief, would enter Attica, he dispatched a herald to Athens. The herald was sent back without any answer, by which all hopes of peace were cut off. As Archidamus was a friend to Pericles, the latter apprehended that he might forbear plundering his estates. With this he immediately acquainted the people; telling them at the same time, that in such a case he made a present of his lands to the public. He then advised the citizens to take no care of defending their country-seats, but to attend only to the city, busy themselves in the equipping of ships, and settle a thorough resolution not to be intimidated with the first evils of war. This proposal the Athenians readily complied with, and appointed Pericles commander in chief, with nine more generals to assist him.

The first year, the Spartan army committed great ravages in Attica, Pericles having no force capable of opposing it, and refusing to engage on disadvantageous

terms, notwithstanding prodigious clamours were raised against him by his countrymen. The allies, however, had no great reason to boast of the advantages they gained this year: an Athenian fleet ravaged the coasts of Peloponnesus; another infested the Locrians, drove out the inhabitants of Ægina, and re-peopled the island from Athens. They likewise reduced Cephælia, and some towns in Acarnania and Leucas which had declared for the Lacedæmonians; and in the autumn, when the Peloponnesians were retired, Pericles entering the Megarian territory, did all the mischief that could be expected from a provoked enemy.

The spring of the second year was very fatal to Athens by a dreadful plague which destroyed great numbers of the citizens, while the Peloponnesians under Archidamus wasted every thing abroad. In the midst of these distresses, however, Pericles retained his courage, and would suffer none of his countrymen to stir without the city either to escape the plague or infect the enemy. He caused a great fleet to be equipped, on board which he embarked 4000 foot and 300 horse, with which he sailed to Epidaurus. Upon this, the enemy withdrew their forces out of Attica; but Pericles was able to do no great matter on account of the plague, which made so great havoc among his men, that he brought back to Athens only 1500 of the 4000 he carried out. By this misfortune the Athenians were thrown into despair; they immediately sued for peace, which the Spartans were now too proud to grant; then turning their rage upon Pericles, they dismissed and fined him. Soon after, Pericles's children and almost all his relations died of the plague; so that this great statesman was overwhelmed with melancholy, and for some time shut himself up from public view: at last, through the persuasion of Alcibiades and some others, he shewed himself to the people. They received him with acclamations, and at his request repealed the unjust law he had made, whereby all Athenians of the half-blood were disfranchised, and then reinstated him in all his former honours. Hereupon he inrolled the only son he had left, who before had been counted a bastard on account of his mother being a Milesian.

This year also the island of Zacynthus was wasted by the Peloponnesians; and the city of Potidæa submitted to the Athenians, after the inhabitants had been driven to such extremity as to feed upon human flesh. The Athenians permitted the men to depart with one garment, and the women with two; after which, the town was re-peopled by a colony from Athens.

The third year of the Peloponnesian war was remarkable for the death of the great Pericles, who was taken off by the plague. Platæa also was besieged by Archidamus; but without success, even though the greatest part of it was set on fire; the Plataeans resolving to submit to every kind of misery rather than abandon the Athenian cause. In the end, therefore, the king of Sparta was obliged to turn the siege into a blockade; and having thrown up an entrenchment fortified with a deep ditch, he left a sufficient number of men to guard his lines, and then returned back to Peloponnesus.

The following summer, the Peloponnesians under the command of Archidamus invaded Attica, where they wasted every thing with fire and sword; at the same time the whole island of Lesbos, except the district of Methymna,

Methymna, revolted from the Athenians, who hereupon invested the city of Mitylene. All this time the city of Platæa was blocked up by the Peloponnesians; and its inhabitants being now greatly distressed for want of provisions, the garrison, consisting of 400 natives and 80 Athenians, came to the desperate resolution of forcing a passage through the enemies lines. When they came to attempt this, however, many of them were intimidated: but 300 persisted in their resolution; and of these, 212 got safe through and marched to Athens, but the rest were compelled to retire.

123
th year.
Mitylene,
taken
the A-
chiens.

In the beginning of the fifth year, the Peloponnesians sent 40 ships to the relief of Mitylene; but without effect, for the place had surrendered before the fleet could come to its assistance. Paches, the Athenian commander, likewise chased away the Peloponnesian fleet upon its arrival; and returning to Lesbos sent the Lacedæmonian minister whom he found in Mitylene, together with a deputation, to Athens. On their arrival, the Lacedæmonian was immediately put to death; and in a general assembly of the people, it was resolved, that all the Mitylenians who were arrived at man's estate should be put to death, and the women and children sold for slaves. The next day, however, this cruel decree was reversed, and a galley sent with all expedition to countermand these bloody orders. This last vessel, however, could not get before the other: but Paches, being a man of great humanity, had taken a day to consider on the orders he had received; during which time, the last mentioned galley arrived; in consequence of which, only about 1000 of the most forward rebels were put to death; the walls of the city were also demolished, their ships taken away, and their lands divided among the Athenians, who let them again to their old masters at very high rents. The same summer the Athenians seized the island of Minoas, lying over against the territory of Megara; and likewise the port Nisæa, which last they fortified, and it proved afterwards a place of the utmost importance to them. At this time also the Plataeans, driven to the last extremity, surrendered to the Lacedæmonians, by whom they were, to the number of 208, including 25 Athenians, put to death, and their women sold for slaves. Their city was soon after raised by their implacable enemies the Thebans, who left only an inn to show where it stood. The fame of Platæa, however, induced Alexander the Great afterwards to rebuild it.

In this year happened the famous sedition of Corcyra, whence other seditions, when their effects rendered them terrible, have been called *Corcyrian*. It hath been already observed, that the war between the Corcyrians and Corinthians brought on the general war throughout Peloponnesus. A great number of Corcyrians were in the beginning of this war carried away prisoners into Peloponnesus, where the chief of them were very well treated, but the rest sold for slaves. The reason of this conduct of the Corinthians was a design they had formed of engaging these Corcyrians to influence their countrymen to side with them and their allies. With this view they treated them with all imaginable lenity and tenderness, insinuating into them by degrees an hatred of democratic government; after which they were told, that they might obtain their liberty upon condition of using all their influence at home in favour of the allies, and to the prejudice of Athens,

124
thea ta-
and ra-

125
tion of
cyra.

This the Corcyrians readily promised, and endeavoured to perform. At first, those who were for an aristocracy prevailed, and murdered all those of the opposite party that fell into their hands, in which they were assisted by a fleet of Peloponnesians; but the Athenians sending first one fleet and then another to the assistance of the distressed party, the Peloponnesians were forced to withdraw; after which, the democratic party sufficiently revenged themselves, and destroyed their antagonists without mercy. The worst of all was, that, this example once set, the several states of Greece felt in their turns the like commotions, which were always heightened by agents from Sparta and Athens; the former endeavouring to settle aristocracy, and the latter democracy, wherever they came.

While the Athenians were thus engaged in a war wherein they were already overmatched, they foolishly engaged in a new one, which in the end proved more fatal than all the rest. The inhabitants of Sicily were split into two factions; the one called the *Doric*, at the head of which was the city of Syracuse; the other the *Ionic*, which owned the Leontines for their chiefs: the latter perceiving themselves too weak without foreign aid, sent one Georgias, a celebrated orator, to apply to Athens for relief; and he by his fine speeches so captivated the giddy and inconstant Athenians, that they ran headlong into a war which they were unable to maintain while engaged with all the Peloponnesians. Enticed by this new prospect, therefore, and grasping at the conquest of Sicily, as well as of all Greece, they sent a fleet to the assistance of the Leontines, under the command of Laches and Chabrias; and they were no sooner sailed, than another fleet for the same purpose was begun to be fitted out. All this time, the plague continued to rage with great violence at Athens, cutting off this year 4000 citizens, besides a much greater number of the meaner sort of people.

116
Athenians
engage in a
war with
Sicily.

The sixth year of the Peloponnesian war was remarkable for no great exploit: Agis the son of Archidamus, king of Sparta, assembled an army in order to invade Attica, but was prevented from so doing by many great earthquakes which happened throughout Greece. The next year, however, he entered Attica with his army, while the Athenians on their part sent a fleet under the command of Demosthenes, to invest the coasts of Peloponnesus. As this fleet passed by Laconia, the commander took notice that the promontory of Pylus, which was joined to the continent by a narrow neck of land, had before it a barren island about two miles in circumference, in which, however, there was a good and safe port, all winds being kept off by the headland, or by the isle. These advantages made him apprehend, that a garrison left here would give the Peloponnesians so much trouble, that they would find it more advisable to protect their own country than to invade that of their neighbours. Accordingly, having raised a strong fortification, he himself with five ships staid to defend it, while the rest of the fleet proceeded on their intended expedition. On the news of this event, the Peloponnesian army immediately returned to besiege Pylus. When they arrived before the place, they took possession of the harbour, and then caused a chosen body of Spartans take possession of the island of Spactertia, after which they attacked the fort with great vigour.

gour. Demosthenes and his garrison defended themselves with great valour; and an Athenian fleet arriving very seasonably, offered battle to the Peloponnesian fleet. This being refused, the Athenians boldly sailed into the harbour, broke and sunk most of the vessels therein, after which they besieged the Spartans in Sphacteria. The Peloponnesians now began to treat with their enemies, and a truce was concluded during the time that negotiations were carried on at Athens. One of the articles of this truce was, that the Peloponnesians should deliver up all their ships, on condition of having them punctually returned in case the treaty did not take effect. The Athenians having heard the Spartan ambassadors, were inclined to put an end to this destructive war: but Cleon, one of their orators, a warm and obstinate man, persuaded his countrymen to insist on very unreasonable terms; upon which the ambassadors returned, and by so doing put an end to the truce. The Peloponnesians then demanded their vessels; but the Athenians refused to deliver them, under pretence of their having broke the truce.

End of the
Coreyrian
siege.

Hostilities being thus recommenced on both sides, the Lacedæmonians attacked the Athenians at Pylus, while the latter attacked the Spartans at Sphacteria. The Spartans, though but an handful of men and under every imaginable discouragement, behaved with such bravery, that the siege proceeded very slowly, so that the people of Athens became very uneasy. They began then to wish they had embraced the offers of the Spartans, and to rail vehemently against Cleon, who, to excuse himself, said, it would be easy for the general of the forces they were at that time sending, to attack the Spartans in the isle, and reduce them at once. Nicias, who had been appointed to this command, replied, that if Cleon believed he could do such great things, he would do well to go thither in person: the latter, imagining this only meant to try him, said he was ready to go with all his heart; whereby Nicias caught him, and declared that he had relinquished his charge. Cleon thereupon said, that he was no general: but Nicias told him that he might become one; and the people, pleased with the controversy, held the orator to his word. Cleon then advancing, told them he was so little afraid of the enemy, that, with a very inconsiderable force, he would undertake, in conjunction with those already at Pylus, to bring to Athens the Spartans who gave them so much trouble in 20 days. The people laughed at these promises: however, they furnished him with the troops he desired; and to their surprise, Cleon brought the Spartans prisoners to Athens within the time appointed.

This summer, likewise, an Athenian fleet was sent to Sicily, with instructions to put in at Coreyra, and assist the government against the Lacedæmonian faction which still subsisted in that island. This they effectually performed; for by their means the exiles fell into the hands of the other party: these they imprisoned; and then drew them out by 20 at a time, to suffer death, which was inflicted with all the circumstances of cruelty that party-rage could suggest. When only 60 remained, they intreated the Athenians to put them to death, and not to deliver them up to their countrymen: but upon this the Coreyrians surrounded the place where they were confined, endeavouring to bury them under their darts; upon which the unhappy cap-

tives all put an end to their own lives.

In the eighth year Nicias reduced the life of Cythera on the coast of Laconia; as likewise Thyrea, on the confines of that country. The latter had been given to the Æginetans when expelled from their own country by the Athenians; and they were now condemned to death, as inveterate enemies of the Athenian state and nation.—In Sicily, one Hermocrates of Syracuse persuaded all the inhabitants of the island to adjust their differences among themselves; upon which the Athenian generals returned home, and for so doing two of them were banished, and the third sentenced to pay a heavy fine.

The Athenians next laid siege to Megara under the conduct of Hippocrates and Demosthenes; but Brasidas a Spartan general coming to their relief, a battle ensued, by which, though neither party got the better, the Lacedæmonian faction prevailed in Megara, and many who favoured the Athenians were forced to withdraw. After this, such as had been banished for adhering to the Lacedæmonians were allowed to return, on their taking an oath to forget what was past, and attempt nothing that might disturb their country. As soon as they were settled, however, they forgot their oath; and causing 100 of those who were most obnoxious to be apprehended, forced the people to condemn them to death. They then changed the whole form of government, introduced an oligarchy, and possessed themselves of the supreme power.

In Bœotia some commotions were raised in favour of the Athenians; but their generals Hippocrates and Demosthenes being defeated by the opposite party, all hopes ceased of the Athenian power being established in Bœotia. In the mean time Brasidas reduced the city of Amphipolis, which greatly alarmed the Athenians, who thereupon sent new supplies of men, money, and ships, to the Macedonian coast; but all their care could not prevent a great desertion from their interest in those parts, where the valour and conduct of Brasidas carried all before him.

In the ninth year, the Spartans made new proposals of peace, which the Athenians were now more inclined to accept than formerly; and sending their affairs very much unsettled by the loss of Amphipolis, a truce for a year was quickly agreed on, while negotiations were in the mean time carrying on for a general peace. This pacific scheme, however, was very soon overthrown by the following accident in Thrace. The city of Scione, and that of Menda, revolted to Brasidas; who, knowing nothing of the truce, sought to draw over Potidæa also. The Athenians, pretending that Scione revolted two days after the truce was concluded, made heavy complaints; asserting that this was a breach of the truce, and that both it and Menda should be restored to them. This not being effected by negotiations, an army was sent against the two cities, by which Menda was reduced; but Scione making an obstinate defence, the siege was turned into a blockade.

In the tenth year, Brasidas made an attempt upon Potidæa; which having failed, the Athenians began to recover some courage. The truce expiring on the day of the Pythian games, Cleon persuaded the Athenians to send an army into Thrace under his own command. It consisted of 1200 foot and 300 horse, all Athenian citizens, who embarked on board 30 galleys. Brasidas

Cleon de-
feated and
killed by
Brasidas.

fidæ had an army much inferior; but observing that the Athenian general was become careless, and neglected discipline, he attacked him. In this engagement Cleon was killed, and the Athenians defeated with the loss of 600 men, while the Spartans lost only seven; but among these was their brave commander Brasidas, whose death affected them almost as much as the loss of their army did the Athenians.

As the death of Cleon deprived the Athenians of one of their best speakers, and one who had been very industrious in promoting the war, they were now much more disposed than formerly to hearken to terms of accommodation. Amongst the Spartans, too, there was a party, at the head of whom was Plitonax their king, who earnestly wished for peace; and as Nicias laboured no less assiduously at Athens to bring about this desirable event, a peace was at last concluded for fifty years between the two nations. The conditions were, that a restitution of places and prisoners should be made on both sides; excepting that Nisæa should remain to the Athenians, who had taken it from the Megarians; and that Platæa should continue with the Thebans, because they absolutely would not give it up. The Bœotians, Corinthians, and Megarians, refused to be included in this peace: but the rest of the allies yielded to it; and it was accordingly ratified, receiving the name of the *Nicias* peace, from Nicias who had so vigorously promoted it.

By this means, however, tranquillity was far from being restored. Such of the states of Peloponnesus as were dissatisfied, began immediately to league among themselves, and to set on foot a new confederacy, the head of which was to be the state of Argos. The Lacedæmonians, too, found it impossible to perform exactly the articles of agreement; the city of Amphipolis in particular, absolutely refused to return under the Athenian government; for which reason the Athenians refused to evacuate Pylius. In the winter, new negotiations were entered into on all sides, but nothing determined, and universal murmuring and discontent took place. These discontents were not a little heightened by Alcibiades, who now began to rival Nicias, and, perceiving the Lacedæmonians made their court mostly to his rival, took all opportunities to incense his countrymen against that nation. Nicias, on the other hand, who wished for nothing so much as peace, used all his endeavours to bring about a reconciliation. The artifices of Alcibiades, however, added to the turbulent and haughty disposition of both nations, rendered this impossible; so that though Nicias went on purpose to Sparta, he returned without doing any thing.

Alcibiades, having thus disposed every thing according to his wishes, and a war being inevitable, he began to take the most prudent methods for preserving his country in safety. With this view, he entered into a league for 100 years with the Argives, which he hoped would keep the war at a distance: he next passed over into the territories of Argos, at the head of a considerable army; and laboured, both at that city and at Patræ, to persuade the people to build walls to the sea, that so they might the more easily receive assistance from the Athenians. But though great preparations for war were now made, nothing was undertaken this year; only the Argives thought to have made themselves masters of Epidaurus, but were hindered by the

Lacedæmonians putting a garrison into it.

The next year (the 14th after the Peloponnesian war was first begun) a Spartan army, under the command of Agis, entered the territory of Argos where the confederate army lay; but just as the engagement was about to begin, a truce was suddenly concluded by two of the Argive generals and the king of Sparta. With this neither party was pleased, and both the king and generals were very ill treated by their citizens. On the arrival of some fresh troops from Athens, therefore, the Argives immediately broke the truce: but the allied army was soon after defeated with great slaughter by Agis; notwithstanding which, however, the Æleans and Athenians invaded Epidaurus. In the winter, a strong party in Argos joined the Lacedæmonians; in consequence of which, that city renounced her alliance with Athens, and concluded one with Sparta for 50 years. In compliment to their new allies, also, the Argives abolished democracy in their city, establishing an aristocracy in its place, and assisted the Lacedæmonians with a considerable body of troops to force the Sicyonians to do the same.

In the beginning of the 15th year, the Argives, with a levity seemingly natural to all the Greeks, renounced their alliance with Sparta, abolished aristocracy, drove all the Lacedæmonians out of the city, and renewed their league with Athens. The Athenians, in the mean time, being convinced of the treachery of Perdiccas king of Macedon, renounced their alliance with him, and declared war against him.

Next year, Alcibiades terminated the disputes in the city of Argos, by the banishment of the Spartan faction; after which he sailed to the island of Melos, whose inhabitants had acted with the greatest inveteracy against his countrymen: perceiving, however, that the reduction of the island would be a work of time, he left a considerable body of forces there, and returned to Athens. In his absence the capital of Melos surrendered at discretion, and the inhabitants were treated with the utmost cruelty; all the men capable of bearing arms being slaughtered, and the women and children carried into captivity.

In the beginning of the 17th year, Nicias was appointed commander of an expedition against the Syracusans, along with Alcibiades and Lamachus as colleagues. But while the necessary preparations were making, all things were thrown into confusion by the despatching of the *Hermæ*, or statues of Mercury, of which there was a great number in the city. The authors of this sacrilege could by no means be discovered, though rewards were offered for this purpose: at last the suspicion fell upon Alcibiades, and for this weighty reason he was commanded to return from Sicily to take his trial. Alcibiades, however, knew the temper of his countrymen too well to trust himself to their mercy; and therefore, instead of returning to Athens, he fled immediately to Sparta, where he met with a gracious reception; while the infuriated Athenians were severely punished by the loss of their army, generals, and fleet in Sicily, which the superior abilities of Alcibiades would in all probability have prevented.

The 19th and 20th years of the war were spent by the Athenians in equipping a new fleet in order to repair their vast losses: but Alcibiades hurt their interests very much, by persuading Tissaphernes the Persian to league

league with the Spartans against them; at the same time he persuaded several of the Ionian states to revolt from Athens, but they were in a short time obliged again to submit. Notwithstanding all these services, however, Alcibiades had rendered himself so hateful to Agis by debauching his wife, that he soon found himself obliged to fly to the Persians, where Tissaphernes gave him a very favourable reception, and profited much by his advice, which was, to let the Greeks weaken one another by their mutual wars, and that the Persians ought never to see one state totally destroyed, but always to support the weaker party.

152
Propoies
The abolition
of democracy
at Athens.

When Tissaphernes had acquiesced with these counsels, Alcibiades privately wrote to some of the officers in the Athenian army at Samos, that he had been treating with the Persians in behalf of his countrymen, but did not chuse to return till the democracy should be abolished; and to incline the citizens to comply with this measure, he told them that the Persian king disliked a democracy, but would immediately assist them if that was abolished, and an oligarchy erected in its stead.

On the arrival of Pisander and other deputies from the army, with the proposals of Alcibiades, the Athenians without hesitation resolved to overturn that democracy which they had all along so strenuously defended. The issue of their present debates was, that Pisander with ten deputies should return to Alcibiades, in order to know on what terms the king of Persia would make an alliance with them; but that cunning Athenian having perceived that Tissaphernes was by no means disposed to assist the Athenians on account of their having been lately successful, he set up such high demands in the king of Persia's name, that the Athenians of themselves broke off the treaty, and thus Alcibiades preserved the friendship of both parties.

153
New form
of government
established.

Pisander having engaged the army at Samos in his scheme of overturning democracy, that form of government was abolished first in the cities subject to Athens, and lastly in the capital itself. Pisander's new scheme was, that the old form of government should be totally dissolved: that five prytanes should be elected: that these five should chuse 100; and that each of the hundred should chuse three: that the 400 thus elected should become a senate with full power; but should occasionally consult with 5000 of the most wealthy citizens, who should thenceforward be esteemed only the people; and that no authority should remain with the lower class. Though the people were not very fond of this change, those who conducted it, being men of great parts, found means to establish it by force; for when the people were gone out of the city to their ordinary employments, the 400, having each a dagger concealed under his vest, attended by a guard of 120 men, entered the senate-house, dissolved the old senate, and without ceremony turned them out; after which the commons, not knowing whom to submit to, or to whom to apply, made no opposition.

The first step of the new governors was to destroy all their enemies; who, however, were not very numerous, so that little blood was shed. They next sent ambassadors to Agis to sue for peace; but he, taking for granted that the Athenians would never defend an oligarchy, gave no answer to the ambassadors, but immediately marched towards the capital with a design

Attica.

to attack it. On his arrival, however, he was quickly convinced of his mistake, being repulsed with loss, and obliged to retire to his old post.

154

In the mean time the Athenian army declared again for a democracy; and having recalled Alcibiades, invested him with full power, and insisted on his immediate return to Athens to restore the ancient government. This measure he refused to comply with, and persuaded them to stay where they were, in order to save Ionia: he also prevailed on them to allow some deputies, who had been sent from the new governors of Athens, to come and deliver their message. To these deputies Alcibiades replied, that they should immediately return to Athens, and acquaint the 400, that they were commanded immediately to resign their power and restore the senate; but that the 5000 might retain theirs, provided they used it with moderation.

155
Great confusion
at Athens.

By this answer, the city was thrown into the utmost confusion; but the new government party prevailing, ambassadors were dispatched to Sparta with orders to procure peace on any terms. This, however, was not to be effected; and Phrynicius, the head of the embassy, and likewise of the new government party, was murdered on his return. After his death, Theramenes, the head of the other party, seized the chiefs of the 400; upon which a tumult ensued that had almost proved fatal to the city itself. The mob, however, being at last dispersed, the 400 assembled, tho' in great fear, and sent deputies to the people, promising to set all things to rights. In consequence of this deputation, a day was appointed for convoking a general assembly, and settling the state; but when that day came, news was brought that the Lacedaemonian fleet appeared in view, and steered directly for Salamis. Thus all was again thrown into confusion; for the people, instead of deliberating on the subject proposed, ran in crowds down to the port, and perceiving the Spartans made towards Eubœa, a fleet of 36 ships was immediately dispatched under the command of Thymochares, to engage the enemy. This fleet was utterly defeated, 22 of the Athenian ships being taken, and most of the others sunk or disabled; but what was worse, this defeat was followed by the revolt of all the country of Eubœa except Orcus.

156
Athenian
fleet destroyed
by the Spartans.

When these dismal tidings arrived at Athens, every thing was given up for lost; and had the Lacedaemonians taken this opportunity of attacking the city, they had undoubtedly succeeded, and thus put an end to the war; but being at all times slow, especially in naval affairs, they gave the Athenians time to equip a new fleet, and to retrieve their affairs. One good effect of this disaster, however, was the putting an end for a time to the internal dissensions of this turbulent people; inasmuch that Thucydides the historian is of opinion, that the republic never enjoyed so much quiet as at this time.

157
Exploits of
Alcibiades.

Alcibiades now shewed his abilities and inclination to serve his country in an eminent manner. By his intrigues he so effectually embroiled the Persians and Peloponnesians with each other, that neither party knew whom to trust. Thrasylbulus, with 55 ships, gained a victory over the Peloponnesian fleet consisting of 73: after which he took 8 galleys coming from Byzantium; which city had revolted from the Athenians, but was soon after taken, and the inhabitants severely fined.

fined. The fleet being afterwards joined by Alcibiades, nine more of the Peloponnesian galleys were taken, the Halicarnassians were constrained to pay a large sum of money, and Cos was strongly fortified; which transactions ended the 21st year of the Peloponnesian war.

In the succeeding years of this famous war, the Athenians had at first great advantages. Thrasylulus gained a signal victory at sea; and Alcibiades gained two victories, one by sea and another by land, in one day; took the whole Peloponnesian fleet, and more spoil than his men could carry away. The Spartans were now humbled in their turn, and sued for peace; but the Athenians were so intoxicated with their success, that they sent back the ambassadors without an answer, which they soon had sufficient reason to repent of. The beginning of the Athenians misfortunes was the taking of Pylus by the Spartans. The Athenians had sent a fleet under the command of one Anytus to its defence: but he was driven back by contrary winds; upon which he was condemned to death, because he could not cause the wind blow from what quarter he pleased: this sentence, however, was remitted on his paying a vast sum of money. This misfortune was quickly followed by another. The Megarians surprised Nisæa; which enraged the Athenians so much, that they immediately sent an army into that country, who defeated the Megarians who opposed them, with great slaughter, and committed horrid devastations.

These misfortunes as yet, however, were overbalanced by the great actions of Alcibiades, Thrasylulus, and Theramenes. When Alcibiades returned, he brought with him a fleet of 200 ships, and such a load of spoils as had never been seen in Athens since the conclusion of the Persian war. The people left their city destitute, that they might crowd to the port, to behold Alcibiades as he landed; old and young blessed him as he passed; and next day when he made a harangue to the assembly, they directed the record of his banishment to be thrown into the sea, absolved him from the curses he lay under, and created him general with full power. Nor did he seem inclined to indulge himself in ease, but soon put to sea again with a fleet of 100 ships. He had not been long gone, however, before all this was forgot. Alcibiades sailed to the Hellespont with part of his fleet, leaving the rest under the command of Antiochus his pilot, but with strict orders to attempt nothing before his return. This command the pilot paid no regard to, but provoked Lyfander the Lacedæmonian admiral to an engagement, and in consequence of his temerity was defeated with the loss of 15 ships, himself being killed in the engagement. On the news of this defeat Alcibiades returned, and endeavoured to provoke the Lacedæmonians to a second battle: but this Lyfander prudently declined; and in the mean time the Athenians, with unparalleled ingratitude and inconstancy, deprived Alcibiades of his command, naming ten new generals in his room.

This was the last step the Athenians had to take for perfecting their ruin. Conon, who succeeded to the command, was defeated by Callicratidas Lyfander's successor; but being afterwards strongly reinforced, the Lacedæmonians were entirely defeated with the loss of

77 ships. Such a victory might at this time have inspired the Athenians with some kind of gratitude towards the generals who gained it: but instead of this, on pretence of their not having assisted the wounded during the engagement, eight of them were recalled; two were wife enough not to return; and the six who trusted to the justice of their country, were all put to death.

The next year Lyfander was appointed commander of what fleet the Peloponnesians had left, with which he took Thafus and Lampacus. Conon was dispatched against him with 180 ships, which being greatly superior to Lyfander's fleet, that general refused to come to an engagement, and was blocked up in the river Ægos. While the Athenians lay there, they grew quite idle and careless; insomuch that Alcibiades, who had built a castle for himself in the neighbourhood, intreated them to be more on their guard, as he well knew Lyfander's abilities. They answered, that they wondered at his assurance, who was an exile and a vagabond, to come and give laws to them; telling him, that if he gave them any farther trouble, they would seize and send him to Athens. At the same time they looked on victory as so certain, that they consulted what they should do with their prisoners; which, by the advice of Philocles their general, was to cut off all their right hands, or, according to Plutarch, their right thumbs; and Adiamantus one of their officers rendered himself very obnoxious by saying, that such idle discourse did not become Athenians. The consequences of such conduct may be easily imagined. Lyfander fell unexpectedly upon them, and gained a most complete victory; Conon, with eight galleys only, escaping to Cyprus; after which Lyfander returned to Lampacus, where he put to death Philocles with 3000 of his soldiers, and all the officers except Adiamantus. This execution being over, he reduced all the cities subject to Athens; and with great civility sent home their garrisons, that so the city might be overstocked with inhabitants, and destitute of provisions, when he came to besiege it; which he did soon after by sea, while Agis with a great army invested it by land.

For a long time the Athenians did not so much as desire a peace; but at last were forced to send deputies to Agis, who sent them to Sparta, where no terms could be granted except they consented to demolish their walls. They next sent to Lyfander, who after a long attendance referred them to Sparta; and thither Theramenes with some other deputies was immediately sent. On their arrival, they found the council of the confederates sitting, who all except the Spartans gave their votes that Athens should be utterly destroyed; but they would not consent to the ruin of that city, which had deserved so well of Greece. On the return of Theramenes, peace was concluded, on condition, that the long walls and the fortifications of the port should be demolished; that they should give up all their ships but 12, receive all they had banished, and follow the fortune of the Lacedæmonians. These few terms were punctually executed. Lyfander caused the walls to be pulled down; all the music in his army playing, on that very day of the year on which they had beat the Persians at Salamine. He likewise established an oligarchy expressly against the will of the people; and thus the ruin of Athens ended the 27th year.

166
The thirty tyrants.

As soon as Lyfander had demolished the long walls, and the fortifications of the Piræum, he constituted a council of thirty, with power, as was pretended, to make laws, but in truth to subjugate the state. These are the persons so famous in history, under the title of *the thirty tyrants*. They were all the creatures of Lyfander: who, as they derived their rise from conquest and the law of the sword, exercised their offices in a suitable manner; that is, with the highest testimonies of pride, insolence, and cruelty. Instead of making laws, they governed without them; appointed a senate, and magistrates, at their will; and, that they might do all things without danger of controul, they sent for a garrison from Lacedæmon; which was accordingly granted them, under the command of Callidius, upon their promise to pay the soldiers regularly. One of the first steps they took was to punish all informers; which, though severe, was popular: but when, through flattery and bribes, they had wholly drawn over Callidius to their party, they suffered bad men to live in quiet, and turned their rage against the good.

167
Critias and Theramenes, their opposite characters.

Critias and Theramenes were at the head of the thirty, men of the greatest power and abilities in Athens. The former was ambitious and cruel without measure, the latter was somewhat more merciful: the former pushed on all the bloody schemes framed by his confederates, and carried into execution many of his own; the latter always opposed them, at first with moderation, at last with vehemence. He said, that power was given them to rule, and not to spoil, the commonwealth; that it became them to act like shepherds, not like wolves; and that they ought to beware of rendering themselves at once odious and ridiculous, by attempting to domineer over all, being such a handful of men as they were. The rest, disliking much the former part of his discourse, caught hold of the latter, and immediately chose out 3000, whom they made the representatives of the people, and to whom they granted this notable privilege, that none of them should be put to death but by judgment of the senate, thereby openly assuming a power of putting any other of the Athenian citizens to death by their own authority. A glorious use they made of this new-assumed privilege; for as many as they conjectured to be no friends to the government in general, or to any of themselves in particular, they put to death, without cause, and without mercy. Theramenes openly opposing this, and absolutely refusing to concur in such measures, Critias accused him to the senate as a man of unsteady principles, sometimes for the people, sometimes against them, always for new things and state-revolutions. Theramenes owned, that he had sometimes changed his measures, but alleged that he had always done it to serve the people. He said that it was solely with this view he made the peace with Sparta, and accepted the office of one of the thirty: that he had never opposed their measures while they cut off the wicked; but, when they began to destroy men of fortune and family, then he owned he had differed with them, which he conceived to be no crime against the state.

168
Theramenes put to death.

While Theramenes was speaking, Critias withdrew, perceiving that the senate were thoroughly convinced of the truth of what Theramenes had said: but he quickly

returned with a guard, crying out, that he had struck Theramenes's name out of the list of the 3000; that the senate had therefore no longer cognizance of the cause, which the thirty had already judged, and condemned him to death. Theramenes perceiving that they intended to seize him, fled to the altar, which was in the midst of the senate-house, and laying his hands thereon, said, *I do not seek refuge here because I expect to escape death or desire it; but that, tearing me from the altar, the impious authors of my murder may interest the gods in bringing them to speedy judgment, and thereby restore freedom to my country.* The guards then haled him from the altar, and carried him to the place of execution, where he drank the poison with undaunted courage, putting the people in mind with his last breath, that as they had struck his name out of the 3000, they might also strike out any of theirs. His death was followed by a train of murders, so that in a short time 60 of the worthiest and most eminent citizens of Athens fell by the cruelty of the thirty. Amongst these, the most pitied was Niceratus, the son of Nicias; a man universally beloved for his goodness, and universally admired for his virtues. As for the Spartans, they, losing their former generosity, were extremely pleased with these things, and by a public decree commanded that such as fled from the thirty tyrants should be carried back bound to Athens: which extraordinary proceeding frightened all Greece; but the Argives and Thebans only had courage to oppose it: the former received the Athenian exiles with humanity and kindness; the latter punished with a mult^o such of their citizens as did not rise and rescue the Athenian prisoners, who in pursuance of the Lacedæmonian decree were carried bound through their territories.

Thrafsybulus, and such as with him had taken shelter in the Theban territory, resolved to hazard every thing, rather than remain perpetual exiles from their country; and though he had but 30 men on whom he could depend, yet considering the victories he had heretofore obtained in the cause of his country, he made an irruption into Attica, where he seized Phyla, a castle at a very small distance from Athens, where in a very short space his forces were augmented to 700 men; and though the tyrants made use of the Spartan garrison in their endeavours to reduce him and his party, yet Thrafsybulus prevailed in various skirmishes, and at last obliged them to break up the blockade of Phyla, which they had formed. The thirty and their party conceiving it very advantageous for them to have the possession of Eleufina, marched thither, and having persuaded the people to go unarmed out of their city, that they might number them, took this opportunity most inhumanly to murder them. The forces of Thrafsybulus increasing daily, he at length possessed himself of the Piræum, which he fortified in the best manner he could; but the tyrants being determined to drive him from thence, came down against him with the utmost force they could raise. Thrafsybulus defended himself with great obstinacy; and in the end they were forced to retreat, having lost before the place not only a great number of their men, but Critias the president of the thirty, another of the same body, and one who had been a captain of the Piræum.

169

he had with him, to make a short speech in a very loud voice to the people, intreating them to consider, that as they were citizens of Athens without, so those against whom they fought, and those who fought to preserve themselves within the fort, were Athenian citizens also; wherefore, instead of thinking how to ruin and destroy their brethren, they ought rather to consult how all differences ought to be composed, and especially ought to rid themselves of those bloody tyrants, who, in the short time they had had the administration in their hands, had destroyed more than had fallen in the Peloponnesian war. The people, though moved by these discourses, differed among themselves; the consequence of which was, that they expelled the thirty, and chose ten men out of each tribe to govern in their stead, whereupon the tyrants retired to Eleusina. The citizens, however, though they changed the government, made no agreement with those in the Piræum; but sent away deputies to Sparta, as did also the tyrants from Eleusina, complaining, that the Athenians had revolted, and desiring their assistance to reduce them. The Spartans sent thereupon a large sum of money to encourage their confederates, and appointed Lyfander commander in chief, and his brother to be admiral; resolving to send sea and land forces to reduce Athens a second time; intending, as most of the Greek states suspected, to add it now to their own dominions. It is very probable that this design of theirs would have taken effect, if Pausanias king of Sparta, envying Lyfander, had not resolved to obstruct it. With this view, he procured another army to be raised against the Athenians, of which himself had the command, and with which he marched immediately to besiege the Piræum. While he lay before the place, and pretended to attack it, he entered into a private correspondence with Thrafsybulus, informing him what propositions he should make in order to force the Lacedæmonians, who were supported by their allies, to grant them peace.

The intrigues of Pausanias had all the success he could wish; the ephori who were with him in the camp concurred in his measures, so that in a short space a treaty was concluded on the following terms: That all the citizens of Athens should be restored to their houses and privileges, excepting the thirty, the ten which had succeeded them and who had acted no less tyrannically than they, and the eleven who during the time of the oligarchy had been constituted governors or keepers of the Piræum; that all should remain quiet for the future in the city; and that, if any were afraid to trust to this agreement, they should have free leave to retire to Eleusina. Pausanias then marched away with the Spartan army, and Thrafsybulus at the head of his forces marched into Athens, where, having laid down their arms, they sacrificed with the rest of the citizens in the temple of Minerva, after which the popular government was restored. Yet quiet was not thoroughly established; the exiles at Eleusina having endeavoured by the help of money to raise an army of foreigners, by whose aid they might recover the authority they had lost: but first, depending on their friends in the city, they sent some of the principal persons amongst them as deputies, to treat with the citizens; but strictly instructed them to show jealousies and excite discords among them. This the latter quickly perceiving, put these persons to death; and then, remonstrating to those

VOL. II.

at Eleusina, that these contentions would undoubtedly end either in their own or the destruction of their country, they offered immediately, to pass an act of oblivion, which they would confirm with an oath.

This being accepted, those who had withdrawn returned to the city, where all differences were adjusted, and both parties most religiously observed the agreement he had made, and thereby thoroughly settled the state. In this whole transaction, the virtue of Thrafsybulus deserves chiefly to be admired. When he first seized the castle of Phyla, the tyrants privately offered to receive him into their number instead of Theramenes, and to pardon at his request any 12 persons he should name: but he generously answered, That his exile was far more honourable than any authority could be, purchased on such terms; and by persisting in his design, accomplished, as we have seen, the deliverance of his country. A glorious deliverance it was; since, as Isocrates informs us, they had put 1400 citizens to death contrary to and without any form of law, and driven 5000 more into banishment, procuring also the death of Alcibiades, as many think, tho' at a great distance from them.

From this time to the reign of Philip of Macedon, the Athenians continued in a pretty prosperous situation, though they never performed any such great exploits as formerly. By that monarch, and his son Alexander, all Greece was in effect subdued; and the history of all the Grecian states from that time becomes much less interesting. Of the history of Athens from that time to the present, the following elegant abridgment is given by Dr Chandler †. “On the death of Alexander, the Athenians revolted, but were defeated by Antipater, who garrisoned Munychia. They rebelled again, but the garrison and oligarchy were reinstated. Demetrius the Phaleron, who was made governor, beautified the city, and they erected to him 360 statues; which, on his expulsion, they demolished, except one in the Acropolis. Demetrius Poliorceces withdrew the garrison, and restored the democracy; when they desired him, and lodged him in the Opithodomos or the back part of the Parthenon, as a guest to be entertained by their goddess Minerva. Afterwards they decreed, that the Piræus, with Munychia, should be at his disposal; and he took the Museum. They expelled his garrison, and he was persuaded by Craterus a philosopher, to leave them free. Antigonus Gonatas, the next king, maintained a garrison in Athens: but, on the death of his son Demetrius, the people, with the assistance of Aratus, regained their liberty; and the Piræus, Munychia, Salamis, and Sunium, on paying a sum of money.

“Philip, son of Demetrius, encamping near the city, destroying and burning the sepulchres and temples in the villages, and laying their territory waste, the Athenians were reduced to solicit protection from the Romans, and to receive a garrison, which remained until the war with Mithridates king of Pontus, when the tyrant Aristion made them revolt.

“Archelaus, the Athenian general, unable to withstand the Roman fury, relinquished the *long walls*, and retreated into the Piræus and Munychia. Sylla laid siege to the Piræus, and to the city, in which Aristion commanded. He was informed, that some persons had been overheard talking in the Ceramicus, and blaming

Sylla.

Aristion for his neglect of the avenues about the Hep-tachalcos, where the wall was accessible. Sylla resolved to form there, and about midnight entered the town at the gate called *Dipylon* or *the Piræan*; having levelled all obstacles in the way between it and the gate of the Piræus. Aristion fled to the Acropolis, but was compelled to surrender by the want of water; when he was dragged from the temple of Minerva, and put to death. Sylla burned the Piræus and Munychia, and defaced the city and suburbs, not sparing even the sepulchres.

“ In the civil war, the Athenians took the side of Pompey. Cæsar generously refused to punish the city, which afterwards cared for its murderers. They next joined Antony, who gave them *Ægina* and *Cea*, with other islands. Augustus was unkind to them; and they revolted, four years before he died. Under Tiberius, the city was declining, but free, and regarded as an ally of the Romans. The high privilege of having a licitor to precede the magistrates, was conferred on it by Germanicus; but he was censured as treating with too much condescension a mixture of nations, instead of genuine Athenians, which race was then considered as extinct.

“ The emperor Vespasian reduced Achaia to a province paying tribute and governed by a pro-consul. Nerva was more propitious to the Athenians; and Pliny, under Trajan his successor, exhorts Maximus to be mindful whither he was sent, to rule genuine Greece, a state composed of free cities. “ You will reverence the gods and heroes their founders. You will respect their pristine glory, and even their age. You will honour them for the famous deeds, which are truly, nay for those which are fabulously, recorded of them. “ Remember, it is Athens you approach.” This city was now entirely dependent on Rome, and was reduced to sell Delos and the islands in its possession.

“ Hadrian, who was at once emperor and an archon of Athens, gave the city laws, compiled from Draco, Solon, and the codes of other legislators; and displayed his affection for it by unbounded liberality. Athens flourished, and its beauty was renewed. Antoninus Pius, who succeeded, and Antoninus the Philosopher, were both benefactors.

“ The barbarians, in the reign of Valerian, besieging Thessalonica, all Greece was terrified, and the Athenians restored their city-wall, which had been dismantled by Sylla, and afterwards neglected.

“ Under the next emperor, who was the archon Gallienus, Athens was besieged; the archontic office ceased; and the Strategus or general, who had before acted as overseer of the agora or market, then became the supreme magistrate. Under Claudius, his successor, the city was taken, but soon recovered.

“ It is related, that Constantine, when emperor, gloried in the title of *general of Athens*; and rejoiced exceedingly on obtaining from the people the honour of a statue with an inscription, which he acknowledged by a yearly gratuity of many bushels of grain. He conferred on the governor of Attica and Athens the title of *grand duke*, *μεγας δουξ*. That office was at first annual, but afterwards hereditary. His son Constantine bestowed several islands on the city, to supply it with corn.

“ In the time of Theodosius the First, 380 years after Christ, the Goths laid waste Thessaly and Epirus;

but Theodorus, general of the Achæans, by his prudent conduct preserved the cities of Greece from pillage, and the inhabitants from being led into captivity. A statue of marble was erected to him at Athens by order of the city; and afterwards one of brass, by command of the emperor, as appears from an inscription in a church dedicated to a faint of the same name, not far from the French convent. It is on a round pedestal, which supports a flat stone serving for the holy table. Eudocia the wife of Theodosius the Second was an Athenian.

“ The fatal period now approached, and Athens was about to experience a conqueror more savage even than Sylla. This was Alaric, king of the Goths; who, under the emperors Arcadius and Honorius, over-ran Greece and Italy, sacking, pillaging, and destroying. Then the Peloponnesian towns were overturned, Arcadia and Lacedæmon were laid waste, the two seas by the Isthmus were burnished with the flames of Corinth, and the Athenian matrons were dragged in chains by barbarians. The invaluable treasures of antiquity, it is related, were removed; the stately and magnificent structures converted into piles of ruin; and Athens was stripped of every thing splendid or remarkable. Synesius, a writer of that age, compares the city to a victim, of which the body had been consumed, and the hide only remained.

“ After this event, Athens became an unimportant place, and as obscure as it once had been famous. We read that the cities of Hellas were put into a state of defence by Justinian, who repaired the walls, which at Corinth had been subverted by an earthquake, and at Athens and Bœotia were impaired by age; and here we take a long farewell of this city. A chafm of near 700 years ensues in its history, except that, about the year 1130, it furnished Roger the First king of Sicily with a number of artificers, whom he settled at Palermo, where they introduced the culture of silk, which then passed into Italy. The worms had been brought from India to Constantinople in the reign of Justinian.

“ Athens, as it were, re-emerges from oblivion in the 13th century, under Baldwin, but besieged by a general of Theodorus Lascaris, the Greek emperor. It was taken in 1427 by Sultan Morat. Boniface, marquis of Monterrat, possessed it with a garrison; after whom it was governed by Delves, of the house of Aragon. On his death, it was seized, with Macedonia, by Bajazet; and then, with the island Zante, by the Spaniards of Catalonia in the reign of the Greek emperor Andronicus Paleologus the elder. These were dispossessed by Reinerius Acciaïoli, a Florentine; who, leaving no legitimate male issue, bequeathed it to the state of Venice. His natural son, Antonio, to whom he had given Thebes with Bœotia, expelled the Venetians. He was succeeded in the dukedom by his kinsman Nerius, who was displaced by his own brother named Antonio, but recovered the government when he died. Nerius leaving only an infant son, was succeeded by his wife. She was ejected by Mahomet on a complaint from Francus the son of the second Antonio, who confined her at Me-gara, and made away with her; but, her son accusing him to Mahomet the Second, the Turkish army under Omar advanced, and he surrendered the citadel in 1455; the Latins refusing to succour him, unless the Athenians would embrace their religious tenets. Mahomet,

it is related, when he had finished the war with the despot of the Morea, four years after, surveyed the city and Acropolis with admiration. The janifaries informed him of a conspiracy; and Fraucus Acciaïoli, who remained lord of Beotia, was put to death. In 1464 the Venetians landed at the Piræus, surpris'd the city, and carried off their plunder and captives to Eubœa.

"It is remarkable, that after these events Athens was again in a manner forgotten. So lately as about the middle of the 16th century, the city was commonly believed to have been utterly destroyed, and not to exist, except a few huts of poor fishermen. Crusius, a learned and inquisitive German, procured more authentic information from his Greek correspondents residing in Turkey, which he published in 1584, to awaken curiosity and to promote farther discoveries. One of these letters is from a native of Nauplia, a town near Argos in the Morea. This writer says, that he had been often at Athens, and that it still contained many things worthy to be seen, some of which he enumerates, and then subjoins, "But why do I dwell on this place? It is as the skin of an animal, which has been long dead."

It now remains to give some idea of the character, government, and religion of this once so famous people.

The Athenians, says Plutarch, are very subject to violent anger; but they are soon pacified. They are likewise easily impressed with humanity and compassion. That this was their temper, is proved by many historical examples. We shall produce a few: The sentence of death pronounced against the inhabitants of Mitylene, and revoked the next day: The condemnation of Socrates, and that of the ten chiefs, each followed by quick repentance and most pungent grief.

The minds of the same people, adds Plutarch, are not formed for laborious researches. They seize a subject, as it were by intuition; they have not patience and phlegm enough to examine it gradually and minutely. This part of their character may seem surprising and incredible. Artisans, and other people of their rank, are in general slow of comprehension. But the Athenians of every degree were endowed with an inconceivable vivacity, penetration, and delicacy of taste. Even the Athenian soldiers could repeat the fine passages of the tragedies of Euripides. Those artisans and those soldiers assisted at public debates, were bred to political affairs, and were equally acute in apprehension and in judgement. We may infer the understanding of the hearers of Demosthenes from the genius of his orations, which were laconic and poignant.

As their inclination, continues Plutarch, leads them to assist and support people of low condition, they like discourse seasoned with pleasantry, and productive of mirth. The Athenians patronize people of low degree; because from them their liberty is in no danger, and because such patronage tends to support a democratical constitution. They love pleasantry; which turn of mind proves that they are a humane social people, who have a taste for raillery and wit, and are not fouled with that reserve which marks the despot or the slave.

They take pleasure in hearing themselves praised; but they can likewise patiently bear raillery and censure. We know with what art and success Aristophanes and Demosthenes applied their praise and their

irony to the Athenian people. When the republic enjoyed peace, says the same Plutarch in another place, it encouraged the adulation of its orators: but when it had important affairs to discuss, when the state was in danger, it became serious; and preferred, to its eloquent sycophants, the honest orators who opposed its follies and its vices; such ingenious and bold patriots as a Pericles, a Phocion, and a Demosthenes.

The Athenians, continues Plutarch, often make their governors tremble, and shew great humanity to their enemies. They were very attentive to the information and instruction of those citizens who were most eminent for their policy and eloquence; but they were on their guard against the superiority of their talents, they often checked their boldness, and repressed their exuberant reputation and glory. That this was their temper, we are convinced by the ostracism; which was established to restrain the ambition of those who had great talents and influence, and which spared neither the greatest nor the best men. The detestation of tyranny and of tyrants, which was inherent in the Athenians, rendered them extremely jealous of their privileges, made them zealous and active in defence of their liberty, whenever they thought it was violated by men in power.

As to their enemies, they did not treat them with rigour. They did not abuse victory by a brutal inhumanity to the vanquished. The act of amnesty, which they passed after the usurpation of the thirty tyrants, proves that they could easily forgive injuries.

It was this mildness, this humanity of disposition, which made the Athenians so attentive to the rules of politeness and decorum. In their war with Philip, having seized one of his couriers, they read all the letters he bore, except one from Olympias to her husband, which they sent back unopened. Such was their veneration of love and conjugal secrecy; those sacred rights which no enmity, no hostility, warrants us to violate!

The taste of the Athenians for all the arts and sciences is too well known to need a particular relation. The views of conquest cherished by a small republic, were extensive and astonishing; but this people, so great, so ambitious in their projects, were, in other respects, of a different character. In the expences of the table, in dress, in furniture, in houses, in short, in private life, they were frugal, simple, modest, poor; but sumptuous and magnificent whenever the honour of the state was concerned. Their conquests, their victories, their riches, their connections with the inhabitants of Asia Minor, never reduced them to luxury, to riot, to pomp, to profusion. Xenophon remarks, that a citizen was not distinguished from a slave by his dress. The wealthiest citizen, the most renowned general, was not ashamed to go himself to market.

We shall finish this picture of the Athenians by the addition of one object more, to which every one will admit they have a right; an object which was prominent and striking, in all their actions and in all their enterprizes: We mean their ardent love of liberty. This was their predominant quality; the main spring of their government. From the beginning of the Persian war, they sacrificed every thing to the liberty of Greece. They left, without hesitation, their cities, their houses, to fight at sea the common enemy, from

Attica.

whom they were in danger of servitude. What a glorious day was it for Athens, when all her allies, growing flexible to the advantageous offers which were made to them by the king of Persia, she replied by Aristides, to the ambassadors of that monarch,—“That it was impossible for all the gold in the world to tempt the republic of Athens: to prevail with her to sell her liberty, and that of Greece.” It was by these generous sentiments that the Athenians not only became the bulwark of Greece, but likewise guarded the rest of Europe from a Persian invasion.

Their great qualities were blended with great failings, seemingly incompatible with patriotism. For the Athenians, notwithstanding their tenacious jealousy of the rights of their country, were a volatile, inconstant, capricious people.

There never was a people more attentive to the worship of the gods than the Athenians. The worship of their principal deities was diffused over all Greece, and even beyond its limits.

Each temple had its particular religious rites: the pomp, the ceremonies, the duration, and the succession of the solemn feasts, were all appointed by fixed rules. The worship paid to each divinity, whether public or private, was founded on traditions, or on laws constantly obeyed. The feast of Bacchus, the Panathenæa, the feast of the mysteries of Eleusis, were celebrated according to established rules, most of which were as ancient as the feasts themselves. The old customs, of which the priests were the guardians, were observed in the temples. It is probable that the priests were consulted on affairs in which the worship of a deity was interested, and that their answer was decisive. We are certain that the Eumolpidae had this authority. They were the interpreters of the ancient laws on which the worship of Ceres was founded, its magnificence, and its mode—laws which were not written, as Lyfias informs us, but were perpetuated by a constant observation. The abuses which had gradually crept into the celebration of those feasts, had given rise to several new regulations; to that of the orator Lycurgus, for example, and to the law of Solon, which enjoined the senate to repair to Eleusis on the second day of the feast: but neither these nor the other particular regulations which we find in Samuel Petit's collection of Attic laws, could make a religious code. There was no general system which comprehended all the branches of their religion, which, by combining all its articles, might regulate their belief and conduct, and direct the judges in their decisions.

Crimes against religion were only punished as they affected the state; and consequently they were tried by the magistrate. Mere raillery, though somewhat profane, was thought productive of no worse consequence than offending the ministers of the gods. The Athenians acknowledged no other religion than the hereditary public worship; no other gods than those they had received from their ancestors; no other ceremonies than those which had been established by the laws of the state, and practised by their country from time immemorial. They were only solicitous to preserve this worship, which was closely interwoven with their government, and made a part of its policy. They were likewise attentive to the ceremonial pomp: because order, the regular vigour of legislation, depends greatly

on the awe impressed by externals. But as to the inconsistent and monstrous romance of fables, foreign opinions, popular traditions, and poetical fictions, which formed a religion quite different from that of the state—in it they were very little interested, and allowed every one to think of it as he pleased.

This explanation will reconcile a seeming contradiction in the conduct of the Athenians, who gave great licence to their poets, and severely punished the citizens who were guilty of impiety. Aristophanes, who made as free with the gods as with the great, was applauded by the Athenians. They condemned Socrates to death, who revered the deity, but disapproved the public manner of worshipping him. The life of Æschylus was in danger from a suspicion that he had revealed some of the secrets of Eleusis in one of his pieces. The wit of Aristophanes's drama was unpunished.

The priests were not confined to the care of the altars; they who were vested with the sacerdotal dignity, which was only incompatible with professions merely useful and lucrative, might likewise hold the most important offices of the commonwealth. This we could prove by a great number of examples; we shall cite that of Xenophon, the illustrious historian and philosopher: he was likewise a famous general, and he was a priest. He was performing the sacerdotal function when he received the news of his son's death, who was killed at the battle of Mantinea.

The sacred ministry was not only compatible with civil offices, but likewise with the profession of arms. The priest and the soldier were often blended. Callias, the priest of Ceres, fought at Plataea. This custom was not peculiar to the Athenians. The Macedemonians, after the battle which we have just mentioned, made three graves for their slain; one for the priests, one for the other Spartans, and one for the Helots.

As every mean employment was incompatible with the sacerdotal dignity, the priests had a revenue fixed to their office. We know that a part of the victims was their right, and that apartments were assigned them near the temples. But, beside these advantages, they had a salary proportioned to the dignity of their functions and to the rank of the deities whom they served. Their salary was probably paid from the revenue of the temples. Those revenues, which kept the temples in repair, and defrayed the sacrificial expences, were very considerable. They were of many different kinds.

A great part of the sacred revenues arose from fines, which individuals were condemned to pay for various offences; fines, of which the tenth part was appropriated to Minerva Polias, and the sixtieth to the other gods and to the heroes whose names their tribes bore. Besides, if the Prytanes did not hold the assemblies conformably with the laws, they were obliged to pay a fine of 1000 drachms to the goddesses. If the Proedri, *i. e.* the senators whose office it was to lay before the assembly the matters on which they were to deliberate, did not discharge that duty according to the rules prescribed to them, they were likewise condemned to pay a fine, which, as the former, was applied to the use of Minerva. By these fines her temple must have been greatly enriched.

Priests their duty.183
Sacred revenues, &c.

Besides this revenue, which was the common property of the gods, and which varied according to the number and degrees of the misdoers, the temples had their permanent revenues: We mean the produce of the lands which were consecrated to the deities. We do not here allude to the lands consecrated to the gods, which were never to be cultivated; such as the territory of Cirrha, proscribed by a solemn decree of the Amphicyons; the land betwixt Megara and Attica, which was consecrated to the goddesses of Eleusis, and many others. We would speak only of those which were cultivated, the fruits of which enriched the temples.

There were likewise lands belonging to the state, the produce of which was destined to defray the expence of the sacrifices which were offered in the name of the public. There were likewise first-fruits which the public officers levied on all lands, for the use of the gods. All these emoluments made a part of the revenue of the temples.

The gods, beside the revenues immediately appertaining to their temples, had certain rights which were granted them by particular compact. The Lepreatæ, for instance, were obliged to pay every year a talent to Olympian Jupiter, on account of a treaty of alliance which they made with the Elæans in one of their wars. The inhabitants of Epidaurus, to obtain leave from the Athenians to cut down olive-trees for statues, which the Pythian priests had commanded them to make, engaged to send deputies every year to Athens, to offer sacrifices in their name to Minerva and to Neptune. But this prerogative was rather honorary than lucrative.

The tenth part of the spoils taken in war was likewise the property of Minerva. Sacred vessels were bought with the effects of the 30 tyrants. In short, the gods were profited by almost every public accident. But what contributed most to enrich the famous temples of Greece, was the money which was constantly brought to them by individuals, in consequence of vows they had made, or to pay for sacrifices which were offered in their names. The credulity of the people was an inexhaustible fund. That credulity enriched the temples of Deli and Eleusis, and supported the magnificence of Delphi. And those immense treasures which were the fruit of superstition, were often a prey to avarice.

These revenues were not deposited with the priests; nor did they expend them. A moderate salary was all their gain; and to offer sacrifices to the deities whose ministers they were, was all their employment.

It is very probable that all the sacred revenues were paid into the hands of officers who were appointed to receive them, and who were to give an account of the discharge of their trust. Nay, we cannot doubt of this, after reading a passage in Aristotle, who, speaking of the officers of the temples, expressly mentions those who were entrusted with the money appertaining to the gods. Citizens, without doubt, of approved integrity, were chosen to this office; and their duty must have been, to keep the temples in repair and order, and to disburse and keep an account of the ordinary sacred expences.

As to the solemn feasts, which were incredibly magnificent, such as the feast of Bacchus, and the Pana-

thenza, they were celebrated at the expence of the Choregus; i. e. of the chief of the choir of each tribe: for each tribe had its poet and its musicians, who sung, emulating each other, hymns in honour of the deity. The richest citizens were appointed chiefs of the different choirs; and as their office was very expensive, to indemnify them in some degree, the Choregus of the victorious tribe had the privilege of engraving his name on the tripod which that tribe suspended to the roof of the temple. This office, though ruinous, was eagerly solicited; and naturally, in a republican state. It led to honours, like the Curule dignity at Rome; and it greatly tended to ingratiate its possessor with a people who were more affected with pleasures than with essential services, and who, consequently, would more highly esteem a profane Choregus than a victorious general.

With regard to the fines, which were in the whole, or in part, the property of Minerva and of the other deities, there were at Athens public treasurers appointed to receive them. They were ten in number, and they were nominated by lot. They were called *Treasurers of the Goddesses, or Receivers of the sacred money*. That money they received in the presence of the senate; and they were empowered to diminish or to annihilate the fine, if they thought it unjust. The statue of Minerva, that of the victories, and the other invaluable pledges of the duration of the state, were deposited with them.

The treasury in which the money consecrated to the gods was kept, was in the citadel, behind the temple of Minerva Polias; and from its situation it was termed *Opihodorus*. It was surrounded with a double wall. It had but one door, the key of which was kept by the Epitates, or chief of the Prytanes: his dignity was very considerable; but it lasted only one day. In this treasury a register was kept, in which were written the names of all those who were indebted to the state; he who owed the smallest fine was not omitted. If the debtors proved insolvent, they were prosecuted with extreme rigour, and often punished with a cruelty which religion could not excuse; though the interest of the gods was the motive, or rather the pretext. The sacred treasurers held a considerable rank among the magistrates, who received the public finances. Of these magistrates there were many kinds, as there were many sorts of revenues.

The Athenian priests did not compose an order distinct and separate from the other orders of the state. They did not form a body united by particular laws, under a chief whose authority extended to all his inferiors. The dignity of sovereign pontiff was unknown at Athens; and each of the priests served his particular temple, unconnected with his brethren. The temples, indeed, of the principal deities; those of Minerva, for instance, of Neptune, of Ceres, and of Proserpine, had many ministers; and in each of them a chief presided, who had the title of *High-priest*. The number of subaltern ministers was in proportion to the rank of the deity; but the priests of one temple were altogether a separate society from those of another. Thus at Athens there was a great number of high-priests, because many deities were worshipped there, whose service required many ministers. The power of each priest was confined to his temple; and there was no fo-

Attica.

vereign pontiff, the minister-general of the gods, and the president at all the feasts.

It naturally follows from this account, that the ministers of the gods at Athens were not judges in matters of religion. They were neither authorized to take cognizance of crimes committed against the deity, nor to punish them. Their function was to offer sacrifices to the gods, and to intreat their acceptance of the adorations of the people. But the punishment of impiety; of sacrilege, of the profanation of mysteries, and of other irreligious crimes, was not entrusted to their zeal.

The priests were not only incapable of avenging crimes against religion by a temporal process; they even could not, without an express order either from the senate or the people, exercise their right of devoting criminals to the infernal gods. It was in consequence of a civil sentence pronounced against Alcibiades, that the Eumolpidæ lanced their anathema against him. It was in virtue of another decree that they revoked their imprecations, when his countrymen wanted his service, and therefore restored him to their favour.

Religious canons, according to M. de Bougainville, fell under the jurisdiction of the Heliastæ.

The government, though often altered, continued pretty much on the plan established by Solon.

The people of Athens were freemen, sojourners, or slaves. The citizens, called in Greek *Politai*, were very numerous; but, what may seem strange, were as many in the time of Cærops, as in the most flourishing state of the commonwealth, hardly ever exceeding 20,000. It was Solon who decreed that none should be accounted free but such as were Athenians both by father and mother. After his time it fell into desuetude, till revived by Pericles, and again at his influence repealed. After the expulsion of the 30 tyrants, Solon's law was restored. A person born of a stranger was styled *Nothos*, a bastard; whereas the son of a free woman was called *Cnestos*, i. e. *legitimate*. There was in Cynosarges a court of judicature, to which causes of illegitimacy properly belonged; and the utmost care was taken to prevent any from being inrolled Athenian citizens, who had not a clear title thereto. The citizens were divided by Cærops into four tribes: the first called *Cæropes*, from Cærops; the second, *Autochthon*, from a king of that name; the third, *Actai*, from Actæus another king of Athens, or rather from *Acte* which signifies a *shore*; the fourth, *Purallia*: these names were altered by Cranaus, and again by Erichonius. In the reign of Erichonius, they were again changed; the soldiers were called *Oplitai*, the craftsmen *Ergatai*, the farmers *Georgoi*, the graziers and shepherds *Aigicorai*: in this state they were when Solon settled the commonwealth, and appointed the senate to be composed of 400, 100 out of each tribe. Clisthenes increased the number of the tribes to 10; and made the senate consist of 500, taking 50 out of each tribe. In succeeding times, two other tribes were added. Each tribe was subdivided into its *Demai* or wards; and with respect to these it was that Solon instituted the public feasts before-mentioned, at which sometimes the whole tribe assembled, sometimes several wards, and sometimes only the inhabitants of one ward.

The second sort of inhabitants we mentioned were called *Metacoï*, i. e. *sojourners*; these were persons

who lived always at Athens, yet were not admitted free denizens; as for such as did not constantly reside in Athens, they were styled *Xenoi*, i. e. *strangers*. The sojourners were obliged to chuse out of the citizens protectors, who were styled *Patrons*: they paid services to the state, and besides these an annual tribute of 12 drachms for every man, and six for every woman; but such as had sons, and paid for them, were exempted. If people fell to poverty, and were not able to pay the tribute, they were seized by the tax-masters, and actually sold for slaves; which, as Diogenes Laertius tells us, was the fate of Xenocrates the philosopher. The sojourners in Attica were under the same law as those in Athens. As to servants, they were freemen, who through indigency were driven to receive wages, and while they were in this state had no vote in the assembly. As to slaves, they were absolutely the property of their masters, and as such were used as they thought fit: They were forbidden to wear clothes, or to cut their hair like their masters; and, which is indeed amazing, Solon prohibited them to love boys, as if that had been honourable: They were likewise debarred from anointing or perfuming themselves, and from worshipping certain deities: They were not allowed to be called by honourable names; and in most other respects were used like dogs. They stigmatized them at their pleasure, that is, branded them with letters in the forehead and elsewhere. However, Theseus's temple was allowed them as a sanctuary, whither, if they were exceedingly ill used, they might fly, and thereby oblige their owners to let them be transferred to another master. In this and many other respects the Athenian slaves were in a much better condition than those throughout the rest of Greece: they were permitted to get estates for themselves, giving a small premium to their masters, who were obliged to make them free if they could pay their ransom; they likewise obtained the same favour from the kindness of their masters, or for having rendered military services to the state. When they were made free, they were obliged to choose patrons; and had likewise the privilege of choosing a curator, who, in case their patrons injured them, was bound to defend them.

The general assembly of the people, which Solon made the dernier resort, was called the *Ecclesia*; and consisted of all the freemen of Athens, excepting such as were *atimoi* or infamous. The meetings of these assemblies were either ordinary or extraordinary. The ordinary were such as were appointed by law, the extraordinary such as necessity required. Of the first there were four in 35 days. In the first assembly they approved or rejected magistrates, heard proposals for the public good, and certain causes. In the second they received petitions, and heard every man's judgment on the matters that were before them. In the third they gave audience to foreign ambassadors. The fourth was employed altogether in affairs relating to the gods and their worship. The extraordinary meetings were appointed by the magistrates when occasion required, whereas to the ordinary assemblies the people came of their own accord. The first were held either in the market-place, in the Pnyx a place near the citadel, or in the theatre of Bacchus; as to the latter, the magistrates who appointed the extraordinary meeting appointed also the place where they should be held.

Attica.

184
People divided into different tribes, &c.

185
General assembly of the people

If any sudden tempest rose, or any earthquake happened, or any sign notoriously inauspicious appeared, the assembly was immediately adjourned, to prevent the people from apprehending unhappy consequences from their deliberations. But if the weather was fair and serene, and nothing happened out of the ordinary course of things, they proceeded to purify the place where the assembly was held, which was done by sprinkling it round with the blood of young pigs: then the crier made a solemn prayer for the prosperity of the republic, and that heaven would bestow a happy issue on their counsels and undertakings; he then pronounced a bitter execration against any who should in that assembly propound what might be disadvantageous to the state. These ceremonies being over, they proceeded to business.

There were several magistrates who had the overseeing and regulating these assemblies. These were, first, the Epitrate, or president of the assembly, who was chosen by lot out of the *Proedri*: his office was to give the signal for the people's voting. Next to him were the *Prytanes*, i. e. a committee of the senate, who of course were present on this occasion: by their order a programma, or scheme of the business to be proposed at the assembly, was previously set up in some public place, that every man might know what business to apply his thoughts to. The *Proedri* were nine in number, appointed by lots out of all the tribes to which the *Prytanes* did not belong: they had the right of proposing to the people what they were to deliberate upon, and their office ended with the assembly; there sat with them assessors, who were to take care that nothing they proposed was detrimental to the commonwealth. The first step to business was the crier's reading the decree of the senate wherein the assembly was to deliberate: when he had finished this, he made proclamation in these words; *Who of the men above 50 will make an oration?* When the old men had done speaking, the crier made proclamation again that any Athenian might then offer his sentiments, whom the law allowed so to do; that is, all such as were above 30 years old, and were not infamous. If such a one rose up to speak, the *Prytanes* interposed, and bid him be silent; and if he did not obey them, the lictors pulled him down by force. When the debates were over, the president permitted the people to vote; which they did by casting first beans, but in after-times pebbles, into certain vessels: these were counted, and then it was declared that the decree of the senate was either rejected or approved; after which, the *Prytanes* dismissed the assembly.

The senate was instituted by Solon to prevent the dangerous consequences of leaving the supreme power in the people. At the time of his institution, it was to consist of 400, 100 out of each tribe; it was increased to 500, when the tribes were augmented to 10; and when they came to 12, it was also swelled to 600. They were elected by lots after this manner: At a day appointed, towards the close of the year, the president of each tribe gave in a list of such persons belonging thereto, as were fit for and desired to appear for this dignity: these names were engraven on tablets of brass, and a number of beans equal to the number of the amount of them, among which were 100 white ones, put into a vessel; and then the names of the candidates and the beans were drawn one by one, and such as were

drawn by the white beans were received into the senate. After the senate was elected, they proceeded to appoint the officers who were to preside in the senate; these were the *Prytanes* before-mentioned, and they were elected thus: The names of the ten tribes were thrown into one vessel, and nine black beans and a white one into another vessel. Then the names of the tribes were drawn with the beans. The tribe to which the white bean answered, presided first; and the rest according to the order in which they were drawn.

The *Prytanes*, while the senate consisted of 500, were 50 in number. For the farther avoiding of confusion therefore, 10 of these presided a week, during which space they were called *Proedri*; and out of these an Epitrate or president was chosen, whose office lasted but one day, and by law no man could hold it more than once: the reason of this was, that he had in his custody the public seal, the keys of the citadel, and the charge of the exchequer. The reader must distinguish between the Epitates and *Proedri* last-mentioned, and those spoken of in the former paragraph, because, though their titles were the same, their office were perfectly distinct. The senate assembled by direction of the *Prytanes* once every day, excepting festivals, and sometimes oftener, in the senate-house, which was thence called *Prytaneum*.

When a member of the senate made a motion for a new law, it was immediately engraven on tablets, that the members when they came next might be prepared to speak to it. At the subsequent assembly the Epitates opened the matter, after which every senator that pleased delivered his sentiments: then any of the *Prytanes* drew up the decree, and repeated it aloud: after which they proceeded to vote, and if there was a majority of white beans, then it became *tesphissna*, and was afterwards propounded to the people: if they approved it, it became a law; otherwise it was of no force longer than the senate who decreed it subsisted. The power of the senate was very great: for they took the account of magistrates at the expiration of their offices; they directed the provisions made for poor citizens out of the public treasure; they had the superintendency of public prisons, and a power of punishing such as committed acts morally evil, though not prohibited by any law; they had the care likewise of the fleet; and besides all these they had many other branches of authority, which it is not necessary for us to mention. Before they took their seats, they were constrained to undergo a very strict examination, wherein the whole course of their lives was inquired into; and if the least slur on their reputation appeared, they were set aside. When this examination was over, they took an oath, whereby they bound themselves to promote in all their councils the public good, to advise nothing contrary to the laws, and to execute their functions exactly. The highest fine the senate could impose was 500 drachms: if they thought the offender deserved a heavier mulct, they then transmitted the cause to the *Thesmotheta*, who punished them as they thought fit. The senators, when their year was out, gave an account of their management to the people: but that they might have the less to do, they always punished such of their number as they found had offended, by expulsion; and in this they were mighty exact. Yet an expelled senator was notwithstanding eligible to any other office, the most

Laws how established, &c.

trivial

Atties. trivial omission being sufficient to occasion a dimission from the senatorial dignity; and therefore, when the tribes chose their senators, they also chose a certain number of subsidiaries, out of which, when a senator was expelled, another was substituted in his place. Each senator was allowed a drachm every day: for it was a constant rule with the Athenians, that the public ought to pay for every man's time; and therefore such of the poor Athenians as thought fit to demand it, had three oboli for going to the assembly. If during their administration any ships of war were built, the senators had crowns decreed them; but if not, they were forbid to sue for them.

Next to the senate was the court of *Areopagus*, for a description of which see that article.

The chief magistrates of Athens were Archons, and inferior to them there were many others; of whom it will be necessary to mention some. In the first place they had Nomophylaces, who were also styled *the eleven*, because they were so many in number, one chosen out of each tribe, and a clerk or secretary who made up the eleventh. Their duty it was to look to the execution of the laws: they had authority to seize robbers and other capital offenders; and if they confessed, to put them to death. Dr Potter thinks they resembled our sheriffs. The Phylarchi were the presidents of the Athenian tribes; but in time this became a military title. The Philobasilus was an officer in each tribe, who did the same things within his jurisdiction as the Basileus did with respect to the state. The Demarchi were the principal magistrates in wards. The Lexarchi were six in number, and were bound to take care that the people came duly to the assemblies; in their custody was the public register of the citizens names. They had under them *Toxotæ*, who were lieutenants or bailiffs; they were sometimes 1000 in number: these men were necessary; but, like most of their sort, were in a manner infamous, as may be gathered from the comedies of Aristophanes; they were generally Scythians, raw-boned, brawny fellows, ready to execute any thing they were commanded. The Nomothetæ were 1000 in number; their business was to watch over and inspect into the laws. There were two sorts of orators in the service of the state. Some were appointed to defend an old law, when a motion was made to repeal it; these had their fee from the state, but the same man was incapable of being elected twice. Besides these, there were 10 settled orators called *Rhetores*, elected by lot; their business was to plead public causes in the senate-house. For this they had their stated fees; and with respect to their qualifications, the laws run thus: "Let no one be a public orator who hath struck his parents, denied their maintenance, or shut them out of his doors; who hath refused to serve in the army; who hath thrown away his shield; who hath been addicted to lewd women, notoriously effeminate, or has run out his patrimony. If any man who has been guilty of these crimes dare to deliver an oration, let him be brought to trial upon the spot. Let an orator have children lawfully begotten, and an estate within Attica; if in his oration he talks impertinently, makes idle repetitions, affects an unbecoming raillery, digresses from the point in question, or, after the assembly is over, abuses the president, let the *Prædri* fine him 50 drachmæ; and if

that is not thought enough, let him be brought before the next assembly and fined again."

We shall conclude this draught of the Athenian government with an account of their courts of justice, which, exclusive of the *Areopagus*, were 10 in number; four had cognizance of criminal, and six of civil causes. These 10 courts were numbered with the 10 first letters of the alphabet, and were thence styled, *Alpha, Beta, Gamma, &c.* When an Athenian was at leisure to hear causes, he wrote his own name, that of his father, and the ward to which he belonged, upon a tablet; this he presented to the *Thesmothetæ*, who returned it again to him with another tablet, with the letter which fell to his lot; then he went to the crier of the court, who presented him a sceptre, and gave him admission. When the causes were over, every judge went and delivered his sceptre to the *Prytanes*, and received a stated fee for every cause that was tried. But as this was intended only to compensate their loss of time, so that there might be no appearance of covetousness, a man was forbid to sit in two courts on the same day. The first criminal court after the *Areopagus*, was that of the *Ephete*. It consisted of 51 members, all upwards of 51 years old. Draco gave it a very extensive jurisdiction; but Solon took away from them the power of judging in any other causes than those of manslaughter, accidental killing, and lying in wait to destroy: the Basileus entered all causes in this court. The second criminal court was called *Delphinium*, because it was held in the temple of Apollo Delphinus; it had cognizance of such murders as were confessed by the criminal, but at the same time justified under some pretence or other. The *Prytaneum* was the third criminal court. It held plea of such cases where death ensued from inanimate things: causes were heard here with the same solemnity as in other courts; and on judgment given, the thing, whatever it was, that had occasioned the death of a man, was thrown out of the territory of Athens. The last criminal court was styled *Phreatum*. It sat in a place not far from the sea-shore; and such persons were brought before this court, as had committed murders in their own country and fled to Attica: the proceedings of this court were so severe, that they did not permit the criminal to come on shore, but obliged him to plead his cause in his vessel; and if he was found guilty, he was committed to the mercy of the winds and seas.

Of the judicatures for hearing civil causes, the first was the *Parabaston*, so called, as some think, because in it no matter could be heard if the cause of action was above one drachm. The *Cainon*, or new court, was the second tribunal. The third was styled the court of *Lycus*, because it assembled in a temple dedicated to that hero, whose statue, represented with the face of a wolf, was set up in all courts of justice. The *Trigonon* was so called, because it was triangular in its form. The court *Metidius* derived its appellation from the architect who built it. The sixth and last court was called *Heliea*; it was by far the greatest, and is generally conceived to have derived its name from the judges sitting in the open air exposed to the sun. All the Athenians who were free citizens were allowed by law to sit in these courts as judges; but before they took their seats were sworn by Apollo Patrius, Ceres, and

and Jupiter the king, that they would decide all things righteously and according to law, where there was any law to guide them, and by the rules of natural equity, where there was none. The Helæatic court consisted at least of 50, but its usual number was 500, judges: when causes of very great consequence were to be tried, 1000 sat therein; and now and then the judges were increased to 1500, and even to 2000. There were many inferior courts in Athens for the decision of trivial causes; but of these there is no necessity of speaking, since we design no more than a succinct view of the Athenian republic, as it was settled by and in consequence of Solon's laws.

ATTICUS (Titus Pomponius), one of the most honourable men of ancient Rome. He understood the art of managing himself with such address, that, without leaving his state of neutrality, he preserved the esteem and affection of all parties. His strict friendship with Cicero did not hinder him from having great intimacy with Hortensius. The contests at Rome between Cinna's party and that of Marius induced him to go to Athens, where he continued for a long time. He was very fond of polite learning, and kept at his house several librarians and readers. He might have obtained the most considerable posts in the government; but chose rather not to meddle, because in the corruption and faction which then prevailed he could not discharge them according to the laws. He wrote Annals. He married his daughter to Agrippa; and attained to the age of 77.

ATTILA, king of the Huns, surnamed *the scourge of God*, lived in the 5th century. He may be ranked among the greatest conquerors, since there was scarcely any province in Europe which did not feel the weight of his victorious arms. See **HUNS**.

ATTIRE, in hunting, signifies the head or horns of a deer. The attire of a stag, if perfect, consists of bur, pearls, beam, gutters, antler, fur-antler, royal, fur-royal, and crotches; of a buck, of the bur, beam, brow-antler, advancer, palm, and spellers.

ATTITUDE, in painting and sculpture, the gesture of a figure or statue; or it is such a disposition of their parts as serves to express the action and sentiments of the person represented.

ATTLEBURY, a town in the county of Norfolk in England. E. Long. o. 40. N. Lat. 52. 23.

ATTOLLENS, in anatomy, an appellation given to several muscles otherwise called *levatoris* and *elevatoris*. See **ANATOMY**, *Table of the muscles*.

ATTORNEY at Law answers to the procurator, or proctor, of the civilians and canonists. And he is one who is put in the place, stead, or turn of another, to manage his matters of law. Formerly every suitor was obliged to appear in person, to prosecute or defend his suit, (according to the old Gothic constitution), unless by special licence under the king's letters patent. This is still the law in criminal cases. And an idiot cannot to this day appear by attorney, but in person; for he hath not discretion to enable him to appoint a proper substitute: and upon his being brought before the court in so defenceless a condition, the judges are bound to take care of his interests, and they shall admit the best plea in his behalf that any one present can suggest. But as, in the Roman law, "*cum olim in usu fuisset, alterius nomine agi non posse, sed, quia hoc non minimam*

incommoditatem habebat, ceperunt homines per procuratores litigare;" so, with us, on the same principle of convenience, it is now permitted in general, by divers ancient statutes, whereof the first is statute West. 2. c. 10. that attorneys may be made to prosecute or defend any action in the absence of the parties to the suit. These attorneys are now formed into a regular corps; they are admitted to the execution of their office by the superior courts of Westminster-hall; and are in all points officers of the respective courts in which they are admitted: and as they have many privileges on account of their attendance there, so they are peculiarly subject to the censure and animadversion of the judges. No man can practise as an attorney in any of those courts, but such as is admitted and sworn an attorney of that particular court: an attorney of the court of king's bench cannot practise in the court of common pleas; nor *vice versa*. To practise in the court of chancery, it is also necessary to be admitted a solicitor therein: and by the statute 22 Geo. II. c. 46. no person shall act as an attorney at the court of quarter-sessions, but such as has been regularly admitted in some former court of record. So early as the statute 4 Hen. IV. c. 18. it was enacted, that attorneys should be examined by the judges, and none admitted but such as were virtuous, learned, and sworn to do their duty. And many subsequent statutes have laid them under farther regulations.

ATTORNEY General, is a great officer under the king, made by letters patent. It is his place to exhibit informations, and prosecute for the crown, in matters criminal; and to file bills in the exchequer, for any thing concerning the king in inheritance or profits; and others may bring bills against the king's attorney. His proper place in court, upon any special matters of a criminal nature, wherein his attendance is required, is under the judges on the left hand of the clerk of the crown: but this is only upon solemn and extraordinary occasions; for usually he does not sit there, but within the bar in the face of the court.

ATTOURNMENT, or **ATTORNNMENT**, in law, a transfer from one lord to another of the homage and service a tenant makes; or that acknowledgment of duty to a new lord.

ATTRACTION, in natural philosophy, a general term used to denote the cause by which bodies tend towards each other, and cohere till separated by some other power. Hence there are four different species of attraction mentioned by philosophers, *viz.* of **COHESION**, **ELECTRICITY**, **MAGNETISM**, and **GRAVITATION**. See those articles.

Concerning the cause of attraction there have been many disputes; the most general opinion at present is, that it is a property originally impressed upon all kinds of matter by the Creator himself, and consequently that it has no natural cause. But others ridicule this account of the matter; affirming, that as the tendency of the different parts of matter towards one another is merely a natural phenomenon, we ought to seek for a natural cause of that phenomenon, it being equally unphilosophical to resolve attraction into a quality of matter, as to solve the phenomena of thunder, whirlwinds, hurricanes, &c. by saying they are qualities of the air.

Des Cartes accounted for attraction by his *materia g X subtilis*;

Attorney
||
Attraction.

Attraction *subtilis*; but as he was at so little pains to accommodate his system to the phenomena of nature, it very soon fell into dispute, and even the existence of any kind of matter more subtle than the common air we breathe has been positively denied. This was running to the opposite extreme, and such an hypothesis was no less obviously false than that of Des Cartes. Hence Sir Isaac Newton himself was obliged to have recourse to the very same hypothesis with Des Cartes, and to suppose that there might be in nature a very subtle and invisible kind of fluid which he called *Ether**, that pervaded the whole creation, and was the cause of the different kinds of attraction we observe.

* See *Ether*.

This supposition of Sir Isaac's hath subjected him to no little censure from inferior geniuses; who without his abilities, or attention to the phenomena of nature, have determined that his admitting the existence of an ethereal fluid was only out of complaisance to the age he lived in. But he himself says no such thing, nor by his manner of expressing himself does he give us any room to think that this supposition proceeded from any thing else than a contemplation of nature: besides, the complying in this manner with an opinion known to be erroneous, would be unworthy of any philosopher, much more of Sir Isaac Newton. But experience has now made it manifest, that there is a kind of matter much more subtle than the common air, and which possesses every quality that Sir Isaac could wish for in his ether. The fluid we mean is that of electricity. Indeed, notwithstanding the different species of attraction abovementioned, it is far from being improbable, that, some time or other, they may be all solved from the action of the electric fluid: certain it is, that no known substance seems so well calculated for being a general cause of attraction as this fluid, whether we consider its omnipresence as surrounding and pervading the whole earth and atmosphere, or the greatness of its power in overcoming every obstacle; and such powers are now allowed by philosophers in general to the electric fluid, that it appears hardly possible to avoid either curtailing those already assigned to it, or allowing it a larger if not an universal sphere of action*.

* See *Atmosphere, Electricity, &c.*

Electric ATTRACTIONS. See **CHEMISTRY**, n^o 15, 27, 64.

ATTRIBUTE, in a general sense, that which agrees with some person or thing; or a quality determining something to be after a certain manner. Thus understanding is an attribute of mind, and extension an attribute of body. That attribute which the mind conceives as the foundation of all the rest, is called its *essential attribute*: thus extension is by some, and solidity by others, esteemed the essential attributes of body or matter.

ATTRIBUTES, in theology, the several qualities or perfections of the Divine nature.

ATTRIBUTES, in logic, are the predicates of any subject, or what may be affirmed or denied of any thing.

ATTRIBUTES, in painting and sculpture, are symbols added to several figures, to intimate their particular office and character. Thus the eagle is an attribute of Jupiter; a peacock, of Juno; a caduceus, of Mercury; a club, of Hercules; and a palm, of Victory.

ATTRITION, the rubbing or striking of bodies one against another, so as to throw off some of their

superficial particles.

ATURÉ, an ancient town in the district of Novempopulana in Aquitania, on the river Aturus; now Aire in Gascony, on the Adour. E. Long. 0. 3. N. Lat. 43. 40.

AVA, a kingdom Asia, in the peninsula beyond the Ganges. The king is very powerful, his dominions being bounded by Mogulistan on the west, Siam on the south, Tonquin and Cochinchina on the east, and by Tibet and China on the north. Several large rivers run through this country, which annually overflow their banks like the Nile, and thus render it extremely fertile. Here are mines of lead and copper, together with some of gold and silver, besides large quantities of the finest oriental rubies, sapphires, emeralds, &c.

Ava, the metropolis of the kingdom of the same name, is situated in E. Long. 96. 30. N. Lat. 21. 0. It is pretty large; the houses built with timber or bamboo canes, with thatched roofs, and floors made of teak plank or split bamboo. The streets are very straight, with rows of trees planted on each side. The king's palace is an exact quadrangle, each side of which is 800 paces, and is surrounded with a brick wall; but the palace itself is of stone. It has four gates; the golden gate, through which all ambassadors enter; the gate of justice, through which the people bring petitions, accusations, or complaints; the gate of grace, through which those pass who have received any favours, or have been acquitted of crimes laid to their charge; and the gate of state, through which his majesty himself passes when he shews himself to the people.

AVADOUTAS, a sect of Indian bramins, who in austerity surpass all the rest. The other sects retain earthen vessels for holding their provisions, and a stick to lean on; but none of these are used by the Avadoutas; they only cover their nakedness with a piece of cloth; and some of them lay even that aside, and go stark naked, befouling their bodies with cow-dung. When hungry, some go into houses, and without speaking, hold out their hand; eating on the spot whatever is given them. Others retire to the sides of holy rivers, and there expect the peasants to bring them provisions, which they generally do very liberally.

AVAIL OF MARRIAGE, in Scots law, that casualty in ward-holding, by which the superior was intitled to a certain sum from his vassal, upon his attaining the age of puberty, as the value or avail of his tocher.

AVALON, a small but ancient city of Burgundy in France, about 500 paces long, and 300 broad. E. Long. 3. 5. N. Lat. 47. 38.

AVANIA, in the Turkish legislature, a fine for crimes, and, on deaths, paid to the governor of the place. In the places wherein several nations live together under a Turkish governor, he takes this profitable method of punishing all crimes among the Christians, or Jews, unless it be the murder of a Turk.

AVARICUM, an ancient town of the Bituriges in Gallia Celtica, situated on the rivulet Avara, in a very fertile soil, (Cæsar). Now Bourges in Berry. E. Long. 2. 30. N. Lat. 47. 10.

AVAST, in the sea-language, a term requiring to stop, or to stay.

Attritio
Avail.

vanchers
AUBACHERS, among hunters, the second
Audrey. branches of a deer's horns.

AUBAGNE, a town of Provence in France, situated on the river Veauve, on the road from Marfelles to Toulon. The flats sometimes hold their fessions at this place. E. Long. 5. 52. N. Lat. 43. 17.

AUBANE, in the customs of France, a right vested in the king of being heir to a foreigner that dies within his dominions.

By this right the French king claims the inheritance of all foreigners that die within his dominions, notwithstanding of any testament the deceased could make. An ambassador is not subject to the right of aubane; and the Swifs, Savoyards, Scots, and Portuguese, are also exempted, being deemed natives and regnicoles.

AUBENAS, a town of Languedoc in France, situated on the river Ardesche, at the foot of the mountains called the *Cevennes*. E. Long. 4. 32. N. Lat. 44. 40.

AUBENTON, a town of Picardy in France, situated on the river Aub. E. Long. 4. 25. N. Lat. 49. 51.

AUBETERRE, a town of France in the Anguinois, on the river Dronne. E. Long. 0. 10. N. Lat. 45. 15.

AUBIGNE, a town of Berry in France, situated on the river Verre, in a flat agreeable country. It is surrounded with high strong walls, wide ditches, and high counterescarpments. The castle is within the town, and is very handsome. E. Long. 2. 20. N. Lat. 47. 29.

AUBIN DU COMIER, a town of Brittany in France. W. Long. 1. 15. N. Lat. 48. 15.

AUBIN, in horsemanship, a broken kind of gait, between an amble and a gallop, accounted a defect.

AUBONNE, a town of Switzerland, in the canton of Beru. E. Long. 5. 54. N. Lat. 48. 30. It is situated near a river of the same name, seven miles north of the lake of Geneva, upon an eminence which has a gentle declivity, at the foot of which runs the river with an impetuous torrent. The town is built in the form of an amphitheatre; on the upper part of which stands a very handsome castle with a fine court, and a portico supported by pillars of a single stone each; above there is a covered gallery that runs round the court; and as the castle stands high, there is a most delightful prospect, not only of the town and neighbouring fields, but of the whole lake of Geneva and the land that surrounds it. At Thonen, in Savoy on the other side of the lake, is a tower covered with tin, which makes a glittering appearance when the sun is in a certain position; and the castle of Aubonne has likewise a tower of the same kind, which at certain hours makes a similar appearance to the Savoyards. The balliage of Aubonne contains several villages, which are mostly at the foot of the mountain Jura. In one part of this mountain there is a very deep cave, wherein those that go down find a natural and perpetual ice-house. At the bottom is heard a great noise like that of a subterranean river, which is supposed to be that of the river Aubonne, because it first appears, with several sources, about 100 paces from the foot of that mountain.

AUBREY, (John), a famous English antiquary, descended from an ancient family in Wiltshire, was born in 1626. He made the history and antiquities of England his peculiar study and delight; and con-

tributed considerable assistance to the famous *Monasticon Anglicanum*. He succeeded to several good estates; but law-suits and other misfortunes consumed them all, so that he was reduced to absolute want. In this extremity he found a valuable benefactress in the lady Long of Draycot in Wilts, who gave him an apartment in her house, and supported him to his death, which happened about the year 1700. He was a man of capacity, learning, and application, a good Latin poet, an excellent naturalist, but somewhat credulous, and tainted with superstition. He left many works behind him. He wrote, 1. *Miscellanies*. 2. *A Perambulation of the county of Surry*, in five volumes, octavo. 3. *The Life of Mr Hobbes of Malmbsury*. 4. *Monumenta Britannica*, or a Discourse concerning Stonehenge, and Roll-Rich stones in Oxfordshire. 5. *Architectonica Sacra*; and several other works still in manuscript.

AUBURN, a market-town in Wiltshire in England. W. Long. 1. 20. N. Lat. 53. 20.

AUBUSSON, a small town of France, in the province of La Marche, and the government of the Lyonnais. Its situation is very irregular, on the river Creuse, in a bottom surrounded with rocks and mountains. A manufacture of tapestry is carried on here, by which the town is rendered very populous. E. Long. 2. 15. N. Lat. 45. 58.

AUCAUGREL, the capital of the kingdom of Adel in Africa, seated on a mountain. E. Long. 44. 25. N. Lat. 9. 10.

AUCH, a city of France, the capital of the county of Armagnac, and the metropolis of all Gascony. The archbishop assumes the title of primate of Aquitaine, and the cathedral is one of the finest in all France. The city stands on the declivity of a mountain near the river Gors. E. Long. 0. 40. N. Lat. 43. 40.

AUCTION, a kind of public sale, very much in use for household goods, books, plate, &c. By this method of sale the highest bidder is always the buyer. This was originally a kind of sale among the ancient Romans, performed by the public crier *sub hasta*, i. e. under a spear stuck up on that occasion, and by some magistrate, who made good the sale by delivery of the goods.

AUDEUS, the chief of the Audeans, obtained the name of an heretic, and the punishment of banishment, for celebrating Easter in the manner of the Jews, and attributing an human form to the Deity. He died in the country of the Goths, about the year 370.

AUDEANISM, the same with anthropomorphism. See ANTHROPOMORPHITES.

AUDIENCE given to ambassadors, a ceremony observed in courts at the admission of ambassadors or public ministers to a hearing.

In England, audience is given to ambassadors in the presence-chamber; to envoys and residents, in a gallery, closet, or in any place where the king happens to be. Upon being admitted, as is the custom of all courts, they make three bows; after which they cover and sit down; but not before the king is covered and sat down, and has given them the sign to put on their hats. When the king does not care to have them covered, and sit, he himself stands uncovered; which is taken as a slight. At Constantinople, ministers usually

Audience
||
Auditory.Auditory
||
Aves.* See Aka-
tomy,
no 405.

have audience of the prime vizier.

AUDIENCE is also the name of a court of justice established in the West-Indies by the Spaniards, answering in effect to the parliament in France. These courts take in several provinces, called also *audiencias* from the names of the tribunal to which they belong.

AUDIENCE is also the name of an ecclesiastical court held by the archbishop of Canterbury, wherein differences upon elections, consecrations, institutions, marriages, &c. are heard.

AUDIENDO & TERMINANDO, a writ, or rather a commission to certain persons, when any insurrection or great riot is committed in any place, for the appealing and punishment thereof.

AUDIENTES, or **AUDITORES**, in church-history, an order of catechumens; consisting of those newly instructed in the mysteries of the Christian religion, and not yet admitted to baptism.

AUDIT, a regular hearing and examination of an account by some proper officers, appointed for that purpose.

AUDITOR, in a general sense, a hearer, or one who listens and attends to any thing.

AUDITOR, according to our law, is an officer of the king, or some other great person, who, by examining yearly the accounts of the under-officers, makes up a general book, with the difference between their receipts and charges, and their allowances to allocations.

AUDITOR of the Receipts, is an officer of the exchequer who files the tellers bills, makes an entry of them, and gives the lord-treasurer a certificate of the money received the week before. He also makes debentures to every teller, before they receive any money, and takes their accounts. He keeps the black book of receipts, and the treasurer's key of the treasury, and sees every teller's money locked up in the new treasury.

AUDITORS of the Revenue, or of the exchequer, officers who take the accounts of those who collect the revenues and taxes raised by parliament, and take the accounts of the sheriffs, excheators, collectors, tenants, and customers, and set them down in a book, and perfect them.

AUDITORS of the Prest and Imprest, are officers of the exchequer, who take and make up the accounts of Ireland, Berwick, the mint, and of any money impressed to any man for the king's service.

AUDITORS Collegiate, Conventual, &c. officers formerly appointed in colleges, &c. to examine and pass their accounts.

AUDITORES. See **AUDIENTES**.

AUDITORIUM, in the ancient churches, was that part of the church where the audientes stood to hear and be instructed.

The auditorium was that part now called *navis ecclesiæ* †. In the primitive times, the church was so strict in keeping the people together in that place, that the person who went from thence in sermon-time was ordered by the council of Carthage to be excommunicated.

AUDITORY, something relating to the sense of hearing.

AUDITORY, or **AUDIENCE**, an assembly of people who attend to hear a person that speaks in public.

AUDITORY is also used for the bench whereon a ma-

gistrate or judge hears causes.

AUDITORY, in ancient churches. See **AUDITORIUM**.

AUDITORY Passage, (*meatus auditorius*), in anatomy; the entrance of the ear *.

AUDITORY nerves. See **ANATOMY**, n° 400, b.

AVEIRO, a considerable city of Portugal, seated near the head of a small gulf formed by the tide at the mouth of the river Vouga. This river forms a small haven with a bar, over which vessels may pass that do not draw above eight or nine feet water. The city stands in a long plain, well watered, and very fertile. This plain is nine miles broad, from Porto to Coimbra; and is bounded on the east by a chain of mountains called *Sara d'Alcoba*, which reach from the one town to the other. Near this city there is salt made in sufficient quantity to serve two or three provinces. Here is a remarkable nunnery, where none are received but the daughters of the ancient nobility. The inhabitants of Aveiro have the singular privilege, that no stranger whatever can pass a night there without leave of the magistrate. W. Long, 9. 8. N. Lat. 40. 30.

AVELLANE, in heraldry, a cross, the quarters of which somewhat resemble a filbert-nut. Sylvanus Morgan says, that it is the cross which ensigns the mound of authority, or the sovereign's globe.

AVELLINO, a city of Italy, in the kingdom of Naples, with a bishop's see. It was almost ruined by an earthquake in 1694. E. Long, 15. 13. N. Lat. 40. 53.

AVE-MARIA, the angel Gabriel's salutation of the Virgin Mary, when he brought her the tidings of the incarnation.—It is become a prayer or form of devotion in the Romish church. Their chaplets and rosaries are divided into so many ave-marias, and so many pater-nosters, to which the Papists ascribe a wonderful efficacy.

AVENA, OATS, a genus of the digynia order, belonging to the triandria class of plants. Of this genus Linnæus enumerates 16 species, of which none deserve notice, except that which is commonly known and cultivated for grain; for a particular account of the culture of which, see **AGRICULTURE**, n° 116, 117.—Oats are an article of the *Materia Medica*. Gruels made from them have a kind of soft mucilaginous quality; by which they obtund acrimonious humours, and prove useful in inflammatory diseases, coughs, hoarseness, and exulcerations of the fauces.

AVENACEOUS, something belonging to or partaking of the nature of oats.

AVENAGE, in law, a certain quantity of oats paid by a tenant to a landlord, instead of rent or some other duties.

AVENCHE, an ancient city of Switzerland, in the canton of Bern, formerly the capital of all Switzerland, but now shews its former greatness only by its ruins. E. Long, 7. 7. N. Lat. 46. 50.

AVENES, a small but strong town in French Flanders, in the county of Hainaut, seated on the river Thespes. It contains about 2500 inhabitants; but the houses are wretchedly built, and the streets irregular. It was fortified by M. Vauban in a strong regular manner. About this place are a prodigious number of white stones proper for building, and used by sculptors for statues: they are known by the name of *Stones of Avenes*.

Avencia. E. Long. 3. 40. N. Lat. 50. 10.

AVENIO, an ancient town of the Cavares, and one of the most opulent in Gallia Narbonensis; now *Avignon*, in Provence. See AVIGNON.

AVENOR, an officer belonging to the king's stables, who provides oats for the horses. He acts by warrant from the master of the horse.

AVENS, in botany. See CARIOPHILLUS.

AVENTINE (John), author of the *Annals of Bavaria*, was born of mean parentage, in the year 1466, at Abensperg in the country just named. He studied first at Ingolstadt, and afterwards in the university of Paris. In 1503, he privately taught eloquence and poetry at Vienna; and in 1507, he publicly taught Greek at Cracow in Poland. In 1509, he read lectures on some of Cicero's pieces at Ingolstadt; and in 1512, was appointed to be preceptor to prince Lewis and prince Ernest, sons of Albert the Wise, duke of Bavaria; and travelled with the latter of those two princes. After this he undertook to write the *Annals of Bavaria*, being encouraged by the dukes of that name, who settled a pension upon him, and gave him hopes that they would defray the charges of the book. This work, which gained its author great reputation, was first published in 1554, by Jerome Zieglerus, professor of poetry in the university of Ingolstadt; and afterwards at Basil in 1580, by Nicholas Cifer. An affront which Aventine received in the year 1529, stuck by him all the rest of his life: he was forcibly taken out of his sister's house at Abensperg, and hurried to a jail; the true cause of which violence was never known: but it would probably have been carried to a much greater length, had not the Duke of Bavaria interposed, and taken this learned man into his protection. Mr Bayle remarks, that the incurable melancholy which from this time possessed Aventine, was so far from determining him to lead a life of celibacy, as he had done till he was 64, that it induced him perhaps to think of marrying. The violence of his new passion was not however so great, but that it suffered him to advise with two of his friends, and consult certain passages of the Bible relative to marriage. The result was, that it was best for him to marry; and having already lost too much time, considering his age, he took the first woman he met with, who happened to be his own maid, ill-tempered, ugly, and extremely poor. He died the 9th of January, 1534, aged 68; leaving one daughter, who was then but two months old. He had a son, who died before.

AVENTINUS MOUNTS, one of the seven hills on which ancient Rome stood. The origin of the name *Aventinus* is uncertain: but this hill was also called *Marcus*, from Murcia the goddess of sloth, who had a little chapel there; and *Collis Dianæ*, from the temple of Diana; likewise *Remonius*, from Remus who wanted to build the city and who was buried there. It was taken within the compass of the city by Ancus Marcius. To the east it had the city walls; to the south, the Campus Figulinus; to the west, the Tiber; and to the north, Mons Palatinus, in circuit two miles and a quarter.

AVENCHURE, in law-books, means a mischance causing the death of a person without felony.

AVENUE, in gardening, a walk planted on each side with trees, and leading to an house, garden-gate, wood, &c. and generally terminated by some distant object.

All avenues that lead to a house ought to be at least as wide as the whole front of the house, if wider they are better still; and avenues to woods and prospects ought not to be less than 60 feet wide. The trees should not be planted nearer to one another than 35 feet, especially if they are trees of a spreading kind; and the same ought to be the distance, if they are for a regular grove.

The trees most proper for avenues with us, are the English elm, the lime, the horse-chestnut, the common chestnut, the beech, and the abele. The English elm will do in all grounds, except such as are very wet and shallow; and this is preferred to all other trees, because it will bear cutting, heading, or lopping in any manner, better than most others. The rough or smooth Dutch elm is approved by some, because of its quick growth; this is a tree which will bear removing very well, it is also green almost as soon as any plant whatever in spring, and continues so as long as any, and it makes an incomparable hedge, and is preferable to all other trees for lofty espaliers. The lime is valued for its natural growth, and fine shade. The horse chestnut is proper for all places that are not too much exposed to rough winds. The common chestnut will do very well in a good soil; and rises to a considerable height, when planted somewhat close; though, when it stands single, it is rather inclined to spread than to grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild state; but it is less to be chosen for avenues than the before-mentioned, because it does not bear transplanting well, but is very subject to miscarry. Lastly, the abele is fit for any soil, and is the quickest grower of any forest-tree. It seldom fails in transplanting; and succeeds very well in wet soils, in which the others are apt to fail. The oak is but little used for avenues, because of its slow growth.

The old method of planting avenues was with regular rows of trees, and this has been always kept to till of late: but we have now a much more magnificent way of planting avenues; this is by setting the trees in clumps, or platoons, making the opening much wider than before, and placing the clumps of trees at about 300 feet distant from one another. In each of these clumps there should be planted either seven or nine trees; but it is to be observed, that this is only to be practised where the avenue is to be of some considerable length, for in short walks this will not appear so lightly as single rows of trees. The avenues made by clumps are fittest of all for parks. The trees in each clump should be planted about 30 feet asunder; and a trench should be thrown up round the whole clump, to prevent the deer from coming to the trees to bark them.

AVENZOAR, ABU MERWAN ABDALMALEK BEN ZOHK, an eminent Arabian physician, flourished about the end of the eleventh or the beginning of the twelfth century. He was of noble descent, and born at Sevil, the capital of Andalusia, where he exercised his profession with great reputation. His grandfather and father were both physicians. The large estate he inherited from his ancestors, set him above practising altogether for gain: he therefore took no fees from the poor, or from artificers, though he refused not the presents of princes and great men. His liberality was extended even to his enemies; for which

Avenue,
Avenzoar.

Avenzoar,
Average.

reason he used to say, that they hated him not for any fault of his, but rather out of envy. Dr Freind writes, that he lived to the age of 135; that he began to practise at 40, or (as others say) at 20; and had the advantage of a longer experience than almost any one ever had, for he enjoyed perfect health to his last hour. He left a son, known also by the name of *Ebn Zohr*, who followed his father's profession, was in great favour with Al Manzur emperor of Morocco, and wrote several treatises of physic.

Avenzoar was cotemporary with Averroes, who, according to Leo Africanus, heard the lectures of the former, and learned physic of him; this seems the more probable, because Averroes more than once gives Avenzoar a very high and deserved encomium, calling him *admirable, glorious, the treasure of all knowledge, and the most supreme in physic from the time of Galen to his own*. Avenzoar, notwithstanding, is by the generality of writers reckoned an empiric: But Dr Freind observes, that this character suits him less than any of the rest of the Arabians. "He was bred," continues that author, "in a physical family, his father and grandfather being both practitioners, whom he always remembers with great gratitude and honour. "We have his own testimony that he had a regular education; and that he not only learned what properly belongs to a physician, but, out of a great desire of knowledge, every thing besides which relates to pharmacy or surgery." Dr Freind afterwards observes, "that he was averse to quackery, and rejects the idle superstitions of astrologers; and throughout all his work professes himself so much of the dogmatical or rational sect, which was directly opposite to the empirical, that he has a great deal of reasoning about the causes and symptoms of distempers; and as in his theory he chiefly, if not only, follows Galen, so he quotes him upon all occasions, oftener than the rest of the Arabians do. Notwithstanding he is so Galenical, there are several particulars in him which seldom or never occur in other authors; and there are some cases which he relates from his own experience, which are worth perusing." He wrote a book intitled, *Tayassir fi'l-madd'wat wa'l-tadbir*, i. e. "The method of preparing medicines and diet," which is much esteemed. This work was translated into Hebrew, in the year of Christ 1280, and thence into Latin by Paravicinus, whose version has had several editions. The author added a supplement to it, under the title of *ʿAmé, or a Collection*. He also wrote a treatise *Fi'l-dawiyat wa'l-ghubdiyat*, i. e. "Of Medicines and Food;" wherein he treats of their qualities.

AVERAGE, in commerce, signifies the accidents and misfortunes which happen to ships and their cargoes, from the time of their loading and sailing, to their return and unloading; and is divided into three kinds. 1. The simple or particular average, which consists in the extraordinary expences incurred for the ship alone, or for the merchandizes alone. Such is the loss of anchors, masts, and rigging, occasioned by the common accidents at sea; the damages which happen to merchants by storm, prize, shipwreck, wet, or rotting; all which must be borne and paid by the thing which suffered the damage. 2. The large and common average, being those expences incurred, and damages

sustained, for the common good and security both of the merchandizes and vessels, consequently to be borne by the ship and cargo, and to be regulated upon the whole. Of this number are the goods or money given for the ransom of the ship and cargo, things thrown overboard for the safety of the ship, the expences of unloading for entering into a river or harbour, and the provisions and hire of the sailors when the ship is put under an embargo. 3. The small averages, which are the expences for towing and piloting the ship out of or into harbours, creeks, or rivers, one third of which must be charged to the ship, and two thirds to the cargo.

AVERAGE is more particularly used for a certain contribution that merchants make proportionably to their losses, who have had their goods cast into the sea in the time of a tempest. It also signifies a small duty which those merchants, who send goods in another man's ship, pay to the master for his care of them over and above the freight. Hence it is expressed in the bills of lading, paying so much freight for the said goods, with primage and average accustomed.

AVERDUPOIS. See AVOIRDUPOIS.

AVERNUS, a lake of Campania in Italy, near Baie, famous among the ancients for its poisonous qualities. The following is the description given of it by Strabo. "Next to Baize lies the Lucrine bay, and within it the lake Avernus. It was here that Homer had described Ulysses as conversing with Tiresias's ghost; for here they said was the oracle sacred to the shades, which Ulysses came and consulted concerning his return. The Avernus is a deep darksome lake, with a narrow entry from the outer bay; it is surrounded with steep banks that hang threatening over it; and is only accessible by the narrow passage thro' which you fall in. These banks were anciently quite overgrown with a wild wood, impenetrable to the human foot. Its gloomy shade impressed an awful superstition upon the minds of the beholders; whence it was reputed the habitation of the Cimmerians who dwell in perpetual night. Whoever sailed thither, first did sacrifice; and endeavoured to propitiate the infernal powers, with the assistance of some priests who attended upon the place, and directed the mystic performance. Within, a fountain of pure water broke out just over the sea; but nobody ever believed it, stating it to be a vein of the river Styx; somewhere near this fountain was the oracle; and the hot waters frequent in those parts made them think they were branches of the burning Phlegethon." The communication with the Lucrine lake is still to be distinguished, altho' filled up with earth; the distance between the two is but a few paces. The poisonous effluvia from this lake were said to be so strong, that they proved fatal to birds endeavouring to fly over it; but after grubbing up the wood, and building round it, no noxious effects were felt. Virgil ascribes the poisonous exhalation not to the lake itself, but to the cavern near it, which was called *Avernus, or Cave of the Sibyl*, and through which the poets feigned a descent to hell. Hence the proper name of the lake is *Lacus Avernus*, the lake near the cavern, as it is called by some ancient authors. It is now called *Averno*; is about two miles long, and one broad; and so far is it now from having any qualities noxious to birds, that many swim upon it. A little to the west

Average
Avernus

is the cave of the sibyl; but its noxious qualities seem also to be lost. There are also some old walls standing, which some suppose to have been a temple of Apollo, and others of Pluto. Among the ancients all the places which emitted poisonous exhalations were called *Averni*.

AVERRHOA, in botany, a genus of the decandria order, belonging to the pentagynia class of plants. Of this genus there are three species, all natives of India, but possessing no remarkable quality.

AVERROES, one of the most subtle philosophers that ever appeared among the Arabians, flourished at the end of the 11th and beginning of the 12th century. He was the son of the high-priest and chief judge of Corduba in Spain: he was educated in the university of Morocco; and studied natural philosophy, medicine, mathematics, law, and divinity. After the death of his father, he enjoyed his posts; but, notwithstanding his being exceeding rich, his liberality to men of letters in necessity, whether they were his friends or his enemies, made him always in debt. He was afterwards stripped of all his posts, and thrown into prison, for heresy; but the oppressions of the judge who succeeded him, caused him to be restored to his former employments.

He died at Morocco in the year 1206. He was excessively fat, though he eat but once a-day. He spent all his nights in the study of philosophy; and when he was fatigued, amused himself with reading poetry or history. He was never seen to play at any game, or to partake in any diversion. He was extremely fond of Aristotle's works, and wrote commentaries on them; whence he was styled *The commentator*, by way of eminence. He likewise wrote a work on the whole art of physic, and many amorous verses; but when he grew old, he threw these last into the fire. His other poems are lost, except a small piece, in which he says, "that when he was young, he acted against his reason; but that, when he was in years, he followed its dictates:" upon which he utters this wish; "Would to God I had been born old, and that in my youth I had been in a state of perfection!" As to religion, his opinions were, that Christianity is absurd; Judaism, the religion of children; Mahometanism, the religion of swine.

AVERROISTS, a sect of peripatetic philosophers, who appeared in Italy some time before the restoration of learning, and attacked the immortality of the soul. They took their denomination from Averroes, the celebrated interpreter of Aristotle*, from whom they borrowed their distinguishing doctrine.

The Averroists, who held the soul was mortal, according to reason or philosophy, yet pretended to submit to the Christian theology, which declares it immortal. But the distinction was held suspicious; and this divorce of faith from reason was rejected by the doctors of that time, and condemned by the last council of the Lateran under Leo X.

AVERRUNCI (DEI); certain gods, whose business it was, according to the Pagan theology, to avert misfortunes. Apollo and Hercules were of the number of these gods, among the Greeks; and Castor and Pollux, among the Romans.

AVERSA, a town of Italy in the kingdom of Naples, with a bishop's see. It is situated in a very fine plain, in E. Long. 14. 20. N. Lat. 41. 0.

AVERSION, according to Lord Kaimes, is opposed

to *affection**, and not to *desire*, as it commonly is. We have an affection to one person; we have an aversion to another: the former disposes us to do good to its object, the latter to do ill.

AVES, one of the Carribee islands, 451 miles south of Porto Rico, with a good harbour for careening of ships. It is so called from the great number of birds that frequent it. There is another of the same name lying to the northward of this, in N. Lat. 15. 0.; and a third near the eastern coast of Newfoundland, in N. Lat. 50. 5.

AVES, the name of Linnæus's second class of animals. See Zoology, n° 8.

AVESBURY, (Robert), an English historian, of whom little more is known, than that he was keeper of the registry of the court of Canterbury in the reign of Edward III. and consequently that he lived in the 14th century. He wrote, *Memorabilia gesta magnifici regis Angliæ domini Edwardi tertii post conquestum, procerumque; tactis primitus quibusdam gestis de tempore patris sui domini Edwardi secundi, que in regnis Angliæ, Scotiæ, et Franciæ, ac in Aquitania et Britannia, non humana sed Dei potentia, contigerunt, per Robertum de Avesbury*. This history ends with the battle of Poitiers, about the year 1356. It continued in manuscript till the year 1720, when it was printed by the industrious Thomas Hearne at Oxford, from a manuscript belonging to Sir Thomas Scabright. It is now become very scarce.

AUGE, a territory of Normandy in France, which gives title to a viscount. It extends from Falaise and Argenton as far as the sea, between the rivers Dives, Vie, and Touques. The arable land is stiff, and produces but little good corn: but they sow fainoin, which succeeds so well that they have five good crops successively: they likewise sow flax and hemp; and have a vast quantity of apples, with which they made cyder. Horses are bred here in great numbers; and the inhabitants fatten the oxen which come from Poitou and Brittany.

AUGEAS, his fabulous history, was king of Elis, and particularly famed for his stable, which contained 3000 oxen, and had not been cleaned for 30 years. Hercules was desired to clear away the filth from this stable in one day; and Augeas promised, if he performed it, to give him a tenth part of the cattle. This task Hercules is said to have performed by turning the course of the river Alpheus through the stable; when Augeas refusing to stand by his engagement, Hercules slew him with his arrows, and gave his kingdom to Phyleus his son, who had shewn an abhorrence of his father's inhumanity.

AUGMENT, in grammar, an accident of certain tenses of Greek verbs, being either the prefixing of a syllable, or an increase of the quantity of the initial vowels.

AUGMENTATION, in a general sense, is the act of adding or joining something to another with a design to render it large.

AUGMENTATION is also used for the additament or thing added.

AUGMENTATION was also the name of a court erected 27 Hen. VIII. so called from the augmentation of the revenues of the crown, by the suppression of religious houses; and the office still remains, wherein there are many

Aves

fection.

Augment-
ation
Augsburgh.

many curious records, tho' the court has been dissolved long since.

AUGMENTATION, in heraldry, are additional charges to a coat-armour, frequently given as particular marks of honour, and generally borne either in the escutcheon or a conton; as have all the baronets of England, who have borne the arms of the Province of Ulster in Ireland.

AUGRE, or AWGRE, an instrument used by carpenters and joiners to bore large round holes; and consisting of a wooden handle, and an iron blade terminated at bottom with a steel bit.

AUGSBURG, a city of Germany, capital of the circle of Suabia, seated near the confluence of the Ardech and Lech, in one of the most beautiful plains that can be imagined. It is one of the largest and handsomest cities of the empire; but the fortifications are after the old manner, and very irregular; the streets are broad and straight; the houses mostly of timber, plastered and whitened without, or adorned with paintings; the rest are of free-stone; the churches and fountains are generally ornamented with fine figures of brass. Many of the churches are flatly, and adorned within with curious workmanship and paintings. That part of the city erected by the noble family of the Fuggers, who are lords of the adjacent country, consists of several streets cross-wise, containing 106 houses: the poor people that inhabit them are maintained by an annual pension. Its magnificent town-house is little inferior to that of Amsterdam, it being a vast square stone-building, with a marble portico; at the top of the front, within the pediment, is a large spread eagle, holding a sceptre and globe in its talons, of brass gilt, said to weigh 2200 weight; the great portal is of a very beautiful reddish marble, over which is a balcony of the same colour, supported by two pillars of white marble; over the gate there are two large griffins of brass; most of the rooms are wainscotted and ceiled with very fine timber: the great hall is very magnificent, and paved with marble; it is 110 feet long, 58 broad, and 52 high, and its roof is supported by eight columns of red marble; the ceiling of the upper wall is of very curious workmanship of polished ash, consisting of compartments, the squares and pannels of which are enriched with gilded sculptures, and filled with pictures and other ornaments; this is likewise supported by eight pillars with bases and chapters of brass: the other rooms are handsomely adorned with very fine paintings.

In the square, near the town-house, is the fountain of Augustus, which is a marble basin, surrounded with iron ballustrados finely wrought: at the four corners are four brass statues as big as the life, two of which are women and two men; in the middle of the basin is a pedestal, at the foot of which are four large sphinxes spouting water out of their breasts; a little above these are four infants holding four dolphins in their arms, which pour water out of their mouths; and over these infants are seatons and pine-apples all of brass; upon the pedestal is the statue of Augustus as large as the life. The fountain most remarkable next to this is that of Hercules, which is a hexagon basin with several brass figures, particularly Hercules engaging the hydra. Another curiosity is the secret gate, which was contrived to let in persons safely in time of war: it has

many engines and divisions with gates and keys, and apartments for guards at some distance from each other, where passengers are examined, that it is impossible for the town to be surpris'd this way; the gates are bolted and unbolted, opened and shut, by unseen operators, insomuch that it looks like enchantment. The water-towers are also very curious, of which there are three seated on a branch of the river Lech, which runs thro' the city in such a torrent as to drive many mills, which work a number of pumps that raise the water in large leaden pipes to the top of the towers; one of these sends water to the public fountains, and the rest to near 1000 houses in the city.

The Lutherans have a college here, which is a vast square building, with a fine clock on the top of the front. In this there are seven different classes, a hall for public disputations, and a theatre for dramatic representations. The cathedral is a large, gloomy, Gothic building, with two spire-steeple; it is adorned with paintings upon whimsical subjects, and has a great gate all of brass, over which are several scripture passages well represented in basso relievo. The Jesuits have a splendid college here, which, with their church, is full of gilding, painting, and carving; they have likewise a fine library. Though half the inhabitants are Lutherans, there are a great many Popish processions. There are no Jews in the town, nor are they suffered to lie there; but they inhabit a village at about a league distance, and pay so much an hour for the liberty of trading in the day-time. The Benedictine abbey is a vast Gothic building, the ceiling of which is said to be the highest in Germany, and overlooks all the rest of the churches; it is adorned with several statues, and has one very grand altar. The church of St Croix is one of the handsomest in Augsburgh for architecture, painting, sculpture, gilding, and a fine spire.

The inhabitants look upon Augustus Cæsar as the founder of the town: it is true, that that emperor sent a colony there; but the town was already founded, though he gave it the name of *Augusta Vindelicorum*. But that which will eternise the memory of this town is the confession of faith which the Protestant princes presented to Charles V. in 1530. Though the Protestants were very powerful at Augsburgh, they could not keep their ground; for the Bavarians drove them from thence: but Gustavus Adolphus restored them again in 1632; since which time they have continued there, and share the government with the Papists. In 1703, the elector of Bavaria took the city after a siege of seven days, and demolished the fortifications: however, the battle of Hochstedt restored their liberty, which they yet enjoy under the government of their own magistrates, the bishop having no temporal dominion in the city. The chapter is composed of persons of quality, who are to bring proofs of their nobility. The canons have a right of electing their own bishop, who is a sovereign, in the same manner as several other of the German bishops. E. Long. 10. 58. N. Lat. 48. 24.

AUGUR, an officer among the Romans appointed to foretel future events, by the chattering, flight, and feeding, of birds. There was a college or community of them, consisting originally of three members with respect to the three Luceres, Rhamneses, and Tatienfes: afterwards the number was increased to nine, four

Augsbu-
Augur

augural
Augury.

of whom were patricians, and five plebeians. They bore an augural staff or wand, as the ensign of their authority; and their dignity was so much respected, that they were never deposed, nor any substituted in their place, tho' they should be convicted of the most enormous crimes. See AUGURY.

AUGURAL, something relating to the augurs.—The augural instruments are represented on several ancient medals.

AUGURAL Supper, that given by a priest on his first admission into the order, called also by Varro *Adjicialis*.

AUGURAL Book, those wherein the discipline and rules of augury were laid down.

AUGURALE, the place in a camp where the general took auspicia. This answered to the *Auguratorium* in the city.

AUGURALE is also used in Seneca, for the ensign or badge of an augur, as the *lituus*.

AUGURATORIUM, a building on the Palatine mount, where public auguries were taken.

AUGURY, in its proper sense, the art of foretelling future events by observations taken from the chattering, singing, feeding, and flight, of birds; though it is used by some writers in a more general signification, as comprising all the different kinds of divination*.

See Divi-
sion.

Augury was a very ancient superstition. We know from Hesiod, that husbandry was in part regulated by the coming or going of birds; and most probably it had been in use long before his time, as astronomy was then in its infancy. In process of time, these animals seem to have gained a greater and very wonderful authority, till at last no affair of consequence, either of private or public concern, was undertaken without consulting them. They were looked upon as the interpreters of the gods; and those who were qualified to understand their oracles were held among the chief men in the Greek and Roman states, and became the assessors of kings, and even of Jupiter himself. However absurd such an institution as a college of Augurs may appear in our eyes, yet, like all other extravagant institutions, it had in part its origin from nature. When men considered the wonderful migration of birds, how they disappeared at once, and appeared again at stated times, and could give no guess where they went, it was almost natural to suppose, that they retired somewhere out of the sphere of this earth, and perhaps approached the ethereal regions, where they might converse with the gods, and thence be enabled to predict events. It was almost natural for a superstitious people to imagine this; at least to believe it, as soon as some impostor was impudent enough to assert it. Add to this, that the disposition in some birds to imitate the human voice must contribute much to the confirmation of such a doctrine. This institution of augury seems to have been much more ancient than that of aruspicy; for we find many instances of the former in Homer, but not a single one of the latter, though frequent mention is made of sacrifices in that author. From the whole of what has been observed, it seems probable that natural augury gave rise to religious augury, and this to aruspicy, as the mind of man makes a very easy transition from a little truth to a great deal of error.

A passage in Aristophanes gave the hint for these observations.

Vol. II.

In the comedy of the Birds, he makes one of them say thus: 'The greatest blessings which can happen to you, mortals, are derived from us; first, we shew you the seasons, viz. Spring, Winter, Autumn. The crane points out the time for sowing, when she flies with her warning notes into Egypt; the bids the sailor hang up his rudder and take his rest, and every prudent man provide himself with winter-garments. Next the kite appearing, proclaims another season, viz. when it is time to shear his sheep. After that the swallow informs you when it is time to put on summer clothes. We are to you, (adds the chorus), Ammon, Dodona, Apollo: for, after consulting us, you undertake every thing; merchandise, purchases, marriages, &c.' Now, it seems not improbable, that the same transition was made in the speculations of men, which appears in the poet's words; and that they were easily induced to think, that the surprising foresight of birds, as to the time of migration, indicated something of a divine nature in them; which opinion Virgil, as an Epicurean, thinks fit to enter his protest against, when he says,

*Haud equidem credo, quia sit divinitus illis
Ingenium.*

But to return to Aristophanes. The first part of the chorus, from whence the afore-cited passage is taken, seems, with all its wildness, to contain the fabulous cant, which the augurs made use of in order to account for their impudent impositions on mankind. It sets out with a cosmogony; and says, That in the beginning were Chaos and Night, and Erebus and Tartarus: That there was neither water, nor air, nor sky: That Night laid an egg, from whence, after a time, Love arose: That Love, in conjunction with Erebus, produced a third kind; and that they were the first of the immortal race, &c.

AUGUST, in chronology, the eighth month of our year, containing 31 days. August was dedicated to the honour of Augustus Cæsar, because, in the same month, he was created consul, thrice triumphed in Rome, subdued Egypt to the Roman empire, and made an end of civil wars; being before called *Sextilis*, or the sixth from March.

AUGUSTA, or AUSTA, an island in the Adriatic sea, on the coast of Dalmatia, near Ragusa, subject to Venice. E. Long. 17. 50. N. Lat. 42. 35.

AUGUSTA *Ausitorum*, a town of Aquitania, so named out of compliment to Augustus, being originally called *Climbernum*, which name it afterwards resumed. In the middle age, it took the name of the people, *Aufsi*; and is now called *Auch*, the capital of Gascony*.

* See Auch.

AUGUSTA *Emerita*, a town of Lusitania on the river Anas, the capital of the province; a colony of the Emeriti, or such soldiers as had served out their legal time, were men of experience, or had received marks of favour. The colony was founded by Augustus; and is now called *Merida*, a city of Spain, in Estremadura, on the river Guadiana. See MERIDAN.

AUGUSTA *Prætoria*, a town and colony of Gallia Cisalpina, and capital of the Salaffii; seated at the foot of the Alps Graia on the Duria. Now *Aoste* in Piedmont. See AOVSTE.

AUGUSTA *Rauracorum*, a town of Gallia Belgica: now a small village called *August*, at the bend of the Rhine northwards, but from the ruins, which are still

August
August.

Augusta to be seen, appears to have been a considerable colony, at the distance of six miles from Basil to the east.

AUGUSTA Sueffonum, a town of Gallia Belgica on the Axona; so called from Augustus, and with great probability supposed to be the Noviodunum Sueffonum of Cæsar. Now *Soissons*, on the river Aisne, in the Ile of France. See *SOISSONS*.

AUGUSTA Taurinorum, a town of the Taurini at the foot of the Alps where the Duria Minor falls into the Po; now *Turin*, the capital of Piedmont *.

AUGUSTA Treba, a town of the Æqui, near the springs of the river Anio in Italy; now *Trevi*, in Umbria, or in the east of the Campagna di Roma †.

AUGUSTA Trevirorum, a town of the Treviri, a people inhabiting between the Rhine and the Meuse, but especially about the Moselle; now *Triers*, or *Treves*, in the circle of the Lower Rhine on the Moselle ‡.

AUGUSTA Vindelicorum, a town of the Licates on the Licus; called by Tacitus a noble colony of *Rætia*; now *Augsburg*, capital of Suabia *.

AUGUSTALES, in Roman antiquity, an epithet given to the flames or priests appointed to sacrifice to Augustus after his deification; and also to the ludi or games celebrated in honour of the same prince on the fourth of the ides of October.

AUGUSTALIA, a festival instituted by the Romans in honour of Augustus Cæsar, on his return to Rome, after having settled peace in Sicily, Greece, Syria, Asia, and Parthia; on which occasion they likewise built an altar to him, inscribed *Fortuna reduci*.

AUGUSTALIS PRÆFECTUS, a title peculiar to a Roman magistrate who governed Egypt, and a power much like that of a proconsul in other provinces.

AUGUSTIN, or *AUSTIN*, (St), the first archbishop of Canterbury, was originally a monk in the convent of St Andrew at Rome, and educated under St Gregory, afterwards pope Gregory I. by whom he was dispatched into Britain with 40 other monks of the same order, about the year 596, to convert the English Saxons to Christianity. They landed in the isle of Thanet; and having sent some French interpreters to king Ethelbert with an account of their errand, the king gave them leave to convert as many of his subjects as they could, and assigned their place of residence at Dorovernum, since called *Canterbury*; to which they were confined till the king himself was converted, whose example had a powerful influence in promoting the conversion of his subjects; but though he was extremely pleased at their becoming Christians, he never attempted to compel them. He dispatched a priest and a monk to Rome, to acquaint the pope with the success of his mission, and to desire his resolution of certain questions. These men brought back with them a pall, and several books, vestments, utensils, and ornaments for the churches. His holiness, by the same messengers, gave Augustin directions concerning the settling of episcopal sees in Britain; and ordered him not to pull down the idol-temples, but to convert them into Christian churches; only destroying the idols, and sprinkling the place with holy water, that the natives, by frequenting the temples they had been always accustomed to, might be the less shocked at their entrance into Christianity. Augustin resided principally at Canterbury, which thus became the metropolitan church of England; and having established bishops in several

of the cities, he died on the 26th of May, 607. The Popish writers ascribe several miracles to him. The observation of the festival of St Augustin was first joined in a synod held under Cuthbert archbishop of Canterbury, and afterwards by the pope's bull in the reign of king Edward III.

AUGUSTINE (St), an illustrious father of the church, was born at Thagaste, a city of Numidia, on the 13th of November, 354. His father, a burges of that city, was called *Patricius*; and his mother, *Monica*, who being a woman of great virtue, instructed him in the principles of the Christian religion. In his early youth he was in the rank of the catechumens; and falling dangerously ill, earnestly desired to be baptized; but the violence of the distemper ceasing, his baptism was delayed. His father, who was not yet baptized, made him study at Thagaste, Madaura, and afterwards at Carthage. Augustine, having read Cicero's books of philosophy, began to entertain a love for wisdom, and applied himself to the study of the holy scriptures; nevertheless, he suffered himself to be seduced by the Manicheans. At the age of 19, he returned to Thagaste, and taught grammar, and also frequented the bar: he afterwards taught rhetoric at Carthage with applause. The insolence of the scholars at Carthage made him take a resolution to go to Rome, tho' against his mother's will. Here also he had many scholars; but disliking them, he quitted Rome, and settled at Milan, and was chosen public professor of rhetoric in that city. Here he had opportunities of hearing the sermons of St Ambrose, which, together with the study of St Paul's epistles, and the conversion of two of his friends, determined him to retract his errors, and quit the sect of the Manicheans: this was in the 32^d year of his age. In the vacation of the year 386, he retired to the house of a friend of his, named *Verecundus*, where he seriously applied himself to the study of the Christian religion, in order to prepare himself for baptism, which he received at Easter, in the year 387. Soon after this, his mother came to see him at Milan, and invite him back to Carthage; but at Ostia, whither he went to embark in order to his return, she died. He arrived in Africa about the end of the year 388; and having obtained a garden-plot without the walls of the city of Hippo, he associated himself with 11 other persons of eminent sanctity, who distinguished themselves by wearing leathern girdles, and lived there in a monastic way for the space of three years, exercising themselves in fasting, prayer, study, and meditation, day and night: from hence sprung up the Augustine friars, or eremites of St Augustine, being the first order of mendicants; those of St Jerome, the Carmelites, and others, being but branches of this of St Augustine. About this time, or before, Valerius bishop of Hippo, against his will, ordained him priest: nevertheless, he continued to reside in his little monastery, with his brethren, who, renouncing all property, possessed their goods in common. Valerius, who had appointed St Augustine to preach in his place, allowed him to do it in his presence, contrary to the custom of the churches in Africa. He explained the creed, in a general council of Africa, held in 393. Two years after, Valerius, fearing he might be preferred to be bishop of another church, appointed him his coadjutor or colleague, and caused him to be ordained

Augustine
Augustus.

dained bishop of Hippo, by Megalus bishop of Calame, then primate of Numidia. St Augustine died the 28th day of August, 430, aged 76 years, having had the misfortune to see his country invaded by the Vandals, and the city where he was bishop besieged for seven months.

The works of St Augustine make ten tomes; the best edition of them is that of Maurin, printed at Antwerp, in 1700. They are but little read at this time, except by the clergy of the Greek church and in the Spanish universities. The bookellers of London receive frequent commissions for them, and indeed for the most of the fathers, from Russia, and also from Spain.

AUGUSTINE (St), a fort of North America, on the east coast of Cape Florida, situated in W. Long. 81. 10. N. Lat. 30. 0. This fort was built by the Spaniards; who were scarce well established there, when they were attacked by Sir Francis Drake in 1586, who reduced and pillaged the fort and town adjacent. In 1665, it underwent a similar fate, being attacked by Captain Davis at the head of a considerable company of bucaners. In 1702, an attempt was made by Colonel More to annex St Augustine to the British dominions. He invested it with only 500 English and 700 Indians; which small force, however, would have been sufficient to reduce the place, had not succours arrived when it was on the point of surrendering. Even then, it is thought that he might have defeated the reinforcement which arrived; but he chose to raise the siege, and retire with precipitation. In 1740, another unsuccessful attempt was made on this fort by general Oglethorpe: it was, however, together with the whole country of Florida, ceded to Great Britain by the treaty of Paris in 1763.

AUGUSTINE, a cape of South America. W. Long. 35. 4. S. Lat. 8. 30.

AUGUSTINES, a religious order in the church of Rome, who follow the rule of St Augustine, prescribed them by pope Alexander IV. Among other things, this rule enjoins to have all things in common, to receive nothing without the leave of their superior; and several other precepts relating to charity, modesty, and chastity. There are likewise nuns of this order. The Augustines are clothed in black, and at Paris are known under the name of the *religious of St Genevieve*, that abbey being the chief of the order.

AUGUSTOBONA, a city of the Tricassens in ancient Gaul, from whom it was afterwards called *Tricasses*, and *Trecassa*; and still farther corrupted to *Traces*, or *Treci*; whence the modern name *Troyes*, in Champagne on the Seine. See *TROYES*.

AUGUSTODUNUM, the capital of the Ædui, where there was a famous academy or school for the education of youth; now *Auxion*, or *Aulun*, in the duchy of Burgundy, on the Arroux. See *AULUN*.

AUGUSTOMAGUS, an ancient town of Gallia Belgica; now *Sentis*, in the Isle of France. E. Long. 2. 30. N. Lat. 49. 10.

AUGUSTOW, a small but strong town of Poland, in the duchy and palatinate of Polakia, seated on the river Nariue. E. Long. 24. 2. N. Lat. 53. 25.

AUGUSTUS (Fort), a small fortress seated on a plain at the head of Lochness in Scotland, between the rivers Taarf and Oich; the last is a considerable

stream, and has over it a stone bridge of three arches. The fort consists of four bastions; within is the governor's house, and barracks for 400 men: it was taken by the rebels in 1746, who immediately deserted it, after demolishing what they could. The name of this fort in Erse is *Kill-chuimin*, or the burial place of the *Cummins*. It lies on the road to the Isle of Sky, which is about 52 miles off; but on the whole way there is not a place fit for the reception of man or horse.

AUGUSTUS (Caius Julius Cæsar Octavianus), the nephew of Julius Cæsar, was born at Rome 63 years before Jesus Christ. When he understood that his uncle had adopted him for his heir, he went to Italy and attached himself to his party. He quarrelled with M. Antonius; but afterward entering into a treaty with him and Lepidus, these three formed the second triumvirate, agreed to a proscription of their respective enemies, and divided the empire among them. Lepidus being abandoned by his army, was sent into exile; and Antonius being reduced to destroy himself, Octavius assumed the title of Emperor, and the appellation of *Augustus*. He was cruel in his triumvirate, but seemed to have adopted new virtues with his imperial dignity; since he now appeared just, affable, moderate, and liberal: he maintained peace; advanced men of merit; and patronised arts and sciences, which under his reign were brought to the greatest perfection. He died at the age of 75. See *ROME*.

AVIARY, a place set apart for feeding and propagating birds. It should be so large, as to give the birds some freedom of flight; and turfed, to avoid the appearance of foulness on the floor.

AVICENA, or AVICENNES, the prince of Arabian philosophers and physicians, was born at Afsena, a village in the neighbourhood of Bokhara. His father was from Balkh in Persia, and had married at Bokhara. The first years of Avicenes were devoted to the study of the Koran, and the Belles Lettres. He soon shewed what he was likely to become afterwards; and the progress he made was so rapid, that, when he was but ten years old, he was perfectly intelligent in the most hidden senses of the Koran.

Abou-Abdoulah, a native of Napoulous in Syria, at that time professed philosophy at Bokhara with the greatest reputation. Avicenes studied under him the principles of logic; but, soon disgusted with the slow manner of the schools, he set about studying alone, and read all the authors that had written on philosophy, without any other help than that of their commentators. Mathematics had no fewer charms for him; and, after reading the first six propositions of Euclid, he got alone to the last, having made himself perfect master of them, and treasured up all of them equally in his memory.

Possessed with an extreme avidity to be acquainted with all sorts of sciences, he likewise devoted himself to the study of medicine. Persuaded that this divine art consists as much in practice as in theory, he sought all opportunities of seeing the sick; and afterwards confessed, that he had learned more from experience than from all the books he had read. He was now in his 16th year, and already was celebrated for being the light of his age. He resolved at this age to resume his studies of philosophy, which medicine had made

Augustus
Avicena.

him neglect; and he spent a year and a half in this painful labour, without ever sleeping all this time a whole night together. If he felt himself oppressed by sleep, or exhausted by study, a glass of wine refreshed his waited spirits, and gave him new vigour for study; if in spite of him his eyes for a few minutes shut out the light, it then happened to him to recollect and meditate upon all the things that had occupied his thoughts before sleep. At the age of 21, he conceived the bold design of incorporating, in one work, all the objects of human knowledge; and carried it into execution in an Encyclopedie of 20 volumes, to which he gave the title of the "Utility of Utilities."

Several great princes had been taken dangerously ill, and Avicenes was the only one that could know their ailments and cure them. His reputation increased daily, and all the kings of Asia desired to retain him in their families.

Mahmud, the son of Sabektekin, the first sultan of the Dynasty of the Samanides, was then the most powerful prince of the east. Imagining that an implicit obedience should be paid by all manner of persons to the injunctions of his will, he wrote a haughty letter to Mamun sultan of Kharazm, ordering him to send Avicenes to him, who was at his court, with several other learned men. Philosophy, the friend of liberty and independence, looks down with scorn on the shackles of compulsion and restraint. Avicenes, accustomed to the most flattering distinctions among the great, could not endure the imperious manner of Mahmud's inviting him to his court, and refused to go there. But the Sultan of Kharazm, who dreaded his resentment, obliged the philosopher to depart with others whom that prince had demanded to be sent to him.

Avicenes pretended to obey; but, instead of repairing to Gazna, he took the rout of Georgian. Mahmud, who had gloried in the thoughts of keeping him at his palace, was greatly irritated at his flight. He dispatched portraits done in crayons of this philosopher to all the princes of Asia, with orders to have him conducted to Gazna, if he appeared in their courts. But Avicenes had fortunately escaped the most diligent search after him. He arrived in the capital of Georgian, where, under a disguised name, he performed many admirable cures.

Cabous then reigned in that country. A nephew, whom he was extremely fond of, being fallen sick, the most able physicians were called in, and none of them were able to know his ailment, or give him any ease. Avicenes was at last consulted. So soon as he had felt the young prince's pulse, he was confident with himself, that his illness proceeded from a violent love, which he dared not to declare. Avicenes commanded the person, who had the care of the different apartments in the palace, to name them all in their respective order. A more lively motion in the prince's pulse, at hearing mentioned one of these apartments, betrayed a part of his secret. The keeper then had orders to name all the slaves that inhabited that apartment. At the name of one of these beauties, the young Cabous could not contain himself; an extraordinary beating of his pulse completed the discovery of what he in vain desired to keep concealed. Avicenes, now fully assured that this slave was the cause of this prince's illness, declared that she alone had the power to cure him.

The Sultan's consent was necessary, and he of course was curious to see his nephew's physician. He had scarce looked at him, when he knew in his features those of the crayoned portrait sent him by Mahmud; but Cabous, far from forcing Avicenes to repair to Gazna, retained him for some time with him, and heaped honours and presents on him.

This philosopher passed afterwards into the court of Nedjeddevie, Sultan of the race of the Bouides. Being appointed first physician to that prince, he found means to gain his confidence to go great a degree, that he raised him to the post of Grand Visir. But he did not long enjoy that illustrious dignity. Too great an attachment for pleasures, especially those of love and the table, made him lose at the same time his post and his master's favour. From that time Avicenes felt all the rigours of adversity, which he had brought upon himself by his ill conduct. He wandered about as a fugitive, and was often obliged to shift the place of his habitation to secure his life from danger. He died at Hamadan, aged 58 years, in the 428th year of the Hegira, and of Christ 1036.

The perfect knowledge he had of phisic did not secure him from the ailments that afflict human nature. He was attacked by several maladies in the course of his life, and particularly was very subject to the colic. His excesses in pleasures, and his infirmities, made a poet say, who wrote his epitaph, that the profound study of philosophy had not taught him good morals, nor that of medicine the art of preserving his own health.

No one composed with greater facility than Avicenes, writing, when he fat down to it, 50 pages generally in a day, without fatiguing himself. The doctors of Chiraz, having made a collection of objections against one of his metaphysical works, sent it to him at Ispahan by Cafem. This learned man, not arriving till towards evening, came to Avicenes's house, with whom he sat discoursing till midnight. When Cafem was retired, he wrote an answer to the objections of the Chirazians, and finished it before sun-rise. He immediately delivered it to Cafem, telling him, that he had made all possible dispatch in order not to detain him any longer at Ispahan.

Avicenes, after his death, enjoyed so great a reputation, that, till the 12th century, he was preferred for the study of philosophy and medicine to all his predecessors. His works were the only writings in vogue in schools, even in Europe. The following are the titles. 1. Of the Utility and Advantage of Sciences, XX books. 2. Of Innocence and Criminality, II books. 3. Of Health and Remedies, XVIII books. 4. On the means of preserving Health, III books. 5. Canons of Phisic, XIV books. 6. On Astronomical Observations, I book. 7. On Mathematical Sciences. 8. Of Theorems, or Mathematical and Theological Demonstrations, I book. 9. On the Arabic Language, and its Proprieties, X books. 10. On the Last Judgment. 11. On the Origin of the Soul, and the Resurrection of Bodies. 12. Of the end we should propose to ourselves in Harangues and Philosophical Argumentations. 13. Demonstration of the collateral Lines in the Sphere. 14. Abridgment of Euclid. 15. On Finity and Infinity. 16. On Phisics and Metaphysics. 17. On Animals and Vegetables,

bles, &c. 18. Encyclopedie, 20 volumes.—Some, however, charge him with having stolen what he published from a celebrated physician who had been his master. This man had acquired so much honour and wealth, that he was solicited by many to take their sons to be his scholars, or even his servants; but being resolved not to discover the secrets of his art, he would receive none of them. Avicene's mother formed the following stratagem: she offered him her son as a servant, pretending he was naturally deaf and dumb; and the youth, by his mother's instructions, counterfeited these defects so well, that the physician, after making several trials to discover the reality of them, took the boy into his service, and by degrees trusted him so far as to leave his writings open in his room when he went abroad: Avicene took that opportunity to transcribe them, and carried the copies to his mother; and after the death of his master he published them under his own name. Indeed if we reflect that he lived but 58 years, that he was a wanderer and a fugitive, and that he was much addicted to his pleasures, we shall have some difficulty to conceive how he could find time to compose so many works. Physic, however, is indebted to him for the discovery of cassia, rhubarb, mirabolans, tamarinds; and from him also, it is said, came to us the art of making fugar.

AVICENIA, in botany, a genus of the angiosperma order, belonging to the didynamia class of plants; of which there are two species, but possessed of no remarkable properties.

AVIGLIANO, a small town of Piedmont in Italy. E. Long. 7. 5. N. Lat. 44. 40.

AVIGNON, a city of Provence in France, the capital of the county of Venaissin, and seated on the banks of the Rhone. It is an archbishop's see, and the residence of several popes at this place for 70 years has rendered it considerable. Its walls are built with free stone, with several square towers, adorned with pinnacles. The ditches are not large, but are in proportion to the height of the walls, and are in some places full of water. This city belongs to the pope, who sends a vice-legate every three years, who in some sense is the governor. Near the Rhone there is a large rock, within the circumference of the walls, upon which is a platform, from whence may be had a prospect of the whole city and the places about it. This city is embellished with magnificent churches, a large square, beautiful buildings, and very agreeable gardens. The palace of the vice-legate is composed of several large square towers, and he gives audience in a great hall which is full of fine paintings, as is also the chapel and the apartments. The annual is near the palace.

The church of Notre Dame is ancient, but not large, and is one of the best adorned in the city. After having ascended about 50 steps, you come to a very ancient portico, which sustains a great tower; as you enter the church on the left hand, you see paintings which equal the finest in Italy. The great altar is very magnificent, and is adorned with a shrine that contains the relics of we know not how many saints. The treasure of the faculty is worthy of the curiosity of the traveller. The little palace where the archbishop resides is formed of three bodies of lodgings, accompanied with courts and small pavilions. It overlooks the Rhone, the city, and the fields. These buildings and

the mint adorn a large square, which is the common walk of the inhabitants.

In Avignon they reckon seven gates, seven palaces, seven colleges, seven hospitals, seven monasteries, seven nunneries, and seven popes who have lived there in 70 years. The church of the Celestines is very magnificent, and full of fine monuments, and the rest are not without their curiosities. The university has four colleges; and the place where the Jews live is a distinct quarter, from whence the Jews who pay tribute dare not stir out without yellow hats, and the women must have something yellow about their heads, to distinguish them from the Christians. Their number is very considerable in a very confined place, where the only way of enlarging their abodes is by building their houses higher. Their synagogue is so dark, that they are obliged to light lamps. However, they are forced to hear a monk preach a sermon every week. There was a stone bridge over the Rhone, which is here very rapid; but the greatest part is carried away, and the vacancy supplied with wood. It had 20 arches, but it was narrow, though above a quarter of a mile long. The curious that travel this way go to see the fountain of Vaucluse, where the river Sorgues, which passes through this city, has its source. Below the bridge there is an island where the Sorgues joins the Rhone, in which are several houses of pleasure. E. Long. 4. 59. N. Lat. 43. 57.

AVILA, a city of Old Castile, in Spain, seated on an eminence on the banks of the river Adaja, and in sight of the mountains of Pico. It is fortified both by nature and art, having a wall 9075 feet in circumference, adorned with 26 lofty towers, and 10 handsome gates. There are 17 principal streets, the houses in which are generally good, and some of them stately. It hath nine squares, 2000 houses, nine parishes, as many monasteries, seven nunneries, two colleges, nine hospitals, 18 chapels, and an allowance of 10,000 ducats yearly for the maintenance of orphans and other poor people. It has an university, and a considerable bishopric; besides a noble cathedral, which has eight dignitaries, 20 canons, and the same number of minor canons. It stands in the middle of a fine large plain, surrounded with mountains, and covered with fruit-trees and vineyards. There is likewise a manufacture of cloth. W. Long. 4. 13. N. Lat. 40. 35.

AVIS, a small town of Alentijo in Portugal, seated on an eminence with a castle near the river Avis. Hence the military order of the knights of Avis have their name. W. Long. 7. 0. N. Lat. 38. 40.

AVISO, a term chiefly used in matters of commerce to denote an advertisement, an advice, or piece of intelligence.

AVISON, (Charles), organist of Newcastle, and a disciple of Geminiani, was the author of an essay on musical expression, published in the year 1752, in which are some judicious reflections on music in general, but his division of the modern authors into classes is rather fanciful than just. Throughout his book he celebrates Marcello and Geminiani; the latter frequently in prejudice to Mr Handel. In the year 1753 came out remarks on Mr Avison's essay on musical expression, the author whereof first points out sundry errors against the rules of composition in the works of Avison. In the same year Avison republished his essay, with a reply

ply to the author of the remarks; and a letter, containing a number of loose particulars relating to music collected in a course of various reading, unquestionably written by Dr Jortin. A vision promoted and assisted in the publication of Marcello's music to the psalms adapted to English words. Of his own composition there are extant five collections of concertos for violins, 44 in number; and two sets of sonatas for the harpsichord and two violins, a species of composition little known in England till his time. The music of A vision is light and elegant, but it wants originality; a necessary consequence of his too close attachment to the style of Geminiani, which in a few particulars only he was able to imitate. *Hawkins's Hist. of Music.*

AUK, in ornithology. See ALCA.

AUKLAND, a town in the bishopric of Durham in England, situated on the river Wère. W. Long. 0. 57. N. Lat. 54. 44.

AULA is used for a court baron, by Spelman; by some old ecclesiastical writers, for the nave of a church, and sometimes for a court-yard.

AULCESTER, a town of Warwickshire in England. W. Long. 1. 47. N. Lat. 52. 15.

AULETES, in antiquity, denotes a flute-player. One of the Ptolemies, kings of Egypt, father of Cleopatra, bore the surname or denomination of *Auletes*.

AULIC, an epithet given to certain officers of the empire, who compose a court which decides, without appeal, in all processes entered in it. Thus we say, *aulic council, aulic chamber, aulic counsellor.*

The aulic council is composed of a president, who is a catholic; of a vice-chancellor, presented by the archbishop of Mentz; and of 18 counsellors, nine of whom are protestants, and nine catholics. They are divided into a bench of lawyers, and always follow the emperor's court; for which reason they are called *justitiam imperatoris*, the emperor's justice, and aulic council. The aulic court ceases at the death of the emperor; whereas the imperial chamber of Spire is perpetual, representing not only the deceased emperor, but the whole Germanic body, which is reputed never to die.

AULIC, in the Sorbonne and foreign universities, is an act which a young divine maintains upon being admitted a doctor in divinity. It begins by an harangue of the chancellor, addressed to the young doctor, after which he receives the cap, and presides at the aulic, or disputation.

AULON, anciently a town and dock or station for ships in Illyricum, on the Adriatic; now *Valona*, or *Volana*, a port-town in the duchy of Ferrara on one of the mouths of the Po. See VALONA.

AULOS, a Grecian long measure, the same with stadium.

AULPS, a town of Provence in France, in the diocese of Trejus, with the title of a Vigueria. E. Long. 6. 25. N. Lat. 43. 40.

AULUS GELLIUS. See GELLIUS.

AUMBRY, a country-word denoting a cup-board. AUME, a Dutch measure for Rhenish wine, containing 40 English gallons.

AUNCCEL-WEIGHT, an ancient kind of balance now out of use, being prohibited by several statutes, on account of the many deceptions practised by it. It consisted of scales hanging on hooks, fastened at each end of a beam, which a man lifted up on his hand. In

many parts of England, auncel-weight signifies meat sold by the hand, without scales.

AUNE, a long measure used in France to measure cloths, stuffs, ribbons, &c. At Rouen, it is equal to one English ell; at Calais, to 1.52; at Lyons, to 1.061; and at Paris, to 0.95.

AUNGERVYLE (Richard), commonly known by the name of *Richard de Bury*, was born in 1281, at St Edmund's Bury, in Suffolk, and educated at the university of Oxford. After which he entered into the order of Benedictine monks, and became tutor to Edward prince of Wales, afterwards king Edward III. Upon the accession of his royal pupil to the throne he was appointed cofferer, then treasurer of the wardrobe, archdeacon of Northampton, prebendary of Lincoln, Sarum, and Litchfield, keeper of the privy seal, dean of Wells, and last of all was promoted to the bishoprick of Durham. He likewise enjoyed the offices of lord high chancellor, and treasurer of England; and discharged two important embassies at the court of France. Learned himself, and a patron of the learned, he maintained a correspondence with some of the greatest geniuses of the age, particularly with the celebrated Italian poet Petrarch. He was also of a most humane and benevolent temper, and performed many signal acts of charity. Every week he made eight quarters of wheat into bread, and gave it to the poor. Whenever he travelled between Durham and Newcastle, he distributed eight pounds sterling in alms; between Durham and Stockton five pounds, between Durham and Aukland five marks, and between Durham and Middleham five pounds. He founded a public library at Oxford, for the use of the students, which he furnished with the best collection of books then in England; and appointed five keepers, to whom he granted yearly salaries. At the dissolution of religious houses in the reign of Henry VIII. Durham college, where he fixed the library, being dissolved among the rest, some of the books were removed to the public library, some to Baliol college, and some came into the hands of Dr George Owen, a physician of Godflow, who bought that college of king Edward VI. Bishop Aungervyle died at his manor of Aukland, April 24. 1345, and was buried in the south part of the cross aisle of the cathedral church of Durham, to which he had been a benefactor. He wrote, 1. *Philobiblos*, containing directions for the management of his library at Oxford, and a great deal in praise of learning, in bad Latin. 2. *Epistole familiarium*; some of which are written to the famous Petrarch. 3. *Orationes ad principes*; mentioned by Bale and Pits.

AUNIS, the smallest province in France, bounded on the north by Poictou, on the west by the ocean, on the east and south by Saintogne, of which it was formerly a part. It is watered by the rivers Seure and Sarente, the former of which has its source at Seure in Poictou. The coast of this small district has the advantage of several ports, the most remarkable of which are Rochefort, Rochelle, Brouge, St Martin de Re, Tremblade, Tonnai, and Charente. The soil of this country is dry, yet produces good corn and plenty of wine. The marshes feed a great number of cattle, and the salt marshes yield the best salt in Europe.

AVOCATORIA, a mandate of the emperor of Germany, addressed to some prince, in order to stop

his unlawful proceedings in any cause appealed to him.

AVOIDANCE, in the canon law, is when a benefice becomes void of an incumbent; which happens either in fact, as by the death of the person; or in law, as by cession, deprivation, resignation, &c. In the first of these cases, the patron must take notice of the avoidance, at his peril; but in avoidance by law, the ordinary is obliged to give notice to the patron, in order to prevent a lapse.

AVOIRDUPOIS. This is the weight for the larger and coarser commodities, such as groceries, cheese, wool, lead, &c. Bakers, who live not in corporation towns, are to make their bread by avoirdupois-weight, those in corporations by troy-weight. Apothecaries buy by avoirdupois-weight, but sell by troy. The proportion of a pound avoirdupois to a pound troy is as 17 to 14.

AVOSETTA, in ornithology. See **RECURVIVOSTRA**.

AVOWEE, one who has a right to present to a benefice. He is thus called in contradistinction to those who only have the lands to which the advowson belongs for a term of years, or by virtue of intrusion or disseisin.

AVOWRY, in law, is where a person distrained sues out a replevin; for then the distrainer must vouch, and justify his plea, which is called his *avowry*.

AURA, among physiologists, an airy exhalation or vapour. The word is Latin, derived from the Greek, *αἶψα*, gentle wind.

AURACH, a town of Germany with a good castle, in the south part of Suabia, in the duchy of Wirtemberg. It is the usual residence of the youngest sons of the house of Wirtemberg, and is seated at the foot of a mountain on the rivulet Ermlt. E. Long. 9. 20. N. Lat. 48. 25.

AURANCHES, the capital of a territory called *Auranchin*, about 30 miles in length, in Lower Normandy in France. The air is mild and temperate, and the best cyder in Normandy is produced here.

The city stands on a hill, near which the river See runs, and is about a mile and a half from the ocean. W. Long. 1. 20. N. Lat. 48. 51.

AURANTIUM, in botany. See **CITRUS**.

AURAY, a small seaport town of Lower Brittany in France, situated in the gulph called *Morbihan*. It is nothing, properly speaking, but a large quay, and a handsome street, being chiefly known for its trade. W. Long. 2. 25. N. Lat. 47. 48.

AURELIA, in natural history, the same with what is more usually called *chrysalis*, and sometimes *nympb* *.

AURELIANUS (Lucius Domitius), emperor of Rome, was one of the greatest generals of antiquity, and commanded the armies of the emperor Claudius with such glory, that after the death of that emperor all the legions agreed to place him on the throne; this happened in the year 270. He carried the war from the east to the west, with as much facility, says a modern writer, as a body of troops marches from Alface into Flanders. He defeated the Goths, Sarmatians, Marcomanni, the Persians, Egyptians, and Vandals; conquered Zenobia queen of the Palmyrenians, and Tetricus general of the Gauls; both of whom were made to grace his triumph, in the year 274. He was killed by one of his generals in Thrace in the year

275, when he was preparing to enter Persia with a great army. See **ROME**.

AURELIUS VICTOR. See **VICTOR**.

AURENGABAD, a city in the East Indies, capital of the province of Balagate, in the dominions of the Great Mogul. It is furnished with handsome mosques and caravanseras. The buildings are chiefly of free-stone, and pretty high, and the streets planted on each side with trees. They have large gardens well stocked with fruit-trees and vines. The soil about it is also very fertile, and the sheep fed in its neighbourhood are remarkably large and strong. E. Long. 75. 30. N. Lat. 19. 10.

AURENG-ZEBE, the Great Mogul. See **INDOSTAN**.

AUREOLA, in its original signification, signifies a jewel, which is proposed as a reward of victory in some public dispute. Hence, the Roman schoolmen applied it to denote the reward bestowed on martyrs, virgins, and doctors, on account of their works of supererogation; and painters use it to signify the crown of glory, with which they adorn the heads of saints, confessors, &c.

AUREUS, a Roman gold coin, equal in value to 25 denarii.—According to Ainsworth, the aureus of the higher empire weighed near five penny-weights; and in the lower empire, little more than half that weight. We learn from Suetonius, that it was customary to give aurei to the victors in the chariot-races.

AURICK, a city of Germany, in East Friesland, in the circle of Westphalia; to which the king of Prussia claims a right. It is situated in a plain surrounded with forests full of game. E. Long. 6. 50. N. Lat. 53. 28.

AURICLE, in anatomy, that part of the ear which is prominent from the head, called by many authors *auris externa*.

AURICLES, are likewise two muscular bags situated at the basis of the heart, and intended as diverticula for the blood during the diastole *.

AURICULAR, whatever belongs or relates to the ear.

AURICULAR Tube, an instrument to facilitate hearing. See **ACOUSTICS**, n^o 2^d 26.

AURIGA, the **WAGGONER**, in astronomy, a constellation of the northern hemisphere, consisting of 23 stars, according to Tycho; 40, according to Hevelius; and 68, in the Britannic catalogue.

AURILLAC, a town of France in the Lower Auvergne, seated on a small river called *Jordane*. It is one of the most considerable towns of the province, has six gates, is very populous, and yet has but one parish. The castle is very high, and commands the town. The abbot is lord of Aurillac, and has episcopal jurisdiction; he is also chief justice of the town. This place is remarkable for having produced several great men. E. Long. 2. 33. N. Lat. 44. 55.

AURIPIGMENTUM, **ORPIMENT**, in natural history. See **ORPIMENT**.

AURISCALPIUM, an instrument to clean the ears, and serving also for other operations in disorders of that part.

AURORA, the morning twilight, or that faint light which appears in the morning when the sun is within 18 degrees of the horizon.

AURORA,

Aurelius

Aurora.

* See Annot.
my, n^o 35^o.

Aurora
Borealis.

AURORA, the goddess of the morning, according to the pagan mythology. She was the daughter of Hyperion and Theia, according to Hesiod; but of Titan and Terra, according to others. It was under this name that the ancients desired the light which foretells the rising of the sun above our hemisphere. The poets represent her as rising out of the ocean, in a chariot, with rosy fingers dropping gentle dew. Virgil describes her ascending in a flame-coloured chariot with four horses.

AURORA BOREALIS, NORTHERN TWILIGHT, or *Streamers*; a kind of meteor appearing in the northern part of the heavens, mostly in the winter-time, and in frosty weather. It is now so generally known, that no description is requisite; and indeed the variety of its appearances is so great, as to render a particular description almost impossible.

¹
This meteor
formerly
very rare.

The aurora borealis, though now so common, seems formerly to have been very rare; and indeed we can scarce avoid attributing to this meteor many of the prodigies that are mentioned by ancient historians, as the flame that appeared over the city of Constantinople, those before the siege of Jerusalem, &c. and its appearances being accounted ominous, shews that it hath in those ages been seen very seldom, in comparison to what it is now. This we are assured of by Dr Halley, who tells us, that when he saw a great aurora borealis in 1716, he had begun to despair of ever seeing one at all; none having appeared, at least in any considerable degree, from the time he was born till then. Notwithstanding this long interval, however, it seems that in some periods the aurora borealis had been seen much more frequently; and perhaps this, as well as other natural phenomena, may have some stated times of returning.

²
History by
Dr Halley.

The only thing that resembles a distinct history of this phenomenon, is what we have from the learned Dr Halley, Phil. Trans. n^o 347. The first account he gives, is of the appearance of what is called by the author, *burning spears*, and was seen at London on January 30th, 1560. This account is taken from a book intitled *A description of Meteors* by W. F. D. D. and reprinted at London in 1654. The next appearance, on the testimony of *Stow*, was on October 7th, 1564. In 1574 also, according to *Camden*, and *Stow* above-mentioned, an aurora borealis was observed two nights successively, viz. on the 14th and 15th of November, with much the same appearances as described by Dr Halley in 1716, and which we now so frequently observe. Again, the same was twice seen in Brabant, in the year 1575; viz. on the 13th of February, and 28th of September. Its appearances at both these times were described by Cornelius Gemma, professor of medicine in the university of Lovain, who seems to have been struck with the utmost horror at the sight; and compares them to spears, fortified cities, and armies fighting in the air. Concerning these four appearances, Dr Halley remarks that they all happened at the same age of the moon, viz. two days after the change. After this, Michael Mæsslin, tutor to the great Kepler, assures us, that at Baknang in the county of Wurtemberg in Germany, these phenomena, which he styles *chaßnata*, were seen by himself no less than seven times in 1580. In 1581, they again appeared in an extraordinary manner in April and September, and in a less

Aurora
Borealis.

degree at some other times of the same year. In 1621, September 24, this phenomenon was observed all over France, and described by Cassendus, who gave it the name of *aurora borealis*; yet neither this, nor any similar appearances posterior to 1574, are described by English writers, till the year 1707; which, as Dr Halley observes, shews the prodigious neglect of curious matters which at that time prevailed. From 1621 to 1707, indeed, there is no mention made of an aurora borealis being seen by any body; and considering the number of astronomers who during that period were in a manner continually poring on the heavens, we may very reasonably conclude that no such thing did make its appearance till after an interval of 86 years. In 1707, a small one was seen in November; and during that year and the next, the same appearances were repeated five times. The next on record, is that mentioned by Dr Halley in March 1716; since which time they have been so common, that no accounts have been kept of them.

It was for a long time a matter of doubt whether this meteor made its appearance only in the northern hemisphere, or whether it was also to be observed near the south pole. This is now ascertained by Mr Forster; who, in his late voyage round the world along with captain Cook, assures us, that he observed them in the high southern latitudes, though with phenomena somewhat different from those which are seen here. On Feb. 17, 1773, as they were in Lat. 58^o south, "A beautiful phenomenon (says he) was observed during the preceding night, which appeared again this and several following nights. It consisted of long columns of a clear white light, shooting up from the horizon to the eastward, almost to the zenith, and gradually spreading on the whole southern part of the sky. These columns were sometimes bent sidewise at their upper extremities; and though in most respects similar to the northern lights (*aurora borealis*) of our hemisphere, yet differed from them in being always of a whitish colour, whereas ours assume various tints, especially those of a fiery and purple hue. The stars were sometimes hid by, and sometimes faintly to be seen through, the substance of these southern lights (*aurora australis*), which have hitherto, as far as I can find, escaped the notice of voyagers. The sky was generally clear when they appeared, and the air sharp and cold, the thermometer standing at the freezing point." On the 16th and 19th of March the same year, the aurora australis was again observed, and the last time rather brighter than before, and the columns formed an arch across the sky.

³
Mr Forster
account
similar
appearances
in the southern
hemisphere.

Dr Halley observed that the aurora borealis described by him arose to a prodigious height, it being seen from the west of Ireland to the confines of Russia and Poland on the east; nor did he know how much further it might have been visible: so that it extended at least 30 degrees in longitude; and, from lat. 50 north, it was seen over all the northern part of Europe; and what was very surprising, in all those places where it was visible, the same appearances were exhibited which Dr Halley observed at London. He observes, with seeming regret, that he could by no means determine its height, for want of observations made at different places; otherwise he might as easily have calculated the height of this aurora borealis, as he did of the fiery

globe in 1719 *. To other philofophers, however, he gives the following exhortation. "When therefore for the future any fuch thing fhall happen, all thofe that are curious in aftronomical matters are hereby admonifhed and intreated to fet their clocks to the apparent time at London, for example, by allowing fo many minutes as is the difference of meridians; and then to note, at the end of every half hour precifely, the exact fituation of what at that time appears remarkable in the fky; and particularly the azimuths of thofe very tall pyramids fo eminent above the reft, and therefore likely to be feen furthest: to the intent that, by comparing thefe obfervations taken at the fame moment in diftant places, the difference of their azimuths may ferve to determine how far thefe pyramids are diftant from us."—With this pathetic advice no two philofophers have yet thought proper to comply, notwithstanding the multitude of opportunities that have fince occurred; a shameful inftance of philofophic indolence! The only faint attempt towards afcertaining this matter we find in the Philofoph. Tranfactions, Vol. LXIV. where a correspondent in North America acquaints Dr Franklin then at London, that an aurora borealis had been feen in America, and afks whether on the fame night there had been any fuch appearance at London. The Doctör replies, that there had indeed been an aurora borealis that night; and that, if it had likewise been feen in America, it muft have been very high.

5
jectures
concerning
the caufe of
the meteor.

With regard to the caufe of the aurora borealis, many conjectures have been formed. The firft which naturally occurred, was, that it was occafioned by the afcent of inflammable fulphureous vapours from the earth, which taking fire in the rarer regions of the atmofphere, exhibited, by its flafhing in different directions, the beautiful appearances we often obferve in the aurora borealis. To this fuppofition Dr Halley objects the immenfe extent of fuch phenomena, and that they are constantly obferved to proceed from north to fouth, but never from fouth to north. This made him very reafonably conclude, that there was fome connection between the poles of the earth and the aurora borealis. The Doctör was in a great meafure unacquainted with the electric power, though he well knew that of magnetifm: he fuppofed therefore, that this earth was hollow, having within it a magnetical fphere, which corresponded in virtue with all the natural and artificial magnets on the furface; the poles of the central magnet not corresponding exactly with thofe of the outer fhell of earth, he thought might be the reafon why the magnetic needle did not always point due north; and the magnetic effluvia paffing through the earth, from one pole of the central magnet to another, might fometimes become vifible, in their courfe, which he thought was from north to fouth, and thus exhibit the beautiful confufations of the aurora borealis. This conjecture, for it could be no more, has commonly been looked upon as an extravagant flight of fancy; but if we confider the matter thoroughly, we fhall find it an undoubted proof of a moft profound and folid genius. Dr Halley, as already obferved, was in a manner totally ignorant of the powers of electricity, and therefore was obliged to work with fuch materials as he had. Had he known that a froke of electricity would give polarity to a needle that had it not, or reverfe the poles of one that had it before, he would un-

doubtedly have concluded the electric and magnetic effluvia to be the fame, and that the aurora borealis was this fluid performing its circulation from one pole of the earth to the other. In fact, this very hypothefis is adopted by S. Beccaria; and by the fuppofed circulation of the electric fluid he accounts for the phenomena of magnetifm and the aurora borealis in a manner perfectly fimilar to that of Dr Halley, only changing the phrafe *magnetic effluvia* for *electric fluid*. The following is the account given us by Dr Priestley, of Beccaria's fentiments on this matter.

"Since a fudden froke of lightning gives polarity to magnets, he conjectures, that a regular and conitant circulation of the whole mafs of the fluid from north to fouth may be the original caufe of magnetifm in general. This is truly a great thought; and, if juft, will introduce greater fimplicity into our conceptions of the laws of nature.

"That this ethereal current is infenfible to us is no proof of its non-exiftence, fince we ourfelves are involved in it. He had feen birds fly fo near a thunder-cloud, as he was fure they would not have done had they been affected by its atmofphere.

"This current he would not fuppofe to arife from one fource, but from feveral, in the northern hemisphere of the earth. The aberration of the common centre of all thefe currents from the north point may be the period of the variation, and the obliquity with which the currents ftrike into the earth may be the caufe of the dipping, of the needle, and alfo why bars of iron more eafily receive the magnetic virtue in one particular diretion.

"He thinks that the aurora borealis may be this electric matter performing its circulation in fuch a ftate of the atmofphere as renders it vifible, or approaching the earth nearer than ufual. Accordingly very vivid appearances of this kind have been obferved to occafion a fluctuation in the magnetic needle."

Here we muft firft remark, that, if this thought, as Dr Priestley fays, is truly great, its greatnefs is juftly due to Dr Halley: we cannot fuppofe S. Beccaria to have been ignorant of Dr Halley's magnetic hypothefis; and if he was not ignorant of it, it is impoffible to avoid believing him to be tacitly obliged to it. On the thought itfelf, however, we muft obferve, that a circulation of an immenfe quantity of electric fluid round the earth bears a ftriking fimilitude to one of Des Cartes's vortices; and as fuch a circulation hath by no means been proved, this very circumftance ought to make us cautious of receiving it. But befides this, Mr Forfter, in the paffage above quoted, furnifhes us with a direct difproof of this circulation; with which, though neither Dr Halley nor S. Beccaria could be acquainted, they might have thought of it as a final proof either of the truth or falfehood of their hypothefis.—If the aurora borealis is no other than the electric fluid performing the abovementioned circulation, it ought to dart from the horizon towards the zenith in the northern hemisphere, and from the zenith to the horizon in the fouthern one: but Mr Forfter plainly tells us, that the columns fhoot up from the horizon towards the zenith as well in the fouthern hemisphere as in the northern; fo that if the aurora borealis is to be reckoned the flafhings of electric matter, its courfe is plainly directed from both poles towards the equator,

Aurora
Borealis.

Aurora
Borealis.

and not from one pole to the other.

Concerning the cause of this phenomenon Mr Canton has the following query: "Is not the aurora borealis the flashing of electrical fire from positive towards negative clouds at a great distance, through the upper part of the atmosphere where the resistance is least?" But to this we must reply in the negative; for in this case it would flash in every direction according to the position of the clouds, as well as from north to south. Besides this query, he conjectures, that when the needle is disturbed by the aurora borealis, that phenomenon proceeds from the electricity of the heated air; and supposes the air to have the property of becoming electric by heat, like the tourmalin. But neither does this hypothesis appear at all probable; because, in such a case, the aurora borealis ought to be most frequent in summer when the air is most heated, whereas it is found to be the reverse. — Lastly, with these electrical hypotheses we shall contrast that of Mr Mairan, who imagined this phenomenon to proceed from the atmosphere of the sun, particles of which were thrown off by its centrifugal force acquired by his rotation on his axis; and that these particles falling upon the atmosphere of the earth near its equatorial parts, were from thence propelled by the diurnal motion of the earth towards the polar regions, where they formed the aurora borealis. This hypothesis, besides its being a mere supposition unsupported by one single appearance in nature, is liable to the objection already mentioned; for in this case the light should dart from the equator to the poles, and not from the poles to the equator: or if we should suppose this matter to be gradually accumulated at each of the poles, we must then make other suppositions, equally vague and ill founded, concerning its getting back with such surprising rapidity in direct opposition to the power which once brought it thither.

The first person that seems to have endeavoured to find any positive proof for the electrical quality of the aurora borealis, is Dr Hamilton of Dublin. He observes, that though this phenomenon is commonly supposed to be electrical, yet he had not seen any attempt to prove that it is so: but the only proof he himself brings is an experiment of Mr Hawkbee, by which the electric fluid is shown to put on appearances somewhat like the aurora borealis, when it passes through a vacuum. He observed, that when the air was most perfectly exhausted, the streams of electric matter were then quite white; but when a small quantity of air was let in, the light assumed more of a purple colour. The flashing of this light therefore from the dense regions of the atmosphere into such as are more rare, and the transitions through mediums of different density, he reckons the cause of the aurora borealis, and of the different colours it assumes.

Dr Hamilton's proof, then, of the electricity of the aurora borealis, consists entirely in the resemblance the two lights bear to one another; and if to this we add, that, during the time of an aurora borealis, the magnetic needle hath been disturbed, electric fire obtained from the atmosphere in plenty, and at some times different kinds of rumbling and hissing sounds heard, we have the sum of all the positive evidence in favour of the electric hypothesis.

Was the aurora borealis the first natural phenomenon the solution of which had been attempted by elec-

Aurora
Borealis.

tricity, no doubt the proofs just now adduced would be very insufficient: but when it is considered, that we have indispensible evidence of the identity of the phenomena of thunder and of electricity; when we also consider, that the higher parts of our atmosphere are continually in a strongly electrified state; the analogy becomes so strong, that we can scarce doubt of the aurora borealis arising from the same cause. The only difficulty is, to give a good reason why the electricity of the atmosphere should be constantly found to direct its course from the poles towards the equator, and not from the equator to the poles; and this we think may be done in the following manner.

1. It is found that all electric bodies, when considerably heated, become conductors of electricity; thus hot air, hot glass, melted resin, sealing wax, &c. are all conductors, till their heat is dissipated, and then they again become electrics.

See Electricity part
II.

2. As the converse of every true proposition ought also to be true, it follows from the above one, that if electrics when heated become conductors, then non-electrics when subjected to violent degrees of cold ought to become electric. In one instance this has been verified by experience: water, which is a conductor when warm or not violently cooled, is found to become electric when cooled to 20° below 0 of Fahrenheit's thermometer. With regard to metallic substances, indeed, no experiments have as yet been made to determine whether their conducting power is affected by cold or not. Very probably we might not be able to produce such a degree of cold as sensibly to lessen their conducting power; but still the analogy will hold; and, as we are by no means able to produce the greatest degree of cold possible, reason will always suggest to us, that if a certain degree of cold changes one conductor into an electric, a sufficient degree of it will also change all others into electrics.

3. If cold is sufficient to change conducting substances into electrics, it must also increase the electric power of such substances as are already electric; that is to say, very cold air, glass, resin, &c. provided they are dry, will be more electric than when they are warmer. With regard to air, which is most to our present purpose, this is rendered extremely probable, by considering that clear frosty weather is of all others the most favourable for electric experiments. They may be made indeed to equal advantage almost in any state of the atmosphere, provided sufficient pains is used, but in dry hard frosts they will succeed much more easily than at any other time.

These three axioms being allowed, the cause of the aurora borealis is easily deduced from them. The air, all round the globe, at a certain height above its surface, is found to be exceedingly cold, and, as far as experiments have yet determined, exceedingly electrical also. The inferior parts of the atmosphere between the tropics, are violently heated during the day-time by the reflection of the sun's rays from the earth. Such air will therefore be a kind of conductor, and much more readily part with its electricity to the clouds and vapours floating in it, than the colder air towards the north and south poles. Hence the prodigious appearances of electricity in these regions, shewing itself in thunder and other tempests of the most terrible kind. Immense quantities of the electric fluid are thus communicated.

nicated to the earth, and the inferior warm atmosphere having once exhausted itself must necessarily be recruited from the upper and colder region. This becomes very probable from what the French mathematicians observed when on the top of one of the Andes. They were often involved in clouds, which, sinking down into the warmer air, appeared there to be highly electrified, and discharged themselves in violent tempests of thunder and lightning; while in the mean time, on the top of the mountain, they enjoyed a calm and serene sky. In the temperate and frigid zones, the inferior parts of the atmosphere never being so thoroughly heated, do not part with their electricity so easily as in the torrid zone, and consequently do not require such recruits from the upper regions; but notwithstanding the difference of heat observed in different parts of the earth near the surface, it is very probable that at considerable heights the degree of cold is nearly equal all round it. Were there a like equality in the heat of the under part, there could never be any considerable loss of equilibrium in the electricity of the atmosphere: but as the hot air of the torrid zone is perpetually bringing down vast quantities of electric matter from the cold air that lies directly above it; and as the inferior parts of the atmosphere lying towards the north and south poles do not conduct in any great degree; it thence follows, that the upper parts of the atmosphere lying over the torrid zone will continually require a supply from the northern and southern regions. This easily shews the necessity of an electric current in the upper parts of the atmosphere from each pole towards the equator: and thus we are also furnished with a reason why the aurora borealis appears more frequently in winter than in summer; namely, because at that time the electric power of the inferior atmosphere is greater on account of the cold than in summer; and consequently the abundant electricity of the upper regions must go almost wholly off to the equatorial parts, it being impossible for it to get down to the earth: hence also the aurora borealis appears very frequent and bright in the frigid zones, the degree of cold in the upper and under regions of the atmosphere being much more nearly equal in these parts than in any other. In some parts of Siberia, particularly, this meteor appears constantly from October to Christmas, and its convulsions are said to be very terrifying. Travellers agree, that here the aurora borealis appears in greatest perfection; and it is to be remarked, that Siberia is the coldest country on earth. In confirmation of this, it may also be observed, that, from the experiments hitherto made with the electrical kite, the air appears considerably more electrical in winter than in summer, though the clouds are known to be often most violently electrified in the summer time; a proof, that the electricity naturally belonging to the air is in summer much more powerfully drawn off by the clouds than in the winter, owing to the excess of heat in summer, as already observed.

A considerable difficulty, however, still remains, from the upright position which the streams of the aurora borealis are generally observed to have; whereas, according to the hypothesis above mentioned, they ought rather to run directly from north to south. This difficulty occurred to Dr Halley: but he answers it by supposing his magnetic effluvia to pass from one pole to another in arches of great circles, arising to a vast

height above the earth, and consequently darting from the places whence they arose almost like the radii of a circle; in which case, being sent off in a direction nearly perpendicular to the surface of the earth, they must necessarily appear erect to those who see them from any part of the surface, as is demonstrated by mathematicians. It is also reasonable to think that they will take this direction rather than any other, on account of their meeting with less resistance in the very high regions of the air than in such as are lower.

But the greatest difficulty still remains: for we have supposed the equilibrium of the atmosphere to be broken in the day-time, and restored only in the night; whereas, considering the immense velocity with which the electric fluid moves, the equilibrium ought to be restored in all parts almost instantaneously; yet the aurora borealis never appears except in the night, although its brightness is such as must sometimes make it visible to us did it really exist in the day-time.

In answer to this it must be observed, that though the passage of electricity through a good conductor is instantaneous, yet through a bad conductor it is observed to take some time in passing. As our atmosphere therefore, unless very violently heated, is but a bad conductor of electricity; though the equilibrium in it is broken, it can by no means be instantaneously restored. Add to this, that as it is the action of the sun which breaks the equilibrium, so the same action, extending over half the globe, prevents almost any attempt to restore it till night; when flashes arise from various parts of the atmosphere, gradually extending themselves with a variety of undulations towards the equator.

It now remains to explain only one particularity of the aurora borealis, namely, that its streams do not always move with rapidity, sometimes appearing quite stationary for a considerable time, and sometimes being carried in different directions with a slow motion. To this indeed we can give no other reply, than that weak electric lights have been sometimes observed to put on the same appearance at the surface of the earth; and much more may we suppose them capable of doing so at great heights above it, where the conductors are both fewer in number and much more imperfect. When M. de Romas was making experiments with an electric kite in Italy, a cylinder of blue light about four or five inches diameter was observed surrounding the string. This was in the day-time; but had it been night, he imagined it must have been four or five feet in diameter; and as the string was 780 feet long, it would probably have seemed pyramidal, pointing upwards like one of the streams of the aurora borealis. A still more remarkable appearance, Dr Priestley tells us, was observed by Mr Hartman. He had been making electrical experiments for four or five hours together in a very small room; and upon going out of it, and returning with a light in his hand, walking pretty quick, he perceived a small flame following him at about three feet distance. Being alarmed at this appearance, he stopped to examine it, upon which it vanished. This last instance is very remarkable, and singular in its kind: from both, however, we are sufficiently warranted to conclude, that small portions of our atmosphere may by various causes be so much electrified as to shine, and likewise be moved from one place to another without parting with the electricity they have

Aurora
Borealis.

have received, for a considerable time.

The corona, or circle, which is often formed near the zenith by the aurora borealis, is easily accounted for in the same manner. As this corona is commonly stationary for some time, we imagine it would be a very proper mark whereby to determine the distance of the meteor itself. If an aurora borealis, for instance, was observed by two persons, one at London, and the other at Edinburgh; by noting the stars among which the corona was observed at each place, its true altitude from the surface of the earth could easily be determined by trigonometry.

Under the article *ATMOSPHERE* it was suggested, that no good proof had been as yet brought for the extreme rarity of the air usually supposed to take place at no very great heights above the earth. The brightness of the meteor there mentioned at 70 miles perpendicular from the surface, as also its figure, seemed to prove the air considerably denser at that distance from the earth. Though the height of the aurora borealis has never been determined, we can scarce imagine it to be greater than that of this meteor, or indeed so great: but although its streams resemble the passage of electric light through a vacuum, it cannot be from thence inferred, that the air is at all in a state similar to the vacuum of an air-pump in those places where the aurora borealis is produced; seeing we have instances of similar appearances being produced in very dense air. The plate of an electrophorus is often so highly electrified, as to throw out flashes from different parts as soon as it is lifted up, and by proper management it may be always made to emit long and broad flashes which shall scarcely be felt by the finger, instead of small, dense, and pungent sparks; so that, though long flashes may be produced in rarefied air, it by no means follows that the same may not also be produced in denser air. As little can we infer any thing from the colours; for we observe the electric spark sometimes white, sometimes blue, and sometimes purple, in the very same state of the atmosphere, and from the same substance.

We shall conclude this article with an account of a paper presented to the Royal Society by Mr Winn, in 1772, wherein he says that the appearance of an aurora borealis is a certain sign of an hard gale of wind from the south or south-west. This he never found to fail in 23 instances; and even thinks, that from the splendor of the meteor, some judgment may be formed concerning the ensuing tempest. If the aurora is very bright, the gale will come on within twenty-four hours, but will be of no long duration; if the light is faint and dull, the gale will be less violent, and longer in coming on, but will also last longer. His observations were made in the English channel, where such winds are very dangerous; and by attending to the aurora, he says he often got easily out of it, when others narrowly escaped being wrecked. This is an exceeding useful observation for sailors: but it cannot be expected that the winds succeeding these meteors should in all places blow from the south-west; though no doubt a careful observation of what winds succeed the aurora borealis, and other meteors, in different parts of the world, might contribute in some measure to lessen the dangers of navigation.

That the aurora borealis ought to be succeeded by winds, may be easily deduced from the hypothesis

last mentioned. If this phenomenon is occasioned by the vast quantity of electric matter conveyed to the equatorial parts of the earth, it is certain that the earth cannot receive any great quantity of this matter at one place without emitting it at another. The electricity, therefore, which is constantly received at the equator, must be emitted nearer the poles, in order to perform its course, otherwise there could not be a constant supply of it for the common operations of nature. It is observed, that electrified bodies are always surrounded by a blast of air, which is sent forth from them in all directions; hence, if the electric matter find a more ready passage through one part of the earth than another, a wind will be found to blow from that quarter. If therefore one of these places happens to be in the Atlantic ocean near the coast of France, or in the bay of Biscay, the electric matter which has been received at the equator during an aurora borealis will be discharged there some time after, and consequently a wind will blow from that quarter, which will be from the south-west to those ships which are in the English channel. It cannot be imagined, however, that all the matter can be discharged from one place; and therefore, according to the different situations of those electrical vents, winds may blow in different directions; and thus the same aurora borealis may produce a south-west wind in the English channel, and a north-west one in Scotland.

AURUM. See *GOLD*.

AURUM Fulminans. See *CHEMISTRY*, n° 356.

AURUM Mosaicum. See *CHEMISTRY*, n° 413.

AURUM Reginae, queen's gold. See *QUEEN*.

AUSA, a town of Terraconensis, in the middle age called *Ausona*; now *Vich de Osona*, a town of Catalonia in Spain. E. Long. 2. N. Lat. 41. 50.

AUSI, an ancient and very savage people of Libya. Herodotus tells us that they were unacquainted with marriage, and had all their women in common. The children were brought up by their mothers till they were able to walk: after which, they were introduced to an assembly of the men, who met every three months; and the man to whom any child first spoke, acknowledged himself its father. They celebrated annually a feast in honour of Minerva, in which the girls divided into two companies, fought with sticks and stones, and those who died of their wounds were concluded not to have been virgins.

AUSIMUM, or *AUXIMUM,* an ancient Roman colony in the Picenum; now *Osimo* or *Ofimo*, in the March of Ancona in Italy. E. Long. 15. N. Lat. 43. 20.

AUSITÆ, or *ÆSITÆ,* a tribe of ancient Arabs, supposed by Bochart to have inhabited the land of Uz mentioned in scripture. See *ARABIA*, n° 4.

AUSONIUS, (in Latin *Decimus*, or rather *Decimus*, Magnus Ausonius), one of the best poets of the fourth century, was the son of an eminent physician, and born at Bourdeaux. Great care was taken of his education, the whole family interesting themselves in it, either because his genius was very promising, or that the scheme of his nativity, which had been cast by his grandfather on the mother's side, made them imagine that he would rise to great honour. He made an uncommon progress in classical learning, and at the age of 30 was chosen to teach grammar at Bourdeaux. He was promoted some time after to be professor of rhetoric; in which

concerning
the reason.

office he acquired so great a reputation, that he was sent for to court to be preceptor to Gratian the emperor Valentinian's son. The rewards and honours conferred on him for the faithful discharge of his office prove the truth of Juvenal's maxim, that when fortune pleases she can raise a man from a rhetorician to the dignity of a consul. He was actually appointed consul by the emperor Gratian, in the year 379, after having filled other considerable posts; for besides the dignity of questor, to which he had been nominated by Valentinian, he was made prefect of the Pretorium in Italy and Gaul after that prince's death. His speech returning thanks to Gratian on his promotion to the consulship is highly commended. The time of his death is uncertain; he was still living in 392, and lived to a great age. The emperor Theodosius had a great esteem for Ausonius, and pressed him to publish his poems. There is a great inequality in his works; and in his manners and his style there is a harshness which was perhaps rather the defect of the times he lived in, than of his genius. Had he lived in Augustus's reign, his verses, according to good judges, would have equalled the most finished of that age. He is generally supposed to have been a Christian: some ingenious authors indeed think otherwise, but, according to Mr Bayle, without just reason. The best edition of his poems is that of Amsterdam in 1671.

AUSTERE, rough, atringent. Thus an austere taste is such a one as constringes the mouth and tongue; as that of unripe fruits, harsh wines, &c.

AUSTERITY, among moral writers, implies severity and rigour. Thus we say, *Austerity of manners, austerities of the monastic life*, &c.

AUSTIN (St). See *St AUGUSTIN*.

AUSTRAL, something relating to the south: thus the six signs on the south side of the equinoctial are called *austral signs*.

AUSTRIA, one of the principal provinces of the empire of Germany towards the east; from which situation it takes its name *Ost-ryck*, in the German language signifying the *East Country*. It is bounded on the north by Moravia; on the east by Hungary; on the south by Stiria; and on the west by Bavaria. It is divided into *Upper* and *Lower*. Upper Austria is situated on the south, and Lower Austria on the north side of the Danube. Vienna the capital is in the Upper Austria, which contains several other very considerable towns. The country is very fertile, has a great many mines, and produces vast quantities of sulphur.

In the ninth and tenth centuries, Austria was the frontier of the empire against the barbarians. In 928, the emperor Henry the Fowler, perceiving that it was of great importance to settle some person in Austria who might oppose these incursions, invested Leopold, surnamed the *Illustrious*, with that country. Otto I. erected Austria into a marquisate in favour of his brother-in-law Leopold, whose descendant Henry II. was created duke of Austria by the emperor Frederic Barbarossa. His posterity becoming extinct in 1240, the states of the country, in order to defend themselves from the incursions of the Bavarians and Hungarians, resolved to put themselves under the protection of Henry marquis of Misnia; but Othogar II. king of Bohemia, being likewise invited by a party in the duchy, took possession of it, alleging not only the invitation of the states,

but also the right of his wife, heiress of Frederic the last duke. The emperor Rodolphus I. pretending a right to this duchy, refused to give Othogar the investiture of it; and afterwards killing him in a battle, procured the right of it to his own family. From this Rodolphus the present house of Austria is descended, which for several centuries past has rendered itself so famous and so powerful, having given 14 emperors to Germany, and six kings to Spain.

In 1477, Austria was erected into an archduchy by the emperor Frederic the Pacific, for his son Maximilian, with these privileges: That they shall be judged to have obtained the investiture of the states, if they do not receive it after having demanded it three times; that if they receive it from the emperor, or the imperial ambassadors, they are to be on horseback, clad in a royal mantle, having in their hand a staff of command, and upon their head a ducal crown of two points; and surrounded with a cross like that of the Imperial crown. The archduke is born privy-counsellor to the emperor, and his states cannot be put to the ban of the empire. All attempts against his person are punished as crimes of lese-majesty, in the same manner as those against the king of the Romans, or Electors. No one dared to challenge him to single combat. It is in his choice to assist at the assemblies, or to be absent; and he has the privilege of being exempt from contributions and public taxes, excepting 12 soldiers which he is obliged to maintain against the Turk for one month. He has rank immediately after the electors; and exercises justice in his states without appeal, by virtue of a privilege granted by Charles V. His subjects cannot even be summoned out of his province upon account of lawsuits, to give witness, or to receive the investiture of fiefs. Any of the lands of the empire may be alienated in his favour, even those that are feudal; and he has a right to create counts, barons, gentlemen, *poets*, and notaries. In the succession to his states, the right of birth takes place; and, failing males, the females succeed according to the lineal right; and if no heir be found, they may dispose of their lands as they please.

AUTERFOITS ACQUIT.

AUTERFOITS Attaint.

AUTERFOITS Convict.

} See the article PLEA
to Indictment.

AUTHENTIC, something of acknowledged and received authority. In law, it signifies something clothed in all its formalities, and attested by persons to whom credit has been regularly given. Thus we say, *authentic papers, authentic instrument*.

AUTHOR, properly signifies one who created or produced any thing. Thus God, by way of eminence, is called the *Author of nature*, the *Author of the universe*.

AUTHOR, in matters of literature, a person who has composed some book or writing.

AUTHORITY, in a general sense, signifies a right to command, and make one's self obeyed. In which sense, we say, the *royal authority*, the *episcopal authority*, the *authority of a father*, &c. It denotes also the testimony of an author, some apophthegm or sentence of an eminent person quoted in a discourse by way of proof.

Authority is represented, in painting, like a grave matron sitting in a chair of state, richly clothed in a garment embroidered with gold, holding in her right-hand a sword, and in her left a sceptre. By her side

Autoch-
thones
||
Automaton

is a double trophy of books and arms.

AUTOCHTHONES, an appellation assumed by some nations, importing that they sprung, or were produced, from the same soil which they still inhabited. In this sense, *Autochthones* amounts to the same with *Abrigines*. The Athenians valued themselves on their being *Autochthones*, *self-born*, or *γεννηεις*, *earth-born*; it being the prevailing opinion among the ancients, that, in the beginning, the earth, by some prolific power, produced men, as it still does plants. The proper *Autochthones* were those primitive men who had no other parent beside the earth. But the name was also assumed by the descendants of these men, provided they never changed their ancient seat, nor suffered other nations to mix with them. In this sense it was that the Greeks, and especially the Athenians, pretended to be *Autochthones*; and, as a badge thereof, wore a golden grasshopper woven in their hair, an insect supposed to have the same origin.

AUTOCRATOR, a person vested with an absolute independent power, by which he is rendered unaccountable to any other for his actions. The power of the Athenian generals, or commanders, was usually limited; so that, at the expiration of their office, they were liable to render an account of their administration. But, on some extraordinary occasions, they were exempted from this restraint, and sent with a full and uncontrollable authority: in which case they were styled *Autokratōres*. The same people also applied the name to some of their ambassadors, who were vested with a full power of determining matters according to their own discretion. These were denominated *πρωτοβουτοι* *Autokratōres*, and resembled our plenipotentiaries.

AUTO DARE, act of faith. See *Act of Faith*.

AUTODIDACTUS, a person self-taught, or who has had no master, or assistant of his studies, besides himself.

AUTOGRAPH, denotes a person's hand-writing, or the original manuscript of any book, &c.

AUTOLITHOTOMUS, he who cuts himself for the stone. Of this we have a very extraordinary instance given by Reiselius, in the *Ephemerides* of the Academy *Natura Curiosorum*, dec. 1. an. 3. obs. 192.

AUTOMATON, (from *αυτο* *ipse*, and *μοωκι* *excitor*), a self-moving machine, or one so constructed, by means of weights, levers, pulleys, &c. as to move for a considerable time, as though endued with animal life. According to this description, clocks, watches, and all machines of that kind, are automata.

Under the article *ANDROIDES*, we observed that the highest perfection to which automata could be carried was to imitate exactly the motions and actions of living creatures, especially of mankind, which are more difficultly imitated than those of other animals. Very surprising imitations, however, have been made of other creatures. So long ago as 400 years before Christ, Archytas of Tarentum is said to have made a wooden pigeon that could fly; nor will this appear at all incredible, when we consider the flute-player made by M. Vaucanson, and the chess-player by M. Kempell. Dr Hook is also said to have made the model of a flying chariot, capable of supporting itself in the air. But M. Vaucanson abovementioned hath distinguished himself still more eminently. That gentleman, encouraged by the favourable reception of his flute-player,

Automat
|
Autum

made a duck, which was capable of eating, drinking, and imitating exactly the voice of a natural one. Nay, what is still more surprising, the food it swallowed was evacuated in a digested state; not that it was really in the state of natural excrement, but only considerably altered from what it was when swallowed; and this digestion was performed on the principles of solution, not of trituration. The wings, viscera, and bones, of this artificial duck, were also formed so as very strongly to resemble those of a living animal. Even in the actions of eating and drinking, this resemblance was preferred; the artificial duck swallowed with avidity and vastly quick motions of the head and throat; and likewise muddled the water with his bill, exactly like a natural one.

M. Le Droz of La Chaux de Fonds in the county of Neuchâtel, hath also executed some very curious pieces of mechanism, which well deserve to be ranked with those already mentioned. One was a clock, which was presented to his Spanish majesty; and had, among other curiosities, a sheep, which imitated the bleating of a natural one; and a dog watching a basket of fruit: when any one attempted to purloin the fruit, the dog gnashed his teeth and barked; and if it was actually taken away, he never ceased barking till it was restored. Besides this, he made a variety of human figures, which exhibited motions truly surprising; but all inferior to Mr Kempell's chess-player, which may justly be looked upon as the greatest masterpiece in mechanics that ever appeared. See *ANDROIDES*.

AUTONOMIA, a power of living or being governed by our own laws and magistrates. The liberty of the cities which lived under the faith and protection of the Romans, consisted in their autonomy, i. e. they were allowed to make their own laws, and elect their own magistrates; by whom justice was to be administered, and not by Roman presidents or judges, as was done in other places which were not indulged the autonomy.

AUTRE-ÉGLISE, a village of Brabant, in the Austrian Netherlands; to which the left wing of the French army extended, when the confederates obtained the victory at Ramillies, in 1706. E. Long. 4. 50. N. Lat. 50. 40.

AUTRICUM, the capital of the Carnutes, a people of Gallia Celtica; afterwards called *Carnotena*, *Carnotenus*, and *Civitas Carnotenus*; now *Chartres* in the Orleanois on the Eure. E. Long. 1. 32. N. Lat. 48. 47.

AUTUMN, the third season of the year, when the harvest and fruits are gathered in. Autumn is represented, in painting, by a man at perfect age, clothed like the vernal, and likewise girded with a starry girdle; holding in one hand a pair of scales equally poised, with a globe in each; in the other hand, a bunch of divers fruits and grapes. His age denotes the perfection of this season; and the balance, that sign of the zodiac which the sun enters when our autumn begins.

Autumn begins on the day when the sun's meridian distance from the zenith, being on the decrease, is a mean between the greatest and the least; which in these countries is supposed to happen when the sun enters Libra. Its end coincides with the beginning of winter. Several nations have computed the years by autumns; the English Saxons, by winters. Tacitus
tells

tells us, the ancient Germans were acquainted with all the other seasons of the year, but had no notion of autumn. Lidyat observes of the beginning of the several seasons of the year, that

Dat Clemens hyemem, dat Petrus ver cathedratus, Æfluat Urbanus, autumnat Bartholomæus.

Autumn has always been reputed an unhealthy season. Tertullian calls it *tentator valetudinum*; and the satyrist speaks of it in the same light, *Autumnus Libitine quæstus acerbe*.

AUTUMNAL POINT, is that part of the equinox from which the sun begins to descend towards the fourth pole.

AUTUMNAL SIGNS, in astronomy, are the signs Libra, Scorpio, Sagittarius, through which the sun passes during the autumn.

AUTUMNAL EQUINOX, that time when the sun enters the autumnal point.

AUTUN, an ancient city of France in the duchy of Burgundy, the capital of the Autois, with a bishop's see. The length of this city is about three quarters of a mile, and its breadth nearly equal. The river Arroux washes its ancient walls, whose ruins are so firm, and the stones so closely united, that they seem almost to be cut out of the solid rock. In this city are the ruins of three ancient temples, one of which was dedicated to Janus, and another to Diana. Here are likewise a theatre and a pyramid, which last is probably a tomb; it stands in a place called the *field of urns*, because several urns had been found there. Here are also two antique gates of great beauty. The city lies at the foot of three great mountains, in E. Long. 4. 15. N. Lat. 45. 50.

AUVERGNE, a province of France, about 100 miles in length, and 75 in breadth. It is bounded on the north, by the Bourbonnois; on the east, by Torez and Velay; on the west, by Limosin, Quercy, and La Marche; and on the south, by Roveryne and the Cevennes. It is divided into upper and lower; the latter, otherwise called *Limagne*, is one of the finest countries in the world. The mountains of Higher Auvergne render it less fruitful; but they afford good pasture, which feeds great numbers of cattle, which are the riches of that country. Auvergne supplies Lyons and Paris with fat cattle, makes a large quantity of cheese, and has manufactures of several kinds. The capital of the whole province is Clermont.

AUXERRE, an ancient town of France in the duchy of Burgundy, and capital of the Auxerrois, with a bishop's see. The episcopal palace is one of the finest in France, and the churches are also very beautiful. This town is advantageously situated for trade with Paris, on the river Yone. E. Long. 3. 35. N. Lat. 47. 54.

AUXILIARY, whatever is aiding or helping to another.

AUXILIARY Verbs, in grammar, are such as help to form or conjugate others; that is, are prefixed to them, to form or denote the moods or tenses thereof: as, *to have* and *to be*, in the English; *être* and *avoir*, in the French; *ho* and *sono* in the Italian, &c. In the English language, the auxiliary verb *am* supplies the want of passive verbs.

AUXONNE, a small fortified town of France, in the duchy of Burgundy; seated on the river Saone, over which there is a bridge of 23 arches, to facilitate

the running off of the waters after the overflowing of the river. At the end of the bridge is a causeway 2250 paces long. E. Long. 5. 22. N. Lat. 47. 11.

AWARD, in law, the judgment of an arbitrator, or of one who is not appointed by the law a judge, but chosen by the parties themselves for terminating their difference. See **ARBITRER** and **ARBITRATION**.

AWLS, among shoemakers, an instrument wherewith holes are bored through the leather, to facilitate the litching or sewing the same. The blade of the awl is usually a little flat and bended, and the point ground to an acute angle.

AWLAN, a small imperial town of Germany, in the circle of Suabia, seated on the river Kochen. E. Long. 11. 15. N. Lat. 48. 52.

AWME, or **AUME**, a Dutch liquid measure containing eight steckans, or 20 verges or verteels, equal to the tierce in England, or to one sixth of a tun of France.

AWN, in botany. See **ARISTA**.

AWNING, in the sea language, is the hanging a sail, tarpawling, or the like, over any part of the ship, to keep off the sun, rain, or wind.

AX, among carpenters, an instrument to hew wood. *Battle-Ax*. See **CELT**.

AXATI, a town of ancient Bætica, in the Bætis; now *Lora*, a small city of Andalusia, in Spain, seated on the Guadalquivir. W. Long. 5. 20. N. Lat. 37. 20.

AXBRIDGE, a town of Somersetshire in England, consisting of one long narrow street. W. Long. 2. 20. N. Lat. 51. 30.

AXEL, a small fortified town in Dutch Flanders. E. Long. 3. 40. N. Lat. 51. 17.

AXENUS. See **EUXINE SEA**.

AXHOLM, an island in the north-west part of Lincolnshire in England. It is formed by the rivers Trent, Idel, and Dan; and is about ten miles long and five broad. The lower part is marshy, but produces an odoriferous shrub called *gall*; the middle is rich and fruitful, yielding flax in great abundance, as also alabaster which is used for making lime. The principal town is called *Axey*, and is now very thinly inhabited.

AXIACE, an ancient town of Sarmatia Europea; now *Oxakovu*, the capital of Budziac Tartary. E. Long. 32. 30. N. Lat. 46. 0.

AXILLA, in anatomy, the arm-pit, or the cavity under the upper part of the arm.

AXILLARY, something belonging to or lying near the axilla. Thus, *axillary artery* is that part of the subclavian branches of the ascending trunk of the aorta which passeth under the arm-pits; *axillary glands* are situated under the arm-pits, enveloped in fat, and lie close by the axillary vessels; and *axillary vein* is one of the subclavians which passes under the arm-pit, dividing itself into several branches, which are spread over the arm.

AXIM, a small territory on the gold-coast in Africa. The climate there is so excessively moist, that it is proverbially said to rain 11 months and 29 days of the year. This excessive moisture renders it very unhealthy; but it produces great quantities of rice, water melons, lemons, oranges, &c. Here are also produced vast numbers of black cattle, goats, sheep, tame pigeons, &c. The whole country is filled with beautiful and populous villages, and the intermediate lands well cultivated;

cultivated; besides which, the natives are very wealthy, from the constant traffick carried on with them by the Europeans for their gold. The capital, which is also called *Axim*, by some *Acombone*, stands under the cannon of the Dutch fort St Antonio. Behind, it is secured by a thick wood that covers over the whole declivity of a neighbouring hill. Between the town and the sea runs an even and spacious shore of beautiful white sand. All the houses are separated by groves of cocoa and other fruit trees, planted in parallel lines, each of an equal width, and forming an elegant vista. The little river *Axim* crosses the town; and the coast is defended by a number of small pointed rocks, which project from the shore, and render all access to it dangerous. The capital is situated in W. Long. 24. o. N. Lat. 5. o. This canton is a kind of republic, the government being divided between the Caboceros or chief men, and Manaceros or young men. It must be observed, however, that in their courts there is not even a pretence of justice: whoever makes the most valuable presents to the judges is sure to gain his cause, the judges themselves alleging the gratitude due for the bribes received, as a reason; and if both parties happen to make presents of nearly equal value, they absolutely refuse to give the cause a hearing.

AXIOM, in philosophy, any plain, self-evident, and received notion, that cannot be made more plain and evident by demonstration. It is also an established principle in some art or science.

AXIOPOLIS, a town of the Triballi in Thracia Inferior; now *Axiopoli*, in Bulgaria. E. Long. 34. o. N. Lat. 45. 40.

AXIS, in geometry, the straight line in a plain figure, about which it revolves, to produce or generate a solid; thus if a semicircle be moved round its diameter at rest, it will generate a sphere, the axis of which is that diameter.

AXIS, in astronomy, is an imaginary right line supposed to pass through the centre of the earth, and the heavenly bodies, about which they perform their diurnal revolutions.

AXIS, in conic-sections, a right line dividing the section into two equal parts, and cutting all its ordinates at right angles.

AXIS, in mechanics. The axis of a balance is that line about which it moves, or rather turns about. Axis of oscillation is a right line parallel to the horizon, passing through the centre about which a pendulum vibrates.

AXIS in *Peritrochic*, one of the six mechanical powers, consisting of a peritrochium or wheel concentric with the base of a cylinder, and moveable together with it about its axis.

AXIS, in optics, is that particular ray of light coming from any object which falls perpendicularly on the eye.

AXIS, in architecture. *Spiral axis*, is the axis of a twisted column drawn spirally in order to trace the circumvolutions without. *Axis of the Ionic capital*, is a line passing perpendicularly through the middle of the eye of the volute.

AXIS of a Vessel, is an imaginary right line passing through the middle of it perpendicularly to its base, and equally distant from its sides.

AXIS, in botany, is a taper column placed in the

centre of some flowers or catkins, about which the other parts are disposed.

AXIS, in anatomy, the name of the second vertebra of the neck; it hath a tooth which goes into the first vertebra, and this tooth is by some called the *axis*.

AXLE. See **AXIS**.

AXMINSTER, a town of Devonshire, situated on the river Ax, in the great road between London and Exeter, in W. Long. 3. 15. N. Lat. 50. 40. It was a place of some note in the time of the Saxons, but now contains only about 200 houses. Here is a small manufactory of broad and narrow cloths, and some carpets are also manufactured after the Turkey manner.

AXUMA, formerly a large city, and capital of the whole kingdom of Abyssinia in Africa, but now reduced to a miserable village scarce containing 100 inhabitants. E. Long. 36. 4. N. Lat. 14. 13.

AXUNGIA, in a general sense, denotes old lard, or the driest and hardest of any fat in the bodies of animals: but more properly it signifies only hogs-lard *.

AXUNGIA Vitri, SANDIVER, or SALT of GLASS, a kind of salt which separates from the glass while it is in fusion. It is of an acrimonious and biting taste. The farriers use it for cleaning the eyes of horses. It is also made use of for cleaning the teeth; and it is sometimes applied to running ulcers, the herpes, or the itch, by way of delicate.

AXYRIS, a genus of the triandria order, belonging to the monœcia class of plants; of which there are four species, but none of them merit a particular description.

AY, a town of France in Champagne, near the river Mame, remarkable for its excellent wines. E. Long. 2. 15. N. Lat. 49. 4.

AYAMONTE, a sea-port town of Andalusia in Spain, with a strong castle built on a rock; seated on the mouth of the river Guadiana. It has a commodious harbour, fruitful vineyards, and excellent wine. W. Long. 8. 5. N. Lat. 37. 9.

AYENIA, in botany, a genus of the pentandria order, belonging to the gynandria class of plants. There are three species, all natives of the West Indies.

AYLMER (John), bishop of London, in the reign of queen Elizabeth, was born in the year 1521, at Aylmer-hall in the parish of Tylney, in the county of Norfolk. Whilst a boy, he was distinguished for his quick parts by the Marquis of Dorset afterwards duke of Suffolk; who sent him to Cambridge, made him his chaplain, and tutor to his children. One of these children was the unfortunate lady Jane Gray, who soon became perfectly acquainted with the Latin and Greek languages. His first preferment was to the archdeaconry of Stow in the diocese of Lincoln, which gave him a seat in the convocation held in the first year of Queen Mary, where he resolutely opposed the return to popery, to which the generality of the clergy were inclined. He was soon after obliged to fly his country, and take shelter among the Protestants in Switzerland. On the accession of Queen Elizabeth, he returned to England. In 1562, he obtained the archdeaconry of Lincoln; and was a member of the famous synod of that year, which reformed and settled the doctrine and discipline of the church of England. In the year 1576, he was consecrated bishop of London. He died in the year 1594, aged 73; and was buried in

* See *Mat. Medica*, n^o 147.

Ayrz St Paul's. He was a learned man, a zealous father of the church, and a bitter enemy to the Puritans. He published a piece entitled, *An harbarowse for faithful and trewe subjects against the late blowne blasfe concerning the government of aewnen, &c.* This was written, whilst he was abroad, in answer to Knox, who published a book at Geneva under this title, *The first blasfe against the monstrous regiment and empire of women.* He is, by Strype, supposed to have published lady Jane Gray's letter to Harding. He also assisted Fox in translating his History of Martyrs into Latin.

AYRY, or AERY, of Hawks, a nest or company of hawks; so called from the old French word *aire*, which signified the fame.

AYSCUE (Sir George), a gallant English admiral, descended from a good family in Lincolnshire. He obtained the honour of knighthood from king Charles I. which however did not withhold him from adhering to the parliament in the civil war: he was by them constituted admiral of the Irish seas, where he is said to have done great service to the protestant interest, and to have contributed much to the reduction of the whole island. In 1651 he reduced Barbadoes and Virginia, then held for the king, to the obedience of the parliament; and soon after the restoration behaved with great honour in the war with the Dutch. In the famous engagement in the beginning of June 1666, when Sir George was admiral of the white squadron, his ship the Royal Prince ran upon the Gallop-land; where being surrounded with enemies, his men obliged him to strike. He went no more to sea after this, but spent the rest of his days in retirement.

AYMOUTH, a town of Scotland in the county of Mers, formerly fortified to curb the garrison of Berwick, from which place it is distant six miles. W. Long. 1. 50. N. Lat. 55. 50.

AZAB, in the Turkish armies, a distinct body of soldiery, who are great rivals of the Janizaries.

AZALEA, UPRIGHT HONEYSUCKLE, or ROSE-BAY, a genus of the monogynia order, belonging to the pentandria class of plants. There are six species, of which the most remarkable are the following. 1. The viscosa, with a white flower, is a low shrub, arising with several stems to the height of two or three feet. The leaves come out in clusters without any order at the end of the shoots, and their edges are set with very short teeth which are rough. The flowers come out in clusters between the leaves, have much the appearance of honeysuckle, and are as well scented. 2. The nudiflora, or red American upright honeysuckle, grows taller than the first; and in its native country will sometimes arrive at the height of 12 feet, but in Britain never rises to above half that height. It hath several stems with oblong smooth leaves. The flower-stalks arise from the division of the branches, which are long and naked, supporting a cluster of red flowers; these are divided at the top into five equal segments which spread open. Another species with bright red flowers was found by Mr Lightfoot upon the tops of many mountains in the highlands of Scotland.—The first two species require a moist soil and a sandy situation, and can only be propagated from slips, as they never produce good seeds in Britain. The autumn is the best time to remove the plants, and their roots ought to be covered in winter.

VOL. II.

AZAI, a town of Touraine in France, seated on the river Indre. E. Long. 10. 35. N. Lat. 47. 18.

AZAMOR, a small sea-port town of the kingdom of Morocco in Africa, formerly very considerable, but ruined by the Portuguese in 1513. W. Long. 7. 0. N. Lat. 32. 50.

AZARAKITES, a sect of Mahometan Arabs *

AZARIAH, or UZZIAH, king of Judah, succeeded his father Amaziah, 810 years before Christ. He assembled an army of above 300,000 men, with which he conquered the Philistines, and demolished the walls of Gath, Jabniel, and Ashdod; built up the walls of Jerusalem; furnished the city with conduits; and planted gardens and vineyards; but at last, being elated with his prosperity, and resolving to usurp the office of high priest, he was struck with a leprosy, which obliged him to remain shut up in his palace for the rest of his days. He died about 759 years before the Christian era, and was succeeded by Jonathan his son.—There are several other persons of this name mentioned in the sacred Scriptures.

AZAZEL. This word relates to the ceremony of the scape-goat, under the Jewish religion. Some call the goat itself by this name, as St Jerom and Theodoret. Dr Spenser says, the scape-goat was to be sent to Azazel; by which is meant the devil. Mr le Clerc translates it *precipitium*, making it to be that steep and inaccessible place to which the goat was sent, and where it was supposed to perish.

AZEM, ASEM, ASSAM, or ACHAM, a country of Asia to the north of Ava, but which is very little known to Europeans. It is said to be very fertile, and to contain mines of gold, silver, iron, and lead, all which belong to the king, who, in consequence of enjoying the produce, requires no taxes from his people. They have also great quantities of gum lac, and coarse silk. It is also thought that the inhabitants of Azem were long ago the inventors of cannon and gunpowder; and that from them the invention past to the inhabitants of Pegu, and from thence to the Chinese.

AZIMUTH, in astronomy, an arch of the horizon, intercepted between the meridian of the place and the azimuth, or vertical circle passing through the centre of the object, which is equal to the angle of the zenith, formed by the meridian and vertical circle: or it is found by this proportion, As the radius to the tangent of the latitude of the place, so is the tangent of the sun's or star's altitude, for instance, to the cosine of the azimuth from the south, at the time of the equinox.

Magnetical AZIMUTH, an arch of the horizon intercepted between the azimuth, or vertical circle, passing thro' the centre of any heavenly body, and the magnetical meridian. This is found by observing the object with an azimuth-compass.

AZIMUTH-Compass, an instrument for finding either the magnetical azimuth or amplitude of an heavenly object.

The learned Dr Knight invented some time since a very accurate and useful sea-compass, which is at present used in the navy, and will be described under the article COMPASS. This instrument, with the following contrivance added by the ingenious Mr Smeaton, answers the purposes of an azimuth and amplitude compass.

Azimuth
compafs.

The cover of the wooden box being taken off, the compafs is in a condition to be made ufe of in the binnacle, when the weather is moderate: but if the fea runs high, as the inner box is hung very free upon its centre, (the better to anfwer its other purpofes), it will be neceffary to flacken the milled nut, placed upon one of the axes that fupport the ring, and to lighten the nut on the outside that corresponds to it. By this means, the inner box and ring will be lifted up from the edges, upon which they reft, when free; and the friftion will be increafed, and that to any degree neceffary, to prevent the too great vibrations, which otherwife would be occafioned by the motion of the fhip.

To make the compafs ufeful in taking the magnetic azimuth or amplitude of the fun and ftars, as alfo the bearings of headlands, fhips, and other objects at a diftance, the brafs edge, defigned at firft to fupport the card, and throw the weight thereof as near the circumference as poffible, is itfelf divided into degrees and halves; which may be eafily eliminated into fmaller parts, if neceffary. The divifions are determined by means of a cat-gut line, ftretched perpendicularly with the box, as near the brafs edge as may be, that the parallax, arifing from a different pofition of the obferver, may be as little as poffible.

Underneath the card are two fmall weights, fiding on two wires, placed at right angles to each other; which being moved nearer to, or farther from, the centre, counterbalance the dipping of the card in different latitudes, or reftore the equilibrium of it, where it happens by any other means to be got too much out of level.

There is alfo added an index at the top of the inner box, which may be put on and taken off at pleafure; and ferves for all altitudes of the object. It confifts of a bar, equal in length to the diameter of the inner box, each end being furnifhed with a perpendicular ftile, with a flit parallel to the fides thereof: one of the flits is narrow, to which the eye is applied; and the other is wider, with a fmall cat-gut ftretched up the middle of it, and from thence continued horizontally from the top of one ftile to the top of the other. There is alfo a line drawn along the upper furface of the bar. Thefe four, viz. the narrow flit, the horizontal cat-gut thread, the perpendicular one, and the line on the bar, are in the fame plane, which difpofes itfelf perpendicular to the horizon, when the inner box is at reft, and hangs free. This index does not move round, but is always placed on, fo as to anfwer the fame fide of the box.

When the fun's azimuth is defired, and his rays are ftrong enough to caft a fhadow, turn about the wooden box, till the fhadow of the horizontal thread, or (if the fun be too low) till that of the perpendicular thread, in one ftile, or the light through the flit on the other, falls upon the line in the index bar, or vibrates to an equal diftance on each fide of it, gently touching the box, if it vibrates too far: obferve, at the fame time, the degree marked upon the brafs edge by the cat-gut line. In counting the degree for the azimuth, or any other angle that is reckoned from the meridian, make ufe of the outward circle of figures upon the brafs edge; and the fituation of the index bar, with regard to the card and needle, will always direct upon what quarter of the compafs the object is placed.

Azimuth
Azmer.

But if the fun does not fhine out fufficiently ftrong, place the eye behind the narrow flit in one of the ftiles, and turn the wooden box about, till fome part of the horizontal, or perpendicular thread appears to interfect the centre of the fun, or vibrate to an equal diftance on each fide of it, uſing fmoked glafs next the eye, if the fun's light is too ftrong. In this method, another obferver will be generally neceffary, to note the degree cut by the nonius, at the fame time that the firft gives notice that the thread appears to fplit the object.

From what has been faid, the other obfervations will be eafily performed: only, in caſe of the fun's amplitude, take care to number the degree by the help of the inner circle of figures on the card, which are the complements of the outer to 90°; and, confequently, fhew the diftance from eaſt to weft.

The azimuth of the ftars may alfo be obſerved by night; a proper light ſerving equally for one obſerver to fee the thread, and the other the degree upon the card.

It may not be amifs to remark farther, that, in caſe the inner box ſhould loſe its equilibrium, and, confequently, the index be out of the plane of a vertical circle, an accurate obſervation may ſtill be made, provided the fun's ſhadow is diſtinct; for, by obſerving firſt with one end of the index towards the fun, and then the other, a mean of the two obſervations will be the truth.

Plate LV. fig. 3. is a perſpective view of the compafs, when in order for obſervation; the point of view being the centre of the card, and the diftance of the eye two feet. A B is the wooden box. C and D are two milled nuts; by means whereof the axis of the inner box and ring are taken from their edges, on which they move, and the friftion increafed, when neceffary. E F is the ring that fupports the inner box. G H is the inner box; and I is one of its axes, by which it is fuſpended on the ring E F. The magnet or needle appears paſſing through the centre, together with a fmall brace of ivory, that confines the cap to its place. The card is a fingle varniſhed paper, reaching as far as the outer circle of figures, which is a circle of thin brafs; the edge whereof is turned down at right angles to the plane of the card, to make it more ſtiff. O is a cat-gut line, drawn down the infide of the box, for determining the degree upon the brafs edge. PQRS is the index bar, with its two ftiles and cat-gut threads; which being taken off from the top of the box, is placed in two pieces, T and V, notched properly to receive it. W is a place cut out in the wood, ſerving as an handle.

AZIMUTH Circles, called alfo *azimuths*, or *vertical circles*, are great circles of the ſphere interfecſting each other in the zenith and nadir, and cutting the horizon at right angles.—Theſe azimuths are repreſented by the rhumbs on common ſea-charts, and on the globe they are repreſented by the quadrant of altitude, when ſcrewed in the zenith. On theſe azimuths is reckoned the height of the ftars and of the fun when not in the meridian.

AZMER, a town of the Eaſt Indies in the dominions of the Great Mogul, capital of a province of the fame name, with a very ſtrong caſtle. It is pretty large, and is ſometimes viſited by the Mogul himſelf. It is about 62 leagues diſtant from Agra. The principal trade of this province is in ſalt-petre.

Azoga
||
Azure.

Azure
||
Azymous.

AZOGA SHIPS, are those Spanish ships commonly called the *quick-silver ships*, from their carrying quick-silver to the Spanish West Indies, in order to extract the silver out of the mines of Mexico and Peru. These ships, strictly speaking, are not to carry any goods unless for the king of Spain's account.

AZONI, in ancient mythology, a name applied by the Greeks to such of the gods as were deities at large, not appropriated to the worship of any particular town or country; but acknowledged in general by all countries, and worshipped by every nation. These the Latins called *dei communes*. Of this sort were the Sun, Mars, Luna, &c.

AZORES, islands in the Atlantic ocean, lying between 25 and 33 degrees of west longitude, and between 36 and 40 degrees of north latitude. They belong to the Portuguese, and are also called the *western isles*, on account of their situation. They were discovered by the Flemings in the 15th century. They are seven in number, *viz.* Tercera, St Michael's, St Mary's, Graciosa, St George's Island, Pico, and Fayal*.

See these
articles.

AZOTH, in ancient chemistry, the first matter of metals, or the mercury of a metal; more particularly that which they call the *mercury of philosophers*, which they pretended to draw from all sorts of metallic bodies.

AZOTUS, AZOTH, or ASHDOD, one of the five cities of the Philistines, and a celebrated sea-port on the Mediterranean, situated about 14 or 15 miles south of Ekron, between that and Afcalon. It was in this city that the idol Dagon fell down before the ark; and so strong a place it was, if we may believe Herodotus, that it sustained a siege of 29 years by Pflammiticus king of Egypt. It was, however, taken by the Maccabees in a much shorter time; who burnt both city and temple, and with them about 8000 men.

AZURE, in a general sense, the blue colour of the sky. See SKY and BLUE.

AZURE, among painters. This word, which at present signifies in general a fine blue colour, was formerly appropriated to *Lapis Lazuli*, called *azure stone*, and to the blue prepared from it. But since a blue has been extracted from cobalt, custom has applied to it the name of *azure*, although it differs considerably from the former, and is incapable of being used for the same purposes, and particularly for painting in oil.

The former at present is called *lapis lazuli*, or only *lapis*; and the blue prepared from it for painting in oil, is called *ultramarine*.—The name *azure* is generally applied to the blue glass made from the earth of cobalt and vitrifiable matters. This glass, which is called *smalt* when in masses, is called *azure* only when it is reduced to a fine powder. Several kinds of azure are distinguished, according to its degrees of beauty, by the names of *fine azure*, *powdered azure*, and *azure of four fires*. In general, the more intense the colour, and the finer the powder, the more beautiful and dear it is. Azure is employed to colour starch; hence it has also been called *starch-blue*. It is used for painting with colours, and for a blue enamel.

AZURE, in heraldry, the blue colour in the arms of any person below the rank of a baron. In the escutcheon of a nobleman, it is called *sapphire*; and in that of a sovereign prince, *Jupiter*. In engraving, this colour is expressed by lines or strokes drawn horizontally.—This colour may signify Justice, Perseverance, and Vigilance; but according to G. Leigh, if it is compounded with

Or	} it signifies	Cheerfulness.
Arg.		Vigilance.
Gul.		Readiness.
Ver.		Enterprize.
Pur.		Goodness.
Sab.		Mournfulness.

French Heralds, *M. Upton*, and his followers, rank this colour before gules.

AZYGOS, in anatomy, a vein rising within the thorax, on the right side, having no fellow on the left; whence it is called *azygos*, or *vena sine pari* *.

* See Ana-
tomy, n^o 387,
k.

AZYMITES, in church-history, Christians who administer the eucharist with unleavened bread. The word is formed from the Greek, *a priv.* and *ζυμη ferment*.—This appellation is given to the Latin by the Greek church, because the members of the former use fermented bread in the celebration of the eucharist. They also call the Armenians and Maronites by the same name, and for the same reason.

AZYMOUS, something unfermented, or made without leaven; as unleavened bread. Sea-bisket is of this kind; and therefore, according to Galen, less wholesome than bread that has been fermented.

B.

B, THE second letter of the English and most other alphabets. It is the first consonant, and first mute, and in its pronunciation is supposed to resemble the bleating of a sheep; upon which account Pierius tells us in his hieroglyphics, that the Egyptians represented the found of this letter by the figure of that animal.

B is also one of those letters which the eastern grammarians call *labial*, because the principal organs employed in its pronunciation are the lips. It is pronounced by pressing the whole length of them together,

and forcing them open with a strong breath. It has a near affinity with the other labials P and V, and is often used for P both by the Armenians and other orientals, as in *Betrus* for *Petrus*, *abfens* for *abfens*, &c.; and by the Romans for V, as in *amabit* for *amavit*, *berna* for *verna*, &c. whence arose that jest of Aurelian on the emperor Bonofus, *Non ut vivat natus est, sed ut bibat*.

Plutarch observes, that the Macedonians changed Φ into B, and pronounced *Bilip*, *Beronice*, &c. for *Philip*, *Pheronice*, &c.; and those of Del-

Baal.

phos used B instead of Π, as *Babylon* for *παβυλον*, *Babylon* for *μαβαρον*, &c.—The Latins said *suppono*, *oppono*, for *subpono*, *obpono*; and pronounced *optinuit*, though they wrote *obtinuit*, as *Quintilian* has observed.—They also used B for F or PH: thus, in an ancient inscription mentioned by *Gruter*, *OBRENDARIO* is used for *OPRENDARIO*.

As a numeral, B was used by the Greeks and Hebrews to denote 2; but among the Romans for 300, and with a dash over it (thus B̄) for 3000.

B is also used as an abbreviation. Thus B. A. stands for bachelor of arts; B. L. for bachelor of laws; and B. D. for bachelor of divinity. B. F. in the preface to the decrees or senatus-consulta of the old Romans signified *bonum factum*. In music, B stands for the tone above A; as B^b, or ^bB, does for B flat, or the semitone major above A. B also stands for bass; and B. C. for *basso continuo*, or thorough bass.

BĀAL, the same as BĒL, or BELUS; an idol of the Chaldeans, and Phœnicians, or Canaanites. The former worshipped Mars under this name, according to *Josephus* *; who, speaking of *Thorus* the successor of *Ninus*, says, "To this Mars the Assyrians erected the first statue, and worshipped him as a god, calling him *Baal*." It is probable the Phœnicians worshipped the sun under the name of *Baal*; for *Josiah*, willing to make some amends for the wickedness of *Manasseh*, in worshipping *Baal* and all the host of heaven, put to death the idolatrous priests that burnt incense unto *Baal*, to the sun, and to the moon, and to the planets, and to all the host of heaven. He likewise took away the horses that the kings of *Judah* had given to the sun, and burnt the chariots of the sun with fire †.

The temples consecrated to this god, are called in the Scripture *Chamanim*, which signifies places inclosed with walls, in which was kept a perpetual fire. *Maunderell*, in his journey from Aleppo to Jerusalem, observed some traces of these inclosures in Syria. In most of them were no statues; in a few there were some, but of no uniform figure.

The word *baal* (in the Punic language), signifies lord or master; and doubtless meant the supreme Deity, the Lord and Master of the universe. It is often joined with the name of some false god, as *Baal-berith*, *Baal-peor*, *Baal-zephon*, and the like. This deity passed from the Phœnicians to the Carthaginians, who were a colony of the Phœnicians; as appears from the Carthaginian names *Hannibal*, *Afdrubal*, &c. according to the custom of the east, where kings and great men added to their own names those of their gods.

This false deity is frequently mentioned in Scripture in the plural number (*Baalim*): which may signify, either that the name *Baal* was given to several different gods; or that there were many statues, bearing different appellations, consecrated to this idol. *Arnobius* tells us, that *Baal* was of an uncertain sex; and that his votaries, when they called upon him, invoked him thus: *Hear us, whether thou art a god or a goddess*.

Some learned men think, that the *Baal* of the Phœnicians is the *Saturn* of the Greeks; which is probable enough from the conformity there is between the human sacrifices offered to *Saturn*, and those which the Scripture tells us were offered to *Baal*. Others are of opinion, that *Baal* was the Phœnician or Tyrian Hercules, a god of great antiquity in Phœnicia.

Baal, Babel.

BĀAL-BERITH, the god of the Shechemites. *Bochart* conjectures, that *Berith* is the same as *Berac*, the daughter of *Venus* and *Adonis*, who was given in marriage to *Bacchus*; and that she gave her name to the city of *Berith* in Phœnicia, and became afterwards the goddess of it. *Baal-berith* signifies Lord of the covenant, and may be taken for the god who precludes over alliances and oaths, in like manner as the Greeks had their *Zweygehoer*, and the Romans their *Deus Fidius*, or *Jupiter Pifius*. The idolatrous Israelites, we are told, made *Baal-berith* their god, *Judg.* viii. 33.

BĀAL-PEOR, *Baal-pegor*, or *Bed-pegor*, an idol of the Moabites and Midianites. We are told, that *Israel* joined himself to *Baal-peor*; and that *Solomon* erected an altar to this idol upon the mount of *Olivet*. *Baal-peor* has been supposed to be no other than a *Priapus*, and that the worship of him consisted in the most obscene practices. Others have thought, that, as *Baal* is a general name signifying Lord, *Peor* may be the name of some great prince deified after his death. *Mede* imagines, that *Peor* being the name of a mountain in the country of *Moab*, on which the temple of *Baal* was built, *Baal-peor* may be only another name of that deity, taken from the situation of his temple; in like manner as *Jupiter* is styled *Olympius*, because he was worshipped in a temple built on mount *Olympus*. *Selden*, who is of this latter opinion, conjectures likewise, that *Baal-peor* is the same with *Pluto*; which he grounds upon these words of the Psalmist *, "They joined themselves unto *Baal-peor*, and eat the offerings of the dead; in this passage, may be meant no more than sacrifices or offerings made to idols, or false gods, who are very properly called the dead, in contradistinction to the true God, who is styled in Scripture the living God.

BĀAL-ZEBUB, *Beel-zebub*, or *Belzebul*; the idol, or god, of the Ekronites. In Scripture he is called the Prince of Devils. His name is rendered the Lord of *Elies*, or the God-fly; which some think was a mock appellation bestowed on him by the Jews. He had a famous temple and oracle at *Ekron*. *Ahaziah* king of *Israel*, having fallen from the terrass of his house into a lower room, and being dangerously hurt, sent to consult this deity, to know if he should be cured of his wounds. The worship of this false god must have prevailed in our Saviour's time, since the Jews accused him of driving out devils in the name of *Belzebul* their prince. *Scaliger* derives the name of this deity from *Baalim-zebubim*, which signifies the Lord of sacrifices.

BABEL, a city and tower undertaken to be built by the whole human race soon after the flood, and remarkable for the miraculous frustration of the attempt by the confusion of languages. As to the situation of ancient *Babel*, most authors are of opinion that it was exactly in the place where the celebrated city of *Babylon* afterwards stood. That it was in the same country, appears indisputably from Scripture; but that it was exactly in the same place is what cannot be proved, nor is it a matter of any consequence.

Authors have been much divided about the motive by which the whole race of mankind were induced to join as one man in such an undertaking. Some have imagined that it was out of fear of a second deluge; others, that they knew beforehand that they were to be dispersed through all the different countries of the world, and

* Antiquit. lib. viii. cap. 7.

† 2 Kings xxiii. 5. 17.

* Psalm cvi.

and built this tower in order to defeat the design of the Deity, because having a tower of such vast height as they proposed, those who were at a distance could easily find their way back again. Had either of these been their design, however, it is probable they would have chosen an eminence rather than a plain for the situation of their tower, or indeed that they would have chosen some high mountain such as Ararat for their mark, rather than any tower at all: for though it is said that they designed the top of their tower to reach to heaven, we can scarce suppose them to have been so absurd, as to imagine this possible, in the sense we understand it; and must therefore rather take it in the limited sense in which it is often used by Moses and his countrymen, where they speak of cities walled up to heaven. Others there are who imagine that the top of this tower was not to reach up to heaven, but to be consecrated to the heavens, *i. e.* to the worship of the sun, moon, and stars; of the fire, air, &c. and other natural powers as deities; and therefore that the true Deity interposed in order to prevent a total and irreparable defection. Certain it is, that the species of idolatry which takes for the objects of its worship those natural agents, as it is the most ancient, so it is by far the most rational, and the most difficult to be disproved. It is much more difficult, for instance, to prove that the sun, which by his enlightening beams gives vigour to the whole creation, is not a deity, than that a log of wood is not one; and hence, if such a system of religion became universally established among mankind, it would be impossible ever afterwards to eradicate it. Indeed that the scheme at Babel, whatever it was, could have been put in execution by man, seems evident from the interposition of the Deity on the occasion; for we cannot suppose that he would have worked a miracle on purpose to defeat that which would have defeated itself if he had let it alone: and he expressly says, That now nothing could be restrained from them; which intimates very plainly, that, had this scheme gone on, the plan which God had laid for the government of the world would have been totally frustrated: and agreeable to this hypothesis Dr Tennison supposes that the tower was of a pyramidal form, in imitation of the spires of flame; and that it was erected in honour of the sun, as being the most probable cause of drying up the flood.

As to the materials made use of in the building of this tower, the scripture informs us that they were bricks and slime or bitumen. According to an eastern tradition, three years were taken up in making the bricks, each of which was 13 cubits long, ten broad, and five thick. Oriental writers say, that the city was 313 fathoms in length, and 151 in breadth; that the walls were 5533 fathoms high, and 33 in breadth; and that the tower itself was no less than 10,000 fathom, or 12 miles high. Even St Jerome affirms from the testimony of eye-witnesses, who as he says had examined the remains of the tower, that it was four miles high; but Ado makes the height to have been no less than 5000 miles. The only account of its dimensions which can be at all depended upon, (supposing it to have been the same which afterwards stood in the midst of the city of Babylon, and round which Nebuchadnezzar built the temple of Belus), is that given under the article BABYLON; n^o 3.

BABEL-MANDEL, the GATE OF MOURNING; a famous strait in the Indian ocean, between the coast of Arabia Felix in Asia, and that of Adel and Zeila in Africa, at the entrance into the Red Sea. By some it is also called the *Straits of Moka*. It is narrow, and difficult to sail through, on account of the sand-banks. At the mouth of the strait is a small island called also *Babel-Mandel*, which is little else than a barren-rock. E. Long. 44. 30. N. Lat. 12. 40.

BABENHAUSEN, a town of Germany in Suabia. E. Long. 9. 16. N. Lat. 48. 39.

BABINA, (*Commonwealth* of); a society Indicously so called, which was founded in Poland in the reign of Sigismund-Augustus, in the 16th century. It took its rise from a set of gentlemen, inhabitants of Lublin, who had agreed to meet at a place called *Babina*, merely for the purposes of mirth and jollity. In time their number increased, and they formed themselves into a regular government, under the presidency of a king, senate, and chief magistrates. The magistrates were elected from something which appeared ridiculous in the character or conduct of any of the members. For instance, if any person was meddling or officious, he was immediately created an archbishop; a blundering or disputatious member, was promoted to the speaker's chair; a boaster of his own courage, and vain-glorious *Thraße*, was honoured with the commission of generalissimo, which was presented him with great ceremony by the subordinate heroes. Those who declined the office for which they were declared qualified, were persecuted with hissings, and abandoned by the society. Thus every vice and every foible was attacked with ridicule; and Babina became, in a short time, the terror, the admiration, and the reformer, of the Polish nation: genius flourished, wit was cultivated, and the abuses which had crept into government and society were corrected by the judicious application of good-humoured satire. Never did any institution of this nature become so general or so useful; but at length it degenerated into a set of buffoons, and banterers of every thing sacred or profane. For several years it was patronised by the kings of Poland, and Sigismund himself became a member, the starosta of Babina telling him jocularly, That "His majesty had certain qualities which entitled him to the first dignity in the commonwealth." Not the least remnant of this society now remains, though it was honoured with extraordinary privileges by kings and emperors.

BABINGTON (Gervase), bishop of Worcester, was born, according to Fuller, in Nottinghamshire; but in what year, is uncertain. He was sent to Trinity college, Cambridge, of which he was made fellow; and, in 1578, was incorporated master of arts at Oxford. He appears, however, to have made Cambridge the place of his residence, where he became an eminent preacher; and, being now doctor in divinity, was made domestic chaplain to Henry earl of Pembroke. In this station he is supposed to have assisted the countess in her translation of the Psalms. In 1588, he was installed prebend of Hereford, and, in 1591, consecrated bishop of Landaff. In 1594, he was translated to the see of Exeter, and thence to Worcester in 1597. About this time, or soon after, he was made queen's counsellor for the marshes of Wales. He was a considerable benefactor to the library belonging to the cathedral of Worcester.

Babel,
Babington.

Baboon,
Babylon.

Worcester, where he was buried, in May 1610, without a monument. The several historians, who have mentioned this prelate, agree in giving him the character of a learned and pious man. His writings, like those of most of his contemporaries, abound with puns and quaint expressions. His works were printed both in folio and quarto in 1615, and again in folio in 1637, under this title: *The works of the right reverend father in God Gervase Babington, late bishop of Worcester, containing comfortable notes upon the five books of Moses, viz. Genesis, &c. As also an exposition upon the Creed, the Ten Commandments, the Lord's Prayer; with a conference betwixt man's frailtie and faith, and three sermons, &c.*

BABOON, in zoology. See SIMIA.

BABYLON, the capital of the ancient kingdom of Babylonia or Chaldaea, and supposed to have stood in E. Long. 44. o. N. Lat. 32. o. Semiramis is said by some, and Belus by others, to have founded this city. But, by whomsoever it was founded, Nebuchadnezzar was the person who put the last hand to it, and made it one of the wonders of the world. The most famous works in and about it were the walls of the city, the temple of Belus, Nebuchadnezzar's palace, the hanging-gardens, the banks of the river, the artificial lake, and canals.

1
City de-
scribed.

The city was surrounded with walls, in thickness 87 feet, in height 350 feet, and in compass 480 furlongs or 60 of our miles. Thus Herodotus, who was himself at Babylon; and though some disagree with him in these dimensions, yet most writers give us the same, or near the same, as he does. Diodorus Siculus diminishes the circumference of these walls very considerably, and takes somewhat from the height of them, as in Herodotus; tho' he seems to add to their breadth, by saying, That six chariots might drive abreast thereon; while the former writes, that one chariot only might turn upon them; but then he places buildings on each side of the top of these walls, which, according to him, were but one story high; which may pretty well reconcile them together in this respect. It is observed, that those who give the height of these walls but at 50 cubits, speak of them only as they were after the time of Darius Hytaspis, who had caused them to be beaten down to that level. These walls formed an exact square, each side of which was 120 furlongs, or 15 miles, in length; and were all built of large bricks cemented together with bitumen, which in a short time grows harder than the very brick and stone which it cements. The city was encompassed, without the walls, with a vast ditch filled with water, and lined with bricks on both sides; and, as the earth that was dug out of it served to make the bricks, we may judge of the depth and largeness of the ditch from the height and thickness of the walls. In the whole compass of the wall there were 100 gates, that is, 25 on each of the four sides, all made of solid brass. Between every two of these gates, at proper distances, were three towers, and four more at the four corners of this great square, and three between each of these corners and the next gate on either side, and each of these towers was ten feet higher than the walls. But this is to be understood only of those parts of the walls where towers were needful for defence. For some parts of them being upon a morass, and inaccessible by an enemy, there the labour and cost

was spared, which, tho' it must have spoiled the symmetry of the whole, must be allowed to have favoured of good economy; though that is what one would not have expected from a prince who had been so determined, as Nebuchadnezzar must have been, to make the city complete both for strength and beauty. The whole number, then, of these towers amounted to no more than 250; whereas a much greater number would have been necessary to have made the uniformity complete all round. From the 25 gates in each side of this square, there was a straight street, extending to the corresponding gate in the opposite wall; whence the whole number of the streets must have been but 50; but then they were each about 15 miles long, 25 of them crossing the other 25 exactly at right angles. Besides these whole streets, we must reckon four half-streets, which were but rows of houses facing the four inner sides of the walls. These four half-streets were properly the four sides of the city within the walls, and were each of them 200 feet broad, the whole streets being about 150 of the same. By this intersection of the 50 streets, the city was divided into 676 squares, each of four furlongs and an half on each side, or two miles and a quarter in compass. Round these squares on every side towards the streets stood the houses, all of three or four stories in height, and beautified with all manner of ornaments; and the space within each of these squares was all void, and taken up by yards, or gardens, and the like, either for pleasure or convenience.

A branch of the Euphrates divided the city into two, running through the midst of it, from north to south; over which, in the very middle of the city, was a bridge, a furlong in length, or rather more, and indeed much more, if we hearken to others, who say it was no less than five stades or furlongs in length, tho' but 30 feet broad, a difference we shall never be able to decide: this bridge, however, is said to have been built with wonderful art, to supply a defect in the bottom of the river, which was all sandy. At each end of this bridge were two palaces; the old palace on the east side, the new one on the west side of the river; the former of which took up four of the squares above-mentioned, and the latter nine. The temple of Belus, which stood next to the old palace, took up another of the same squares.

The whole city stood in a large flat or plain, in a very fat and deep soil; that part or half of it, on the east side of the river, was the old city; and the other on the west was added by Nebuchadnezzar, both being included within the vast square bounded by the walls aforesaid. The form of the whole was seemingly borrowed from Nineveh, which was also 480 furlongs; but, though it was equal in dimensions to this city, it was less with respect to its form, which was a parallelogram, whereas that of Babylon was an exact square. It is supposed, that Nebuchadnezzar, who had destroyed that old seat of the Assyrian empire, proposed that this new one should rather exceed it; and that it was in order to fill it with inhabitants, that he transported such numbers of the captives from other countries hither; though that is what may be disputed, seeing he therein only followed the constant practice of the kings of Assyria, who thought this the most certain means of assuring their conquests either to themselves or their posterity.

Babyl

But it plainly appears, that it was never wholly inhabited; so that, even in the meridian of its glory, it may be compared with the flower of the field, which flourisheth to-day, and to-morrow is no more. It never had time to grow up to what Nebuchadnezzar visibly intended to have made it; for, Cyrus removing the seat of the empire from after to Shushan, Babylon fell by degrees to utter decay: yet it must be owned, that no country was better able to support so vast and populous a city, had it been completed up to its first design. But so far was it from being finished according to its original design, that, when Alexander came to Babylon, Q. Curtius tells us, "No more than 90 furlongs of it were then built:" which can be no otherwise understood than of so much in length; and, if we allow the breadth to be as much as the length (which is the utmost that can be allowed), it will follow, that no more than 8100 square furlongs were then built upon: but the whole space within the walls contained 14,400 square furlongs; and therefore there must have been 6300 square furlongs remaining unbuild, which, Curtius tells us, were plowed and sown. And, besides this, the houses were not contiguous, but all built with a void space on each side, between house and house.

The next great work of Nebuchadnezzar was the temple of Belus. The wonderful tower, however, that stood in the middle of it, was not his work, but was built many ages before; that, and the famous tower of Babel, being, as is commonly supposed, one and the same structure. This tower is said to have been composed of eight pyramidal ones raised above one another, and by Herodotus said to have been a furlong in height; but as there is an ambiguity in his expression, it has been disputed whether each of the towers was a furlong in length, or the whole of them taken together. On the latter supposition, which is the most probable, this tower must have exceeded the highest of the Egyptian pyramids by 179 feet, though it fell short of its breadth at the basis by 33. The way to go up was by stairs on the outside round it; whence it seems most likely, that the whole ascent was, by the benching in, drawn in a sloping line from the bottom to the top eight times round it; and that this made the appearance of eight towers, one above the other. Till the times of Nebuchadnezzar, it is thought this tower was all the temple of Belus; but as he did by the other ancient buildings of the city, so he did by this, making great additions thereto, by vast edifices erected round it, in a square of two furlongs on every side, and just a mile in circumference, which exceeded the square at the temple of Jerusalem by 1800 feet. On the outside of these buildings was a wall, which inclosed the whole; and, in consideration of the regularity wherewith this city was to all appearance marked out, it is supposed, that this wall was equal to the square of the city wherein it stood, and so is concluded to have been two miles and an half in circumference. In this wall were several gates leading into the temple, and all of solid brass; which it is thought may have been made out of the brazen sea, and brazen pillars, and other vessels and ornaments of the kind, which Nebuchadnezzar had transported from Jerusalem; for in this temple he is said to have dedicated his spoils from that of Jerusalem.

In this temple were several images or idols of massy gold, and one of them, as we have seen, 40 feet in height; the same, as supposed, with that which Nebuchadnezzar consecrated in the plains of Dura. For though this last is said to have been 60 cubits, or 90 feet high, these dimensions appear so incredible, that it has been attempted to reconcile them into one, by supposing, that in the 90 feet the height of the pedestal is included, and that the 40 feet are for the height of the statue without the pedestal; and, being said to have weighed 1000 talents of Babylon, it is thence computed, that it was worth three millions and a half of our money. In a word, the whole weight of the statues and decorations, in Diodorus Siculus, amounting to 5000 odd talents in gold, the whole is estimated at above one and twenty millions of our money; and a sum about equal to the same, in treasure, utensils, and ornaments, not mentioned, is allowed for.

Next to this temple, on the east side of the river, stood the old palace of the kings of Babylon, being four miles in circumference. Exactly opposite to it, on the other side of the river, was the new palace built by Nebuchadnezzar, eight miles in circumference, and consequently four times as big as the old one.

But nothing was more wonderful at Babylon than the hanging-gardens, which Nebuchadnezzar made in compliance to his wife Amyte; who, being a Mede, and retaining a strong inclination for the mountains and forests of her own country, was desirous of having something like them at Babylon. They are said to have contained a square of four plethra, or 400 feet, on each side; and to have consisted of terraces one above another, carried up to the height of the wall of the city, the ascent from terrace to terrace being by steps ten feet wide. The whole pile consisted of substantial arches upon arches, and was strengthened by a wall surrounding it on every side, 22 feet thick; and the floors on each of them were laid in this order: first, on the tops of the arches was laid a bed or pavement of stones 16 feet long, and four feet broad; over this was a layer of reed mixed with a great quantity of bitumen; and over this two courses of brick, closely cemented together with plaster; and over all these were thick sheets of lead, and on these the earth or mould of the garden. This floorage was designed to retain the moisture of the mould; which was so deep, as to give root to the greatest trees which were planted upon every terrace, together with great variety of other vegetables pleasing to the eye. Upon the uppermost of these terraces was a reservoir, supplied by a certain engine with water from the river, from whence the gardens on the other terraces were supplied.

The other works attributed to Nebuchadnezzar by Berosus and Abydenus, were the banks of the river, the artificial canals, and the great artificial lake said to have been sunk by Semiramis. The canals were cut out on the east side of the Euphrates, to convey the waters of that river, when it overflowed its banks, into the Tigris, before they reached Babylon. The lake was on the west side of Babylon; and, according to the lowest computation, 40 miles square, 160 in compass, and in depth 35 feet, as we read in Herodotus, or 75, as Megasthenes will have it; the former, perhaps, measured from the surface of the sides, and the

Babylon.

the latter from the tops of the banks that were cast up upon them. This lake was dug to receive the waters of the river, while the banks were building on each side of it. But both the lake, and the canal which led to it, were preferred after that work was completed, being found of great use, not only to prevent all overflows, but to keep water all the year, as in a common reservoir, to be let out, on proper occasions, by sluices, for the improvement of the land.

The banks were built of brick and bitumen, on both sides of the river, to keep it within its channel; and extended on each side throughout the whole length of the city, and even farther, according to some, who reckon they extended 160 furlongs, or twenty miles; whence it is concluded they must have begun two miles and an half above the city, and have been continued an equal distance below it, the length of the city being no more than 15 miles. Within the city they were built from the bottom of the river, and of the same thickness with the walls of the city itself. Opposite to each street, on either side of the river, was a brazen gate in the said wall, with stairs leading down from it to the river: these gates were open by day, and shut by night.

Berosus, Megasthenes, and Abydenus, attribute all these works to Nebuchadnezzar; but Herodotus tells us, the bridge, the banks, and the lake, were the work of a queen after him, called *Nitocris*, who may have finished what Nebuchadnezzar left imperfect, and thence have had the honour this historian gives her of the whole.

The tower or temple stood till the time of Xerxes. But that prince, on his return from the Grecian expedition, having first plundered it of its immense wealth, demolished the whole, and laid it in ruins. Alexander, on his return to Babylon from his Indian expedition, proposed to rebuild it, and accordingly set 10,000 men on work to clear away the rubbish. But, his death happening soon after, a stop was put to all further proceedings in that design. After the death of that conqueror, the city of Babylon began to decline apace; which was chiefly owing to the neighbourhood of Seleucia, built by Seleucus Nicator, as is said, out of spite to the Babylonians, and peopled with 500,000 persons drawn from Babylon, which by that means continued declining till the very people of the country were at a loss to tell where it had stood.

Such is the description we have by ancient historians of the grandeur of this city; which, if these accounts are not exaggerated, must have exceeded every piece of human grandeur that hath yet appeared. Many of the moderns, however, are of opinion that these magnificent descriptions are very far from being true; although it is certain that few other arguments can be brought against the reality of them, than that we do not see things of a similar kind executed in our own days. The following are the arguments used on this subject by the president Goguet.

“ Authors have greatly extolled the public works and edifices which once rendered Babylon one of the wonders of the world. We may reduce all these objects to five principal heads: 1. the height of its walls; 2. the temple of Belus; 3. the hanging gardens; 4. the bridge built over the river Euphrates, and the quays which lined that river; 5. the lake and canals dug by

the hand of man to distribute the waters of the Euphrates.

“ All these works, so marvellous in the judgment of antiquity, appear to me to have been extremely exaggerated by the authors who have spoken of them. How can we conceive, in effect, that the walls of Babylon could have been 318 feet high, and 81 in thickness, in a compass of near ten leagues?

“ I shall say the fame of that square building, known under the name of the *temple of Belus*. It was composed of eight towers placed one above another, diminishing always as they went up. Herodotus does not tell us what was the height of this monument. Diodorus says, that it surpassed all belief. Strabo fixes it to one stadium, a measure which answers nearly to 600 of our feet. For in the time of this geographer the stadia were much more considerable than in the first ages. The entire mass of this building ought to have been answerable to its excessive height; and this is also the idea that the ancients designed to give us of it. We may judge by the following fact. Xerxes had entirely demolished this temple. Alexander undertook to rebuild it. He designed to begin by clearing the place and removing the ruins. Ten thousand workmen who were employed two months in this work, were not, say they, able to finish it.

“ The riches inclosed in the temple of Belus were proportioned to its immensity. Without speaking of the tables and censers, the cups and other sacred vases, of massy gold, there was a statue 40 feet high, which alone weighed 1000 Babylonish talents. In short, according to the inventory that the ancients have given us of the riches contained in this temple, the total sum would amount to two hundred and twenty millions and a half of French livres. Exaggerations like these destroy themselves.

“ As to the hanging gardens, according to all appearance they never existed. The silence of Herodotus on a work so singular and so remarkable, determines me to place in the rank of fables all that the other writers have delivered upon this pretended wonder. Herodotus had carefully visited Babylon. He enters into such details as prove that he has omitted none of the rarities of that city. Can we presume that he would have passed over in silence such a work as the hanging gardens? All the authors who have spoken of it are of much later date than this great historian. None of them except Berosus speaks on his own testimony. It is always on the report of others. Diodorus had extracted from Ctesias what he says of these famous gardens. There is also great appearance that Strabo had drawn from the same source. In a word, the manner in which Quintus Curtius expresses himself, sufficiently shews how much the existence of these gardens appeared to him suspicious. He judged they owed the greatest part of it to the imagination of the Greeks.

“ Let us now speak of the bridge of Babylon, which the ancients have placed in the number of the most marvellous works of the east. It was near 100 fathoms in length, and almost four in breadth. We cannot deny but that a great deal of art and labour was necessary to lay the foundations, which it could not be easy to settle in the bed of an extremely deep and rapid river, which also rolls along a prodigious quantity of mud, and whose bottom is entirely sandy. They had there-

Babyl.

7
Goguet's
arguments
against the
truth of the
foregoing
relation.

therefore taken many precautions to secure the piers of the bridge of Babylon. They were built of stones joined and fastened together with cramps of iron, and their joints filled with melted lead. The front of the piers, turned towards the current of the Euphrates, was defended by buttresses extremely advanced, which diminished the weight and force of the water, by cutting it at a great distance. Such was the bridge of Babylon.

"While we do justice to the skill of the Babylonians in conducting these works, we cannot help remarking the bad taste which at all times reigned in the works of the eastern nations. The bridge of Babylon furnishes a striking instance of it. This edifice was absolutely without grace, or any air of majesty. The breadth of it was in no fort of proportion to its length. The distance between the piers was also very ill contrived. They were distant from each other only 11 feet and a half. Finally, this bridge was not arched. We may judge of its effect on the view.

"The Babylonians, however, were not the only people who were ignorant of the art of turning an arch. This secret, as far as I can find, was unknown to all the people of remote antiquity, who, generally speaking, do not appear to have been very skilful in stone-cutting.

"As for the quays which lined the Euphrates, we may believe that they were grand and magnificent; but I shall not easily believe that they surpassed those which we have daily under our eyes. In this respect, I believe Paris may dispute it, for magnificence, and for the extent of the work, with all the cities of the universe."

BABYLON, a town of Egypt near the eastmost branch of the river Nile, now supposed to be *Grand Cairo*, or this city to stand near its ruins. E. Lon. 31. 12. N. Lat. 30. 5.

BABYLONIA, or CHALDEEA, a kingdom of Asia, and the most ancient in the world, being founded by Nimrod the grandson of Ham, who also, according to the margin of our Bibles, founded Nineveh the capital of the kingdom of Assyria. Indeed, these two kingdoms seem to have always continued in such a state of friendship, that we can scarce help thinking they must have been the same, or perhaps Babylonia was for some time a province of Assyria. Nothing certain is known concerning either of them, except what may be gathered from Scripture. From thence we learn, that in the days of Abraham there was a king of *Shinar*, called *Ammraphel*, who, under the king of *Elam* or *Persia*, made war upon the *Canaanites*. From this time we have nothing that can be depended upon till the days of *Nabonassar*, the first king of *Babylon* mentioned in *Ptolemy's* canon. It is plain indeed, both from Scripture and profane history, that *Babylonia* subsisted as a distinct kingdom from *Assyria* even when the latter was in all its glory. The most probable account of the matter is this. The empire of *Assyria* was founded by *Pul*, on the ruins of that of *Damascus* or *Syria*, in the days of *Menahem* king of *Judah*. This king left two sons, *Tiglath-Pileser*, and *Nabonassar*. To the former he bequeathed the empire of *Assyria*, and to the latter that of *Babylon*. *Tiglath-Pileser* resided at *Nineveh*, the original seat of the *Assyrian* empire; while *Nabonassar*, who was the younger brother, held his residence at *Babylon*. As the two kingdoms were governed by princes of the same family, we may well suppose a perfect harmony to have reigned between them, the younger branch at *Babylon* acknowledging

a kind of subjection to the elder at *Nineveh*. That the *Babylonian* empire was of *Assyrian* origin, we are assured by the prophet *Isaiah*, in the following words. "Behold the land of the *Chaldeans*: this people was not till the *Assyrian* founded it for them that dwelt in the wilderness; they set up the towers thereof; they built the palace thereof." As to the kingdom of *Assyria*, the Scripture mentions only five kings, viz. *Pul*, *Tiglath-Pileser*, *Shalmaneser*, *Sennacherib*, and *Ezra-baddon*; whose history, as related by the sacred writers, is it needless to mention particularly here. From the days of *Nabonassar* to *Nabopolassar*, that is, from the year before Christ 747 to 626, the kings of *Babylon* made no figure, and were therefore probably in a state of dependence on the kings of *Assyria*; but at that time, in the reign of *Cyaxares*, the *Sardanapalus* of the Greeks, *Nineveh* was taken and destroyed by the *Medes* and *Babylonians*, and the seat of the empire transferred to *Babylon*. This *Nabopolassar* was the father of the famous *Nebuchadnezzar*, for whose history we must refer to the sacred writers; and from his time to that of the *Belshazzar* of *Daniel*, and *Nabonadius* of other authors, the history of *Babylon* is little better than a mere blank. Of the reduction of *Babylon* by *Cyrus*, which happened at this time, we have the following account.

War had been begun betwixt the *Medes*, *Persians*, and *Babylonians*, in the reign of *Nerglissar* the father of *Nabonadius*, which had been carried on with very bad success on the side of the *Babylonians*. *Cyrus*, who commanded the *Median* and *Persian* army, having subdued the several nations inhabiting the great continent from the *Ægean* sea to the *Euphrates*, bent his march towards *Babylon*. *Nabonadius*, hearing of his march, immediately advanced against him with an army. In the engagement which ensued, the *Babylonians* were defeated; and the king, retreating to his metropolis, was blocked up and closely besieged by *Cyrus*. The reduction of this city was no easy enterprise. The walls were of a prodigious height, the number of men to defend them very great, and the place stored with all sorts of provisions for 20 years. *Cyrus*, despairing of being able to take such a city by storm, caused a line of circumvallation to be drawn quite round it, with a large and deep ditch; reckoning, that if all communication with the country were cut off, the besieged would be obliged to surrender through famine. That his troops might not be too much fatigued, he divided his army into twelve bodies, appointing each body its month to guard the trenches; but the besieged, looking upon themselves to be out of all danger by reason of their high walls and magazines, insulted him from the ramparts, and looked upon all the trouble he gave himself as so much unprofitable labour.

After *Cyrus* had spent two whole years before *Babylon*, without making any progress in the siege, he at last thought of the following stratagem, which put him in possession of it. He was informed, that a great annual solemnity was to be held at *Babylon*; and that the inhabitants on that occasion were accustomed to spend the whole night in drinking and debauchery. This he therefore thought a proper time for surprising them; and accordingly sent a strong detachment to the head of the canal leading to the great lake, with orders, at a certain time, to break down the great bank which

Babylonia.

was between the lake and the canal, and to turn the whole current into the lake. At the same time he appointed one body of troops at the place where the river entered the city, and another where it came out; ordering them to march in by the bed of the river as soon as they should find it fordable. Towards the evening he opened the head of the trenches on both sides the river above the city, that the water might discharge itself into them; by which means, and the breaking down of the great dam, the river was soon drained. Then the two abovementioned bodies of troops, according to their orders, entered the channel; the one commanded by Gobryas, and the other by Gadates; and finding the gates all left open by reason of the disorders of that riotous night, they penetrated into the very heart of the city without opposition; and meeting, according to agreement, at the palace, they surprised the guards, and cut them in pieces. Those who were in the palace opening the gates to know the cause of this confusion, the Persians rushed in, took the palace, and killed the king, who came out to meet them sword in hand. Thus an end was put to the Babylonian empire; and Cyrus took possession of Babylon for one called in Scripture *Darius the Mede*, most probably *Cyaxares II.* uncle to Cyrus. From this time Babylonia never was erected into a distinct kingdom, but hath always followed the fortune of those great conquerors who at different times have appeared in Asia. It is now frequently the object of contention between the Turks and Persians.

The Assyrian and Babylonian history, according to the Greek writers, is so dark and full of fable, that we have not thought proper to trouble our readers with it, especially as the whole is contained in the transactions of a few sovereigns, viz. *Ninus, Semiramis, Ninias, and Sardanapalus*, Kings of Assyria, and *Belsis, or Nanybrus*, the first king of Babylon: See these articles. Concerning the nature of the country, manners, customs, &c. of the ancient Babylonians, the following account is collected by M. Sabbathier.

“As all the nations under the dominion of Cyrus, beside the ordinary tributes, were obliged to maintain him and his army, the monarch and his troops were supported by all Asia. The country of Babylon alone was obliged to maintain him four months of the year; its fertility, therefore, yielded a third of the produce of Asia. The government of this country, which the Persians termed *satrapy*, was richer, and more extensive, than any of the rest. It maintained for the king, besides the war-horses, a stud of 800 stallions, and 16,000 mares. So great a number of Indian dogs were likewise bred in this province for the king, that four of its cities kept those animals; and in return, they were exempted from all taxes and tributes.

“It rained very seldom in this country, according to Herodotus. The earth was watered by the river, which was here diffused by human industry, as the Nile is over Egypt by nature: for all the country of Babylon was divided by canals, the greatest of which was navigable, and flowed from south to north, from the Euphrates to the Tigris. In short, it was one of the finest countries for corn in the world; but for producing trees, the fig-tree, the vine and the olive, it was not famous. It was so luxuriant in grain, that it commonly yielded a hundred times more than what was

Babylonia

grown; and in its good years it yielded three hundred times more than it received. The leaves of its wheat and barley were four inches broad. “*Tho’ I know,*” says Herodotus, “that the millet and the sesame of that country grow to the size of trees, I will not describe them particularly; lest those who have not been in Babylonia should think my account fabulous.”

“They had no oil but what they made from Indian corn. The country abounded with palm-trees, which grew spontaneously; and most of them bore fruit, of which the inhabitants made bread, wine, and honey. They cultivated these trees and their fig-trees in the same manner. Some of them, as of other trees, the Greeks called *male ones*. They tied the fruit of the male to the trees which bore dates; that the mosquito, leaving the male, might cause the date to ripen, by penetrating it; for without that assistance it came not to maturity. Mosquitos bred in the male palms, as in the wild fig-trees.

“But we must not here omit to give an account of the peculiar and surprising construction of their boats of skins, in which they sailed along the river to Babylonia. These boats were invented by the Armenians, whose country lay north from Babylonia. They made them with poles of willow, which they bent, and covered with skins: the bare side of the skins they put outwards; and they made them so tight, that they resembled boards. The boats had neither prow nor stern, but were of a round form, like a buckler. They put straw on the bottom. Two men, each with an oar, rowed them down the river, laden with different wares, but chiefly with palm-wine. Of these boats some were very large, and some very small. The largest carried the weight of 500 talents. There was room for an ark in one of their small boats; they put many into a large one. When they had unloaded, after their arrival at Babylonia, they sold the poles of their boats, and the straw; and loading their asses with the skins, returned to Armenia: for they could not fail up the river, its current was so rapid. For this reason they made their boats of skins, instead of wood; and on their return to Armenia with their asses, they applied the skins to their former use.

“As to their dress, they wore a linen shirt, which came down to their feet. Over it they wore a woollen robe; their outer garment was a white vest. Their shoes resembled those of the Thebans. They let their hair grow. On their heads they wore a turban. They rubbed their bodies all over with fragrant liquors. Each man had a ring on his finger; and an elegant cane in his hand, with an apple at the top, or a rose, a lily, or an eagle, or some other figure: for they were not suffered to use canes without devices.

“With regard to their policy, Herodotus thinks that their best law was one which the Hæneti, an Illyrian people, likewise observed in every town and village. When the girls were marriageable, they were ordered to meet in a certain place, where the young men likewise assembled. They were then sold by the public crier; but he first sold the most beautiful one. When he had sold her at an immense price, he put up others to sale, according to their degrees of beauty. The rich Babylonians were emulous to carry off the finest women, who were sold to the highest bidders. But as the

young

bylonia. young men who were poor could not aspire to have fine women, they were content to take the ugliest with the money which was given them: for when the crier had fold the handsome, he ordered the ugliest of all the women to be brought; and asked, if any one was willing to take her with a small sum of money. Thus she became the wife of him who was most easily satisfied; and thus the finest women were sold; and from the money which they brought, small fortunes were given to the ugliest, and to those who had any bodily infirmity. A father could not marry his daughter as he pleased; nor was he who bought her allowed to take her home, without giving security that he would marry her. But, after the sale, if the parties were not agreeable to each other, the law enjoined that the purchase-money should be restored. The inhabitants of any of their towns were permitted to buy wives at these auctions. Such were the early customs of the Babylonians.

“ But they afterwards made a law, which prohibited the inhabitants of different towns to intermarry, and by which husbands were punished for treating their wives ill. When they had become poor by the ruin of their metropolis, fathers used to prostitute their daughters for gain. There was a sensible custom among the Babylonians, worthy to be related. They brought their sick into the forum, to consult those who passed, on their diseases; for they had no physicians. They asked those who approached the sick, if they ever had the same distemper? if they knew any one who had had it? and how he was cured? Hence, in this country, every one who saw a sick person was obliged to go to him, and inquire into his distemper.

“ They embalmed their dead with honey; and their mourning was like that of the Egyptians.

“ There were three Babylonian tribes, who lived only upon fish, and who prepared them in the following manner: they dried them in the sun, and then beat them in a mortar to a kind of flour, which after they had sifted through linen, they baked it in rolls.

“ The Babylonians at first worshipped only the sun and the moon; but they soon multiplied their divinities. They deified Baal, Bel, or Belus, one of their kings, and Merodach-Baladan. They also worshipped Venus, under the name of *Mylitta*. She and Belus were the principal deities of the Babylonians. They counted their day from sun-rise to sun-rise. They solemnized five days of the year with great magnificence, and almost the same ceremonies with which the Romans celebrated their Saturnalia.

“ The Babylonians were very much addicted to judicial astrology. Their priests, who openly professed that art, were obliged to commit to writing all the events of the lives of their illustrious men; and on a fancied connection between those events and the motions of the heavenly bodies, the principles of their art were founded. They pretended that some of their books, in which their historical transactions and revolutions were accurately compared with the courses of the stars, were thousands of years old. This assertion of their judicial astrologers we may reasonably dispute; but that their astronomers had made a long series of observations, is incontrovertibly true. It is certain that some of those observations were extant in the days of Aristotle, and that they were older than the empire of the Babylonians. See *History of ASTRONOMY*.

BABYLOINICS, BABYLONICA, in literary history, a fragment of the ancient history of the world, ending at 267 years before Christ; and composed by Berofus, or Berofus, a priest of Babylon, about the time of Alexander. Babylonics are sometimes also cited in ancient writers by the title of *Caldæica*. The Babylonics were very consonant with scripture, as Josephus and the ancient Christian chronologers assure; whence the author is usually supposed to have consulted the Jewish writers. Berofus speaks of an universal deluge, an ark, &c. He reckons ten generations between the first man and the deluge; and marks the duration of the several generations by *sarai*, or periods of 223 lunar months; which, reduced to years, differ not much from the chronology of Moses.—The Babylonics consisted of three books, including the history of the ancient Babylonians, Medes, &c. But only a few imperfect extracts are now remaining of the work; preserved chiefly by Josephus, and Syncellus, where all the passages of citations of ancient authors out of Berofus are collected with great exactness. Annius of Viterbo, to supply the loss, forged a complete Berofus out of his own head. The world has not thanked him for the imposture.

BABYROUSSA, in zoology, a synonyme of a species of fus. See *Sus*.

BAC, in navigation, is used for a praam, or ferry-boat.

BAC, in brewing, a large flat kind of tub, or vessel, wherein the wort is put to stand and cool before boiling. The ingredients of beer pass through three kinds of vessels. They are mashed in one, worked in another, and cooled in a third called *bacs* or *coolers*.

BAC, in distillery, vessels into which the liquor to be fermented is pumped from the cooler, in order to be worked with yeast.

BACK-MAKERS, is one who makes liquor-backs, under-backs, coolers, mash-tuns, working-tuns, &c. for the brewers. The workmanship is partly carpentry, in a particular manner, for it must be tight enough to hold liquor; and partly cooperage, *viz.* the mash-tun, or vat, which is hooped. There are not many of this trade; and it requires chiefly strength, with a little art. A small stock of stuff, besides tools, will set a man up tolerably well; but, with 200l or 300l. he will make a good figure in business.

BACA, or **BAZA**, a town of Spain in the kingdom of Granada. W. Long. 3. 6. N. Lat. 37. 18. It is situated in a valley called *Hoya de Baza*. It is encompassed with old walls, and has a castle half ruined. It contains about 4000 houses, but has nothing remarkable except the church dedicated to the Virgin Mary. The land about it is well cultivated for half a league round, and is fertile in wheat, wine, honey, hemp, and flax, being watered by the little river Guadalatin.

BACACUM, a town of the Nervii in Gallia Belgica; now *Bavay*, in Hainault. E. Long. 3. 40. N. Lat. 50. 25.

BACAIM, a handsome sea-port town of the kingdom of Visapour on the Malabar coast in Asia. It is subject to the Portuguese; and stands in E. Long. 73. 10. N. Lat. 19. 0.

BACASERAY, a town in the peninsula of Crim Tartary, and, as the khan usually takes up his residence there, it may be considered as the capital of the country.

Bacca E. Long. 35. 10. N. Lat. 45. 30.

Bacchus.

BACCA, BERRY, in botany, is used to signify such fruits as consist of a pericarpium full of juice and seeds, without any valves.

BACCARACH, a town of Germany in the lower Palatinate; formerly imperial and free, but now subject to the elector Palatine. It is famous for excellent wine; and is situated on the Rhine, in E. Long. 7. 5. N. Lat. 49. 57.

BACCHANALIA, feasts celebrated in honour of Bacchus by the ancients. The two most remarkable were called the *greater* and *lesser*. The latter, called *lenaea*, from a word signifying a *wine-press*, were held in the open fields about autumn; the greater, called *Dionysia*, from one of the names of Bacchus, were celebrated in the city, about the spring-time. Both these feasts were accompanied with games, spectacles, and theatrical representations, and it was at this time the poets contended for the prize of poetry. Those who were initiated into the celebration of these feasts, represented some Silenus; others, Pan; others, Satyrs; and in this manner appeared in public, night and day, counterfeiting drunkenness, dancing obscenely, and committing all kinds of licentiousness and debauchery. See the article BACCHUS.

BACCHARIS, PLOUGHMAN'S SPIKENARD, a genus of the polygamia superflua order, belonging to the syngenesia class of plants. Of this genus there are seven species, all natives of warm climates; but none of them merit notice except the two following. 1. The ivyfolia, or African tree-groundfell, is a native of the Cape of Good Hope, as also of Peru and other warm parts of America. It grows to the height of five or six feet; and though there is little beauty in the flower, has been long admitted into the gardens of the curious. It is pretty hardy, and will live abroad in moderate winters in England, but is usually kept in green-houses, and placed abroad only in summer. It may be propagated either by cuttings, or by seeds, which ripen well in this country. 2. The halimifolia, or Virginia groundfell-tree, is a native of Virginia and other parts of North America. It grows about seven or eight feet high, with a crooked shrubby stem; and flowers in October: the flowers are white, and not very beautiful; but the leaves continuing green, has occasioned this shrub to be admitted into many curious gardens. It may be propagated by cuttings; and will live very well in the open air, though severe frost will sometimes destroy it.

BACCHINI (Benedict), a Benedictine monk, and one of the most learned men in his time, was born at Borgo San Domino, in 1651; and wrote a great number of books, in Latin and Italian, the most considerable of which is a Literary Journal. He died at Bologna, in 1721, aged 70.

BACCHUS, a follower of Aristoxenus, supposed by Fabricius to have been tutor to the emperor Marcus Antoninus, and consequently to have lived about A. C. 140. He wrote in Greek a very short introduction to music in dialogue, which, with a Latin translation thereof, Meibomius has published. It seems it was first published in the original by Merfennus, in his Commentary on the first six chapters of Genesis; and that afterwards he published a translation of it in French, which Meibomius, in the preface to his edition of the

ancient musical authors, censures as being grossly erroneous.

BACCHUS, in ancient poetry, a kind of foot composed of a short syllable, and two long ones; as the word [avári]. It takes its name from the god Bacchus, because it frequently entered into the hymns composed in his honour. The Romans called it likewise *anotrius*, *tripidius*, *saltans*.

BACCHUS, in Heathen mythology, the god of wine, with whose fabulous adventures every school-boy is acquainted. This personage is seldom named in modern times but as a sensual encourager of feast and jollity; but he was regarded in a more respectable light by the ancients, who worshipped him in different countries under the following appellations: in Egypt, he was called *Osiris*; in Mylia, *Fanaces*; in India, *Dionysus*; *Liber*, throughout the Roman dominions; *Adoneus*, in Arabia; and *Pentheus*, by the Lucanians. Mythologists furnish reasons for all these different names given to the same God, which may be seen in the second volume of Banier's Mythology.

It is natural to suppose that the Greeks and Romans, as usual, bestowed upon the one Bacchus which they worshipped, the several actions and attributes of the many divinities known by that name, and by other equivalent denominations in different countries. However, antiquity chiefly distinguished two gods under the title of *Bacchus*: that of Egypt, the son of Ammon, and the same as Osiris; and that of Thebes in Beotia, the son of Jupiter and Semele.

The Egyptian Bacchus was brought up at Nyfa, a city of Arabia Felix, whence he acquired the name of *Dionysus*, or the God of Nyfa; and this was the conqueror of India. Though this Bacchus of the Egyptians was one of the elder gods of Egypt, yet the son of Semele was the youngest of the Grecian deities. Diodorus Siculus tells us, that Orpheus first deified the son of Semele by the name of Bacchus, and appointed his ceremonies in Greece, in order to render the family of Cadmus, the grandfather of the Grecian Bacchus, illustrious.

The great Bacchus, according to Sir Isaac Newton, flourished but one generation before the Argonautic expedition. This Bacchus, says Hermippus, was potent at sea, conquered eastward as far as India, returned in triumph, brought his army over the Hellespont, conquered Thrace, and left music, dancing, and poetry there. And, according to Diodorus Siculus, it was the son of Semele who invented farces and theatres, and who first established a music-school, exempting from all military functions such musicians as discovered great abilities in their art; on which account, says the same author, musicians formed into companies have since frequently enjoyed great privileges.

Dr Burney * observes, that the dithyrambs which gave birth to dramatic representations, are as ancient as the worship of Bacchus in Greece; and there is little doubt but that the ceremonies of his mysteries gave rise to the pomp and illusions of the theatre. Many of the most splendid exhibitions upon the stage for the entertainment of the people of Athens and Rome, being performed upon the festivals of Bacchus, gave occasion to the calling all those that were employed in them, whether for singing, dancing, or reciting,

Bacchus.
Bacchus.

* Hist. of Music, p. 293. seq.

citing, *servans of Bacchus.*

Paufanias, in his *Attics*, fpeaks of a place at Athens, confacrated to *Bacchus the fnger*; this named, he fays, for the fame reafon as Apollo is called the *chief and condutor* of the mufes. Whence it fhould feem that Bacchus was regarded by the Athenians not only as the god of wine, but of fong; and it muft be owned, that his followers, in their cups, have been much inclined to finging ever fince. Indeed we are certain, that in none of the orgies, proceffions, triumphs, and feftivals, infituted by the ancients to the honour and memory of this prince of *bons vivans*, mufic was forgotten, as may be fill gathered from ancient fculpture, where we find not only that muficians, male and female, regaled him with the lyre, the flute, and with fong; but that he was accompanied by fawns and fatyrs playing upon timbrels, cymbals, bagpipes, and horns: thefe Suidas calls his *miniftrals*; and Strabo gives them the appellations of *Bacchi, Sileni, Nymphæ, Bacche, Lenæ, Thyæ, Mamillones, Naiades, Nymphæ, and Tityri.*

Thefe representations have furnifhed fubjects for the fineft remains of ancient fculpture; and the moft voluptuous paffages of ancient poetry are defcriptions of the orgies and feftivals of Bacchus.

The *orgia*, or feafts and facrifices performed in honour of this god in Greece, were chiefly celebrated on the mountains of Thrace by wild diftracted women called *Bacche*. The *Orgia* were likewife called *Orphica*, from their founder Orpheus. However, Servius fays, that at firft *Orgia* was a common name for all kinds of facrifices among the Greeks, and of the fame import with the word *ceremonia* among the Romans. Virgil calls the feafts of Bacchus *Orgia tritæria*, from their being celebrated once in three years.

They had certainly their rife in Egypt, where Ofiris was the model of the Grecian Bacchus; from thence they paffed into Greece, Italy, Gaul, and were adopted almoft throughout the whole pagan world. They were at firft performed with fimplicity and decorum; but afterwards they degenerated into fo much folly and licentiousnefs, that hiftorians affure us the debaucheries prafticed in them during the night time were fo enormous, as to oblige the Roman fenate, in the 556th year of the city, 186 B. C. to abolifh them entirely throughout the Roman dominions. After their prohibition, however, recorded at large by Livy *, feveral perfons feem to have continued their ufe: Tacitus † gives an elegant defcription of the Bacchanalia as celebrated by Meffalina. The orgies of Bacchus furnifhed Æfchylus with a fubject for one of his tragedies; from whence may be acquired a truer idea of them before their corruption than from any other remains of antiquity.

The orgies being a commemoration of the march of the elder Bacchus into India, and that prince having had in his train muficians of both fexes, fatyrs, and fawns, or men equipped like fawns and fatyrs, thefe were afterwards employed in the proceffions and orgies, and formed into bands of mufic, playing upon drums and cymbals, and crying out *Evæhe Bacche!*

In the Jultinian garden at Rome there is a marble vafe of moft precious workmanfhip, upon which is a representation of thefe orgies of Bacchus. This vafe, from the beauty of the fculpture, is fuppofed to be by the hand of Saurus. The whole pomp of one of thefe

proceffions is there admirably reprefented; in which are introduced Bacchus, the Bacchanals, the Mænades, the players on flutes, matrons, and virgins, with the Crotalum, or cymbalum, and tympanum; fawns and fatyrs, holding in their hands vafes and cups; priefts leading the victims deftined for facrifice, fuch as the boar, the he-goat, and the bull; and, laftly, old Silenus, drunk, upon his afs, which he is hardly able to guide.

With refpect to *Bacchanalian Songs*, as the ancient Greeks and modern French have at all times had the beft wine to drink, they feem to have been the moft happy in finging its praifes. Anacreon will authorife this opinion with refpect to the Greeks; and the French have many Anacreons, among whom may be numbered the abbe de Chaulieu, La Chapelle, La Fare, and St Aulajfe.

But Bacchus is faid by Diodorus † to have invented † Lib. iv. beer, for the ufe of mankind in fuch parts of the globe as are unfit for the culture of the grape; and our gluey potatoes, with the black juice of Oporto, have fometimes infpired the bards of this ifland with wit and jollity in their drinking fongs. And indeed our catches, by the ingenuity of the mufical compofer, are perhaps fraught with more pleafantry, and are productive of more genuine mirth, than the Bacchanalian hymns of any other people on the globe.

BACCHYLIDES, a famous Greek poet, was the nephew of Simonides, and the cotemporary and rival of Pindar. Both fung the victories of Hiero at the public games. Befides odes to athletic victors, he was author of *Love Verfes; Profodies; Dithyrambics; Hymns; Pæans; Hyporchemes; Parthenia*, or fongs to be fung by a chorus of virgins at feftivals. The chronology of Eufebius places the birth of Bacchylides in the 82^d Olympiad, about 450 B. C.

BACCIO, or BACCUS, (Andrew), a celebrated phyfician in the 16th century, born at St Elpidio. He prafticed phyfic at Rome with great reputation, and was firft phyfician to pope Sixtus V. The moft fcarce and valuable of his works are, 1. *De thermis.* 2. *De naturali vinorum hiftoria.* 3. *De venenis et antidotis.* 4. *De gemmis ac lapidibus pretiofis.*

BACHELOR, or BATCHELOR, a man who fill continues in the ftate of celibacy, or who was never married.

BACHELOR is a word of uncertain etymology, it not being known what was its original fenfe. Junius derives it from *Baccalarij, foilij*; Menage, from *Bas Chevalier*, a knight of the loweft rank; Spelman, from *Baculus*, a ftaff; Cujas, from *Buccella*, an allowance of provifion. The moft probable derivation of it feems to be from *Bacca Laurus*, the berry of a laurel or bay; bachelors being young and of good hopes, like laurels in the berry. In Latin, *Baccalaureus*.

BACHELOR was anciently a denomination given to thofe who had attained to knighthood, but had not a number of vaffals fufficient to have their banner carried before them in the field of battle; or if they were not of the order of bannerets, were not of age to difplay their own banner, but obliged to march to battle under another's banner. It was alfo a title given to young cavaliers, who, having made their firft campaign, received the military girdle accordingly. And it ferved to denominate him who had overcome another in a tournament,

Bacchus
Bachelor.

Barye,
ibid.

† Lib. iv.

namment, the first time he ever engaged.

Knights BACHELORS were so called, as being the lowest order of knights, or inferior to bannerets.

BACHELORS, in an university-sense, are persons that have attained to the baccalaureate, or who have taken the first degree in the liberal arts and sciences. Before a person can be admitted to this degree at Oxford, it is necessary that he study there four years; three years more may entitle him to the degree of master of arts; and in seven years more he may commence bachelor of divinity. At Cambridge, the degrees are usually taken much the same as at Oxford, excepting in law and physic; in either of which the bachelor's degree may be taken in six years. In France, the degree of bachelor of divinity is attained in five year's study; that is, in two years of philosophy, and three of divinity.

BACHERAC, a town of the Palatine of the Rhine, situated on the western shore of that river, in E. Long. 7°, and N. Lat. 58°. It is remarkable for excellent wine, from thence called *Bacherac*.

BACHIAN, one of the Molucca islands, belonging to the Dutch; situated under the equator, in E. Long. 125°.

BACHU, a city of Shirvan in Persia, and the best haven in the Caspian sea. It is defended by a double wall, as also by a ditch and redoubts, made by the Russians when they were masters of the place. It had a sumptuous castle, but it is reduced to a ruinous state by the Russians. Formerly many merchants resided here, and carried on a considerable traffick in raw silk; but that commerce is now given up. All the country round is much impregnated with sulphur, which renders the water very unpleasant. The neighbourhood of this city supplies the countries adjacent with naphtha, brimstone, and rock-salt; and is the only place thereabouts which produces saffron. Round Bachu are several very steep craggy mountains, on which are siting watch-towers. E. Long. 49. 5. N. Lat. 40. 0.

BACK, in anatomy. See *BACK-Bone*.

BACK, in the menage, and among farriers. A horse's back should be straight, not hollow, which is called *saddle backed*: horses of this kind are generally light, and carry their heads high, but want in strength and service. A horse with a weak back is apt to flumble. In the French riding-schools, to mount a horse *a dos*, is to mount him bare-backed, without a saddle.

BACK-Bone, or SPINE. See ANATOMY, n° 29, &c.

BACK-Gammon, an ingenious game played with dice and tables, to be learned only by observation and practice.

BACK-Painting, the method of painting mezzotint prints, passed on glass, with oil-colours *.

* See Mezzotint.

The art consists chiefly in laying the print upon a piece of crown-glass, of such a size as fits the print. In order to do this, take your print, and lay it in clean water for two days and two nights, if the print be on very strong, close, and hard gummed paper; but if upon an open, soft, spongy paper, two hours will sometimes suffice, or more, according as the paper is.

The paper or picture having been sufficiently soaked, take it out and lay it upon two sheets of paper, and cover it with two more; and let it lie there a little to soak out the moisture.

In the mean time, take the glass the picture is to be

put upon, and set it near the fire to warm; take Strasbourg turpentine, warm it over the fire till it is grown fluid, then with a hog's-hair brush spread the turpentine very smoothly and evenly on the glass.

When this has been done, take the mezzotint print from between the papers, and lay it upon the glass; beginning first at one end, rubbing it down gently as you go on, till it lie close, and there be no wind bladders between.

Then, with your fingers, rub or roll off the paper from the back-side of the print, till it looks black; i. e. till you can see nothing but the print, like a thin film, left upon the glass, and set it by to dry.

When it is dry, varnish it over with some white transparent varnish, that the print may be seen through it; and then it is fit for painting.

The utmost care will be necessary in rubbing or rolling the paper of the print, so as not to tear it, especially in the light parts.

You may, instead of soaking your prints two days and two nights, roll them up and boil them for about two hours, more or less, according to the quality of the paper, in water; and that will render it as fit for rubbing, rolling, or peeling, as the other way.

This being done, and your oil-colours prepared, ground very fine, and tempered up very stiff, lay on the back-side of the transparent prints such colours as each particular part requires; letting the master-lines of the print still guide your pencil, and so each particular colour will lie fair to the eye on the other side of the glass, and look almost as well as a painted piece, if it be done neatly.

The shadows of the print are generally sufficient for the shadow of every colour; but if you have a mind to give a shadow by your pencil, then let the shadows be laid on first, and the other colours afterward.

In laying on colours in this kind of back-painting, you need not be curious as to the laying them on smooth. This is not at all requisite here, where the chief aim is only to have the colours appear well on the fore side of the print; and therefore the only care to be used in this work, is to lay the colours on thick enough, that its body may strike the colour of it plainly through the glass.

BACK-Staff, a name formerly given to a sea-quadrant invented by Captain Davis; because the back of the artist is turned towards the sun at the time of observation. See QUADRANT.

BACK-Stays, of a ship, are ropes belonging to the main-mast and fore-mast, and the masts belonging to them; serving to keep them from pitching forwards or overboard.

BACK-Tack, in Scots law: When a wadsetter, instead of posessing the wadset-lands, grants a tack thereof to the reverfor for payment of a certain sum in name of tack-duty, that tack is called a *back tack* *.

BACK-Worm. See FILANDERS.

BACKING, in horsemanship. See HORSEMANSHIP. BACKING the Sails, in navigation; to arrange them in a situation that will force the ship to retreat, or move backwards. This is, however, only done in narrow channels, when a ship is carried along sidewise by the tide or current, and wants to avoid any thing that may interrupt her progress, as shoals, vessels at anchor, &c. or in the line of battle, when a ship wants to be im-

* See Law, Part III, n° 109, 110.

imme-

immediately opposite to another with which she is engaged.

BACKS, among dealers in leather, denote the thick-cut and best-tanned hides, used chiefly for soles of shoes.

BACKS, in brewing and distilling. See **Bac**.

BACULARIUS, in writers of the middle age, an ecclesiastical apparitor, or verger; who carries a staff, *baculus*, in his hand, as an emblem of his office.

BACON, swines flesh salted, and dried in the chimney.—Old historians and law-writers speak of the *service of the bacon*, a custom in the manor of Whichenacre in Staffordshire, and priory of Dunmore in Essex; in the former of which places, by an ancient grant of the lord, a sitch of bacon, with half a quarter of wheat, was to be given to every married couple who could swear, that, having been married a year and a day, they would never within that time have once exchanged their mate for any other person on earth, however richer, fairer, or the like. But they were to bring two of their neighbours to swear with them that they believed they swore the truth. On this the lord of another neighbouring manor, of Rudlow, was to find a horse saddled, and a sack to carry the bounty in, with drums and trumpets, as far as a day's journey out of the manor: all the tenants of the manor being summoned to attend, and pay service to the bacon. The bacon of Dunmore, first erected under Henry III. was on much the same footing; only the tenor of the oath was, that the parties had never once repented, or wished themselves unmarried again.

BACON (Roger), a Franciscan friar of amazing genius and learning, was born near Ilchester in Somersetshire, in the year 1214. He began his studies at Oxford; but in what school, or college, is uncertain. Thence he removed to the university of Paris, which, in those times, was esteemed the centre of literature. Here, we are told, he made so rapid a progress in the sciences, that he was esteemed the glory of that university, and was much caressed by several of his countrymen, particularly by Robert Grossethead, afterwards bishop of Lincoln, his singular friend and patron. About the year 1240, he returned to Oxford; and assuming the Franciscan habit, prosecuted his favourite study of experimental philosophy, with unremitting ardour and assiduity. In this pursuit, in experiments, instruments, and in scarce books, he tells us, he spent, in the space of 20 years, no less than L. 2000; which, it seems, was given him by some of the heads of the university, to enable him to prosecute his noble inquiries. By such extraordinary talents, and astonishing progress in sciences, which, in that ignorant age, were totally unknown to the rest of mankind, whilst they raised the admiration of the more intelligent few, could not fail to excite the envy and malice of his illiterate fraternity; who found no difficulty of possessing the vulgar with the notion of Bacon's dealing with the devil. Under this pretence, he was restrained from reading lectures; his writings were confined to his convent; and finally, in 1278, he himself was imprisoned in his cell. At this time, he was 64 years of age. Nevertheless, being permitted the use of his books, he went on in the rational pursuit of knowledge, corrected his former labours, and wrote several curious pieces. When he had been 10 years in confinement, Jerom de Afcoli being elected pope, Bacon solicited his holiness to be

released; in which, it seems, he did not immediately succeed. However, towards the latter end of that pope's reign, he obtained his liberty, and spent the remainder of his life in the college of his order, where he died in the year 1294, in the 80th year of his age, and was buried in the Franciscan church. Such are the few particulars which the most diligent researches have been able to discover concerning this very great man, who, like a single bright star in a dark hemisphere, shone forth the glory of his country, and the pride of human nature.

His works are, 1. *Epistola fratris Rogeri Baconis de secretis operibus artis et naturæ, et de nullitate magiæ*. Paris 1542, 4to. Basil, 1593, 8vo. 2. *Opus majus*. Lond. 1733, fol. published by Dr Jebb. 3. *Theaurus chemicus*. Francf. 1603, 1620. This was probably the editor's title; but it contains several of our author's treatises on this subject. These printed works of Bacon contain a considerable number of essays, which, in the catalogue of his writings by Bale, Pits, &c. have been considered as distinct books; but there remain in different libraries several manuscripts not yet published. By an attentive perusal of his works, the reader will be astonished to find, that this great luminary of the 13th century was a great linguist, and a skilful grammarian; that he was well versed in the theory and practice of perspective; that he understood the use of convex and concave glasses, and the art of making them; that the *camera obscura*, burning-glasses, and the power of the telescope, were known to him; that he was well versed in geography and astronomy; that he knew the great error in the kalendar, assigned the cause, and proposed the remedy; that he understood chronology well; that he was an adept in chemistry, and was really the inventor of gun-powder; that he possessed great knowledge in the medical art; that he was an able mathematician, logician, metaphysician, and theologian.

BACON (Sir Nicholas), lord keeper of the great seal in the reign of Queen Elizabeth, was born at Chiffershurst, in Kent, in 1510, and educated at the university of Cambridge; after which he travelled into France, and made some stay at Paris. On his return, he settled in Gray's-inn, and applied himself with such assiduity to the study of the law, that he quickly distinguished himself so, that on the dissolution of the monastery of St Edmund's Bury, in Suffolk, he had a grant from king Henry VIII. in the 36th year of his reign, of several manors. In the 38th of the same king, he was promoted to the office of attorney in the court of Wards, which was a place both of honour and profit. In this office he was continued by King Edward VI; and in 1552 he was elected treasurer of Gray's-inn. His great moderation and consummate prudence preserved him through the dangerous reign of Queen Mary. In the very dawn of that of Elizabeth he was knighted; and on the 22^d of December 1558, the great seal of England, being taken from Nicholas Heath archbishop of York, was delivered to him with the title of *lord keeper*, and he was also made one of the Queen's privy council. He had a considerable share in the settling of religion: as a statesman, he was remarkable for a clear head and deep counsels: but his great parts and high preferment were far from raising him in his own opinion, as appears from the modest answer he gave Queen Elizabeth, when she told him his house at Red-

grave was too little for him; "Not so, madam, (returned he), but your majesty has made me too great for my house." After having had the great seal more than 20 years, this able statesman and faithful counsellor was suddenly removed from this life, as Mr Mallet informs us, by the following accident: he was under the hands of the barber, and thinking the weather warm, had ordered a window before him to be thrown open, but fell asleep as the current of fresh air was blowing in upon him, and awaked some time after distempered all over. He was immediately removed into his bed chamber, where he died a few days after, on the 26th of February 1578-9, equally lamented by the queen and her subjects. He was buried in St Paul's, where a monument was erected to him, which was destroyed by the fire of London in 1669. Mr Granger observes, that he was the first lord keeper that ranked as lord chancellor; and that he had much of that penetrating genius, solidity, and judgment, persuasive eloquence, and comprehensive knowledge of law and equity, which afterwards shone forth with so great a lustre in his son, who was as much inferior to his father in point of prudence and integrity, as his father was to him in literary accomplishments.

BACON (Francis), lord high chancellor of England under king James I. was son of Sir Nicholas Bacon lord keeper of the great seal, in the reign of queen Elizabeth, by Anne daughter of Sir Anthony Cook, eminent for her skill in the Latin and Greek tongues. He was born 1560; and shewed such marks of genius, that he was particularly taken notice of by queen Elizabeth when very young. He was educated at Trinity college, Cambridge; and made such incredible progress in his studies, that, before he was 16, he had not only run through the whole circle of the liberal arts as they were then taught, but began to perceive those imperfections in the reigning philosophy, which he afterwards so effectually exposed, and thereby not only overturned that tyranny which prevented the progress of true knowledge, but laid the foundation of that free and useful philosophy which has since opened a way to so many glorious discoveries. On his leaving the university, his father sent him to France; where, before he was 19 years of age, he wrote a general view of the state of Europe: but Sir Nicholas dying, he was obliged suddenly to return to England; when he applied himself to the study of the common law, at Gray's-inn. At this period the famous earl of Essex, who could distinguish merit, and who passionately loved it, entered into an intimate friendship with him; zealously attempted, though without success, to procure him the office of queen's solicitor; and, in order to comfort his friend under the disappointment, conferred on him a present of land to the value of 1800*l*. Bacon, notwithstanding the friendship of so great a person; notwithstanding the number and power of his own relations; and, above all, notwithstanding the early prepossession of her majesty in his favour; met with many obstacles to his preferment during her reign. In particular, his enemies represented him as a speculative man, whose head was filled with philosophical notions, and therefore more likely to perplex than forward public business. It was not without great difficulty that lord treasurer Burleigh obtained for him the reversion of register to the Star-chamber, worth about

1600*l*. a year, which place fell to him about 20 years after. Neither did he obtain any other preferment all this reign; though if obedience to a sovereign in what must be the most disagreeable of all offices, viz. the calling reflections on a deceased friend, entitled him, he might have claimed it. The people were so clamorous even against the queen herself on the death of Essex, that it was thought necessary to vindicate the conduct of the administration: this was assigned to Bacon, which brought on him universal censure, nay his very life was threatened. Upon the accession of king James, he was soon raised to considerable honours; and wrote in favour of the union of the two kingdoms of Scotland and England, which the king so passionately desired. In 1616, he was sworn of the privy-council. He then applied himself to the reducing and re-composing the laws of England. He distinguished himself, when attorney-general, by his endeavours to restrain the custom of duels, then very frequent. In 1617, he was appointed lord keeper of the great seal. In 1618, he was made lord chancellor of England, and created lord Verulam. In the midst of these honours and applauses, and multiplicity of business, he forgot not his philosophy, but in 1620 published his great work intitled *Novum Organum*. We find, by several letters of his, that he thought convening of parliaments was the best expedient for the king and people. In 1621, he was advanced to the dignity of Viscount St Albans, and appeared with the greatest splendour at the opening of the session of parliament. But he was soon after surpris'd with a melancholy reverse of fortune. For, about the 12th of March, a committee of the house of commons was appointed to inspect the abuses of the courts of justice. The first thing they fell upon was bribery and corruption, of which the lord chancellor was accused. For that very year complaints being made to the house of commons of his lordship's having received bribes, those complaints were sent up to the house of lords, and new ones being daily made of a like nature, things soon grew too high to be got over. The king found it was impossible to save both his chancellor, who was openly accused of corruption, and Buckingham his favourite, who was secretly and therefore more dangerously attacked as the encourager of whatever was deemed most illegal and oppressive: he therefore forced the former to abandon his defence, giving him positive advice to submit himself to his peers, and promising upon his princely word to free him in the last determination, or, if that could not be, to reward him afterwards with ample retribution of favour. The chancellor, though he foresaw his approaching ruin if he did not plead for himself, resolved to obey; and the house of peers, on the 3^d of May 1621, gave judgment against him, "That he should be fined 40,000*l*. and remain prisoner in the tower during the king's pleasure; that he should for ever be incapable of any office, place, or employment, in the state or commonwealth; and that he should never sit in parliament, or come within the verge of the court." The fault which, next to his ingratitude to Essex, thus tarnished the glory of this illustrious man, is said to have principally proceeded from his indulgence to his servants, who made a corrupt use of it. One day, during his trial, passing through a room where several of his domestics were sitting, upon their rising up to salute him,

he said, "Sit down, my masters; your rife hath been my fall." *Stephens*, p. 54. And we are told by Rulworth in his historical collections, "That he treasured up nothing for himself or family, but was over-indulgent to his servants, and connived at their takings, and their ways betrayed him to that error; they were profuse and expensive, and had at their command whatever he was master of. The gifts taken were for the most part for interlutory orders; his decrees were generally made with so much equity, that though gifts rendered him suspected for unjust, yet never any decree made by him was reversed as unjust." It was peculiar to this great man (say the authors of the *Biogr. Brit.*) to have nothing narrow and selfish in his composition: he gave away without concern whatever he possessed; and believing other men of the same mould, he received with as little consideration. He retired, after a short imprisonment, from the engagements of an active life, to which he had been called much against his genius, to the shade of a contemplative one, which he had always loved. The king remitted his fine, and he was summoned to parliament in the first year of king Charles the first. It appears from the works composed during his retirement, that his thoughts were still free, vigorous, and noble. The last five years of his life he devoted wholly to his studies. In his recess he composed the greatest part of his English and Latin works. He expired on the 9th of April, 1626; and was buried in St Michael's church at St Albans, according to the direction of his last will, where a monument of white marble was erected to him by Sir Thomas Meautys formerly his secretary, and afterward clerk of the privy council under two kings. A complete edition of this great man's works was published at London in the year 1740.—Addison has said of him, That he had the sound, distinct, comprehensive knowledge of Aristotle, with all the beautiful light, graces, and embellishments, of Cicero.—The honourable Mr Walpole calls him the *Prophet of Arts* which Newton was afterwards to reveal; and adds, that his genius and his works will be universally admired as long as science exists. "As long as ingratitude and adulation are despicable, so long shall we lament the depravity of this great man's heart. Alas! that he who could command immortal fame, should have stooped to the little ambition of power."

BACON (sir Nathaniel), knight of the bath, and an excellent painter, was a younger son of the lord keeper, and half brother to the great sir Francis. He travelled into Italy, and studied painting there; but his manner and colouring approaches nearer to the style of the Flemish school. Mr Walpole observes, that at Culford, where he lived, are preserved some of his works; and at Gorbambury, his father's seat, is a large picture by him in oil, of a cook-maid with a dead fowl, admirably painted, with great nature, neatness, and lustre of colouring. In the same house is a whole length of him, by himself, drawing on a paper, his sword and pallet hung up, and a half length of his mother by him.

BACONTHORP (John), called the *resolute doctor*, a learned monk, was born towards the end of the 13th century, at Baconthorp a village in Norfolk. He spent the early part of his life in the convent of Blackney, near Walsingham in the same county; whence he removed to Oxford, and from thence to Paris; where being

distinguished for his learning, he obtained degrees in divinity and laws, and was elected the principal of Averrois's*. In 1329 he returned to England, and was immediately chosen twelfth provincial of the English Carmelites. In 1333 he was sent for to Rome; where, we are told, he first maintained the pope's sovereign authority in cases of divorce, but that he afterwards retracted his opinion. He died in London in the year 1346. Leland, Bale, and Pits, unanimously give him the character of a monk of genius and learning. He wrote, 1. *Commentaria seu quaestiones super quatuor libros sententiarum*; and, 2. *Compendium legis Christi, et quodlibeta*: both which underwent several editions at Paris, Milan, and Cremona. Leland, Bale, and Pits, mention a number of his works never published.

BACTRIA, or BACTRIANA, now *Chorassan* or *Khorassan*, an ancient kingdom of Asia, bounded on the west by Margiana, on the north by the river Oxus, on the south by Mount Paropimus, and on the east by the Asiatic Scythia and the country of the Massagetæ. It was a large, fruitful, and well-peopled country, containing according to Ammianus Marcellinus 1000 cities, though of these only a few are particularly mentioned by historians, of which that formerly called *Maracanda*, now *Samarcand*, is the most considerable.

Of the history of this country we know but little. Authors agree that it was subdued first by the Assyrians, afterwards by Cyrus, and then by Alexander the Great. Afterwards it remained subject to Seleucus Nicator and his successors till the time of Antiochus Theos; when Theodotus, from governor of that province, became king, and strengthened himself so effectually in his kingdom, while Antiochus was engaged in a war with Ptolemy Philadelphus king of Egypt, that he could never afterwards dispossess him of his acquisitions. His posterity continued to enjoy the kingdom for some time, till they were driven out by the Scythians, who reigned in Bactria in the time of Adrian, Antoninus Pius, &c. The Scythians were in their turn driven out by the Huns or Turks, and these often conquered by the Saracens and Tartars; nevertheless they continued in possession of this country in the time of Ladislaus IV. king of Hungary*.

In early times the Bactrians differed little in their manners from the Nomades; and being near neighbours of the Scythians, who were a very warlike people, the Bactrian soldiers were reckoned the best in the world. Their appearance was very savage; being of an enormous stature, having a terrible aspect, rough beards, and long hair hanging down their shoulders. Some authors assert that they kept dogs on purpose to devour such as arrived at extreme old age, or who were exhausted by long sickness. They add, that for all their fierceness, the Bactrian husbands were such dupes to their wives, that they durst not complain of them even for conjugal infidelity, to which it seems the latter were very much addicted.

BACTROPERATA, an ancient appellation given to philosophers by way of contempt, denoting a man with a staff and a budget.

We suppose it is of the same people that Pauchasius Radbertus speaks under the corrupt name of *Baccoperitas*, or *Bacchionites*, whom he describes as philosophers who had so great a contempt for all earthly things, that they kept nothing but a dish to drink out of; and

perata.

* See *Avur-*
ras.

* See *Kis-*
ras.

that one of this order seeing a peasant scooping up the water in his hand, threw away his cup as a superfluity: which is nothing but the old story of Diogenes the Cynic.

BACULE, in fortification, a kind of portcullis, or gate, made like a pit-fall with a counterpoise, and supported by two great flakes. It is usually made before the corpa-de-guard, not far from the gate of a place.

BACULOMETRY, the art of measuring accessible or inaccessible heights, by the help of one or more baculi, flaves, or rods. See **GEOMETRY**.

BACURIUS, or **BATURUS**, king of the Iberians, a people on the side of the Caspian sea. One day being a-hunting, he lost sight of his company, through a great storm and sudden darkness; upon which he vowed to the God of his Christian slave, that if he were delivered he would worship him alone: the day breaking up immediately, he made good his promise, and became the apostle of his country.

BADAGSHAN, a very ancient city of Great Bukharia, in the province of Balkh, situated at the foot of those high mountains which separate Indostan from Great Tartary. The city is exceedingly strong by its situation; and belongs to the khan of proper Bukharia, who uses it as a kind of state-prison to secure those he is jealous of. The town is not very big, but well built, and very populous. It stands on the north side of the river Amu, about 100 miles from its source, and is a great thoroughfare for the caravans designed for little Bukharia. The inhabitants are enriched by mines of gold, silver, and rubies, which are in the neighbourhood; and those who live at the foot of the mountains gather a great quantity of gold and silver dust brought down in the spring by torrents occasioned by the melting of the snow on the top.

BADAJOZ, a large and strong town, capital of Estremadura in Spain. It is seated on the river Guadiana, over which there is a fine bridge built by the Romans. On this bridge the Portuguese were defeated in 1661, by Don John of Austria. W. Long. 7. 3. N. Lat. 38. 35.

BADELONA, a town of Catalonia in Spain, seated on the Mediterranean. Lord Peterborough landed here in 1704, when, with Charles then king of Spain, he laid siege to Barcelona, from which it is ten miles distant. E. Long. 2. 20. N. Lat. 41. 12.

BADEN (the district of), in Switzerland, has three cities, Baden, Keisers-Stoul, and Klingnaw, besides a town that passes for a city, namely, *Zurzach*. It is one of the finest countries in Switzerland, and is watered with three navigable rivers, the Limmet, Rufs, and Are. The land is fertile in corn and fruit, and there are places on the sides of the Limmet which produce wine. It maintains a communication between the cantons of Zurich and Bern, being seated between their north extremities. It extends on one side to the Are, as far as the place where it falls into the Rhine, and on the other side beyond the Rhine, where there are some villages which depend thereon. Most of the inhabitants are Papists. By the treaty of peace at the conclusion of the war which broke out in 1712 between the Protestant and Popish cantons, this country was yielded to the Protestant cantons of Zurich and Bern. Before, it was the property of the eight old cantons; however, as the canton of Glaris had taken no part in

this war, by the consent of both parties its right was still continued.

BADEN, the capital of the above district, is an agreeable city, moderately large, seated on the side of the Limmet, in a plain flanked by two high hills, between which the river runs. This city owes its rise to its baths, which were famous before the Christian era. Several monuments of antiquity have been found here from time to time, particularly in 1420. When they were opening the large spring of the baths, they found statues of several heathen gods, made of alabaster; Roman coins, made of bronze, of Augustus, Vespasian, Decius, &c.; and several medals of the Roman emperors, of gold, silver, copper, and bronze. There are two churches in Baden; one of which is collegiate, and makes a good appearance; the other is a monastery of the Capuchins, near the town-house. This last building serves not only for the assemblies of their own council, but also for those of the cantons. The diet assembles there in a handsome room made for that purpose; the deputies of Zurich sit at the bottom behind a table, as the most honourable place; the ambassadors of foreign powers are seated on one side to the right, and the deputies of the other cantons are ranged on each side the room. The bailiff of Baden resides in a castle at the end of a handsome wooden bridge, which is covered in. Before this castle there is a stone pillar, erected in honour of the emperor Trajan, who paved a road in this country 85 Italian miles in length. The inhabitants are rigid Roman-catholics, and formerly behaved in a most insolent manner to the Protestants, but they are now obliged by their masters to be more submissive. The baths which are on each side the river are a quarter of a league from the city. Joining to the small baths there is a village, and to the large a town which may pass for a second Baden. It is seated on a hill, whose ascent is steep. There the baths are brought into inns and private houses, by means of pipes, which are about 60 in all. There are also public baths in the middle of the town, from a spring which rises in the street, where the poor bathe gratis, but they are exposed quite naked to all that pass by. All the baths are hot, and one to so great a degree as to scald the hand; and they are impregnated with a great deal of sulphur, with some allum and nitre. They are useful for drinking as well as bathing; and are said to cure all diseases from a cold cause, headaches, vertigos, &c. They strengthen the senses, cure diseases of the breast and bowels, asthma, and obstructions. They are peculiarly excellent for womens diseases. E. Long. 8. 25. N. Lat. 47. 27.

BADEN (the Margravate of), in the circle of Swabia, in Germany, is bounded by the Palatinate of the Rhine, on the north; by the Black Forest, on the east; by Switzerland, on the south; and by the Rhine, which divides it from Alsace, on the east: and is about 90 miles in length, from north to south; but not above 20 in breadth, where it is widest. It is a very populous and fruitful country, abounding in corn and wine. Venison and wild fowl are so plentiful, that they are the common diet of the peasants. The rivers that water this territory, are the Rhine, Ens, Wirrmb, and Plints, which yield plenty of fish. They feed their hogs with chestnuts, which make the bacon excellent. They have free-stone for building, and marble of all colours. They have

have fome agate, and great quantities of hemp and flax for exportation. The chief towns are Baden, Durlach, Stolhafen, Raftadt, Gersbach, Pforfheim, and Hochberg.

BADEN, the chief city of the above margravate, has a caſtle that ſtands on the top of a hill, which is the reſidence of a prince. The town is ſeated among hills, on rocky and uneven ground, which renders the ſtreets inconvenient and crooked. It is famous for its baths, the ſprings of which are ſaid to be above 300. Some of them are hot, and accounted to be very good in nervous cafes. They partake of falt, allum, and ſulphur. E. Long. 9. 24. N. Lat. 48. 50.

BADEN, a town of Germany, in the arch-duchy of Auſtria, ſeated on the Little Suechat, is a neat little walled town, ſtanding in a plain not far from a ridge of hills which run out from the mountain Cetius. It is much frequented by the people of Vienna, and the neighbouring parts, on account of its baths. The ſprings ſupply two convenient baths within the town, five without the walls, and one beyond the river. They are good for diſtempers of the head, the gout, dropſy, and moſt chronic diſtempers. It is obſervable that all theſe Badens take their names from the baths. E. Long. 17. 10. N. Lat. 48. 0.

BADENOCH, the moſt northerly part of Inverneſſhire, in Scotland, extending about 33 miles in length from eaſt to weſt, and 27 from north-eaſt to ſouth-weſt where broadest. It has no conſiderable town, and is very barren and hilly, but abounds with deer, and other kinds of game.

BADEN-WEILLER, a town of Germany, belonging to the lower Margravate of Baden. E. Long. 7. 50. N. Lat. 47. 55.

BADGER, in zoology, the Engliſh name of a ſpecies of urſus. See URſUS.

BADGER, in old law-books, one that was licenſed to buy corn in one place, and carry it to another to ſell, without incurring the puniſhment of an engroſſer.

BADIA, an ancient town of Bætica on the Anas; now ſuppoſed to be *Badajoz* on the Guadiana *.

BADIANE, or **BANDIAN**, the feed of a tree which grows in China, and ſmells like aſiſe-feed. The Chineſe, and the Dutch in imitation of them, ſometimes uſe the badiane to give their tea an aromatic taſte.

BADIS, a fortrefs of Livonia, ſubject to Ruſſia. E. Long. 23. 10. N. Lat. 59. 15.

BADIUS (Conrad), and (Stephen Robert), his brother; French refugees; celebrated as printers at Geneva, and Conrad as an author. The latter died in 1566.

BÆTERRÆ, an ancient town of the Tertolages in Gallia Narbonenſis; now *Befiers*, on the eaſt bank of the Obriſ, now *Orbis*, or *Orbe*, in Lower Languedoc *.

BÆTICA, a province of ancient Spain, ſo called from the famed river Bætis, afterwards *Tarteffus*, now *Guadalquiverr*, or the great river. It was bounded on the weſt by Luſitania; on the ſouth, by the Mediterranean, and Sinus Gaditanus; on the north, by the Cantabric ſea, now the Bay of Biſcay. On the eaſt and north-eaſt, its limits cannot be ſo well aſcertained, as they are very reaſonably thought to have been in a continual ſtate of fluctuation, as each petty monarch had an opportunity of encroaching upon his neighbour. The province was divided in two by the river Bætis already mentioned. On the one ſide of which, towards

the Anas, were ſituated the Turdetani, from whence the kingdom was called *Turdetania*, though more generally known by the name of *Bæturia*. On the other ſide were ſituated the Baſtuli, Baſtetani, and Conteſtani, along the Mediterranean coaſts. The Baſtuli were ſuppoſed to be of Phœnician extraſt, and dwelt along the coaſts of the Mediterranean, till, driven from thence by the Moors, they fled into the mountainous parts of Galicia, which they then called from their own name *Baſtulia*. The Baſtetani were ſeated higher up, on the ſame coaſts. The territories of both theſe made part of what has ſince become the kingdom of *Granada*; in which there is a ridge of very high mountains called from the abovementioned people, the *Baſtetanian mountains*. Mention is alſo made of their capital *Baſtetana*; a place of ſuch ſtrength, that King Ferdinand was ſix months beſieging it before he could take it from the Moors.—The whole province of Bætica, according to the moſt probable account, contained what is now called *Andaluſia*, part of the kingdom of Grenada, and the outward boundaries of Eſtremadura.

BÆTIS. See BÆTICA.

BETULO, a town of ancient Spain, in the Terraconenſis; now *Badelma* in Catalonia *.

BÆTYLIA, anointed ſtones, worſhipped by the Phœnicians, by the Greeks before the time of Cæſar, and by other barbarous nations. They were commonly of a black colour, and conſecrated to ſome god, as Saturn, Jupiter, the Sun, &c.—Some are of opinion that the true original of theſe idols is to be derived from the pillar of ſtone which Jacob erected at Bethel, and which was afterwards worſhipped by the Jews.

Theſe *bætylia* were much the object of the veneration of the ancient heathens. Many of their idols were no other. In reality, no fort of idol was more common in the eaſtern countries, than that of oblong ſtones erected, and hence termed by the Greeks, *xoivis, pillars*. In ſome parts of Egypt they were planted on both ſides of the highways. In the temple of Heliogabalus, in Syria, there was one pretended to have fallen from heaven. There was alſo a famous black ſtone in Phrygia, ſaid to have fallen from heaven. The Romans ſent for it and the prieſts belonging to it with much ceremony, Scipio Naïca being at the head of the embaffy.

BÆZA, a city of Andaluſia in Spain, ſeated on a high hill, three miles from the Guadalquiverr; it is the ſee of a biſhop, and has a kind of univerſity founded by John D' Avila. It was taken from the Moors about the end of the 15th century. E. Long. 3. 15. N. Lat. 37. 45.

BAFFETAS, or **BASTAS**, a cloth made of coarſe white cotton-thread, which comes from the Eaſt Indies. That of Suratt is the beſt.

BAFFIN'S BAY, a gulph of North America, running north eaſt from Cape Farewell in Weſt Greenland, from 60° to 80° of north latitude.

BAFFO, a conſiderable town in the iſland of Cyprus, with a fort built near ancient Paphos, of which ſome conſiderable ruins yet remain, particularly ſome broken columns, which probably belonged to the temple of Venus. E. Long. 32. 20. N. Lat. 34. 50.

BAG, in commerce, a term ſignifying a certain quantity of ſome particular commodity: a bag of al-

Bætis
Bag.

* See *Badelma*.

Eag

Bagdad.

monds, for instance, is about 300 weight; of aniseeds, from 300 to 400, &c.

Bags are used in most countries to put several sorts of coin in, either of gold, silver, brass, or copper. Bankers, and others, who deal much in current cash, label their bags of money, by tying a ticket or note at the mouth of the bag, signifying the coin therein contained, the sum total, its weight, and of whom it was received. Tare is allowed for the bag.

BAG, among farriers, is when, in order to retrieve a horse's lost appetite, they put in an ounce of asa-fœtida, and as much powder of safin, into a bag, to be tied to the bit, keeping him bridled for two hours, several times a-day; as soon as the bag is taken off, he will fall to eating. The same bag will serve a long time.

BAGAMADER, or BAGAMEDRI, a province of the kingdom of Abyssinia in Africa. It is said to receive its name from the great number of sheep bred in it; *meder* signifying land or earth, and *bag* a sheep. Its length is estimated about 60 leagues, and its breadth 20: but formerly it was much more extensive; several of its provinces having been dismembered from it, and joined to that of Tigre. A great part of it, especially towards the east, is inhabited by wandering Gallas and Caffres.

BAGDAD, a celebrated city of Asia in Irak Arabi, seated on the eastern banks of the Tigris, in E. Long. 43. 40. N. Lat. 33. 15. By many authors this city is very improperly called *Babylon*. The latter stood on the Euphrates at a considerable distance.

This city, for many years the capital of the Saracæn empire, was founded by the khalif Al Mansur, the founder of the house of Al Abbas, after an attempt by the Rawandians to assassinate him, as already mentioned*.

The reasons assigned by the Arabian historians for building the city of Bagdad are, That the abovementioned attempt to assassinate the khalif had disgusted him at his Arabian subjects in general, and that the spot where Bagdad stood was at a considerable distance from the city of Cufa particularly; the inhabitants of which were remarkable for their treachery and inconsistency, of which Al Mansur himself had felt several instances. Besides, the people of Irak, who had always continued faithful to him, represented, that by building his capital near the confluence of the Euphrates and Tigris, it would be in a great measure secured from the insults and attacks of those who should have an inclination to dispute the khalifat with him; and that by being situated as it were in the middle of the tract comprehending the districts of Basrah, Cufa, Wafet, Mawfel, and Swada, at no great distance from those cities, it would be plentifully supplied with provisions by means of the aforesaid rivers.

Concerning the origin of the name *Bagdad*, there are various accounts, which, being equally uncertain and trifling, merit no attention. The first city that went by this name was situated on the western bank of the Tigris; from whence Al Mansur dispatched his son Al Mohdi with a body of Moslem troops, to the opposite bank. Here the young prince took post, and fortified the place on which he had encamped with a wall, in order to cover his troops, as well as the workmen employed by his father on the other side of the river, from the incursions of the Persians, who seemed

to have taken umbrage at the erection of a new metropolis so near the frontiers of their dominions. Hence that part of the city soon afterwards built on the eastern banks of the Tigris, received the name of the *Camp*, or *Fortress*, of *Al Mohdi*. The khalif had a superb and magnificent palace both in the eastern and western part of the town. The eastern palace was surrounded on the land-side by a semicircular wall that had six gates; the principal of which seems to have been called *the gate of prefects*, whose entrance was generally killed by the princes and ambassadors that came to the khalif's court. The western part of the city was entirely round, with the khalif's palace in the centre, and having the great mosque annexed to it. The eastern part consisted of an interior and exterior town, each of which was surrounded by a wall. For some time the building of the city went but slowly on, owing to a scarcity of materials for building; for which reason the khalif was sometimes inclined to remove the materials of Al Madayan the ancient metropolis of the Persian empire. But, upon trial, he found the stones to be of such an immense size, that the removal of them to Bagdad would be attended with great difficulty and expence; besides, he considered that it would be a reflection upon himself to have it said that he could not finish his metropolis without destroying such a pile of building as perhaps could not be paralleled in the whole world; for which reasons he at length gave over his design, and erected the city of Bagdad, most probably, out of the ruins of the ancient cities of Selenia and Ctesiphon, putting an end to his undertaking in the 149th year of the Hegira, or four years after the city was begun.

From the building the city of Bagdad, to the death of Al Mansur, nothing very remarkable happened, excepting some irruptions made into the territories of the Greeks, and by the Arabs into some of the khalif's other territories. In the 157th year of the Hegira also, a grievous famine was felt in Mesopotamia, which was quickly after followed by a plague that destroyed great numbers. This year likewise, the Christians, who had been all along very severely dealt with by Al Mansur, were treated with the utmost rigour by Musa Ebn Mofaab the khalif's governor; every one who was unable to pay the enormous tribute exacted of them being thrown into prison without distinction.

The next year, being the 158th of the Hegira, the khalif set out from Bagdad, in order to perform the pilgrimage to Mecca: but being taken ill on the road, he expired at Bir Maimun, whence his body was carried to Mecca; where, after 100 graves had been dug, that his sepulchre might be concealed, he was interred, having lived, according to some 63, according to others 68 years, and reigned 22. He is said to have been extremely covetous, and to have left in his treasury 600,000,000 dirhems, and 24,000,000 dinars. He is reported to have paid his cook by assigning him the heads and legs of the animals dressed in his kitchen, and to have obliged him to procure at his own expence all the fuel and vessels he had occasion for.

When Al Mansur expired at Bir Maimun, he had only his domestics and Rabi his freedman with him. The latter of these, for some time, kept his death concealed, and pretended to have a conference with him; in which, as he gave out, the khalif commanded him

Death of Al Mansur.4
Succeeded by Al Mohdi.

to

to exact an oath of allegiance to Al Mohdi his son, as his immediate successor, and to Ifa Ebn Mufa his cousin-german, as the next apparent heir to the crown. He then dispatched a courier to Bagdad with the news of Al Manfur's death; upon which Al Mohdi was unanimously proclaimed khalif. Ifa Ebn Mufa, however, no sooner heard this news, than he began to entertain thoughts of setting up for himself at Cufa where he then resided; and in order to facilitate the execution of his scheme, fortified himself in that city. But Al Mohdi, being apprized of his defection, sent a detachment of 1000 horse to bring him to Bagdad; which being done, Al Mohdi not only prevailed upon him to own his allegiance to him, but also to give up his right to the succession for 10,000 according to some, or according to others for 10,000,000, dinars.

From the accession of Al Mohdi, to the 164th year of the Hegira, the most remarkable event was the rebellion of Al Mokanna. This impious impostor, whose true name was Hakem Ebn Hesham, came originally from Khorasan, and had been an under secretary to Abu Moslem governor of that province. He afterwards turned soldier, and passed thence into Mawaralnahr, where he gave himself out for a prophet. The name of Al Mokanna, as also that of Al Borkai, that is, the *veiled*, he took from his custom of covering his face with a veil or girdle mask, to conceal his deformity; he having lost an eye in the wars, and being otherwise of a deplorable appearance; though his followers pretended he did this for the same reason that Moses did, viz. lest the splendor of his countenance should dazzle the eyes of his beholders. In some places he made a great many proselytes, deluding the people with a number of juggling tricks which they swallowed as miracles, and particularly by causing the appearance of a moon to rise out of a well for many nights together; whence he was also called, in the Persian tongue, *Sazendeh mak*, or the *moon-maker*. This wretch, not content with being reckoned a prophet, arrogated to himself divine honours; pretending that the Deity resided in his person, having proceeded to him from Abu Moslem, in whom he had taken up his residence before. At last this impostor raised an open rebellion against the khalif, and made himself master of several fortified places in Khorasan, so that Al Mohdi was obliged to send one of his generals with an army against him. Upon the approach of the khalif's troops, Al Mokanna retired into one of his strong fortresses which he had well provided for a siege; and sent his emissaries abroad to persuade the people that he raised the dead to life, and foretold future events. But being closely besieged by the khalif's forces, and seeing no possibility of escaping, he gave poison in wine to his whole family and all that were with him in the castle; when they were dead, he burnt their bodies, together with all their furniture, provisions, and cattle; and lastly he threw himself into the flames, or, as others say, into a tub of aqua fortis, or some other preparation, which consumed every part of him except the hair. When the besiegers therefore entered the place, they found no living creature in it, except one of Al Mokanna's concubines, who, suspecting his design, had hid herself, and now discovered the whole matter. This terrible contrivance; however, failed not to produce the desired effect. He had promised his

followers, that his soul should transmigrate into the form of an old man riding on a greyish coloured beast, and that after for many years he would return and give them the earth for their possession; which ridiculous expectation kept the sect in being for several years.

All this time war had been carried on with the Greeks, but without any remarkable success on either side. In the 164th year of the Hegira, however, Al Mohdi ordered his son Harun Alrafschid to penetrate into the Greek territories with an army of 95,000 men. Harun, then, having entered the dominions of the empress Irene, defeated one of her commanders that advanced against him; after which he laid waste several of the imperial provinces with fire and sword, and even threatened the city of Constantinople itself. By this the empress was so terrified, that she purchased a peace with the khalif by paying him an annual tribute of 70,000 pieces of gold; which, for the present at least, delivered her from the depredations of these barbarians. After the signing of the treaty, Harun returned home laden with spoils and glory. This year, according to some of the oriental historians, the sun one day, a little after his rising, totally lost his light in a moment, without being eclipsed, when neither any fog nor any cloud of dust appeared to obscure him. This frightful darkness continued till noon, to the great astonishment of the people settled in the countries where it happened.*

In the 169th year of the Hegira, Al Mohdi was poisoned, tho' undesignedly, by one of his concubines named *Hafsanah*. She had designed to destroy one of her rivals whom she imagined to have too great an ascendancy over the khalif, by giving her a poisoned pear. This the latter, not suspecting any thing, gave to the khalif; who had no sooner eaten it than he felt himself in exquisite torture, and soon after expired.

On the death of Al Mohdi, he was succeeded by his eldest son Al Hadi; who having formed a design to deprive his younger brother Harun Alrafschid of his right of succession, and even to assassinate him, was poisoned by his vizier in the 170th year of the Hegira; and on his death, the celebrated khalif Harun Alrafschid ascended the throne.

This was one of the best and wisest princes that ever sat on the throne of Bagdad. He was also extremely fortunate in all his undertakings, tho' he did not much extend his dominions by conquest. In his time the Moslem empire may be said to have been in its most flourishing state, though, by the independency of the Moslems in Spain, who had formerly set up a khalif of the house of Ommyiah, his territories were not quite so extensive as those of some of his predecessors. He possessed the provinces of Syria, Palestine, Arabia, Persia, Armenia, Natolia, Media or *Aderbijan*, Babylonia, Assyria, Sindh, Sijistan, Khorasan, Tabrelstan, Jorjan, Zablestan or *Sablstan*, Mawaralnahr or *Great Bukharia*, Egypt, Libya, Mauritania, &c.; so that his empire was by far the most powerful of any in the world, and extended farther than the Roman empire ever had done.

The first instance of Harun's good fortune, and which was taken for a presage of a prosperous and happy reign, was his finding a valuable ring which he had thrown into the Tigris to avoid being deprived of it by his brother Al Hadi. He was able to give the

divers no other direction than by throwing a stone from the bridge of Bagdad, about the same place of the river in which he had thrown the ring; notwithstanding which, they found it without any great difficulty.

14
Divides the empire among his sons, and settles the succession.

In the 186th year of the Hegira, beginning January 10th, 802, the khalif divided the government of his extensive dominions among his three sons in the following manner: To Al Amin the eldest, he assigned the provinces of Syria, Irak, the three Arabias, Mesopotamia, Assyria, Media, Palestine, Egypt, and all that part of Africa extending from the confines of Egypt and Ethiopia to the straits of Gibraltar, with the dignity of khalif; to Al Mamun the second, he assigned Persia, Kerman, the Indies, Khorasan, Taberistan, Cabeltan and Zablestan, together with the vast province of Mawaralnahr; and to his third son Al Kafem, he gave Armenia, Natolia, Jorjan, Georgia, Circassia, and all the Moslem territories bordering upon the Euxine sea. As to the order of succession, Al Amin was to ascend the throne immediately after his father's decease; after him, Al Mamun; and then Al Kafem, whom he had surnamed *Al Mutaman*.

15
His successful wars with the Greeks.

The most considerable exploits performed by this khalif were against the Greeks, who by their perfidy provoked him to make war upon them, and whom he always overcame. In the 187th year of the Hegira, the khalif received a letter from the Greek emperor Nicephorus soon after he had been advanced to the imperial dignity, commanding him to return all the money he had extorted from the empress Irene, though that had been secured to him by the last treaty concluded with that princess, or expect soon to see an imperial army in the heart of his territories. This insolent letter so exasperated Harun, that he immediately assembled his forces and advanced to Heraclea, laying the country through which he passed waste with fire and sword. For some time also he kept that city strictly besieged; which so terrified the Greek emperor, that he submitted to pay an annual tribute. Upon this, Harun granted him a peace, and returned with his army. But a hard frost soon after happening in these parts, Nicephorus took for granted that Al Rashid would not pay him another visit, and therefore broke the treaty he had concluded. Of this the khalif receiving advice, he instantly put himself in motion; and, notwithstanding the inclemency of the weather, forced the emperor to accept of the terms proposed. According to a Persian historian, before the hostilities at this time commenced, Nicephorus made the khalif a present of several fine swords, giving him thereby plainly to understand that he was more inclinable to come to blows than to make peace with him. All these swords Harun cut afunder with his famous sword *Samsamah*, as if they had been so many radishes, after which severe proof there did not appear the least flaw in the blade; a clear proof of the goodness of the sword, as the cutting the others with it was of the strength of Harun's arm. This sword had fallen into Al Rashid's hands among the spoils of Ebn Dakikan, one of the last Hamyaritic princes of Yaman; but is said to have belonged originally to a valiant Arab named *Amru Ebn Maadi Carh*, by whose name it generally went among the Moslems. This man is said to have performed very extraordinary feats with his sword, which induced a certain prince to

Bagdad.

borrow it from him; but he not being able to perform any thing remarkable with it, complained to Amru that it had not the desired effect: upon which that brave man took the liberty to tell him, that he had not sent him his arm along with his sword.

In the 188th year of the Hegira, war was renewed with the Greeks, and Nicephorus with a great army attacked the khalif's forces with the utmost fury. He was, however, defeated with the loss of 40,000 men, and received three wounds in the action; after which the Moslems committed terrible ravages in his territories, and returned home laden with spoils. The next year Harun invaded Phrygia; defeated an imperial army sent to oppose him; and having ravaged the country, returned without any considerable loss. In the 190th year of the Hegira, commencing November 27th 805, the khalif marched into the Imperial territories with an army of 135,000 men, besides a great number of volunteers and others who were not enrolled among his troops. He first took the city of Heraclea, from whence he is said to have carried 16,000 prisoners; after which he made himself master of several other places; and, in the conclusion of the expedition, he made a descent on the island of Cyprus, which he plundered in a terrible manner. This success so intimidated Nicephorus, that he immediately sent the tribute due to Harun, the withholding of which had been the cause of the war; and concluded a peace upon the khalif's own terms; one of which was, that the city of Heraclea should never be rebuilt. This perhaps Harun would not have so readily granted, had not one Rafe Ebn Al Leith revolted against him at Samarcand, and assembled a considerable force to support him in his defection.

16
Rebellion in Khorasan.

The next year, being the 191st of the Hegira, the khalif removed the governor of Khorasan from his employment, because he had not been sufficiently attentive to the motions of the rebel Rafe Ebn Al Leith. As this governor had also tyrannized over his subjects in the most cruel manner, his successor no sooner arrived than he sent him in chains to the khalif; but notwithstanding all Harun's care, the rebels made this year a great progress in the conquest of Khorasan.

Next year, the khalif found it necessary to march in person against the rebels, who were daily becoming more formidable. The general rendezvous of his troops was in the plains of Rakka, from whence he advanced at the head of them to Bagdad. Having at that place supplied the troops with every thing necessary, he continued his march to the frontiers of Jorjan, where he was seized with an illness which grew more violent after he had entered that province. Finding himself therefore unable to pursue his journey, he resigned the command of the army to his son Al Mamun, retiring himself to Tus in Khorasan. We are told by Khondemir, that, before the khalif departed from Rakka, he had a dream wherein he saw a hand over his head, full of red earth, and at the same time heard a person pronouncing these words, "See the earth where Harun is to be buried." Upon this he demanded where he was to be buried; and was instantly answered, "At Tus." This dream greatly discomposing him, he communicated it to his chief physician, who endeavoured to divert him, telling the khalif that the dream had been occasioned by the thoughts of his expedition against the rebels.

17
The khalif's death predicted by a dream.

He

He therefore advised him to pursue some favourite diversion that might draw his attention another way. The khalif accordingly, by his physician's advice, prepared a magnificent regale for his courtiers, which lasted several days. After this, he put himself at the head of his forces, and advanced to the confines of Jorjan, where he was attacked by the distemper that proved fatal to him. As his disorder increased, he found himself obliged to retire to Tus; where being arrived, he sent for his physician, and said to him, "Gabriel, do you remember my dream at Rakka? we are now arrived at Tus, the place, according to what was predicted in that dream, of my interment. Send one of my eunuchs to fetch me a handful of earth in the neighbourhood of this city." Upon this, *Masfur*, one of his favourite eunuchs, was dispatched to bring a little of the soil of the place to the khalif. He soon returned, and brought a handful of red earth, which he presented to the khalif with his arm half bare. At the sight of this, Harun instantly cried out, "In truth this is the earth, and this the very arm, that I saw in my dream." His spirits immediately failing, and his malady being greatly increased by the perturbation of mind ensuing upon this sight, he died three days after, and was buried in the same place. According to *Abul Faraj*, *Bashir Ebn Al Leith* the arch-rebel's brother was brought in chains to the khalif, who was then at the point of death. At the sight of whom Harun declared, that if he could speak only two words he would say *kill him*; and immediately ordered him to be cut to pieces in his presence. This being done, the khalif soon after expired, in the year of the Hegira 193, having reigned 23 years. The distemper that put an end to his days is said to have been the bloody flux.

Upon the arrival of a courier from Tus, with the news of *Al Rashid's* death, his son *Al Amin* was immediately proclaimed khalif; and was no sooner seated on the throne, than he formed a design of excluding his brother *Al Mamun* from the succession. Accordingly he deprived him of the furniture of the imperial palace of Khorasan; and in open violation of his father's will, who had bestowed on *Al Mamun* the perpetual government of Khorasan, and of all the troops in that province, he ordered these forces to march directly to Bagdad. Upon the arrival of this order, *Al Mamun* expostulated with the general *Al Fadl Ebn Rabi* who commanded his troops, and endeavoured to prevent his marching to Bagdad; but without effect, for he punctually obeyed the orders sent by the khalif. *Al Mamun*, however, took care not to be wanting in fidelity to his brother. He obliged the people of Khorasan to take an oath of fidelity to *Al Amin*, and reduced some who had actually excited a considerable body of the people to revolt, while the general *Al Fadl* having ingratiated himself with the khalif by his ready compliance with his orders, was chosen prime vizir, and governed with an absolute sway; *Al Amin* abandoning himself entirely to drunkenness.

Al Fadl was a very able minister; though, fearing *Al Mamun's* resentment if ever he should ascend the throne, he gave *Al Amin* such advice as proved in the end the ruin of them both. He told him that his brother had gained the affection of the people of Khorasan by the good order and police he had established among them; that his unwearied application to the administration of

justice had so attracted their esteem, that the whole province was entirely at his devotion; that his own conduct was by no means relished by his subjects, whose minds were almost totally alienated from him; and, therefore, that he had but one part to act, which was to deprive *Al Mamun* of the right of succession that had been given him by his father, and transfer it to his own son *Mufa*, though then but an infant. Agreeable to this pernicious advice, the khalif sent for his brother *Al Kafem* from Mesopotamia, and recalled *Al Mamun* from Khorasan, pretending he had occasion for him as an assistant in his councils.

By this treatment *Al Mamun* was so much provoked, that he resolved to come to an open rupture with his brother, in order if possible to frustrate his wicked designs. Instead, therefore, of going to Bagdad as he had been commanded, he cut off all communication between his own province and that capital; pretending, that as his father Harun had assigned him the lieutenancy of Khorasan, he was responsible for all the disorders that might happen there during his absence. He also coined money, and would not suffer *Al Amin's* name to be impressed upon any of the dirhems or dinars struck in that province. Not content with this, he prevailed upon *Rafe' Ebn Al Leith*, who had been for some time in rebellion, to join him with a body of troops; whose example was soon after followed by *Harthema Ebn Aafan*; which put him in possession of all the vast territory of Khorasan. Here he governed with an absolute sway, officiated in the mosque as *Imam*, and from the pulpit constantly harangued the people.

The following year, being the 195th year of the Hegira, beginning October 4th 810, the khalif *Al Amin*, finding that his brother set him at defiance, declared war against him, and sent his general *Al Ebn Ifa* with an army of 60,000 men to invade Khorasan. *Al Mamun*, being informed that *Al Amin* was advancing against him with such a powerful army, put on foot all the troops he could raise, and gave the command to *Thaheer Ebn Hofein*, one of the greatest generals of his age. *Thaheer* being a man of undaunted resolution, chose only 4000 men, whom he led against *Al Amin's* army. *Al Amin*, seeing so small a number of troops advancing against him, was transported with joy, and promised himself an easy victory. Despising his enemies, therefore, he behaved in a secure and careless manner; the consequence of which was, that his army was entirely defeated, and himself killed, his head being afterwards sent as a present to *Al Mamun*, who amply rewarded *Thaheer* and *Harthema* for their services.

After this victory, *Al Mamun* assumed the title of *khalif*; ordered *Al Amin's* name to be omitted in the public prayers, and made all necessary preparations for carrying the war into the very heart of his brother's dominions. For this purpose he divided his forces into two bodies, and commanded them to march into Irak by different routes. One of them obeyed the orders of *Thaheer*, and the other of *Harthema*. The first directed his march towards *Ahwaz*, and the other towards *Holwan*, both of them proposing to meet in the neighbourhood of Bagdad, and after their junction to besiege that city.

In the 196th year of the Hegira, *Thaheer Ebn Hofein* made a most rapid progress with the troops under his command. Having advanced towards *Ahwaz*, there

 there

20,000 Moslems with his own hands; to which he added, that vast numbers had also been executed by his companions, but that of these he could give no precise account.

In the 223^d year of the Hegira, the Greek emperor Theophilus invaded the khalif's territories, where he behaved with the greatest cruelty, and by destroying Sozopetra the place of Al Motasem's nativity, notwithstanding his earnest intertreats to the contrary, occasioned the terrible destruction of *Amerium* mentioned under that article. The rest of this khalif's reign is remarkable for nothing but the execution of Afilun, who was accused of holding correspondence with the khalif's enemies. After his death a great number of idols were found in his house, which were immediately burned, as also several books said to contain impious and detestable opinions.

In the 227th year of the Hegira died the khalif Al Motasem, in the 48th or 49th year of his age. He reigned eight years eight months and eight days, was born in the eighth month of the year, fought eight battles, had 8000 slaves, and had 8,000,000 dinars and 80,000 dirhems in his treasury at his death, whence the oriental historians give him the name of *Al Motamen*, or the *Octonary*. He is said to have been so robust, that he once carried a burden of 1000 pounds weight several paces. As the people of Bagdad disturbed him with frequent revolts and commotions, he took the resolution to abandon that city, and build another for his own residence. The new city he built was first called *Samarra*, and afterwards *Sarra Manray*, and stood in the Arabian Irak. He was attached to the opinion of the Motazalites, who maintain the creation of the Koran, and both he and his predecessor cruelly persecuted those who believed it to be eternal.

Al Motasem was succeeded by Al Wathek Billah, who the following year, being the 228th of the Hegira, invaded and conquered Sicily. Nothing remarkable happened during the rest of his reign; he died in the 232^d year of the Hegira, and was succeeded by his brother Al Motawakkel.

The new khalif began his reign with an act of the greatest cruelty. The late khalif's vizier having treated Al Motawakkel ill in his brother's lifetime, and opposed his election to the khalifat, was on that account now sent to prison. Here the khalif ordered him to be kept awake for several days and nights together: after this, being suffered to fall asleep, he slept a whole day and a night; and after he awoke was thrown into an iron furnace lined with spikes or nails heated red hot, where he was miserably burnt to death. During this reign nothing remarkable happened, except wars with the Greeks, which were carried on with various success. In the year 859 too, being the 245th of the Hegira, violent earthquakes happened in many provinces of the Moslem dominions; and the springs at Mecca failed to such a degree, that the celebrated well Zemzem was almost dried up, and the water sold for 100 dirhems a bottle.

In the 247th year of the Hegira the khalif was assassinated at the instance of his son Al Montaser; who succeeded him, and died in six months after. He was succeeded by Al Moftain, who in the year of the Hegira 252 was forced to abdicate the throne by his brother Al Motazz, who afterwards caused him to be pri-

vately murdered. He did not long enjoy the dignity of which he had so iniquitously possessed himself; being deposed by the Turkish militia (who now began to set up and depose khalifs as they pleased) in the 255th year of the Hegira. After his deposition, he was sent under an escort from Sarra Manray to Bagdad, where he died of thirst or hunger, after a reign of four years and about seven months. The fate of this khalif was peculiarly hard: the Turkish troops had mutinied for their pay; and Al Motazz, not having money to satisfy their demands, applied to his mother named *Kabibah* for 50,000 dinars. This she refused, telling him that she had no money at all, although it afterwards appeared that she was possessed of immense treasures. After his deposition, however, she was obliged to discover them, and even deposit them in the hands of the new khalif Al Mokhtadi. They consisted of 1,000,000 dinars, a bushel of emeralds, and another of pearls, and three pounds and three quarters of rubies of the colour of fire.

Al Mokhtadi, the new khalif, was the son of one of Al Wathek's concubines named *Korb*, or *Karb*, who is by some supposed to have been a Christian. The beginning of his reign is remarkable for the irruption of the Zenjians, a people of Nubia, Ethiopia, and the country of Caffres, into Arabia, where they penetrated into the neighbourhood of Bafra and Cufa. The chief of this gang of robbers, who, according to some of the Arab historians, differed but little from wild beasts, was Ali Ebn Mohammed Ebn Abdalrahman, who falsely gave himself out to be of the family of Ali Ebn Abu Taleb. This made such an impression upon the Shiites in those parts, that they flocked to him in great numbers; which enabled him to seize upon the cities of Bafra and Ramlah, and even to pass the Tigris at the head of a formidable army. He then took the title of *Prince of the Zenjians*, in order to ingratiate himself with those barbarians of whom his army was principally composed.

In the 256th year of the Hegira, Al Mokhtadi was barbarously murdered by the Turks who had raised him to the throne, and was succeeded by Al Motamed the son of Al Motawakkel. This year the prince of the Zenjians, Ali, or as he is also called *Al Habib*, made incursions to the very gates of Bagdad, doing prodigious mischief wherever he passed. The khalif therefore sent against him one Jolan with a considerable army. He was overthrown, however, with very great slaughter by the Zenjian, who made himself master of 24 of the khalif's largest ships in the bay of Bafra, put a vast number of the inhabitants of Obolla to the sword, and seized upon the town. Not content with this, he set fire to it, and soon reduced it to ashes, the houses mostly consisting of the wood of a certain plane-tree called by the Arabians *Saj*. From thence he marched to Abadan, which likewise surrendered to him. Here he found an immense treasure, which enabled him to possess himself of the whole district of Ahwaz. In short, his forces being now increased to 80,000 strong, most of the adjacent territories, and even the khalif's court itself, were struck with terror.

In the 257th year of the Hegira, Al Habib continued victorious, defeated several armies sent against him by the khalif, reduced the city of Basrah, and put 20,000 of the inhabitants to the sword. The follow-

ing year, the khalif, supported by his brother Al Mowaffek, had formed a design of circumscribing the power of the Turkish soldiery, who had for some time given law to the khalifs themselves. But this year the Zenjians made so rapid a progress in Persia, Arabia, and Irak, that he was obliged to suspend the execution of his design, and even to employ the Turkish troops to assist his brother Al Mowaffek in opposing these robbers. The first of the khalif's generals who encountered Al Habib this year, was defeated in several engagements, and had his army at last entirely destroyed. After this Al Mowaffek and another general named *Mosleh* advanced against him. In the first engagement *Mosleh* being killed by an arrow, the khalif's troops retired; but Al Mowaffek put them afterwards in such a posture of defence, that the enemy durst not renew the attack. Several other sharp encounters happened this year, in which neither party gained great advantage; but, at last, some contagious distempers breaking out in Al Mowaffek's army, he was obliged to conclude a truce, and retire to Wafet to refresh his troops.

In the 259th year of the Hegira, commencing Nov^r 7th 872, the war between the khalif and Al Habib still continued. Al Mowaffek, upon his arrival at Bagdad, sent Mohammed surnamed *Al Mowalled* with a powerful army to act against the Zenjians; but he could not hinder them from ravaging the province of Ahwaz, cutting off about 50,000 of the khalif's subjects, and dismantling the city of Ahwaz; and notwithstanding the utmost efforts of all the khalif's generals, no considerable advantages could be gained either this or the following year.

In the 261st year of the Hegira, beginning October 16th 874, Mohammed Ebn Wafel, who had killed the khalif's governor of Fars, and afterwards made himself master of that province, had several engagements with Al Habib, but with what success is not known. The khalif, having been apprized of the state of affairs on that side, annexed the government of Fars, Ahwaz, and Basra, to the prefecture he had given to Mufa Ebn Boga, whom he looked upon as one of the best generals he had. Mufa, soon after his nomination to that post, sent Abdalrahman Ebn Mosleh as his deputy to Ahwaz, giving him as a colleague and assistant one Tifam, a Turk. Mohammed Ebn Wafel, however, refusing to obey the orders of Abdalrahman and Tifam, a fierce conflict ensued, in which the latter were defeated, and Abdalrahman taken prisoner. After this victory, Mohammed advanced against Mufa Ebn Boga himself; but that general, finding he could not take possession of his new government without a vast effusion of blood, recalled the deputies from their provinces, and made the best of his way to Sarra Manray. After this, Yakub Ebn Al Leit, having taken Khorasan from the descendants of Thaher, attacked and defeated Mohammed Ebn Wafel, seizing on his palace, where he found a sum of money amounting to 40,000,000 dirhems.

The next year Yakub Ebn Leit being grown formidable by the acquisition of Ahwaz and a considerable portion of Fars, or at least the Persian Irak, declared war against the khalif. Against him Al Motamed dispatched Al Mowaffek; who having defeated him with prodigious slaughter, plundered his camp, and pursued him into Khorasan; where meeting with no opposition,

he entered Nisabur, and released Mahomet the Thaherian, whom Yakub had detained in prison three years. As for Yakub himself, he made his escape with great difficulty, tho' he and his family continued several years in possession of many of the conquests he had made. This war with Yakub proved a seasonable diversion in favour of Al Habib, who this year defeated all the forces sent against him, and ravaged the district of Wafet.

The following year, being the 263^d of the Hegira, beginning September 24th 876, the khalif's forces, under the command of Ahmed Ebn Lebuna, gained two considerable advantages over Al Habib; but being at last drawn into an ambuscade, they were almost totally destroyed, their general himself making his escape with the utmost difficulty; nor were the khalif's forces able, during the course of the next year, to make the least impression upon these rebels.

In the 265th year of the Hegira, beginning September 3^d 878, Ahmed Ebn Tolun rebelled against the khalif, and set up for himself in Egypt. Having assembled a considerable force, he marched to Antioch, and besieged Sima the governor of Aleppo, and all the provinces known among the Arabs by the name of *Al Awafem* in that city. As the besieged found that he was resolved to carry the place by assault, they thought fit, after a short defence, to submit, and to put Sima into his hands. Ahmed no sooner had that officer in his power, than he caused him to be beheaded; after which he advanced to Aleppo, the gates of which were immediately opened unto him. Soon after, he reduced Damascus, Hems, Hamath, Kinnisrin, and Al Rakka, situated upon the eastern bank of the Euphrates. This rebellion so exasperated Al Motamed, that he caused Ahmed to be publicly cursed in all the mosques belonging to Bagdad and Irak; and Ahmed on his part ordered the same malediction to be thundered out against the khalif in all the mosques within his jurisdiction. This year also a detachment of Al Habib's troops penetrated into Irak, and made themselves masters of four of the khalif's ships laden with corn; then they advanced to Al Nomanic, laid the greatest part of it in ashes, and carried off with them several of the inhabitants prisoners. After this they possessed themselves of Jarjaraya, where they found many prisoners more, and destroyed all the adjacent territory with fire and sword. This year there were four independent powers in the Moslem dominions, besides the house of Ommiyah in Spain; *viz.* The African Moslems, or Aglabites, who had for a long time acted independently; Ahmed in Syria and Egypt; Al Leit in Khorasan; and Al Habib in Arabia and Irak.

In the 266th year of the Hegira, beginning August 23^d 879, Al Habib reduced Ramhormoz, burnt the stately mosque there to the ground, put a vast number of the inhabitants to the sword, and carried away great numbers, as well as a vast quantity of spoil.— This was his last successful campaign; for the year following, Al Mowaffek, attended by his son Abul Abbas, having attacked him with a body of 10,000 horse, and a few infantry, notwithstanding the vast disparity of numbers (Al Habib's army amounting to 100,000 men), defeated him in several battles, recovered most of the towns he had taken, together with an immense quantity of spoil, and released 5000 women that had

been

241. been thrown into prison by these barbarians. After these victories, Al Mowaffek took post before the city of Al Mabiya', built by Al Habib, and the place of his residence; burnt all the ships in the harbour; thoroughly pillaged the town; and then entirely dismantled it. After the reduction of this place, in which he found immense treasures, Al Mowaffek pursued the flying Zenjians, put several of their chiefs to the sword, and advanced to Al Moktara, a city built by Al Habib. As the place was strongly fortified, and Al Habib was posted in its neighbourhood, with an army, according to Abu Jaafar Al Tabari, of 500,000 men, Al Mowaffek perceived that the reduction of it would be a matter of some difficulty. He therefore built a fortress opposite to it, where he erected a mosque, and coined money. The new city, from its founder, was called by the Arabs *Al Mowaffekia*, and soon rendered considerable by the settlement of several wealthy merchants there. The city of Al Mokhtara being reduced to great straits was at last taken by storm, and given up to be plundered by the khalif's troops; after which Al Mowaffek defeated the numerous forces of Al Habib in such a manner, that they could no more be rallied during that campaign.

The following year, being the 268^h of the Hegira, Al Mowaffek penetrated again into Al Mabiya', and demolished the fortifications which had been raised since its former reduction, though the rebels disputed every inch of ground. Next year he again attacked Al Habib with great bravery; and would have entirely defeated him, had not he been wounded in the breast with an arrow, which obliged him to found a retreat. However, as soon as he was cured of his wound, Al Mowaffek advanced a third time to Al Mabiya', made himself master of that metropolis, threw down the walls that had been raised, put many of the inhabitants to the sword, and carried a vast number of them into captivity.

The 27th year of the Hegira, commencing July 11th 883, proved fatal to the rebel Al Habib. Al Mowaffek made himself a fourth time master of Al Mabiya', burnt Al Habib's palace, seized upon his family, and sent them to Sarra Manray. As for the usurper himself, he had the good fortune to escape at this time; but being closely pursued by Al Mowaffek into the province of Alwaz, where the shattered remains of his forces were entirely defeated, he at last fell into the hands of the victor, who ordered his head to be cut off, and carried through a great part of that region which he had so long disturbed. By this complete victory Al Mowaffek obtained the title of *Al Nasir Lidmilah*, that is, the protector of Mahometanism. This year also died Ahmed Ebn Tolun, who had seized upon Egypt and Syria, as we have already observed; and was succeeded by his son *Khamarawiyah*.

The next year, a bloody engagement happened between the khalif's forces commanded by Al Mowaffek's son, and those of Khamarawiyah, who had made an irruption into the khalif's territories. The battle was fought between Al Ramla and Damascus. In the beginning, Khamarawiyah found himself so hard pressed, that his men were obliged to give way; upon which, taking for granted that all was lost, he fled with great precipitation, even to the borders of Egypt; but, in the mean time, his troops being ignorant of the flight of their general, returned to the charge, and gained a

complete victory. After this, Khamarawiyah, by his just and mild administration, so gained the affections of his subjects, that the khalif found it impossible to gain the least advantage over him. In the 276th year of the Hegira, he overthrew one of the khalif's generals named *Abul Saf*, at Al Bathnia near the city of Damascus; after which he advanced to Al Rakka on the Euphrates, and made himself master of that place. Having annexed several large provinces to his former dominions, and left some of his friends in whom he could confide to govern them, he then returned into Egypt, the principal part of his empire, which now extended from the Euphrates to the borders of Nubia and Ethiopia.

The following year, being the 278th of the Hegira, was remarkable for the death of Al Mowaffek. ⁴⁸ He died of the elephantiasis or leprosy; and, while in his last illness, could not help observing, that of 100,000 men whom he commanded, there was not one so miserable as himself. This year is also remarkable for the first disturbances raised in the Moslem empire by the Karmatians. The origin of this sect is not certainly known; but the most common opinion is, that a poor fellow, by some called *Karmata*, came from Khuzestau to the villages near Cufa, and there pretended great sanctity and strictness of life, and that God had enjoined him to pray 50 times a-day; pretending also to invite people to the obedience of a certain Imam of the family of Mahomet: and this way of life he continued till he had made a very great party, out of whom he chose twelve as his apostles to govern the rest, and to propagate his doctrines. He also assumed the title of prince, and obliged every one of his earlier followers to pay him a diwar a year. But Al Haidam, the governor of that province, finding men neglected their work, and their husbandry in particular, to say those 50 prayers a-day, seized the fellow, and, having put him in prison, swore that he should die. This being overheard by a girl belonging to the governor, she, out of compassion, took the key of the dungeon at night from under her master's head, released the man, and restored the key to its place while her master slept. The next morning the governor found his prisoner gone; and the accident being publicly known, raised great admiration; Karmata's adherents giving out that God had taken him into heaven. After this he appeared in another province, and declared to a great number of people he got about him, that it was not in the power of any person to do him hurt; notwithstanding which, his courage failing him, he retired into Syria, and was never heard of any more. After his disappearance, the sect continued and increased; his disciples pretending that their master had manifested himself to be a true prophet, and had left them a new law wherein he had changed the ceremonies and form of prayer used by the Moslems, &c. From this year, 278, these sectaries gave almost continual disturbance to the khalifs and their subjects, committing great disorders in Chaldea, Arabia, and Mesopotamia, and at length established a considerable principality.

In the 279th year of the Hegira died the khalif Al ⁵⁰ Motamed; and was succeeded by Al Motaded, son to Egypt's daughter Motaded. The first year of his reign, Al Motaded demanded in marriage the daughter of Khamarawiyah, sultan, or khalif, in Egypt; which was agreed to by ⁵⁰ Al Motaded. ⁴⁹ Origin of the Karmatians. ⁵⁰ Egypt's daughter married to the khalif Al Motaded. ⁵⁰ him &c.

him with the utmost joy, and their nuptials were solemnized with great pomp in the 282^d year of the Hegira. He carried on a war with the Karmatians; but very unsuccessfully, his forces being defeated with great slaughter, and his general Al Abbas taken prisoner. This khalif also granted to Harun, son to Khamarawiyah, the perpetual prefecture of Awafam and Kinnifin, which he annexed to that of Egypt and Syria, upon condition that he paid him an annual tribute of 45,000 dinars. He died in the year of the Hegira 289, and was succeeded by his son Al Moctafi.

51
Egypt, &c.
recovered
by the khalif Al Moctafi.

This khalif proved a warlike and successful prince. He gained several advantages over the Karmatians, but was not able to reduce them. The Turks, however, having invaded the province of Mawaralnahr, were defeated with great slaughter; after which Al Moctafi carried on a successful war against the Greeks, from whom he took Seleucia. After this he invaded Syria and Egypt, which provinces he recovered from the house of Ahmed Ebn Tolun.

52
Distressed
state of the
khalifs after
his death.

The reduction of Egypt happened in the 292^d year of the Hegira, after which the war was renewed with success against the Greeks and Karmatians. The khalif died in the 295th year of the Hegira, after a reign of about six years and a half. He was the last of the khalifs who made any figure by their warlike exploits. His successors Al Moktader, Al Kalicr, and Al Radi, were so distressed by the Karmatians and numberless usurpers who were every day starting up, that by the 325th year of the Hegira they had nothing left but the city of Bagdad. In the 324th year of the Hegira, commencing November 30th 935, the khalif Al Radi, finding himself distressed on all sides by usurpers, and having a vizir of no capacity, instituted a new office superior to that of vizir, which he intitled *Emir Al Omra*, or *Commandant of commandants*. This great officer was trusted with the management of all military affairs, and had the entire management of the finances in a much more absolute and unlimited manner than any of the khalifs vizirs ever had. Nay, he officiated for the khalif in the great mosque at Bagdad, and had his name mentioned in the public prayers throughout the kingdom. In short, the khalif was so much under the power of this officer, that he could not apply a single dinar to his own use without the leave of the Emir Al Omra. In the year 325, the Moslem empire, once so great and powerful, was shared among the following usurpers.

53
Division of
the Moslem
empire in
the 325th
year of the
Hegira.

The cities of Wafet, Bafra, and Cufa, with the rest of the Arabian Irak, were considered as the property of the Emir Al Omra, though they had been in the beginning of the year seized upon by a rebel called Al Baridi, who could not be driven out of them.

The country of Fars, Faristan, or *Perfia* properly so called, was possessed by Amado'ddawla Ali Ebn Buiya, who resided in the city of Shiraz.

Part of the tract denominated *Al Fehal*, together with Persian Irak, which is the mountainous part of *Perfia*, and the country of the ancient Parthians, obeyed Rucno'ddawla, the brother of Amado'ddawla, who resided at Ispahan. The other part of that country was possessed by Washmakin the Deylamite.

Diyar Rabia, Diyar Beer, Diyar Modar, and the city of Al Mawfel, or Mosul, acknowledged for their sovereign a race of princes called *Hamadanites*.

Egypt and Syria no longer obeyed the khalifs, but Mahomet Ebn Taj, who had formerly been appointed governor of these provinces.

Bagdad.

Africa and Spain had long been independent.

Sicily and Crete were governed by princes of their own.

The provinces of Khorasan and Mawaralnahr were under the dominion of Al Nafr Ebn Ahmed, of the dynasty of the Sammanians.

The provinces of Tabrestan, Jorjan, or Georgiana, and Mazanderan, had kings of the first dynasty of the Deylamites.

The province of Kerman was occupied by Abu Ali Mahomet Ebn Eylla Al Sammani, who had made himself master of it a short time before; and,

Lastly, the provinces of Yamama and Bahrein, including the district of Hajr were in the possession of Abu Thaler the Karmatian.

Thus the khalifs were deprived of all their dominions, and reduced to the rank of sovereign pontiffs; in which light, though they continued for some time to be regarded by the neighbouring princes, yet their power never arrived to any height. In this low state the khalifs continued till the year of the Hegira 656, commencing January 8th 1258. This year was rendered remarkable by the taking of Bagdad by Hulaku the Mogul or Tartar; who likewise abolished the khalifat, putting the reigning khalif Al Mostafem Billah to a most cruel death. These daboical conquerors, after they had taken the city, massacred, according to custom, a vast number of the inhabitants; and after they had plundered it, set it on fire. The spoil they took from thence was prodigiously great, Bagdad being then looked upon as the first city in the world.

55
Bagdad
taken by
the Tartars

Bagdad remained in the hands of the Tartars or Moguls to the year of the Hegira 795, of Christ 1392, when it was taken by Tamerlane from Sultan Ahmed Ebn Weis; who being incapable of making head against Tamerlane's numerous forces, found himself obliged to send all his baggage over the Tigris, and abandon his capital to the conqueror. He was, however, hotly pursued by his enemy's detachments to the plain of Karbella, where several skirmishes happened, and a considerable number of men were lost on both sides. Notwithstanding this disaster, he found means to escape the fury of his pursuers, took refuge in the territories of the Greek emperor, and afterwards repossessed himself of the city of Bagdad. There he remained till the year of the Hegira 803, when the city was taken a second time by Tamerlane; who nevertheless restored it to him, and he continued sovereign of the place till driven from thence by Miran Shah. Still, however, he found means to return; but in the 815th year of the Hegira was finally expelled by Kara Yusef the Turkman. The descendants of Kara Yusef continued masters of Bagdad till the year of the Hegira 875, of Christ 1470, when they were driven out by Ufun Cafsun. The family of this prince continued till the year of the Hegira 914, of our Lord 1508, when Shah Ishmael, surnamed *Suffi* or *Soffi*, the first prince of the royal family reigning in Iran or *Perfia*, till the dethroning of the late Shah Hofsain, made himself master of it. From that time to this Bagdad has continued to be a bone of contention between the Turks and Persians. It was taken by Soliman surnamed the *magnificent*.

56
History
of the city
since that
time.

Acad. *Acet.*, and retaken by Shah Abbas the great, king of Persia: but being at last besieged by Amurath or Morad IV. with a formidable army, it was finally obliged to surrender to him in the year 1638; since which time the Persians have never been able to make themselves masters of it for any length of time.

It is now two miles long, one broad, and five in circumference. The walls are built with brick, covered with earth, and strengthened with large towers like bastions. The ditches are broad, and five or six fathom deep. There are four gates, three on the land side, and one towards the river, which is passed over by a bridge of boats, that are placed at the distance of a boat's length from each other; the number of them is about 40. The castle is within the city, near one of the gates, on the north side of the town, and is built with fine white free stone, but now looks as if it were covered with earth. It is seated partly upon the river, and is surrounded by a single wall. It has likewise small towers, on which cannon are placed. The ditch is narrow, and about two or three fathom deep. On the west side of the river is an open town, which may be entered at any time of the night as well as in the day. This is called by some the *suburbs* of Bagdad; the houses of which are miserably built, as are also those in the city itself, for they are but one story high, and generally raised with earth. All the buildings that are good are owing to the Persians. Some of the mosques are tolerably handsome, with large domes, covered with painted tiles; and there are bazars in the streets, covered on the top, which are full of shops, where the merchants carry on their trade. There are ten caravan-serais, or public inns, only two of which are commodious.

The Turks have a garrison here of 10,000 men, which are doubled in time of war, with about 200 pieces of cannon. There are likewise 12,000 militia; and yet Bagdad would be but thinly peopled, if great numbers did not resort thither on account of its trade, for which reason the Armenians and Jews take up near half the city. Some part of the year the air is here intolerably hot; and then the inhabitants lie on the tops of their houses, which are terraced, in the night. The winter is so mild, that the peasants plough the land in December; at which time there are narcissuses, hyacinths, violets, &c. in full flower. There are very few trees or shrubs herabouts, except liquorice which is in great plenty. Nor is there cultivated land about Bagdad sufficient to maintain it with provisions; not but that part of Irak Arabi, that lies between the rivers Euphrates and Tigris, formerly called *Mesopotamia*, is fruitful enough, but it wants a sufficient number of inhabitants; and if it were not for the rivers, by which all sorts of necessaries are brought to their doors, they would often be in a starving condition.

The Mahometan women are very richly dressed, and wear bracelets on their arms, and jewels in their ears. The Arabian women have the partition between their nostrils bored, wherein they wear rings. Not far from this city there are springs of naphtha, which they burn there instead of candles. There are three sorts of Christians among the inhabitants; Nestorians, Armenians, and Jacobites. The first have a church; the two last perform their devotion at a chapel about a mile from Bagdad. Besides the Jews that live in the city, there

are many that come out of devotion, every year, to visit the tomb of the prophet Ezekiel, which they believe to be about 30 miles from this place. This likewise is in the road for the caravans that come out of Persia in pilgrimage to Mecca.

BAGGAGE, in military affairs, denotes the clothes, tents, utensils of divers sorts, provisions, and other necessaries belonging to the army.

Before a march, the waggons with the baggage are marshalled according to the rank which the several regiments bear in the army; being sometimes ordered to follow the respective columns of the army, sometimes to follow the artillery, and sometimes to form a column by themselves. The general's baggage marches first; and each waggon has a flag, shewing the regiment to which it belongs.

Packing up the BAGGAGE, vasa colligere, was a term among the Romans, for preparing to go to war, or to be ready for an expedition.

The Romans distinguished two sorts of baggage; a *greater*, and *less*. The lesser was carried by the soldier on his back, and called *farcina*; consisting of the things most necessary to life, and which he could not do without. Hence *colligere farcinas*, packing up the baggage, is used for decamping, *castra movere*. The greater and heavier was carried on horses and vehicles, and called *onera*. Hence *onera vehicularum, farcinas hominum*. The baggage-horses were denominated *fagmentarii equi*.

The Roman soldiers in their marches were heavy laden; inasmuch, that they were called by way of jeit, *muli mariani*, and *ærunna*. They had four sorts of luggage, which they never went without, *viz.* corn, or *buccellatum*, utensils, vails, and arms. Cicero observes, that they used to carry with them above half a month's provisions; and we have instances in Livy, where they carried provisions for a whole month. Their utensils comprehended those proper for gathering fuel, dressing their meat; and even for fortification, or intrenchment; and what is more, a chain for binding captives. For arms, the foot carried a spear, shield, saw, basket, rutrum, hatchet, lorum, falx, &c. Also stakes or pales, *vallis*, for the sudden fortifying a camp; sometimes seven or even twelve of these pales were carried by each man, though generally, as Polybius tells us, only three or four. On the Trajan column we see soldiers represented with this sardle of corn, utensils, pales, &c. gathered into a bundle and laid on their shoulders. Thus injured to labour, they grew strong, and able to undergo any fatigue in battle; the greatest heat of which never tired them, or put them out of breath. In after-times, when discipline grew slack, this luggage was thrown on carriages and porter's shoulders.

The Macedonians were not less injured to hardship than the Romans: when Philip first formed an army, he forbid all use of carriages; yet, with all their load, they would march, in a summer's day, 20 miles in military rank.

BAGLANA, or **BUGLANA**, a province of the kingdom of Dekkan in the Mogul's empire. It is bounded on the north and east by Guzerat and Ballagat; and on the south and west by that part of Vizianpur called *Konkan*, belonging to the Marattas. It ends in a point at the sea-coast between Daman and Balfora, and is the least province in the kingdom. The Portuguese

Bagnagar
||
Bag-pipe.

guese territories begin in this province at the port Damman, 21 leagues south of Surat; and run along the coast by Bassaim, Bombay, and Chawl, to Dabul, almost 50 leagues to the north of Goa.

BAGNAGAR, a town of Asia, in the dominions of the Great Mogul, and capital of the kingdom of Gollconda in the peninsula on this side the Ganges. The inhabitants within the town are the better sort; the merchants and meaner people inhabiting the suburbs, which is three miles long. It is chiefly remarkable for a magnificent reservoir of water, surrounded with a colonnade supported by arches. It is seated on the river Nawa, in E. Long. 96. o. N. Lat. 15. 30.

BAGNARA, a sea-port town of Italy in the kingdom of Naples, in the farther Calabria, with the title of a duchy. E. Long. 16. 8. N. Lat. 38. 15.

BAGNAREA, a town of Italy in St Peter's patrimony, and in the territory of Orvieta, with a bishop's see. E. Long. 12. 10. N. Lat. 42. 36.

BAGNERES, a town of France, in Gascony, and in the county of Bigorre, so called from its mineral waters. It is seated on the river Adour, in E. Long. o. 12. N. Lat. 43. 3.

BAGNIALACK, a large town of Turkey in Europe, in the province of Bosnia. E. Long. 18. 10. N. Lat. 44. o.

BAGNIO, an Italian word, signifying a bath: we use it for a house with conveniences for bathing, cupping, sweating, and otherwise cleansing the body; and sometimes for worse purposes. In Turkey, it is become a general name for the prisons where the slaves are inclosed, it being usual in these prisons to have baths.

BAGNOLAS, a town of Lower Languedoc in France. It has a very handsome square, and two fountains which rise in the middle of the town; the waters of which, being received in a basin, are conveyed by a canal out of town, and from thence to the lands about it. E. Long. 4. 43. N. Lat. 44. 10.

BAGNOLIANS, in church-history, a sect of heretics, who in reality were Manichees, though they somewhat disguised their errors. They rejected the Old Testament, and part of the New; held the world to be eternal; and affirmed that God did not create the soul when he infused it into the body.

BAGOI, among the ancient Persians, were the same with those called by the Latins *Spadones*, viz. a species of eunuchs, in whom the canal of the penis was so contorted by a tight vinculum, that they could not emit the semen.

BAG-PIPE, a musical instrument, of the wind kind, chiefly used in Scotland and Ireland. The peculiarity of the bag-pipe, and from which it takes its name, is, that the air which blows it is collected into a leathern bag, from whence it is pressed out by the arm into the pipes. These pipes consist of a bass, and tenor or rather treble; and are different according to the species of the pipe. The bass part is called the *drone*, and the tenor or treble part the *chanter*. In all the species, the bass never varies from its uniform note, and therefore very deservedly gets the name of *drone*; and the compass of the chanter is likewise very limited. There is a considerable difference between the Highland and Lowland bag-pipe of Scotland; the former being blown with the mouth, and the latter with a small bellows; though this difference is not essential, every species of

bag-pipe being capable, by a proper construction of the reeds, of producing music either with the mouth or bellows. The following are the species of bag-pipes most commonly known in this country.

1. The *Irisb Pipe*. This is the softest, and in some respects the most melodious of any, so that music-books have been published with directions how to play on it. The chanter, like that of all the rest, has eight holes like the English flute, and is played on by opening and shutting the holes as occasion requires; the bass consists of two short drones, and a long one. The lowest note of the chanter is D on the German flute, being the open note on the counter string of a violin; the small drone (one of them commonly being stopped up) is tuned in unison with the note above this, and the large one to an octave below, so that a great length is required in order to produce such a low note, on which account the drone hath sometimes two or three turns. The instrument is tuned by lengthening or shortening the drone till it sounds the note desired.

2. The *Highland Bag-Pipe*. This consists of a chanter and two short drones, which found in unison the lowest note of the chanter except one. This is exceedingly loud, and almost deafening if played in a room; and is therefore mostly used in the fields, for marches, &c. It requires a prodigious blast to found it; so that those unaccustomed to it cannot imagine how Highland pipers can continue to play for hours together, as they are often known to do. For the same reason, those who use the instrument are obliged either to stand on their feet, or walk, when they play. This instrument hath but nine notes; its scale, however, hath not yet been reduced to a regular standard by comparing it with that of other instruments, so that we can say nothing about its compass.

3. The *Scotts Lowland Pipe*. This is likewise a very loud instrument, though less so than the former. It is blown with bellows, and hath a bass like the Irish pipe. This species is different from all the rest; as it cannot play the natural notes, but hath F and C sharp. The lowest note of a good bag-pipe of this kind is unison with C sharp on the tenor of a violin tuned concert-pitch; and as it hath but nine notes, the highest is D in alt. From this peculiar construction, the Highland and Lowland bag-pipes play two species of music essentially different from one another, as each of them also is from every other species of music in the world. Hence these two species of bag-pipes deserve notice as curiosities; for the music which they play is accompanied with such peculiar ornaments, or what are intended as such, as neither violin, nor even organ, can imitate, but in a very imperfect manner.

4. The *Small Pipe*. This is remarkable for its smallness, the chanter not exceeding eight inches in length; for which reason, the holes are so near each other, that it is with difficulty they can be closed. This hath only eight notes, the lower end of the chanter being commonly stopped. The reason of this is, to prevent the flurring of all the notes, which is unavoidable in the other species, so that in the hands of a bad player they become the most shocking and unintelligible instruments imaginable; but this, by having the lower hole closed, and also by the peculiar way in which the notes are expressed, plays all its tunes in the way called by the Italians *fiaccato*, and cannot slur at all. It hath no species

Bag-pi

of music peculiar to itself; and can play nothing which cannot be much better done upon other instruments; though it is surprising what volubility some performers on this instrument will display, and how much they will overcome the natural disadvantages of it. Some of this species, instead of having drones like the others, have their bass parts consisting of a winding cavity in a kind of short case, and are tuned by opening these to a certain degree by means of sliding covers; from which contrivance they are called *shuttle-pipes*.—Besides these, there are a variety of others, called *Italian, German, Organ, &c.* bag-pipes, which have nothing different in their construction from those above described, nor any good quality to recommend them.

As to the origin of bag-pipe music, some are of opinion, that it is to be derived from the Danes; but Mr Pennant thinks differently, and gives the following reasons for deriving it from Italy.

“Neither of these instruments (the Highland and Lowland bag-pipes above described) were the invention of the Danes, or, as is commonly supposed, of any of the northern nations; for their ancient writers prove them to have been animated by the *clangor tubarum*. Notwithstanding they have had their sock-pipe long amongst them, as their old songs prove, yet we cannot allow them the honour of inventing this melodious instrument; but must assert, that they borrowed it from the invaded Caledonians. We must still go farther, and deprive even that ancient race of the credit; and derive its origin from the mild climate of Italy, perhaps from Greece.

“There is now in Rome a most beautiful bas-relievo, a Grecian sculpture of the highest antiquity, of a bag-piper playing on his instrument, exactly like a modern highlander. The Greeks had their *Ανεμολις*, or instrument composed of a pipe and blown-up skin: the Romans in all probability borrowed it from them, and introduced it among their swains, who still use it under the names of *piva* and *cornu-musa*.

“That master of music, Nero, used one; and had not the empire been so suddenly deprived of that great artist, he would (as he graciously declared his intention) have treated the people with a concert, and, among other curious instruments, would have introduced the *utricularius* or bag-pipe. Nero perished; but the figure of the instrument is preserved on one of his coins, but highly improved by that great master: it has the bag and two of the vulgar pipes; but was blown with a bellows, like an organ; and had on one side a row of nine unequal pipes, resembling the syrinx of the god Pan. The bag-pipe, in the unimproved state, is also represented in an ancient sculpture; and appears to have had two long pipes or drones, and a single short pipe for the fingers. Tradition says, that the kind played on by the mouth was introduced by the Danes; as theirs was wind-music, we will admit that they might have made improvement; but more we cannot allow: they were skilled in the use of the trumpet; the highlanders in the pibroch, or bag-pipe.

*Non tuba in usu illis, conjecta at sibia in utrem
Dat belli signum, et martem vocat horrida in arma*.”*

Formerly there were in the Isle of Skie a kind of colleges where the Highland bag-pipe was taught; the teachers making use of pins stuck in the ground, instead of marks for musical notes. One of these colleges,

George Mackie, the reformer of the Lowland bag-pipe, is said to have attended seven years. He had before been the best performer on that instrument in that part of the country where he lived; but, while attending the college at Skie, he adapted the graces of the Highland music to the Lowland pipe. Upon his return, he was heard with astonishment and admiration; but unluckily, not being able to commit his improvements to writing, and indeed the nature of the instrument scarce admitting of it, the knowledge of this kind of music hath continued to decay ever since, and will probably soon wear out altogether. What contributes much to this is, that bag-pipers, not content with the natural nine notes which their instrument can play easily, force it to play tunes requiring higher notes, which disorders the whole instrument in such a manner as to produce the most horrid discords; and this practice brings, though undeservedly, the instrument itself into contempt.

BAGUETTE, in architecture, a small round moulding, less than an astragal, and so called from the resemblance it bears to a ring.

BAHAMA ISLANDS, called also the *Lucaya islands*, the easternmost of all the Antilles, or Carribbees, lying in the Atlantic ocean, stretching from north-east to south-west, between the 21st and 28th degree of north latitude, and between 72 and 81 degrees of west longitude. They are very numerous; but only 12 are particularly noticed by geographers, because the dangers attending the navigation among them are so great, that many of them have scarce ever been visited by Europeans.

It was upon one of these, to which he gave the name of *St Salvadore*, that Columbus first landed when he discovered America. Banzoni, one of the first navigators, says, that the sailor, who on this occasion first discovered land, and called out that he saw a fire, was denied the reward promised to the first discoverer, under a pretence that the same had been discovered by Columbus two hours before; and that for this reason the sailor afterwards went into Africa, and turned Mahometan.

Columbus perceiving that this island was but small, and the inhabitants poor, immediately set sail in quest of richer countries, and the Bahama islands were afterwards totally neglected by the Spaniards. In 1667, one Captain Sayle, an Englishman, was forced upon the island of St Salvadore, now *Providence*, by stress of weather; and upon his return to England, made so favourable a report of the Bahama islands in general to his employers the proprietors of Carolina, that six of them obtained a grant for the island of Providence, and the Bahama islands in general, between the latitudes of 22 and 27 degrees. The names of their first proprietors were George duke of Albemarle, William Lord Craven, Sir George Carteret, John Lord Berkeley, Anthony Lord Ashley, and Sir Peter Colliton. But though this was the first legal settlement that had been made of these islands, they had long before (particularly the island of Providence) been a shelter for pirates, and other disorderly people, who lived either by plundering the wrecks of ships, or supplying with spirits, &c. the ships that happened to touch there.

In 1672, Captain Sayle paid another visit to Providence island; and on his return made the government so sensible of the advantages that would accrue to England

England from the possession of the Bahama islands in general, that they resolved to send thither a governor and some settlers; and the first governor sent thither was one Mr Chillingworth, a gentleman of capacity and character. By this time the natives of the Bahamas had been either butchered or carried off by the Spaniards or pirates; and Mr Chillingworth, on his arrival, found he had a very unruly set of men to deal with. England was at that time over-run with dissolute people of both sexes; who, embracing the encouragement given by government, shipped themselves off for Providence in great numbers; and these meeting with the pirates and coasters already settled there, the whole formed so ungovernable a colony, that Mr Chillingworth, in endeavouring to reclaim them, was himself forced off to Jamaica, and an unrestrained anarchy ensued among the settlers. These disorders continued for some years; neither the government, nor the proprietors, thinking it worth while to be at the expence of checking them. At last, one Mr Clark accepted of a proprietary commission to be governor; but the Spaniards, who had all along fomented the disorders, no sooner understood that the English intended to resettle the island, than they invaded it, destroyed all the stock, and burnt the houses of the inhabitants. It is even said, that, having carried off the governor in chains, they afterwards cruelly put him to death.

After this depopulation, the island of Providence, and all the other Bahamas, were abandoned; the English removing to Carolina and other American settlements. At the time this disaster happened, the principal town of the island, since called *Nassau*, consisted of 150 houses. The vast consequence of the situation of these islands, however, especially in time of war, prompted a great number of people to come thither again, both from England and the continent of America. By the year 1690, New Providence became so populous, that the proprietors thought fit to appoint one Cadwallader Jones to be their governor; and he accordingly arrived there on the 19th of June that year.

According to all accounts, this governor Jones was of a very rough arbitrary disposition; and as the people he was sent to govern retained pretty much the spirit of their predecessors, it was no wonder that there were frequent quarrels between them. At last Jones being impeached of high treason by one Bulkley, was thrown into prison, where he lay for some time; but afterwards was released, and Bulkley imprisoned. However, the proprietors finding it would be highly improper to continue Jones in his government, removed him, and appointed one Trott to succeed him. Under governor Trott the town of Nassau recovered its former size; its houses amounting to 160; and having a fort for its protection, on which were mounted 28 guns besides demiculverins.

In 1697 the proprietors, with the consent of king William, appointed Nicholas Webb, Esq; to the government of the Bahama islands; and, in this gentleman's time, New Providence enjoyed a state of tolerable tranquillity, and was reckoned to contain about 400 negroes. One Mr Lightfoot, who was afterwards governor, endeavoured to set up a sugar-work on New Providence, for which the soil was extremely proper; but the means taken by a good governor for the improvement of this perverse colony, proved the very

means of weakening it: for the pirates, finding now no longer any harbour in the Bahama islands, no longer spent their money there; and the inhabitants being at the same time refrained from the cruel practice of plundering wrecks, grew poor and discontented. Perpetual altercations now happening between them and their governors, their differences were by the Lords proprietors generally referred to the government of South Carolina; which equally discontented the governor and people, both complaining that they were treated only as a dependent province of that colony.

In this untoward situation matters continued till the year 1700, when one Elias Hasket was promoted to the government of the Bahama islands. But he was scarcely settled when the inhabitants put him in irons, and sent him off the island, choosing by their own authority Ellis Lightfoot, Esq; to succeed him. On this occasion the proprietors shewed no resentment, and Lightfoot remained in possession of the government till 1703. At that time the dissensions which prevailed at New Providence, encouraged the French and Spaniards to make a descent upon it from Petit Guaves. The island was then completely ruined; the town of Nassau was burnt, the fort dismantled, its guns nailed up, and the governor with half the negroes carried off. As to the white inhabitants, their enemies took very little concern about them, and they retired to the woods till the danger was over. Returning from thence, and finding the island entirely ruined, they found means to remove themselves to other settlements. So little care did the proprietors take all this time of the affairs of New Providence, that they did not even know the catastrophe that had befallen them: nay, they even named one Birch, to supersede Lightfoot; but when he came thither, he found the island entirely abandoned, so he was obliged to return.

After this the Bahama islands became once more the residence of pirates and free-booters of all kinds, and of all nations, especially the English and Irish, who committed more depredations on the British trade than both the French and Spaniards. At last, upon an address of the House of Lords, king George I. gave orders for fortifying and settling the island of Providence, and expelling these robbers. The plan was committed to Captain Woods Rogers, a celebrated navigator, who in the year 1718 failed as governor of Providence, with a force sufficient to reduce the pirates. Before his arrival, governor Bennet of Bermudas had sent a sloop to Providence, requiring the pirates to surrender themselves, by which they were entitled to a late proclamation of pardon. About 150 of the pirates, among whom were several of their captains, gladly accepted of this summons, and surrendered themselves. Upon the arrival of Captain Rogers at this island in 1718, he found about 300 men capable of bearing arms; many of whom had been pirates themselves, and none of them under any apprehensions from that wicked fraternity; but all of them determined in the most resolute manner to defend themselves against the French and Spaniards; which, by the assistance of 100 regulars the captain had brought with him, they were very soon enabled to do.

The first measure of Rogers's government was to read his Majesty's commission to himself in presence of all the inhabitants of the island; after which he admitted

mitted to the benefit of the proclamation about 200 of the remaining pirates that surrendered themselves. In settling his council, he nominated six adventurers who attended him from England; and had the good fortune to meet aloft with six inhabitants of the island, who pretended they had never been pirates, upon which he admitted them likewise. He himself had been appointed captain of the independent company that came with him from England; and the judge of the admiralty, the collector of customs, the chief justice, the secretary, the register, the provost marshal and officers, had all their commissions from England. Under his government the colony thrived so well, that in a short time the number of white people amounted to 1500; and so sensible was government of his services, that when he returned to England in 1721 to solicit some supplies, he received a new commission as governor, and had a salary of L. 400 a-year settled upon him. Captain Rogers indeed had interested himself so much in the affairs of his colony, that he greatly hurt his own circumstances; for the Spaniards having twice attacked the Bahama islands with 2000 men, Mr Rogers defeated them without having any support from the other colonies, except what he engaged on his own personal credit. He died within two or three years after his return to his government; and since that time nothing remarkable has happened to these islands, only that the colonies on them have still continued to thrive.

BAHAMA, the largest of all the abovementioned islands, and from which they take their name, is situated in N. Lat. 26. 45. and is about fifteen leagues from the peninsula of Florida. According to the best accounts, it is fifty miles in length, and in some places sixteen in breadth. The air is serene, and the island well watered and fruitful, yet is inhabited only by a few stragglers, who subsist by selling necessaries to the ships which the currents drive upon the coast. This island is said to have formerly produced guaiacum, sarsaparilla, and red wood; all of which were destroyed by the Spaniards. The inhabitants are obliged to bring all their necessaries from Carolina, excepting some white fowl, and a particular kind of rabbit which they rear. From some papers in the Philosophical Transactions it appears that spermaceti whales have been cast ashore upon these islands; but the writer adds, that he never heard of one of that species being killed in the sea; so fierce and active are they when alive.

BAHAR, or BARRE, in commerce, weights used in several places in the East Indies.

There are two of these weights; one the great bahar, with which they weigh pepper, cloves, nutmegs, ginger, &c. and contains 550 pounds of Portugal, or about 524 lb. 9 oz. avoirdupois weight. With the little bahar, they weigh quicksilver, vermilion, ivory, silk, &c. It contains about 437 lb. 9 oz. avoirdupois weight.

BAHAREN, an island in the Persian gulf, situated in E. Long. 50. o. N. Lat. 26. o. This island is chiefly remarkable for its pearl-fishery, and has often changed its masters. It fell with Ormus under the dominion of the Portuguese, was again restored to Persia by Thamas Khouli Kan; and after his death the confusion into which his empire was thrown, gave an opportunity to an enterprising and ambitious Arab of taking possession of the island, where he still main-

tains his authority. Baharen was famous for its pearl-fishery even at the time when pearls were found at Ormus, Kerek, Kasby, and other places in the Persian gulf; but it is now become of much greater consequence; all the other banks having been exhausted, while this has suffered no sensible diminution. The time of fishing begins in April, and ends in October. It is confined to a tract four or five leagues in breadth. The pearls taken at Baharen, though not so white as those of Ceylon or Japan, are much larger than those of the former place, and more regularly shaped than those of the latter. They have a yellowish colour; but have also this good quality, that they preserve their golden hue, whereas the whiter kind lose much of their lustre by keeping, especially in hot countries. The annual revenue from the Baharen pearl-fishery is computed at about L. 157,500. The greatest part of the pearls that are uneven are carried to Constantinople and other parts of Turkey, where the larger go to compose ornaments for head-dresses, and the smaller are used in embroideries. The perfect pearls must be reserved for Surat, whence they are distributed through all Indostan.

BAHI, a province of the island of Lucon or Manila, one of the Philippine islands in the East Indies, belonging to the Spaniards. It is remarkable for producing excellent betel, which the inhabitants, Spaniards as well as natives, perpetually chew from morning till night. It is also the place where most of the ships are built. But the natives suffer much from this work; 200 and sometimes 400 of them being constantly employed in it, on the mountains, or at the port of Cavite. The king allows these labourers a piece-of-eight per month, with a sufficient quantity of rice. The whole province contains about 6000 tributary natives.

BAHIA, DE TODOS LOS SANTOS, a province of Brasil in South America, belonging to the Portuguese, and the richest in the whole country; but unhappily the air and climate do not correspond with other natural advantages; yet so fertile is the province in sugar and other commercial articles, that the Portuguese flock hither not only as it is the seat of affluence, but also of pleasure and grandeur. The capital, called *St Salvador*, or *Ciudad de Bahia*, is populous, magnificent, and beyond comparison the most gay and opulent city in Brasil. It stands on a bay in S. Lat. 12. 11. is strong by nature, well fortified, and always defended by a numerous garrison. It contains 12,000 or 14,000 Portuguese, and about three times as many negroes, besides people of different nations, who chuse to reside in that city.

BAHIR, a Hebrew term signifying *famous* or *illustrious*; but particularly used for a book of the Jews, treating of the profound mysteries of the cabbala, being the most ancient of the Rabbinical works.

BAHUS, a strong town of Sweden, and capital of a government of the same name, seated on a rock in a small island, in E. Long. 11. 10. N. Lat. 57. 52.

BAJA, BAYJAH, or BEGIA, a town of the kingdom of Tunis in Africa, supposed to be the ancient *Vacca* of Sallust, and *Oppidum Vaggense* of Pliny. It was formerly, and still continues to be, a place of great trade, and the chief market of the kingdom for corn, of which the adjacent territories produce such abundance, that they can supply more than the whole kingdom

Baja
Baikal.

with it; and the Tunesians say, that if there was in the kingdom such another town as this for plenty of corn, it would become as cheap as sand. Here is also a great annual fair, to which the most distant Arabian tribes resort with their families and flocks. Notwithstanding all this, however, the inhabitants are very poor, and great part of the land about the town remains uncultivated, through the cruel exactions of the government, and the frequent incursions of the Arabs who are very powerful in these parts. The town stands on the declivity of a hill on the road to Constantinople, about 10 leagues from the northern coast, and 36 south-west from Tunis; and hath the convenience of being well watered. On the highest part is a citadel that commands the whole place, but is now of no great strength. The walls were raised out of the ruins of the ancient Vacca, and have some ancient inscriptions.

BAJA, a populous town of Hungary, seated on the Danube, in E. Long. 19. 50. N. Lat. 46. 40.

BAIÆ, an ancient village of Campania in Italy, between the promontory of Misenum and Puteoli, on the Sinus Baianus. It was anciently famous for its hot baths, which served the wealthier Romans for the purposes both of medicine and pleasure. According to some writers, it had its name from *Baius*, one of Ulysses's companions who was there buried. The agreeableness of the situation invited many to build villas and even palaces in its neighbourhood. It is now called *Bajah*, and has some ancient ruins remaining, but is otherwise inconsiderable. E. Long. 14. 45. N. Lat. 41. 6.

BAJADOR, a cape on the west coast of Africa, south of the Canary islands. W. Long. 15. 20. N. Lat. 27. 0.

BAJAZET I. Sultan of the Turks, a renowned warrior but a tyrant, was conquered by Tamerlane, and exposed by him in an iron cage; the fate he had destined for his adversary if he had been the victor. He dashed his head against the bars of this prison, and killed himself, in 1413. See the article **TURKS**.

BAIKAL, a great lake in Siberia, lying between 52 and 55 degrees of north latitude. It is reckoned to be 500 wersts in length; but only 20 or 30 broad, and in some places not above 15. It is environed on all sides by high mountains. In one part of it, which lies near the river Bargusin, it throws up an inflammable sulphureous liquid called *maltha*, which the people of the adjacent country burn in their lamps. There are likewise several sulphureous springs near this lake. Its water at a distance appears of a sea-green colour: it is fresh; and so clear, that objects may be seen in it several fathoms deep. It does not begin to freeze till near the latter end of December, and thaws again about the beginning of May: from which time till September, a ship is seldom known to be wrecked on it; but by the high winds which then blow, many shipwrecks happen. This lake is called by the neighbouring people *Sviatoie More*, or the *Holy Lake*; and they imagine, that when storms happen on it, they will be preferred from all danger by complimenting it with the title of *Sea*. When it is frozen over, people travel upon it in the road to China; but they must be very sharp shod, otherwise they cannot stand upon the ice, which is exceedingly smooth. Notwithstanding that the ice on this lake is sometimes two ells thick,

there are some open places in it to which tempestuous winds will often drive those who are crossing it, in which case they are irrecoverably lost. The camels that pass along have a particular kind of shoes sharp at bottom, and the oxen have sharp irons driven thro' their hoofs, without which it would be impossible for them to pass. Here are plenty of large sturgeon and pike; with many feals of the black, but none of the spotted, kind. It contains several islands; and the borders are frequented by black fables and civet-cats.

BAIL, **BALLIUM**, (from the French *bailler*, which comes of the Greek βαλλω, and signifies to deliver into hands), is used in our common law for the freeing or setting at liberty of one arrested or imprisoned upon any action, either civil or criminal, on surety taken for his appearance at a day and place certain.

The reason why it is called *bail*, is because by this means the party restrained is delivered into the hands of those that bind themselves for his forthcoming, in order to a safe keeping or protection from prison; and the end of bail is to satisfy the condemnation and costs, or render the defendant to prison.

With respect to bail in civil cases, it is to be observed, that there is both common and special bail. Common bail is in actions of small concernment, being called *common*, because any sureties in that case are taken; whereas in causes of greater weight, as actions upon bonds, or speciality, &c. where the debt amounts to 10 l. *special* bail or surety must be taken, such as subsidy-men at least, and they according to the value.

The commitment of a person being only for safe custody, wherever bail will answer the fate intention, it ought to be taken; as in most of the inferior crimes: but in felonies, and other offences of a capital nature, no bail can be a security equivalent to the actual custody of the person. For what is there that a man may not be induced to forfeit, to save his own life? and what satisfaction or indemnity is it to the public, to seize the effects of them who have bailed a murderer, if the murderer himself be suffered to escape with impunity? Upon a principle similar to which, the Athenian magistrates, when they took a solemn oath never to keep a citizen in bonds that could give three sureties of the same quality with himself, did it with an exception to such as had embezzled the public money, or been guilty of treasonable practices.

Bail may be taken either in court, or in some particular cases, by the sheriff or other magistrate; but most usually by the justices of the peace. To refuse or delay to bail any person bailable, is an offence against the liberty of the subject, in any magistrate, by the common law; as well as by the statute Westm. 1. 3 Edw. I. c. 15. and the *habeas corpus* act, 31 Car. II. c. 2. And, lest the intention of the law should be frustrated by the justices requiring bail to a greater amount than the nature of the case demands, it is expressly declared by statute 1 W. & M. ft. 2. c. 1. that excessive bail ought not to be required; though what bail shall be called *excessive*, must be left to the courts, on considering the circumstances of the case, to determine. And on the other hand, if the magistrate takes insufficient bail, he is liable to be fined, if the criminal doth not appear.

In *civil* cases, every defendant is bailable. But it is otherwise in

Criminal

Criminal matters. Regularly, all offences either against the common law or act of parliament, that are below felony, the offender ought to be admitted to bail, unless it be prohibited by some special act of parliament.—By the ancient common law, before and since the conquest, all felonies were bailable, till murder was excepted by statute: so that persons might be admitted to bail almost in every case. But the statute Westm. 1. 3 Edw. I. c. 15. takes away the power of bailing in treason, and in divers instances of felony. The statutes 23 Hen. VI. c. 9. and 1 & 2 Ph. & Mar. c. 13. give farther regulations in this matter: and upon the whole we may collect, that no justices of the peace can bail, 1. Upon an accusation of treason: nor, 2. Of murder: nor, 3. In case of manslaughter, if the prisoner be clearly the slayer, and not barely suspected to be so; or if any indictment be found against him: nor, 4. Such as, being committed for felony, have broken prison; because it only carries a presumption of guilt, but is also superadding one felony to another: 5. Persons outlawed: 6. Such as have abjured the realm: 7. Persons taken with the mainour, or in the fact of felony: 8. Persons charged with arson: 9. Excommunicated persons, taken by writ de *excommunicato capiendo*: all which are clearly not admissible to bail by the justices. Others are of a dubious nature, as, 10. Thieves openly defamed and known: 11. Persons charged with other felonies, or manifest and enormous offences, not being of good fame: and 12. Accessories to felony, that labour under the same want of reputation. These seem to be in the discretion of the justices, whether bailable or not. The last cases are such as *must* be bailed upon offering sufficient surety; as, 13. Persons of good fame, charged with a bare suspicion of manslaughter, or other infamous homicide: 14. Such persons, being charged with petit larceny or any felony, not before specified: or, 16. With being accessory to any felony. Lastly, it is agreed, that the court of king's bench (or any judge thereof in time of vacation) may bail for any crime whatsoever, be it treason, murder, or any other offence, according to the circumstances of the case. And herein the wisdom of the law is very manifest. To allow bail to be taken commonly for such enormous crimes, would greatly tend to elude the public justice: and yet there are cases, though they rarely happen, in which it would be hard and unjust to confine a man in prison, though accused even of the greatest offence. The law has therefore provided one court, and only one, which has a discretionary power of bailing in any case: except only, even to this high jurisdiction, and of course to all inferior ones, such persons as are committed by either house of parliament, so long as the session lasts; or such as are committed for contempts by any of the king's superior courts of justice *.

Clerk of the BAILS, is an officer belonging to the court of the King's Bench: he files the bail-pieces taken in that court, and attends for that purpose.

BAIL, or BALE, in the sea-language. The seamen call throwing the water by hand out of the ship's or boat's hold, *bailing*. They also call those hoops that bear up the tilt of a boat, its *bails*.

BAILIE, in Scots law, a judge anciently appointed by the king over such lands not erected into a regality as were supposed to fall to the crown by forfeiture or other-

wise, now abolished. It is also the name of a magistrate in royal boroughs, and of the judge appointed by a baron over lands erected into a barony *.

BAILIFF, (*ballivus*), from the French word *baillif*, that is, *praefectus provinciae*: and as the name, so the office itself was answerable to that of France; where there are eight parliaments, which are high courts from whence there lies no appeal, and within the precincts of the several parts of that kingdom which belong to each parliament there are several provinces to which justice is administered by certain officers called *baillifs*; and in England there are several counties in which justice hath been administered to the inhabitants by the officer who is now called *sheriff* or *viscount*, (one of which names descends from the Saxons, the other from the Normans); and though the sheriff is not called *baillif*, yet it is probable that was one of his names also, because the county is often called *balliva*. And in the statute of Magna Charta, cap. 28. and 14 Ed. 3. c. 9. the word *baillif* seems to comprise as well sheriffs, as bailiffs of hundreds. As the realm is divided into counties, so every county is divided into hundreds; within which in ancient times the people had justice ministered to them by the officers of every hundred. But now the hundred courts, except certain franchises, are swallowed in the county-courts; and the bailiff's name and office is grown into contempt, they being generally officers to serve writs, &c. within their liberties. Though, in other respects, the name is still in good esteem: for the chief magistrates in divers towns, are called *baillifs*, or *baillies*; and sometimes the persons to whom the king's castles are committed are termed *baillifs*, as the *baillif of Dover castle*, &c.

Of the ordinary bailiffs there are several sorts, viz. sheriff's bailiffs, bailiffs of liberties, &c.

Sheriff's bailiffs, or sheriff's officers, are either bailiffs of hundreds, or special bailiffs. Bailiffs of hundreds are officers appointed over those respective districts by the sheriffs, to collect fines therein; to summon juries; to attend the judges and justices at the assizes, and quarter-sessions; and also to execute writs and process in the several hundreds. But as these are generally plain men, and not thoroughly skilful in this latter part of their office, that of serving writs, and making arrests and executions, it is now usual to join special bailiffs with them; who are generally mean persons employed by the sheriffs on account only of their adroitness and dexterity in hunting and seizing of their prey.

Bailiffs of liberties are those bailiffs who are appointed by every lord within his liberty, to execute process and do such offices therein as the bailiff errant doth at large in the county; but bailiffs errant or itinerant, to go up and down the county to serve process, are out of use.

There are also bailiffs of forests, and bailiffs of manors, who direct husbandry, fell trees, gather rents, pay quit-rents, &c.

Water-BAILIFF, an officer appointed in all port-towns, for the searching of ships, gathering the toll for anchorage, &c. and arresting persons for debt, &c. on the water.

BAILIWICK, that liberty which is exempted from the sheriff of the county; over which liberty the lord thereof appoints his own bailiff, with the like power within his precinct as an under sheriff exercises under

Bailiff,
Bailiwick.

Baillet
||
Bailment.

the sheriff of the county: Or it signifies the precinct of a bailiff, or the place within which his jurisdiction is terminated.

BAILLET (Adrian), a very learned French writer and critic, born in 1649, at the village of Neuville near Beauvais in Picardy. His parents were too poor to give him a proper education, which however he obtained by the favour of the bishop of Beauvais, who afterward presented him with a small vicarage. In 1680, he was appointed librarian to M. de Lamoignon, advocate general to the parliament of Paris; of whose library he made a copious index in 35 vols folio, all written with his own hand. He died in 1706, after writing many works, the principal of which are, *A History of Holland from 1600, to the peace of Nimeguen in 1679*, 4 vols 12mo; *Lives of the Saints*, 3 vols folio, which he professed to have purged from fables; *Fugemens des Savans*, which he extended to 9 vols 12mo; and *The Life of Des Cartes*, 2 vols 4to. which he abridged, and reduced to 1 vol. 12mo.

BAILLEUL, a town of France, in the earldom of Flanders, formerly very strong, but now without any fortifications. It has been several times burnt by accident, and contains now only about 500 houses. E. Long. 2. 55. N. Lat. 40. 35.

BAILEMENT, in law, is a delivery of goods in trust, upon a contract, expressed or implied, that the trust shall be faithfully executed on the part of the bailee. As if cloth be delivered, or (in our legal dialect) bailed, to a taylor to make a suit of clothes, he has it upon an implied contract to render it again when made, and that in a workmanly manner. If money, or goods be delivered to a common carrier, to convey from Oxford to London, or from Glasgow to Edinburgh, &c. he is under a contract in law to pay, or carry them to the person appointed. If a horse, or other goods, be delivered to an inn-keeper or his servants, he is bound to keep them safely, and restore them when his guest leaves the house. If a man takes in a horse, or other cattle, to graze and depasture in his grounds, which the law calls *agistment*, he takes them upon an implied contract to return them on demand to the owner. If a pawnbroker receives plate or jewels as a pledge, or security, for the repayment of money lent thereon at a day certain, he has them upon an expres contract or condition to restore them if the pledger performs his part by redeeming them in due time; for the due execution of which contract, many useful regulations are made by statute 30 Geo. II. c. 24. And so, if a landlord distrains goods for rent, or a parish officer for taxes, these for a time are only a pledge in the hands of the distrainers; and they are bound by an implied contract in law to restore them on payment of the debt, duty, and expences, before the time of sale; or, when sold, to render back the overplus. If a friend delivers any thing to his friend to keep for him, the receiver is bound to restore it on demand: and it was formerly held, that, in the mean time he was answerable for any damage or loss it might sustain, whether by accident or otherwise; unless he expressly undertook to keep it only with the same care as his own goods, and then he should not be answerable for theft or other accidents. But now the law seems to be settled on a much more rational footing; that such a general bailment will not charge the bailee with any loss, unless it hap-

pens by gross neglect, which is construed to be an evidence of fraud: but, if the bailee undertakes specially to keep the goods safely and securely, he is bound to answer all perils and damages that may befall them for want of the same care with which a prudent man would keep his own.

BAILO; thus they style at Constantinople the ambassador of the republic of Venice, who resides at the Porte. This minister, besides his political charge, acts there the part of a consul of Venice.

BAINBRIDGE (Dr John), an eminent physician and astronomer, born at Aßby de la Zouche in Leicestershire, in 1582. He taught a grammar-school for some years, and practised physic, employing his leisure hours in astronomy, which was his favourite study: at length he removed to London, was admitted a fellow of the college of physicians, and raised his character by his description of the comet in 1618. The next year Sir Henry Savile appointed him his first professor of astronomy at Oxford; and the masters and fellows of Merton-college made him first junior, and then superior, reader of Linacre's lecture. He died in 1643, having written many works, some of which have never been published: but the MSS. are preserved in the library of Trinity-college, Dublin.

BAIOCAO, a copper-coin, current at Rome, and throughout the whole state of the church, ten of which make a julio, and an hundred a Roman crown.

BAIRAM, or **BEIRAM**, a Turkish word which signifies a solemn feast. The Mahometans have two Bairams; the *Great*, and the *Little*. The *Little Bairam* is properly that held at the close of the fast *Ramazân*, beginning with the first full moon in the following month *Shawal*. This is called in Arabic *Id al Fetz*, or *the Feast of breaking the Fast*; by European writers, *the Turkish Easter*, because it succeeds *Ramazân*, which is their Lent, more usually the *Great Bairam*, because observed with great ceremony and rejoicing at Constantinople, and through Turkey, for three days, and in Persia for five or six days, at least by the common people, to make themselves amends for the mortification of the preceding month.—The feast commencing with the new moon, the Mahometans are very scrupulous in observing the time when the new moon commences; to which purpose, observers are sent to the tops of the highest mountains, who, the moment they spy the appearance of a new moon, run to the city, and proclaim *Muzdabak*, "welcome news;" as it is the signal for beginning the festivity.—The *Great Bairam*, is properly that held by the pilgrims at Mecca, commencing on the tenth of *Dhu Ihajia*, when the victims are slain, and lasting three days. This is called by the Arabs, *Id al adba*, that is, *the feast of sacrifice*, as being celebrated in memory of the sacrifice of *Abram*, whose son *God* redeemed with a great victim. By European writers it is called the *Lesser Bairam*, as being less taken notice of by the generality of the people, who are not struck with it, because the ceremonies, it is observed withal, are performed at Mecca, the only scene of the solemnity.—On the feast of *Bairam*, after throwing little stones, one after another, into the valley of *Mina*, they usually kill one or more sheep, some a goat, bullock, or even a camel; and, after giving part thereof to the poor, eat the rest with their friends. After this, they shave themselves. The

Bail
||
Bairam.

second is a day of rest. On the third, they set out on their return home.

BAIT, among fishermen, implies a substance proper to be fastened to a hook, in order to catch the different sorts of fish. See FISHING.

BAITING, the act of smaller or weaker beasts attacking and harassing greater and stronger. In this sense we hear of the baiting of bulls or bears by mastiffs, or bull-dogs with short noses that they may take the better hold.

Utility may be pled, in some degree, in justification of *bull-baiting*. This animal is rarely killed without being first baited; the chaffing and exercise thereof makes his flesh tenderer and more digestible. In reality, it disposes it for putrefaction; so that, unless taken in time, baited flesh is soon lost. But a spirit of barbarism had the greatest share in supporting the sport: bulls are kept on purpose, and exhibited as standing spectacles for the public entertainment. The poor beasts have not fair play: they are not only tied down to a stake, with a collar about their necks, and a short rope, which gives them not above four or five yards play; but they are disarmed too, and the tips of their horns cut off, or covered with leather, to prevent their hurting the dogs. In this sport, the chief aim of the dog is to catch the bull by the nose, and hold him down; to which end, he will even creep on his belly: the bull's aim, on the contrary, is, with equal industry, to defend his nose; in order to which, he thrusts it close to the ground, where his horns are also in readiness to toss the dog.—Bull-baiting was first introduced into England, as an amusement, in the reign of King John, about 1209.

BAJULUS, an ancient officer in the court of the Greek emperors. There were several degrees of bajuli; as, the grand *bajulus*, who was preceptor to the emperor; and the simple *bajuli*, who were sub-preceptors.

The word is derived from the Latin verb *bajulare*, to carry or bear a thing on the arms or on the shoulders; and the origin of the office is thus traced by antiquaries. Children, and especially those of condition, had anciently, beside their nurse, a woman called *gerula*, as appears from several passages of Tertullian; when weaned, or ready to be weaned, they had men to carry them about and take care of them, who were called *geruli* and *bajuli*, a *gerendo* & *bajulando*. Hence it is, that governors of princes and great lords were still denominated *bajuli*, and their charge or government *bajulatio*, even after their pupils were grown too big to be carried about. The word passed in the same sense into Greece.

BAJULUS is also used by Latin writers in the several other senses wherein bailiff is used among us *.

BAJULUS was also the name of a conventual officer in the ancient monasteries, to whom belonged the charge of gathering and distributing the money and legacies left for masses and obits; whence he was also denominated *bajulus obituum novorum*.

BAKAN, a large and handsome town of Afla in the East Indies, in the kingdom of Ava. E. Long. 68. o. N. Lat. 19. 35.

BAKER (Sir Richard), author of the Chronicle of the kings of England, was born at Sissingherst, in Kent, about the year 1568. After going through the usual course of academical learning at Hart-hall,

in Oxford, he travelled into foreign parts; and upon his return home was created master of arts, and soon after, in 1603, received from king James I. the honour of knighthood. In 1620, he was high sheriff of Oxfordshire; but engaging to pay some of the debts of his wife's family, he was reduced to poverty, and obliged to betake himself for shelter to the Fleet prison, where he composed several books, among which, are, 1. *Meditations and Disquisitions on the Lord's Prayer*. 2. *Meditations, &c. on several of the Psalms of David*. 3. *Meditations and Prayers upon the seven Days of the Week*. 4. *Cato Variegatus*, or *Cato's Moral Distichs varied, &c.*—Mr Granger observes, that his Chronicle of the Kings of England was ever more esteemed by readers of a lower class, than by such as had a critical knowledge of history. The language of it was, in this reign, called *polite*; and it long maintained its reputation, especially among country gentlemen. The author seems to have been sometimes more studious to please than to inform, and with that view to have sacrificed even chronology itself to method. In 1658, Edward Philips, nephew to Milton, published a third edition of this work, with the addition of the reign of Charles I. It has been several times reprinted since, and is now carried as low as the reign of George I. Sir Richard also translated several works from the French and Italian; and died very poor, in the Fleet prison, on the 18th of February, 1645.

BAKER (Thomas), an eminent mathematician, was born at Ilton, in Somersetshire, about the year 1625, and entered at Magdalen-hall, Oxon, in 1640; after which he was vicar of Bishop's-Nymmet, in Devonshire, where he wrote *The Geometrical Key, or the Gate of Equations unlocked*; by which he gained a considerable reputation. A little before his death, the members of the Royal Society sent him some mathematical queries, to which he returned so satisfactory an answer, that they presented him a medal, with an inscription full of honour and respect. He died at Bishop's-Nymmet, on the 5th of June, 1690.

BAKER (Thomas), a dramatic writer, was the son of an eminent attorney in the city of London. His turn was entirely to comedy, and his plays are five in number, viz. 1. *Act* at Oxford. 2. *Fine Ladies air*. 3. *Hampstead Heath*. 7. *Humours of the age*. 5. *Tunbridge Walks*. All of them have a considerable share of merit; yet only one among the number stands on the present list of acting plays, viz. *Tunbridge Walks*. It is said that the character of Maiden in this play, which is perhaps the original of almost all the Fribbles, beau Mizens, &c. that have been drawn since, and in which effeminacy is carried to an height beyond what any one could conceive to exist in any man in real life, was absolutely, and without exaggeration, a portrait of the author's own former character; whose understanding having at length pointed out to him the folly he had so long been guilty of, he reformed it altogether in his subsequent behaviour, and wrote this character, in order to set it forth in the most ridiculous light, and wran others from that rock of contempt which he had himself for some time been wrecked upon. Whether this gentleman's attachment to the muses drew him from any application to business, or from what other cause, is not known; but during the latter part of his life he stood on indifferent

Baker
Baking.

terms with his father, who allowing him a very scanty income, he was obliged to retire into Worcester-shire, where he is reported to have died of that loathsome disorder the *morbus pediculofus*.

BAKER, a person whose occupation or business is to bake bread. See the articles BAKING and BREAD.

The learned are in great doubt about the time when baking first became a particular profession, and bakers were introduced. It is however generally agreed, that they had their rise in the east, and passed from Greece to Italy after the war with Pyrrhus, about the year of Rome 583. Till which time every house-wife was her own baker: for the word *pistor*, which we find in Roman authors before that time, signified a person who ground or pounded the grain in a mill or mortar to prepare it for baking, as Varro observes. According to Athenæus, the Cappadocians were the most applauded bakers, after them the Lydians, then the Phœnicians.—To the foreign bakers brought into Rome, were added a number of freed-men, who were incorporated into a body, or, as they called it, a *college*; from which neither they nor their children were allowed to withdraw. They held their effects in common, and could not dispose of any part of them. Each bake-house had a patronus, who had the superintendency thereof; and these patroni elected one out of their number each year, who had superintendency over all the rest, and the care of the college. Out of the body of the bakers were every now and then one admitted among the senators.—To preserve honour and honesty in the college of bakers, they were expressly prohibited all alliance with comedians and gladiators; each had his shop or bake-house, and they were distributed into fourteen regions of the city. They were excused from guardianships and other offices, which might divert them from their employment.—By our own statutes bakers are declared not to be handicrafts. No man for using the mysteries or sciences of baking, brewing, furgery, or writing, shall be interpreted a handicraft. The bakers were a brotherhood in England before the year 1155, in the reign of king Henry II. though the white bakers were not incorporated till 1307, by king Edward III. and the brown bakers not till 1621, in king James I.'s time. Their hall is in Harp-lane, Thames-street; and their court-day on the first Monday of the month.—They make the 19th company; and consist of a warden, 4 masters, 30 assistants, and 140 men on the livery, besides the commonalty.—The French had formerly a great baker, *grand panetier de France*, who had the superintendency of all the bakers of Paris. But, since the beginning of this century, they have been put under the jurisdiction of the lieutenant-general de police. In some provinces of France, the lord is the only baker in his seignery; keeping a public oven, to which all the tenants are obliged to bring their bread. This right is called *four-nagium*, or *fournaticum*, and makes part of the *bannalite*.

BAKEWELL, a pretty large town of Derbyshire, in England, seated on the river Wye, on the north-side of the Peak. It has a considerable trade in lead. W. Long. 2. 30. N. Lat. 55. 15.

BAKHUISEN (Ludolph), a painter and engraver, was born at Embden in 1631, and died 1709. He excelled in sea-pieces, particularly storms.

BAKING, the art of preparing bread, or reducing

Baking.

meals of any kind, whether simple or compound, into bread. See the article BREAD.

The various forms of baking among us may be reduced into two, the one for unleavened, the other for leavened bread. For the first, the chief is manchet-baking; the process whereof is as follows. The meal, ground and bolted, is put into a trough; and to every bushel are poured in about three pints of warm ale, with barm and salt to season it. This is kneaded well together, with the hands through the brake; or, for want thereof, with the feet, through a cloth: after which, having lain an hour to swell, it is moulded into manchets; which, scorched in the middle, and pricked up at top, to give room to rise, are baked in the oven by a gentle fire.—For the second, sometimes called *cheat-bread baking*, it is thus: Some leaven (saved from a former batch) filled with salt, laid up to sour, and at length dissolved in water, is strained through a cloth into a hole made in the middle of the heap of meal in the trough; then it is worked with some of the flour into a moderate consistence: this is covered up with meal, where it lies all night; and in the morning the whole heap is stirred up, and mixed with a little warm water, barm, and salt, by which it is seasoned, foisted, and brought to an even leaven: it is then kneaded, moulded, and baked, as before.

Method of raising a bushel of flour, with a tea-spoonful of barm; by James Stone, of Amport, in Hampshire.—Suppose you want to bake a bushel of flour, and have but one tea-spoonful of barm. Put your flour into your kneading-trough or trendle; then take about three quarters of a pint of warm water, and take the tea-spoonful of thick iteary barm and put it into the water, stir it until it is thoroughly mixed with the water: then make a hole in the middle of the flour large enough to contain two gallons of water, pour in your small quantity; then take a stick about two feet long, (which you may keep for that purpose), and stir in some of the flour, until it is as thick as you would make batter for a pudding; then strew some of the dry flour over it, and go about your usual business for about an hour: then take about a quart of warm water more, and pour in; for in one hour you will find that small quantity raised so, that it will break through the dry flour which you shook over it; and when you have poured in the quart of warm water, take your stick as before, and stir in some more flour, until it is as thick as before; then shake some more dry flour over it, and leave it for two hours more, and then you will find it rise and break through the dry flour again; then you may add three quarts or a gallon of warm water, and stir in the flour and make it as thick as at first, and cover it with dry flour again; in about three or four hours more you may mix up your dough, and then cover it up warm; and in four or five hours more you may put it into the oven, and you will have as light bread as though you had put a pint of barm. It does not take above a quarter of an hour more time than the usual way of baking, for there is no time lost but that of adding water three or four times.

The author of this method assures us that he constantly bakes this way in the morning about six or seven o'clock, puts the flour out, and puts this small quantity of barm into the before-mentioned quantity of water, in an hour's time some more, in two hours more

a greater quantity, about noon makes up the dough, and about six in the evening it is put into the oven, and he has always good bread, never heavy nor bitter.

When you find, he says, your body of flour spunged large enough, before you put in the rest of your water, you should, with both your hands, mix that which is spunged and the dry flour all together, and then add the remainder of warm water, and your dough will rise the better and easier.

The reason he assigns why people make heavy bread is, not because they have not barm enough, but because they do not know that barm is the same to flour as fire is to fuel; that, as a spark of fire will kindle a large body by only blowing of it up, so will a thimblefull of barm, by adding of warm water, raise or sponge any body of flour; for warm water gives fresh life to that which is before at work: so that the reason of making bread heavy is, because the body spunged is not large enough, but was made up and put into the oven before it was ripe.

In regard to the difference of seasons, he prescribes, that in the summer you should put your water blood-warm; and in winter, in cold frosty weather, as warm as you can bear your hand in it without making it smart; being sure you cover up your dough very warm in the winter, and your covering of it with dry flour every time you add warm water will keep in the heat; when you have added six or eight quarts of warm water, as before mentioned, in such a gradual way, you will find all that body of flour which is mixed with the warm water, by virtue of that one tea-spoonful of barm, brought into great agitation, waxing, or fermenting; for it is to the flour what the spirit is to the body, it soon fills it with motion.

BAKOU, a town of Persia, in the province of Shivan, situated at the extremity of the Gulf of Chilan on the Caspian Sea. E. Long. 51. 30. N. Lat. 40. 20.

BALA, a town of Merionethshire in Wales. W. Long. 3. 37. N. Lat. 52. 54.

BALÆNA, or WHALE, in zoology, a genus of the mammalia class, belonging to the order of cetæ. The characters of this genus are these: The balæna, in place of teeth, has a horny plate in the upper jaw, and a double fistula or pipe for throwing out water. The species are four, *viz.*

1. The myticetus, or common whale, which has many turnings and winding in its nostrils, and has no fin on the back. This is the largest of all animals; it is even at present sometimes found in the northern seas 90 feet in length; but formerly they were taken of a much greater size, when the captures were less frequent, and the fish had time to grow. Such is their bulk within the arctic circle; but in those of the torrid zone, where they are unmolested, whales are still seen 160 feet long. The head is very much disproportioned to the size of the body, being one third the size of the fish: the under lip is much broader than the upper. The tongue is composed of a soft spongy fat, capable of yielding five or six barrels of oil. The gullet is very small for so vast a fish, not exceeding four inches in width. In the middle of the head are two orifices, through which it spouts water to a vast height, and with a great noise, especially when disturbed or wounded. The eyes are not larger than those of an ox, and when the crystalline humour is dried, it does not appear

larger than a pea. They are placed towards the back of the head, being the most convenient situation for enabling them to see both before and behind; as also to see over them, where their food is principally found. They are guarded by eye-lids and eye-lashes, as in quadrupeds; and they seem to be very sharp-sighted.

Nor is their sense of hearing in less perfection; for they are warned, at great distances, of any danger preparing against them. It would seem as if nature had designedly given them these advantages, as they multiply little, in order to continue their kind. It is true, indeed, that the external organ of hearing is not perceptible, for this might only embarrass them in their natural element; but as soon as the thin scarf-skin after mentioned is removed, a black spot is discovered behind the eye, and under that is the auditory canal, that leads to a regular apparatus for hearing. In short, the animal hears the smallest sounds at very great distances, and at all times, except when it is spouting water; which is the time that the fishers approach to strike it. What is called *whalebone*, adheres to the upper jaw; and is formed of thin parallel laminae, some of the longest four yards in length: of these there are commonly 350 on each side, but in very old fish more; about 500 of them are of a length fit for use, the others being too short. They are surrounded with long strong hair, not only that they may not hurt the tongue, but as strainers to prevent the return of their food when they discharge the water out of their mouths.—The real bones of the whale are hard, porous, and full of marrow. Two great strong bones sustain the upper lip, lying against each other in the shape of an half-moon.

The tail is broad and femilunar; and when the fish lies on one side, its blow is tremendous. The tail alone it makes use of to advance itself forward in the water; and it is surprising to see with what force and celerity its enormous bulk cuts through the ocean. The fins are only made use of for turning in the water, and giving a direction to the velocity impressed by the tail. The female also makes use of them, when pursued, to bear off her young, clapping them on her back, and supporting them by the fins on each side from falling. The whale varies in colour; the back of some being red, the belly generally white. Others are black, some mottled, others quite white; according to the observation of Martin, who says, that their colours in the water are extremely beautiful, and that their skin is very smooth and slippery. The outward or scarf skin of the whale is no thicker than parchment; but this removed, the real skin appears, of about an inch thick, and covering the fat or blubber that lies beneath: this is from eight to twelve inches in thickness; and is, when the fish is in health, of a beautiful yellow. The muscles lie beneath; and these, like the flesh of quadrupeds, are very red and tough. The penis is eight feet in length, inclosed in a strong sheath. The teats in the female are placed in the lower part of the belly.

In copulation, the female joins with the male, as is asserted, *more humano*; and once in two years feels the access of desire. Their fidelity to each other exceeds that of whatever we are told of, even the constancy of birds. Some fishers, as Anderson informs us, having struck one of two whales, a male and a female, that were in company together, the wounded fish made a long and terrible resistance: it struck down a boat with three men

Blains,
or Whale.

in it, with a single blow of its tail, by which all went to the bottom. The other still attended its companion, and lent it every assistance; till, at last, the fish that was struck, sunk under the number of its wounds; while its faithful associate, disdainful to survive the loss, with great bellowing, stretched itself upon the dead fish, and shared his fate.—The whale goes with young nine or ten months, and is then fatter than usual, particularly when near the time of bringing forth. It is said that the embryo, when first perceptible, is about 17 inches long, and white; but the cub, when excluded, is black, and about 10 feet long. She generally produces one young one, and never above two. When the suckles her young, she throws herself on one side on the surface of the sea, and the young one attaches itself to the teat.

*
Offspring;
parental af-
fection, &c.

Nothing can exceed the tenderness of the female for her offspring; she carries it with her wherever she goes, and, when hardst pursued, keeps it supported between her fins. Even when wounded, the milk clasps her young one; and when she plunges to avoid danger, takes it to the bottom; but rises sooner than usual, to give it breath again. The young ones continue at the breast for a year; during which time, they are called by the sailors, *short-heads*. They are then extremely fat, and yield above 50 barrels of blubber. The mother at the same time is equally lean and emaciated. At the age of two years they are called *stunts*, as they do not thrive much immediately after quitting the breast: they then yield scarce above 20 or 24 barrels of blubber: from that time forward they are called *skull-fish*, and their age is wholly unknown.

Every species of whale propagates only with those of its own kind, and does not at all mingle with the rest: however, they are generally seen in shoals, of different kinds together, and make their migrations in large companies from one ocean to another. They are gregarious animals; which implies their want of mutual defence against the invasions of smaller, but more powerful, fishes. It seems astonishing, therefore, how a shoal of these enormous animals find subsistence together, when it would seem that the supplying even one with food would require greater plenty than the ocean could furnish. To increase our wonder, we not only see them herding together, but usually find them fatter than any other animals of whatsoever element. We likewise know that they cannot swallow large fishes, as their throat is so narrow, that an animal larger than an herring could not enter. How then do they subsist and grow so fat? A certain sort of small snail, or (as Linnaeus says) the *medusa* * or sea-blubber, is sufficient for this supply. Content with this simple food, it pursues no other animal, leads an inoffensive life in its element, and is harmless in proportion to its strength to do mischief.

Enemies.

As the whale is an inoffensive animal, it is not to be wondered that it has many enemies, willing to take advantage of its disposition, and inaptitude for combat. There is a small animal, of the shell-fish kind, called the *whale-lice*, that sticks to its body, as we see shells sticking to the foul bottom of a ship. This insinuates itself chiefly under the fins; and whatever efforts the great animal makes, it still keeps its hold, and lives upon the fat, which it is provided with instruments to ar-

The sword-fish †, however, is the whale's most terrible enemy. "At the sight of this little animal," says Anderson, "the whale seems agitated in an extraordinary manner; leaping from the water as if with affright: wherever it appears, the whale perceives it at a distance, and flies from it in the opposite direction. I have been myself," continues he, "a spectator of their terrible encounter. The whale has no instrument of defence except the tail: with that it endeavours to strike the enemy; and a single blow taking place, would effectually destroy its adversary: but the sword-fish is as active as the other is strong, and easily avoids the stroke; then bounding into the air, it falls upon its great sub-jacent enemy, and endeavours not to pierce with its pointed beak, but to cut with its toothed edges. The sea all about it is seen dyed with blood, proceeding from the wounds of the whale; while the enormous animal vainly endeavours to reach its invader, and strikes with its tail against the surface of the water, making a report at each blow louder than the noise of a cannon." In calm weather, the fishermen lie upon their oars as spectators of this combat, until they perceive the whale at the last gasp: then they row towards him; and his enemy retiring at their approach, they enjoy the fruits of the victory.—The whale has another desperate enemy, a kind of shark, of different sizes from one to three fathoms; so voracious, that it tears large pieces of flesh from the whale, as if they had been dug with shovels.

Conflict
with the
sword-fish

To view these animals in a commercial light, we must observe, that the English were late before they engaged in the whale-fishery: it appears by a set of queries, proposed by an honest merchant in the year 1575, in order to get information in the business, that we were at that time totally ignorant of it, being obliged to send to *Bjakaie for men skilful in the catching of the whale, and ordering of the oil, and one cooper skilful to set up the staved casks*. This seems very strange; for by the account O'ther gives of his travels to King Alfred, near 700 years before that period, it is evident that he made that monarch acquainted with the Norwegians practising the whale-fishery; but it seems all memory of that gainful employ, as well as of that able voyager O'ther, and all his important discoveries in the north, were lost for near seven centuries.

10
Anecdotes
of the
whale-
trade.Huckluyt's
Col. of Voy-
I. 414.

It was carried on by the Biscayeners long before we attempted the trade; and that for the sake not only of the oil, but also of the whalebone, which they seem to have long trafficked in. The earliest notice we find of that article in our trade is by Huckluyt, who says it was brought from the Bay of St Laurence by an English ship that went there for the *barbes* and *synnes* of whales and train oil, A. D. 1594, and who found there 700 or 800 *whale synnes*, part of the cargo of two great *Bjakaie* ships, that had been wrecked there three years before. Previous to that, the ladies staves must have been made of split cane, or some tough wood, as Mr Anderson observes in his Dictionary of Commerce; it being certain that the whale fishery was carried on, for the sake of the oil, long before the discovery of the use of whalebone.

The great resort of these animals was found to be on the inhospitable shores of Spitzbergen, and the European ships made that place their principal fishery, and for numbers of years were very successful: the English com-

commenced that business about the year 1598, and the town of Hull had the honour of first attempting that profitable branch of trade. At present it seems to be on the decline, the quantity of fish being greatly reduced by the constant capture for such a vast length of time: some recent accounts inform us, that the fishers, from a defect of whales, apply themselves to seal-fishery, from which animals they extract an oil. This we fear will not be of very long continuance; for these shy and timid creatures will soon be induced to quit those shores by being perpetually harassed, as the morse or walrus has already in a great measure done. We are also told, that the poor natives of Greenland begin even now to suffer from the decrease of the seal in their seas, it being their principal subsistence; so that, should it totally desert the coast, the whole nation would be in danger of perishing through want.

In old times the whale seems never to have been taken on our coasts, but when it was accidentally flung ashore: it was then deemed a royal fish, and the king and queen divided the spoil; the king asserting his right to the head, her majesty to the tail.—For the manner of taking whales, see *Whale-Fishing*.

2. The *phyfalus*, or *fin-fish*, is distinguished from the common whale by a fin on the back, placed very low and near the tail. The length is equal to that of the common kind, but much more slender. It is furnished with whale-bone in the upper jaw, mixed with hairs, but short and knotty, and of little value. The blubber also on the body of this kind is very inconsiderable. These circumstances, added to its extreme ferenceness and agility, which renders the capture very dangerous, cause the fishers to neglect it. The natives of Greenland, however, hold it in great esteem, as it affords a quantity of flesh which to their palate is very agreeable.

The lips are brown, and like a twisted rope: the spout-hole is as it were split in the top of its head, through which it blows water with much more violence, and to a greater height, than the common whale. The fishers are not very fond of seeing it, for on its appearance the others retire out of those seas.

Some writers conjecture this species to have been the *Phocaena*, and *phyfeter*, or blowing-whale of Oppian, *Ælian*, and *Pliny*: but since those writers have not left the least description of it, it is impossible to judge which kind they meant; for in respect to the faculty of spouting out water, or blowing, it is not peculiar to any one species, but common to all the whale kind.

The *phyfalus* inhabits the European and American oceans: it feeds upon herrings and other small fish.

3. The *boops*, or *pike-headed whale*, has a double pipe in its snout, three fins like the former, and a hard horny ridge on its back. The belly is full of longitudinal folds or rugæ. It frequents the northern ocean. The length of that taken on the coast of Scotland, as remarked by Sir Robert Sibbald, was 46 feet, and its greatest circumference 20. This species takes its name from the shape of its nose, which is narrower and sharper-pointed than that of other whales.

4. The *mufculus* has a double pipe in its front, and three fins; the under jaw is much wider than the upper one. It frequents the Scotch coasts, and feeds upon herrings.

Linneus makes the *phyfeter* and *delphinus*, which are ranked among the whales by some writers, two di-

stinct genera. See *PHYFETER* and *DELPHINUS*.

BALAGATE, a province of the Mogul empire, and the largest of the three that compose the kingdom of Dekkan. It has *Kandish* and *Barar* to the north, *Tellinga* to the east, *Baglana* with part of *Guzerat* to the west, and *Vishapur* to the south. It is a fruitful and pleasant country, abounding with cotton and sugar. Here they have sheep without horns; but so strong, that when bridled and saddled they will carry boys of ten years of age. Its present capital is *Aurengabad*, but formerly was *Dowlet Abad*; and from the latter the whole province is sometimes called *Dowlet-Abad*.

BALAGATE Mountains, a chain of mountains which divides the coast of Malabar from that of *Coromandel*, running almost the whole length of the peninsula on this side the *Ganges*. Some parts of them are covered with fine red earth, which is blown by the strong west winds as far as the island of *Ceylon*; and when the rays of the sun are reflected from these mountains, they seem to be all on fire. They make surprising alterations in the seasons; for on the north side of *cape Comorin*, it is winter in *May*, *June*, *July*, *August*, and *September*, in which months it is summer on the south side of the cape; on one side there are continual tempests, thunder and lightning, while the other enjoys a constant serenity. When black clouds are gathered about the mountains, they are followed by sudden rain, which causes the overflowing of the rivers, and choaks them up with sand, inasmuch that they are unnavigable for some time afterwards. The buildings and clothes of the inhabitants are scarce sufficient to defend them from the weather. They live upon rice, milk, roots, and herbs, with very little meat: they have likewise a sort of small arrac, but are never given to drunkenness; nor do they import foreign vices, for they never travel abroad.

BALAGNIA, a town of *Muscovy* in the province of *Little Novogorod*, seated on the *Wolga*. E. Long. 45. 5. N. Lat. 50. 36.

BALAGUER, a city of *Catalonia* in *Spain*, seated on the north bank of the river *Sagra*, at the foot of a high mountain, on which there was formerly a fortress. E. Long. 0. 48. N. Lat. 41. 38.

BALAMBUAN, or **PADAMBUAN**, a strong town of *Asia* in the *Indies* on the east end of the island of *Java*, and capital of a territory of the same name. E. Long. 115. 30. S. Lat. 7. 50.

BALANCE, or **BALLANCE**, one of the six simple powers in mechanics, principally used in determining the equality or difference of weights in heavy bodies, and consequently their masses or quantities of matter.

The balance is of two kinds; the ancient, and the modern. The ancient, or *Roman*, called also the *statera Romana*, or *steel-yard*, consists of a lever or beam, moveable on a centre, and suspended near one of its extremities: the bodies to be weighed are applied on one side of the centre; and their weight is shewn by the division marked on the beam, where the weight, which is moveable along the lever, keeps the *steel-yard* in equilibrium. This balance is still frequently used in weighing heavy bodies.

The modern balance now generally used consists of a lever or beam suspended exactly in the middle, having scales or basons hung to each extremity. The lever

Balagate
||
Balance.

Balance.

is called the *juggon* or *beam*; and the two moieties thereof on each side the axis, the *brachia* or *arms*. The line on which the beam turns, or which divides its brachia, is called the *axis*; and, when considered with regard to the length of the brachia, is esteemed a point only, and called the *centre of the balance*: the handle whereby it is held, or by which the whole apparatus is suspended, is called *trutina*; and the slender part perpendicular to the beam, whereby either the equilibrium or preponderancy of bodies is indicated, is called the *tongue* of the balance. Thus in fig. 4. *a b* is the beam, divided into two equal brachia or arms by the white spot in the centre, which is the axis or centre of the balance, and *c* is the tongue. The trutina, on which the axis is suspended, is not represented in this figure, in order to render the other parts more conspicuous.

Plate LV.

It follows, from what has been observed, therefore, that in the Roman balance, the weight used for a counterpoise is the same, but the points of application varies; in the common balance the counterpoise is various, and the point of application the same. The principle on which each is founded, may be very easily understood from the following observations, and the general properties of the lever. See LEVER.

The beam AB, fig. 7. is a lever of the first kind; but, instead of resting on a fulcrum, is suspended by something fastened to its centre of motion; consequently the mechanism of the balance depends on the same theorems as the lever.

Hence as the quantity of matter in known weight is to its distance from the centre of motion, so is the distance of the unknown weight to its quantity of matter. Hence the nature and use of the steel-yard is easily known. Let AB (fig. 7.) represent an instrument of this kind; *a*, the trutina or handle on which the beam turns; *k*, a ring on which the balance may be suspended on a nail, or hook; *f*, the hook on which the body to be weighed is hung; *c*, a collar or guard by which the hook *f* is fastened to the beam; *g*, a moveable collar; *h*, a swivel; *i*, the counterpoise. From what has been said it evidently follows, that if the body to be weighed be fastened to the hook *f*, and the whole suspended by the ring *k*, the division on which the counterpoise is placed to maintain an equilibrium in the balance, will shew the weight of the body required; provided the weight of the counterpoise *i* be known, and the large divisions, 1, 2, 3, &c. be equal to the distance between the centre of the balance and the screw which fastens the guard *c* to the shorter arm of the balance. It will also be necessary that the steel-yard itself, with its whole apparatus, exclusive of the counterpoise, be *in equilibrio*, when suspended on the ring *k*. If the body to be weighed be heavier than the divisions on the longer arm will indicate, the balance is turned the lower side upwards, and suspended on the other ring *h*, by which means the divisions become shorter, because the distance between the trutina *d*, and the screw on which the guard *c* moves, is less: the divisions in the figure on this side extending to 17, whereas they extend only to six on the other. It will be unnecessary perhaps to observe, that the same precaution, with regard to the centre of gravity when the balance is suspended, is also necessary when this side of the balance is used, as we before mentioned

Balance.

with regard to the other.

We have already observed, that in the common scales the two brachia or arms of the balance, *e f*, e.g. fig. 5. are equal to each other, and consequently equal weights placed in the scales *d, d*, will be *in equilibrio* when the balance is suspended on its centre *e*, as in the figure, where the ring at the extremity of the trutina is hung on the tapering rod *a b*, fixed in the foot or basis *c*.

The Deceitful BALANCE, or that which cheats by the inequality of its brachia, is founded on the same principle as the steel-yard. Let there be, for example, a balance fo constructed, that both the brachia with their scales shall equiperponderate, but that the length of the one arm shall be to that of the other as 10 to 9. In this case, a weight of nine pounds put into the longest arm, will counterpoise one of ten pounds put into the shorter one: but the cheat is immediately discovered by shifting the weight from one scale to the other; in which case, the balance will no longer remain *in equilibrio*.

Assay-BALANCE, a very nice balance used in doctrinal operations, to determine exactly the weight of minute bodies. This balance should be made of the best steel, and of the hardest kind; because that metal is not so easily spoiled with rust, as iron; and it is more apt than any other to take a perfect polish, which at the same time prevents the rust.

The structure of the assayer's scale is little different from that of common scales, otherwise than by its nicety and smallness. The longer the beam of it is, the more exact may the weight of a body be found; however, 10 or 12 inches are a sufficient length. Let the thickness of it be so little, that two drams may hardly be hung at either of its extremities, without its bending; for the largest weight put upon it seldom exceeds one dram. The whole surface of this beam must be altogether without ornaments, which only increase the weight and gather dust, &c. The beam is suspended, in a fork, the two legs of which are steel springs joined at top, but kept together below with a brass joint clasp, parallel, and two lines and a half distant from each other. This clasp being taken off, and the legs of the fork being stretched out, the axis of the beam may be put into two holes made for that purpose at the ends of the legs, or be taken away from them. Let a very sharp needle be fixed in the head of the fork, standing perpendicularly downwards, if the fork is suspended, and so long, as that it may almost touch the top of the tongue of the beam put into the fork when in equilibrium. This needle is the mark of the equilibrium; and, that the artists may be able to observe this, the legs of the fork must be broader in that place, and have an opening two or three lines wide; this fork may be adorned at pleasure, provided the motion of the balance is not hindered by such ornaments: then take two scales made of thin plate of silver, one inch and a half in diameter, hanging on three small silk fringes, almost as long as the beam, tied together at top, with a silver hook in form of an S, and hang them to the extremities of the beam: a smaller silver dish, or blued steel, somewhat less than one inch in diameter, belongs to each of these scales. You first put into these dishes, with a pair of pincers, the bodies to be weighed, or with a spoon or a small shovel, when they are pounded, and then you put them into the scales; therefore the small dishes

Balance.

dishes must be perfectly equal in weight. We use them, that bodies may be more conveniently put into and taken out of the scales, and that these, which are vastly thin, may not be bent or soiled, and thence rendered false by wiping.

This balance is suspended on a moveable brads or copper support, which consists of a pedestal, and of a column set upon it about 20 inches high, at the top of which comes out at right angles an arm one inch long. At the extremity of this arm, put a small pulley three lines in diameter, another at the top of the column, and a third near the bottom of it; all which pulleys must turn very easily on their axis. At the distance of one inch and a half below the upper arm, let another arm one inch and a half long come out of the column at right angles, having a hole through it two lines long, a quarter of a line broad, and placed perpendicularly below the pulley of the upper arm, to receive a small plate, one inch and a half long; and of such breadth and thickness, as that it may freely move up and down, and yet not have too much play within the hole. This plate must also have a small hook at each extremity.

And as such a balance will hardly stand still in the open air, and becomes false when spoiled with dust; it must be put, together with its support, into a small case as represented in fig. 8. having glasses, a, a, a , at top and all round it, that you may see what is within.

Manner of using the assay BALANCE.—Pass a silk string over the three pulleys of the support, and tie it at its upper extremity to the small hook introduced into the hole of the inferior arm; then put the support in the middle of the small case, and pass the other extremity of the silk string below, through a hole bored in the middle of the lower part of the frame, containing the window in the forepart of the case, and fasten it to a small weight of a cubic form. Suspend the fork of the balance on the inferior hook of the plate. By this means if you move backwards and forwards the weight fastened to the string, placed upon the top of the drawer jutting out beyond the forepart of the case, the balance within is either lifted up, or let down. But you must put the bodies to be weighed, and the weights themselves, in the small silver dishes; and these, when loaded, into the scales, through the side-windows, which must be opened for that purpose. When any thing is to be added to or taken out of them, you do it with the small pincers; or, if it is powder, with the small shovel or spoon: but you must let the balance down every time any thing is to be added or taken away, that the scales may rest upon the bottom of the case; and shut the windows before the balance is lifted up again, especially if the air is not perfectly calm.

Hydrostatic BALANCE, an instrument contrived to determine accurately the specific gravity of both solid and fluid bodies. It is constructed in various forms; but we shall content ourselves here with describing that which appears of all others the most accurate.

VCG, (fig. 6.) is the stand or pillar of this hydrostatic balance, which is to be fixed in a table. From the top A, hangs, by two silk strings, the horizontal bar BB, from which is suspended, by a ring s , the fine beam of a balance b ; which is prevented from descending too low on either side by the gently springing piece $txyz$, fixed on the support M. The harness is annulated

Balance.

at o , to shew distinctly the perpendicular position of the examen, by the small pointed index fixed above it.

The strings by which the balance is suspended, passing over two pulleys, one on each side the piece at A, go down to the bottom on the other side, and are hung over the hook at v ; which hook, by means of a screw P, is moveable, about one inch and a quarter, backward and forward, and therefore the balance may be raised or depressed so much. But if a greater elevation or depression be required, the sliding piece S, which carries the screw P, is readily moved to any part of the square brads rod VK, and fixed by means of a screw.

The motion of the balance being thus adjusted, the rest of the apparatus is as follows. HH is a small board, fixed upon the piece D, under the scales d and c , and is moveable up and down in a long slit in the pillar above C, and fastened at any part by a screw behind. From the point in the middle of the bottom of each scale hangs, by a fine hook, a brads wire ad and ac . These pass through two holes nm in the table. To the wire ad is suspended a curious cylindrical wire, rs , perforated at each end for that purpose: this wire rs is covered with paper, graduated by equal divisions, and is about five inches long.

In the corner of the board at E, is fixed a brads tube, on which a round wire bl is so adapted as to move neither too tight nor too free, by its flat head I. Upon the lower part of this moves another tube Q, which has sufficient friction to make it remain in any position required: to this is fixed an index T, moving horizontally when the wire bl is turned about, and therefore may be easily set to the graduated wire rs . To the lower end of the wire rs hangs a weight L; and to that a wire pn , with a small brads ball g about one-fourth of an inch diameter. On the other side, to the wire ac , hangs a large glass-bubble R, by a horse-hair.

Let us first suppose the weight L taken away, and the wire pn suspended from S; and, on the other side, let the bubble R be taken away, and the weight F suspended at c , in its room. This weight F we suppose to be sufficient to keep the several parts hanging to the other scale in equilibrium; at the same time that the middle point of the wire pn is at the surface of the water in the vessel N. The wire pn is to be of such a size, that the length of one inch shall weigh four grains.

Now it is evident, since brads is eight times heavier than water, that for every inch the wire sinks in the water it will become half a grain lighter, and half a grain heavier for every inch it rises out of the water: consequently, by sinking two inches below the middle point, or rising two inches above it, the wire will become one grain lighter or heavier. Therefore, if, when the middle point is at the surface of the water in equilibrium, the index T be set to the middle point a of the graduated wire rs , and the distance on each side ar and as contains 100 equal parts; then, in weighing bodies the weight is required to the hundredth part of a grain, it may be easily had by proceeding in the following manner.

Let the body to be weighed be placed in the scale d . Put the weight X in the scale c ; and let this be so determined, that one grain more shall be too much, and one grain less too little. Then the balance being moved gently up or down, by the screw P, till the equilibrium be nicely shewn at o ; if the index T be at the

Balance
||
Balayan.

middle point *a* of the wire *r*, it shews that the weights put into the scale *e* are just equal to the weight of the body. By this method we find the absolute weight of the body: the relative weight is found by weighing it hydrostatically in water, as follows.

Instead of putting the body into the scale *e*, as before, let it hang with the weight *F*, at the hook *c*, by a horse-hair, as at *R*, supposing the vessel *O* of water were made. The equilibrium being then away, the index *T* standing between *a* and *r*, at the 36 division, shews the weight of the body put in to be 1095.36 grains. As it thus hangs, let it be immersed in the water of the vessel *O*, and it will become much lighter: the scale *e* will descend till the beam of the balance rest on the support *z*. Then suppose 100 grains put into the scale *d* restore the equilibrium precisely, so that the index *T* stand at the 36 division above *a*; it is evident that the weight of an equal bulk of water would, in this case, be exactly 100 grains.

After a like manner this balance may be applied to find the specific gravity of liquids, as is easy to conceive from what has been said.

BALANCE of Trade. That which is commonly meant by the balance of trade, is the equal importing of foreign commodities with the exporting of the native. And it is reckoned that nation has the advantage in the balance of trade, which exports more of the native commodities, and imports less of the foreign. The reason of this is, that, if the native commodities be of a greater value than are exported, the balance of that account must be made up in bullion or money; and the nation grows so much richer, as the balance of that account amounts to.

BALANCE of a Clock, or Watch, is that part which regulates the beats *.

BALANCE-Fish. See **SQUALUS**.

BALANCER, in the history of insects, a style, or oblong body, ending in a protuberance or head, found under each wing of the two-winged flies; these serve to poise the body of the fly.

BALANCING, among seamen, the contracting a sail into a narrower compass, in a storm, by retrenching, or folding up a part of it at one corner: this method is used in contradistinction to reefing, which is common to all the principal sails; whereas balancing is peculiar to few, such as the mizen of a ship, and the main-sail of those vessels wherein it is extended by a boom. See **BOOM** and **REEF**.—The balance of the mizen is thus performed: the mizen yard is lowered a little, then a small portion of the sail is rolled up at the peak or upper corner, and fastened to the yard about one fifth inward from the outer end or yard arm toward the mast. See **MIZEN**.—A boom main-sail is balanced, after all its reefs are taken in, by rolling up a similar portion of the hindmost or utmost lower corner called the *clue*, and fastening it strongly to the boom, having previously wrapped a piece of old canvas round the part (which is done in both cases) to prevent the sail from being fretted by the cord which fastens it.

BALANUS, in zoology, the trivial name of a species of *lepas*. See **LEPAS**.

BALAUSTIA, in botany. See **PUNICA**.

BALAYAN, a province of the island of Manila in the East Indies, belonging to the Spaniards.—It lies

next to the city of Manila, and extends along the coast on the east side of the island, a little beyond the bay of Batangas. There were formerly gold mines in it, but they have been long since abandoned. It is inhabited by about 2500 tributary Indians, and abounds in cotton, rice, and palm-trees. The province is well cultivated; and the Spaniards, generally speaking, have country-houses in it.

BALBASTRO, an episcopal town of Spain, in the kingdom of Arragon, and capital of a district of the same name. E. Long. *o.* 20. N. Lat. 41. 50.

BALBEC, a city of Asia, in Syria, anciently called *Heliopolis*, and by the Arabians the *wonder of Syria*.

It is now, however, remarkable only for its ruins *.

BALBINUS (*Decimus Cælius*), the Roman emperor, being chosen by the senate in 237, was massacred by the soldiers, who had a dislike to such emperors as were elected only by the senators. This prince was eloquent, and wrote pretty good verses.

BALBOA (*Vasco Nugnes de*), a Castilian; a celebrated navigator, and one of the first discoverers of South America. He was beheaded by the Spanish governor of St Mary, through jealousy of his growing reputation, in 1517, aged 42.

BALBUS (*Lucius Cornelius Theophanes*) was born at Cadiz, and distinguished himself by his valour in the war carried on by the Romans in Spain against Sertorius and the Lusitanians, on which account Pompey gave him the privileges of a Roman citizen. He was consul in the 714th year of Rome, and was the first foreigner on whom that dignity was conferred. He was the friend of Pompey, Cæsar, Crassus, and Cicero.—There were many other illustrious Romans of the name of *Balbus*.

BALCONY, in architecture, a projection in the front of a house, or other building, supported by pillars or consoles, and encompassed with a balustrade.

BALDACHIN, or **BALDAQUIN**, in architecture, a building in form of a canopy, supported by pillars, and frequently used as a covering to insulated altars. Some also use the term *baldachin* for the shell over a door.

BALDINUCCI (*Philip*), of Florence; a connoisseur in the polite arts, and the continuator of Vasar's lives of the painters. He died in 1696, aged 72.

BALDIVIA, or **VALDIVIA**, a sea-port town of Chili, in America, belonging to the Spaniards. It is situated between the rivers Callacules and Portero, where they fall into the fourth sea. W. Long. 80. 5. S. Lat. 40. 5. It was built in 1551 by the Spanish general Baldivia, from whom it takes its name. We may judge of its importance from the sum granted annually by the king for maintaining the garrison, and keeping the fortifications in repair, being no less than 300,000 pieces of eight. It is defended by four strong castles, mounting 100 pieces of fine brass cannon. Notwithstanding which, however, as the garrison is composed mostly of transported criminals, on whom no dependance can be placed, and generally ill supplied with ammunition, &c. it could make but a poor defence. In 1643 it was easily taken by the Dutch, who would probably have maintained their conquest against all the power of the Spanish viceroy, had they not been obliged to relinquish it through sickness and famine. The inhabitants of Baldivia amount to about 2000.

Baldness
Bale.

The trade is less considerable than formerly, because the gold mines in the neighbourhood are shut up; yet several large ships are employed in the trade between this port and that of Lima, which consists of gold, corn, hides, and salt provisions, which are exchanged for slaves, sugar, chocolate, and European commodities and manufactures.

BALDNESS, a defect of hair, chiefly on the sinciput. It differs from *alopecia*, *areæ*, *opisthæ*, and *tinea*, as these all arise from some vice in the nutritious humour; *baldness*, from the defect of it. When the eyelids shed their hair, it is called a *ptilosis*. Among the causes of baldness, immoderate venery is reputed one of the chief: old age usually brings it on of course. Some will have the proximate cause of baldness to be the dryness of the brain, and its shrinking from the cranium; it having been observed, that in bald persons there is always a vacuity or empty space between the skull and the brain.—*Calvus*, *bald-pate*, was a frequent term of reproach among the Romans; among whom this defect was in great disrepute. Hence divers arts to conceal it, as false hair, a *galericulus* contrived on purpose. The later Romans, however, seem to have been reconciled to baldness; for we find among them a kind of officers, or servants, called *glabratores*, or *glabrarii*, whose business was to take off the hair from all parts, even from the head. In an ancient inscription, there is mention of one Diophantus, T. I. CÆSARIS ORNATOR GLABR. that is, *ornator Glabrarius*.

BALDOC, a town of Herefordshire, in England, chiefly noted for its trading in malt. W. Long, o. 10. N. Lat. 51. 55.

BALDOCK (Ralph de), bishop of London in the reigns of Edward I. and II. was educated at Moreton-college, in Oxford; became dean of St Paul's; and afterwards promoted to the see of London; and at last was made lord high chancellor of England. He had a very amiable character both for morals and learning; and wrote *Historia Anglica*, or An History of the British Affairs down to his own Time; and, A Collection of the Statutes and Constitutions of the church of St Paul. Bishop Baldock died at Stepney, July 24. 1313.

BALDWIN, archbishop of Canterbury, was born of obscure parents at Exeter, where, in the early part of his life, he taught a grammar-school; after which he took orders, and was made archdeacon of Exeter: but he resigned that dignity, and became a Cistercian monk in the monastery of Ford in Devonshire, of which in a few years he was made abbot. In the year 1180, he was consecrated bishop of Worcester. In 1184, he was promoted to the see of Canterbury by Pope Lucius III. and, by his successor Urban III. was appointed legate for that diocese. He laid the foundation of a church and monastery in honour of Thomas Becket, at Hackington, near Canterbury, for secular priests; but, being opposed by the monks of Canterbury and the Pope, was obliged to desist. In 1190 he crowned king Richard I. at Westminster; and soon after followed that prince to the Holy land, where he died at the siege of Ptolemais. Giraldus Cambrensis, who accompanied him in this expedition, says he was of a mild disposition, and of great abstinence. He wrote various tracts on religious subjects, which were collected and published by Bertrand Tiffier in 1662.

BALE (John), bishop of Ossory in Ireland, was

born at Cove, near Dunwich in Suffolk, in the year 1495. At 12 years of age he was entered in the monastery of Carmelites at Norwich, and was thence sent to Jesus-college in Oxford. He was educated a Roman catholic, but was converted to the Protestant religion by Thomas lord Wentworth. On the death of lord Cromwell, favourite of Henry VIII. who protected him from the persecutions of the Romish clergy, he was obliged to retire into the Low Countries, where he continued eight years. Soon after the accession of Edward VI. he was recalled; and being first presented to the living of Bishop's-Stocke in Hampshire, in 1552, he was nominated to the see of Ossory. During his residence in Ireland he was remarkably assiduous in propagating the Protestant doctrines; and to very little purpose, and frequently at the hazard of his life. Once, in particular, they murdered five of his domestics, who were making hay in a meadow near his house; and would probably have done the same by him, if the sovereign of Kilkenny had not come to his assistance with 100 horse and 300 foot. On the accession of Queen Mary, the tide of opposition became so powerful, that, to avoid assassination, he embarked for Holland, but was very unfortunate in his escape. First he was taken by a Dutch man of war, and robbed by the captain of all his effects. Then, being forced by stress of weather into St Ives in Cornwall, he was confined on suspicion of treason. Being however released after a few days confinement, the ship anchored in Dover road, where he was again seized on a false accusation. After his arrival in Holland, he was kept prisoner for three weeks, and at length obtained his liberty on paying 30 l. From Holland he travelled to Basil in Switzerland, where he continued till Queen Elizabeth ascended the throne. After his return to England, he was, in 1560, made prebendary of Canterbury, probably not chusing to return to his former flock of wolves. He died in November 1563, at Canterbury, in the 68th year of his age. He was so severe a writer against the church of Rome, that his books are particularly prohibited in the expurgatory index published at Madrid, in folio, in the year 1667. He is the earliest dramatic writer in the English language, or at least author of the first pieces of that kind that we find in print. Of his writings in that way, no fewer than 21 have been enumerated; only 3 of them, however, have been seen in print, viz. 1. God's promises, an interlude; 2. St John Baptist, an interlude; 3. Concerning the laws of nature corrupted: the first of which has been reprinted by Doddsley in the first volume of his collection of old plays, and the only copy extant of the last is preserved in St Sepulchre's library in Dublin. As to the rest, they are mentioned by himself, as his own, in his account of the writers of Britain before mentioned.—He also translated the tragedies of Pammachius.—His other works are very numerous; but the chief is his Catalogue of British authors: a book of some merit, as it contains some information which is not elsewhere to be found; but he has destroyed his credit by his intemperate Billingigate abuse of all those who differed from him in religion. The authentic part of his work is transcribed from Leland. The title of it is, *Illustrium Majoris Britanniae scriptorum catalogus, a Japheto sanctissimi Noah filio ad an. Dom. 1557.*

BALE, in commerce. Any goods packed up in cloth, and

Bale.

Bale
Balk.

and corded round very tight, in order to keep them from breaking, or preserve them from the weather; is called a *bale*.—A bale of cotton yarn is from 300 to 400 weight; of raw silk, is from 100 to 400; of lockram or dowlaps, either three, three and a half, or four pieces.

Bale-Goods, among the English merchants, are all such as are imported or exported in bales; but the French give that name to certain hard-wares, and other sorts of merchandize, which come to Paris, and are commonly made by bad workmen, of indifferent materials.

BALEARIC ISLANDS, the ancient name of the islands Majorca, Minorca, and Ivica, in the Mediterranean. See *MAJORCA*, &c.

BALEY (Walter), the son of Henry Baley of Warrnell in Dorsetshire, was born at Potsham in the same county, and educated at Winchester school. From thence he was sent to Oxford; and, after two years probation, was admitted perpetual fellow of New college in the year 1550. Having taken his degrees in arts, he practised physic, and in 1558 was proctor of the university. About this time he obtained a prebend of Wells, which he resigned in 1579. In the year 1561 he was appointed queen's professor of physic, in 1563 proceeded doctor in that faculty, and afterwards became one of her majesty's physicians in ordinary. He was thought skilful in his profession, and had considerable practice. He died in 1592, aged 63; and was buried in the inner chapel of New college. His works are, 1. *A discourse of three kinds of pepper in common use*, 1588, 8vo. 2. *Brief treatise of the preservation of the eye-sight*. First printed in the reign of Elizabeth, in 12mo; afterwards at Oxford in 1616, and 1654, 8vo. 3. *Directions for health, natural and artificial; with medicines for all diseases of the eyes*, 1626, 4to. 4. *Explicatio Galeni de potu convalescentium et senum*, &c. Manuscript, formerly in lord Aylebury's library.

BALI, an island of Asia, in the East Indies, forming the north side of the straits of Java, through which the East-India ships sometimes return from China to Europe: but the passage is commonly difficult on account of contrary winds. The island is extremely populous, and abounds in rice and other productions proper to the climate. The inhabitants are Pagans, and very warlike. E. Long. 115. 30. S. Lat. 9. 0.

BALIOL, or **BALLIOL**, (Sir John de), founder of Baliol-college, in Oxford, was the son of Hugh Baliol, of Bernard's castle, in the diocese of Durham; and was a person very eminent for his power and riches. During the contentions and wars between King Henry III. and his barons, he firmly adhered to the king. In 1263, he began the foundation and endowment of Baliol-college, which was afterwards perfected by his widow. He died in the year 1269.

BALIOL, **BALLIOL**, or **BOILLIOL**, (John), the brother of Alexander king of Scotland, and competitor with Robert Bruce for that crown*.

BALISORE, a sea-port town of Asia, in the East Indies, to the north-west of the bay of Bengal. It is about four miles from the sea by land, but 20 by the river; seated in a very fruitful soil producing rice, wheat, aromatic seeds, tobacco, &c. The inhabitants make several sorts of stuffs of cotton, silk, and a kind

Balistes
Balk.

of grass. The English, French, and Dutch, have factories here; but they are now of no great account. E. Long. 85. 20. N. Lat. 21. 30.

BALISTES, in ichthyology, a genus of fishes belonging to the order of amphibia nantes. The characters are these: the head is flat; there are eight teeth in each side, and the two anterior ones are longest; in the place of gills, the balistes has an aperture immediately above the pectoral fins; the body is flat, the scales are joined together by the skin, and the belly is keeled. The species of this genus are eight; viz.

1. The monoceros, whose head-fin consists of but one ray, and the tail-rays are carinated. It is called the *unicorn-fish* by Catfish; who informs us, that the guts of this fish are full of small shells and coralline substances, which by the strength and hardness of its jaws it is enabled to ground very small. These fish, he adds, are not eat, being accounted poisonous. They most frequent those seas, amongst the Bahama islands, where the corals are in greatest plenty. 2. The hippidus, whose head-fin is uniradiated; and there is a round black spot in the tail-fin. The body is rough, and bristly towards the tail. The spine or horn is situated between the eyes; the snout is subulated; and instead of a belly-fin, it has a jagged sharp spine. This species is a native of Carolina. 3. The tomentosus, whose head-fin is biradiated, and the body of it towards the hind part is hairy. It is a native of America. 4. The papillosus, has a biradiated back-fin, and a papillous body. 5. The verrucosus, has a triradiated back-fin; and the tail is full of little warts. In the place of a belly-fin, this species has a large, thick, warty ray. It has 25 small reversed sharp spines at the side of the tail, disposed in four rows. It is a native of India. 6. The aculeatus has a triradiated back-fin; and the spines of the tail lean upon each other. It is also a native of India. 7. The vetula, or old-wife, has a triradiated back-fin; the belly-fin is longitudinal, and somewhat carinated; and the tail-fin is forked. It is found at Ascension island. 8. The ringens, has a triradiated back-fin; there are three folds on each side of the head, and the tail-fin is forked. This species is likewise found at Ascension island.

BALIVO AMOVENDO, in law, was a writ for removing a bailiff from his office, for want of having sufficient land in his bailwick to answer the king and his people, according to the statute of Westminister, 2 reg. Orig. 78.

BALK, among builders, is sometimes used for the summer-beam of a house; sometimes for the poles and rafters, which support the roofs of barns, &c.; and sometimes for the beams used in making sea-holds.

BALK, or **BALKH**, a province of Great Bukharia in Asia, about 360 miles long, and 250 broad, situated to the south of the province of Samarkand, and to the east of Bukharia Proper. It is the least of the three provinces that make up what is called *Great Bukharia*; but being extremely fertile and well cultivated, the prince draws a great revenue from it. The country particularly abounds with silk, of which the inhabitants make pretty manufactures. The Uzbecks subject to the khan of Balkh are the most civilized of all the Tartars inhabiting Great Bukharia, owing probably to their commerce with the Persians: they are likewise more industrious, and more honest, than the rest;

Plate I. VI.
fig. 2.

Fig. 3.

* See the article Scotland.

ref; but in other respects have the same customs with the rest of the Tartars. The province is subdivided into several counties; the most remarkable of which are Khotlan, or Katlan, Tokharestan, and Badaghsan. Its chief cities are Balk, Fariyab, Talkhan, Badaghsan, and Anderab.

BALK, the capital of the abovementioned province, situated on the frontiers of Persia, in E. Long. 65. 20. N. Lat. 37. 0. It is probably the ancient Bactra, capital of the kingdom of Bactria; and is said by the Persians to have been founded by Kay-umarraz the first king of Persia, because he met his brother upon the spot where it stood, after he had been lost for a long time; *balghiden*, or *balghiden*, in the Persian language, signifying to receive and embrace a friend. The first kings of Persia who resided in the province of Media or *Aderbijan*, considered this city as one of their principal frontiers on the side of Scythia. In the 27th year of the Hegira, of Christ 647, Balk was reduced by the Arabs, under the command of Abdallah Ebn Amer. It continued subject to Arab princes till the year of the Hegira 432, of Christ 1041; when it was reduced by Togrol Beg, the Tangrolipix of the Greeks, and prince of the Seljukian dynasty. It was taken by Jenghiz Khan, A. D. 1221, who with his usual and unparalleled cruelty caused all the inhabitants to be brought without the walls and massacred without mercy. In 1369, Sultan Hofcin the last of the race of Jenghiz Khan was driven from Balkh by Tamerlane, whose successors were driven out by the Uzbecks in the 15th century. It was afterwards redeemed by Shah Ismael Suî; but finally wrested out of his hands by the Uzbek Tartars, between whom and the Persians it is the occasion of almost continual wars. It was, not long since, the residence of a khan of Tartars. It is the most considerable city possessed in these parts by the Mahometan Tartars, is large, well built, and populous, the houses consisting for the most part of stone or brick. The fortifications consist of bulwarks of earth, fenced without with a strong wall high enough to cover the soldiers employed in defence of those fortifications. As this place is the resort of all the business transacted between the Indies and Great Bukharia, trade flourishes extremely at Balkh; especially as it has a fine river passing through its suburbs, which is of vast service to the town. This river falls into the Amu, in N. Lat. 38. 30. upon the confines of Great Bukharia and Kowarazm. The khan's palace, or castle, is a large edifice built after the oriental manner; and consists almost entirely of marble, of which there are fine quarries in the neighbourhood. The khan of Balk, however, was obliged in 1739 to submit to the Persians under Khoulî Kan; but, since that time, has most probably regained his independency.

BALKERS, in the fishery, persons placed on rocks, and eminences at sea, to spy the herring droves, and give notice to the fishermen, by waving boughs, what way they go, and where they may be found.

BALL, in a general sense, a spherical and round body, whether naturally so, or formed into that figure by art.

BALL, in the military art, comprehends all sorts of bullets for fire-arms, from the cannon to the pistol. Cannon-balls are of iron; musquet-balls, pistol-balls, &c. are of lead. The experiment has been tried of

iron balls for pistols and fuses; but they are justly rejected, not only on account of their lightness, which prevents them from flying straight, but because they are apt to furore the barrel of the pistol, &c.

BALL, in pyrotechnics, is also a composition of various combustible ingredients, serving to burn, smoke, give light, &c. In this sense we read of fire-balls, light-balls, smoke-balls, stink-balls, sky-balls, water-balls, land-balls.

Fire-BALLS, are bags of canvas filled with gun-powder, sulphur, salt-petre, pitch, &c. to be thrown by the soldiers, or out of mortars, in order to fire the houses, incommode trenches, advanced posts, or the like.—The Greeks had divers kinds of fire-balls, or *Πυροβολοι* *λιθοι*; one kind called, more particularly, *αυλιαντα*, or *αυλιαντις*, made of wood, sometimes a foot or even a cubit long; their heads being armed with spikes of iron, beneath which were hemp, pitch, and other combustibles, which being set on fire, they were cast among the enemy. The preparations of fire-balls, among the moderns, consists of several operations, *viz.* making the bag, preparing the composition, tying, and, lastly, dipping the ball. 1. The bags for this purpose are either oval or round. 2. The composition wherewith fire-balls are filled, is various: To ten pounds of meal-gunpowder add two of salt-petre, one of sulphur, and one of colophony; or, to six pounds of gunpowder, add four of salt-petre, four of sulphur, one of powdered glass, half a pound of antimony, as much camphor, an ounce of sal-ammoniac, and four of common salt, all pulverised. Sometimes they even fill fire-balls with hard granadoes. 3. For tying the fire-balls, they prepare two iron rings, one fitted round the aperture, where the ball is to be lighted, the other near its base. A cord is tied to these rings in such a manner, as that the several turns represent semicircles of the sphere cutting the globe thro' the poles: over the cords, extended according to the length of the ball, others are tied, cutting the former at right angles, and parallel to each other, making a knot at each intersection: lastly, after putting in a leaden-bullet, the rest of the space is filled with tow or paper. 4. Thus completed, the fire-ball remains to be dipped in a composition of melted pitch four pounds, colophony two, and linseed oil or oil of turpentine two; after dipping, they cover it round with tow, and dip again, till it be brought to the just diameter required.

Light BALLS, are such as diffuse an intense light around; or they are balls which, being cast out of the hand or a mortar, burn for some time, and illuminate the adjacent parts. 1. Luminous or light-balls for the hand, are made of ground powder, salt-petre, brimstone, camphor, and borax, all sprinkled with oil, and moulded into a mass with suet; and this is wrapped up in tow, with a sheet of strong paper over it. To fire it, they make a hole into it with a bodkin, into which they put some priming that will burn slow. Its use is to be cast into any works they would discover in the night-time. 2. For the larger light-balls, or those to be thrown to a greater distance, they melt equal quantities of sulphur, turpentine, and pitch; and herein dip an earthen or stone-ball, of a diameter much less than that of the mortar out of which the fire-ball is to be cast: then rolling it in gun-powder, and covering it round with gauze, they dip it again, and

and repeat the rest till it come to fit the cavity of the mortar: lastly, they sprinkle it around with gun-powder. This, being once kindled, will strongly illuminate all around the place where it is thrown, and give opportunity to examine the state and condition thereof.

Smoke or Dark BALLS, those which fill the air with smoke, and thus darken a place to prevent discoveries. To prepare a darkening ball, make an oval or spherical bag, melt rosin over the coals, and add an equal part of salt-petre not purified, also of sulphur, and a fifth part of charcoal. The whole being well incorporated, put in tow first shred, and fill the bags with this composition, and dip it after the same manner as a fire-ball.

Stink-BALLS, those which yield a great stench where fired to annoy the enemy. Their preparation is thus: Melt ten pounds of pitch, six of rosin, twenty of salt-petre, eight of gun-powder, and four of colophony; to these add two of charcoal, six of horse-hoofs cut small, three of assa-fœtida, one of stinking saracens, and any other offensive ingredients. The rest is in the former.

Sky-BALLS, those cast on high out of mortars, and which, when arrived at their height, bursting like rockets, afford a spectacle of decoration. Sky-balls are made of a wooden shell, filled with various compositions, particularly that of the stars of rockets. These are sometimes intermixed with crackers and other combustibles, making rains of fire, &c.

Water-BALLS, those which swim and burn a considerable time in the water, and at length burst therein. These are made in a wooden shell, the cavity of which is filled with refined salt-petre, sulphur, saw-dust boiled in water of salt-petre, and dried; to which sometimes other ingredients are added, as iron filings, Greek pitch, amber dust, powdered glass, and camphor. The ingredients are to be ground, mixed up, and moistened with linseed oil, nut oil, olive oil, hempseed oil, or petrol. At the bottom is placed an iron coffin, filled with whole gunpowder, that the ball may at last burst with a greater noise: and, lastly, the ball is, by the addition of lead or otherwise, made of the same specific gravity with water.

Land-BALLS are those which, being thrown out of a mortar, fall to the ground, burn, and burst there. The ingredients are much the same as in the *water-balls*, only the specific gravity is not attended to.

BALL of a Pendulum, the weight at the bottom. In shorter pendulums, this is called the *bob*.

BALL, among the Cornish miners, signifies a tinmine.

BALL, among printers, a kind of wooden tunnel stuffed with wool, contained in a leather cover, which is nailed to the wood, with which the ink is applied on the forms to be wrought off. See *PRINTING*.

Horse-BALLS, among farriers. Horses have a very nice taste; it is therefore proper to give the more disagreeable drugs in the form of balls, and to make drenches of the more palatable. Balls should be of an oval shape, not exceeding the size of a pullet's egg; and should be dipped in sweet oil to make them slip down the easier. Some horses have a strait gullet, which makes them very averse to a ball being thrust down their throats; such horses had better have drenches given them, or their medicines may be mixed with

bran, or in their mashes. See *FARRIERY, passim*.

BALL Vein, in mineralogy, a name given by the miners of Suffex to a sort of iron ore, common there, and wrought to considerable advantage. It yields not any great quantity of metal, but what it has runs freely in the fire; it is usually found in loose masses, not in the form of a stratum, and is often covered with one or more crusts. It generally contains some sparkling particles; and is usually of a circular form in the perfect masses, thickest in the middle, and gradually thinner as it approaches the sides. The ores of Suffex in general are poor, but they require very little trouble in the working; so that a considerable profit is made annually from them.

BALL and Socket is an instrument made of brass, with a perpetual screw, so as to move horizontally, vertically, and obliquely; and is generally used for the managing of surveying and astronomical instruments.

Puff-BALL, the English name of the lycoperdon*. *Martial BALLS*, in pharmacy, are a mixture of filings of iron and of cream of tartar, formed into a solid consistence and form of a ball, which is used to impregnate water or other liquids with iron dissolved by the tartareous acid. To make these balls, one part of filings of iron and two parts powdered cream of tartar are mixed well together, and put into an earthen or iron vessel with some water. This mixture is to be stirred from time to time, till it becomes almost dry; and then it is to receive more water, and to be stirred as before. This treatment is to be continued till it acquires, when nearly dry, somewhat of the consistence and tenacity of softened rosin. Then it is to be rolled up into the form of a ball, which is generally kept tied up in a rag; and when intended to be used, it is to be infused in water, till it gives some colour to that liquid. The infusion of martial balls is tonic, vulnerary, discutient, and appetitive; and is employed both internally and externally*.

Iron being soluble in all acids, is attacked in this preparation by the tartareous acid, which reduces it to a kind of neutral salt not crystallizable. This salt would remain liquid, and would form a soluble martial tartar, called *tartarised tincture of Mars*. If proper proportions of filings of iron and cream of tartar be used, and treated long enough for an entire and complete combination, nothing would be obtained but a liquor or magma, which could not be preferred in a solid form, but would be continually moist. Therefore, in the martial ball there is a good deal of the cream of tartar and filings of iron not combined together, by which its solidity is preserved.

Mercurial BALLS, in pharmacy, are an amalgam of mercury and tin, sufficiently solid to be moulded, and to preserve a given form. The method of making them is by adding mercury to melted tin, and pouring the fluid mass into a round hollow mould.—These balls are employed to purify water, in which they are boiled; for which purpose travellers often carry some along with them. Nothing, however, can be more pernicious than such a practice, should the water contain any nitrous acid, which it very often does.

BALLS of Silk-worms and Spiders, are little cases or cones woven of silk, wherein those insects deposit their eggs. Spiders are extremely tender of their balls, which they carry about with them, adhering to the papillæ about

* See *Lycoperdon*.* See *Iron*.

Ballaghan
Ball.

about their anus. Grew mentions balls or bags of a species of silk-worms in Virginia, as big as hens eggs, and containing each four aurelias.

Zoologists speak of a sort of balls of hair covered over with a smooth shining coat, or shell, found in the stomachs of oxen, cows, calves, horses, sheep, and goats. See the article BEZOAR.

BALLAGHAN, a town of Ireland, in the county of Sligo, and province of Connaught. W. Long. 9. 50. N. Lat. 53. 48.

BALLAN, a town of France in the diocese of Mons, with the title of a marquise, seated on the river Orne. E. Long. 0. 20. N. Lat. 48. 10.

BALLAD, or **BALLET**, a kind of song, adapted to the capacity of the lower class of people; who, being mightily taken with this species of poetry, are thereby not a little influenced in the conduct of their lives. Hence we find, that seditious and designing men never fail to spread ballads among the people, with a view to gain them over to their side.

BALLAST, any heavy matter, as stones, gravel, iron, &c. thrown into the hold of a ship, in order to make her sink a proper depth in the water, that she may be capable of carrying a sufficient quantity of sail without oversetting.

There is often great difference in the proportion of ballast required to prepare ships of equal burden for a voyage; the quantity being always more or less, according to the sharpness or flatness of the ship's bottom, which seamen call the *floor*.

The knowledge of ballasting a ship with propriety, is certainly an article that deserves the attention of the skilful mariner: for although it is known, that ships in general will not carry a sufficient quantity of sail till they are laden so deep that the surface of the water will nearly glance on the extreme breadth amidships, yet there is more than this general knowledge required; since, if she has a great weight of heavy ballast, as lead, iron, &c. in the bottom, it will place the centre of gravity too low in the hold; and although this will enable her to carry a great sail, she will nevertheless sail very heavily, and run the risk of being dismasted by her violent rolling.

To ballast a ship, therefore, is the art of disposing those materials so that she may be duly poised, and maintain a proper equilibrium on the water, so as neither to be too *stiff*, nor too *crank*, qualities equally pernicious: as in the first, although the ship may be fitted to carry a great sail, yet her velocity will not be proportionably increased; whilst her masts are more endangered by her sudden jerks and excessive labouring; and in the last, she will be incapable of carrying sail, without the risk of oversetting.

Stiffness in ballasting, is occasioned by disposing a great quantity of heavy ballast, as lead, iron, &c. in the bottom, which naturally places the centre of gravity very near the keel; and that being the centre about which the vibrations are made, the lower it is placed, the more violent will be the motion of rolling.

Crankness, on the other hand, is occasioned by having too little ballast, or by disposing the ship's lading so as to raise the centre of gravity too high, which also endangers the mast in carrying sail when it blows hard: for when the masts lose their perpendicular height, they strain on the shrouds in the nature of a lever, which in-

VOL. II.

Ballatoons
Ballet.

creases as the sine of their obliquity; and a ship that loses her masts is in great danger of being lost.

The whole art of ballasting, therefore, consists in placing the centre of the gravity to correspond with the trim and shape of the vessel, so as neither to be too high nor too low; neither too far forward, nor too far aft; and to lade the ship so deep, that the surface of the water may nearly rise to the extreme breadth amidships; and thus she will be enabled to carry a good sail, incline but little, and ply well to the windward.

Ships are said to be *in ballast*, when they have no other loading. Masters of vessels are obliged to declare the quantity of ballast they bear, and to unload it at certain places. They are prohibited unloading their ballast in havens, roads, &c. the neglect of which has ruined many excellent ports.—Ships and vessels taking in ballast in the river Thames, are to pay for much a tun to Trinity-house, Deptford; who shall employ ballastmen, and regulate them; and their lighters to be marked, &c. on pain of 10l.

BALLATOONS, large heavy luggage-boats used for carrying wood by the river from Aitracan and the Caspian sea to Moscow. These will carry from 100 to 200 ton, and have from 100 to 120 men employed to row and tow them along.

BALLENDEN (Sir John), a Scottish poet, in the reign of James V. of Scotland, was descended from an ancient family in that kingdom. His father, Mr Thomas Ballenden of Auchinoul, was director to the chancery in the year 1540, and clerk register in 1541. Where our poet was educated, we are not informed; but from one of his poems we learn, that in his youth he had some employment at the court of king James V. and that he was in great favour with that prince. Having taken orders, and being created doctor of divinity at the Sorbonne, he was made canon of Ross, and archdeacon of Murray. He likewise obtained the place of clerk register, but was afterwards deprived of that employment by the factions of the times; however, in the succeeding reign, of Mary, he recovered that office, and was one of the lords of session. Being a zealous papist, he, in conjunction with Dr Laing, was extremely assiduous in retarding the progress of the reformation; till at last, finding the opposition too powerful, he quitted Scotland, and went to Rome, where he died in the year 1550. He is generally esteemed one of the best Scottish poets of that age. His works are, 1. *The history and chronicles of Scotland of Hector Boetius* (Boethius), translated by Mr John Ballenden. Edinb. 1536. This is not a mere translation, Ballenden having corrected several mistakes of his author, and made large additions. It is in folio, and black letter. 2. *Cosmography to the history of Scotland*, with a poetical proem. 3. *A description of Albany*. 4. *Translation of Boethius's description of Scotland*. 5. *Epistles to king James V.* Bale says he had seen these letters. 6. Several poems in Carmichael's collection of Scottish poems; besides many others in manuscript, in private libraries in Scotland. 7. *Virtue and vice*, a poem addressed to king James V.

BALLERUS, in ichthyology, the trivial name of a species of cyprinus. See **CYPRINUS**.

BALLET, **BALET**, or **BALETO**, a kind of dramatic poem, representing some fabulous action or subject divided into several entries; wherein several per-

6 G fons

sons appear, and recite things under the name of some deity, or other illustrious character.

BALLET is more particularly used for a kind of comic dance, consisting of a series of several airs of different kinds of movements, which together represent some subject or action. They are performed chiefly by masks representing sylvans, tritons, nymphs, shepherds, and the like; and consist of three parts, the entry, figure, and the retreat. The word is of Greek origin, formed from βαλλω, *jacere*, to cast, throw, or toss; whence also in writers of the middle age, we find *ballationes* for *saltationes*, dancings; and *ballare*, for *saltare*, to dance.

BALLET, in the English poetry. See BALLAD.

BALLIAGE, or BAILIAGE, in commerce, a small duty paid to the city of London by aliens, and even denizens, for certain commodities exported by them.

BALLICONNEL, a town of Ireland, in the county of Cavan and province of Ulster. W. Long. 7. 45. N. Lat. 54. 6.

BALLISHANNON, a large town of Ireland, in the county of Donegal, or Tyrconnel, with a good haven. W. Long. 8. 25. N. Lat. 54. 25.

BALLISTA, a machine used by the ancients for shooting darts; it resembled in some measure our cross-bow. The word is Latin, signifying a cross-bow; and is derived from the Greek, βάλλω, to shoot, or throw.

Vegetius informs us, that the ballista discharged darts with such rapidity and violence, that nothing could resist their force; and Athenæus adds, that Agriſtratus made one of little more than two feet in length, which shot darts 500 paces.

Plate LVI. fig. 4. represents the ballista used in sieges, according to the chevalier Folard: 2, 2, the base of the ballista; 3, 4, upright beams; 5, 6, transverse beams; 7, 7, the two capitals in the upper transverse beam, (the lower transverse beam has also two similar capitals, which cannot be seen in this transverse figure); 9, 9, two posts or supports for strengthening the transverse beams; 10, 10, two skains of cords fastened to the capitals; 11, 11, two arms inserted between the two strands, or parts of the skains; 12, a cord fastened to the two arms; 13, darts which are shot by the ballista; 14, 14, curves in the upright beams, and in the concavity of which cushions are fastened, in order to break the force of the arms which strike against them with great force when the dart is discharged; 16, the arbor of the machine, in which a groove or canal perfectly straight is formed, and in which the darts are placed in order to their being shot by the ballista; 17, the nut of the trigger; 18, the roll or windlass, about which the cord is wound; 19, an hook, by which the cord is drawn towards the centre and the ballista cocked; 20, a stage or table on which the arbor is in part sustained.

BALLISTEUM, or BALLISTÆA, in antiquity, a military song or dance used on occasions of victory. Vopiscus has preserved the *ballisteum* sung in honour of Aurelian, who, in the Sarmatian war, was said to have killed 48 of the enemy in one day with his own hand. *Mille, mille, mille, mille, mille, mille decollavit; mille, mille, mille vivat, qui mille, mille occidit. Tantum vini habet nemo, quantum fudit sanguinis.* The same writer subjoins another popular song of the same kind: *Mille Francos, mille Sarmatas, semel occidimus;*

mille, mille, mille, mille, mille Perfas quærimus. It took the denomination *ballisteum* from the Greek βάλλω, *jacere*, or *jacere*, to cast or toss, on account of the motions used in this dance, which was attended with great elevations and swiftings of the hands. The *ballistea* were a kind of popular ballads, composed by poets of the lower class, without much regard to the laws of metre.

BALLOON, or BALLON, in a general sense, signifies any spherical hollow body, of whatever matter it be composed, or for whatever purposes it be designed. Thus, with chemists, balloon denotes a round short-necked vessel, used to receive what is distilled by means of fire; in architecture, a round globe on the top of a pillar; and among engineers, a kind of bomb made of pasteboard, and played off in fire-works, either in the air or on the water, in imitation of a real bomb.

BALLOON also denotes a kind of game something resembling tennis. The balloon is played in the open field, with a great round ball of double leather blown up with wind, and thus driven to and fro with the strength of a man's arm, fortified with a brace of wood.

BALLOON, or BALLOEN, is more particularly used, among voyagers, for the state-barges of Siam. The balloons are a kind of brigantine, managed with oars, of very odd figures, as serpents, sea-horses, &c. but, by their sharpness and number of oars, of incredible swiftness. The balloons are said to be made of a single piece of timber, of uncommon length; they are raised high, and much decorated with carving at head and stern: some are gilt over, and carry 120 or even 150 rowers on each side. The oars are either plated over with silver, or gilt, or radiated with gold; and the dome or canopy in the middle, where the company is placed, is ornamented with some rich stuff, and furnished with a ballustrade of ivory, or other costly matter, enriched with gilding. The edges of the balloon just touch the water, but the extremities rise with a sweep to a great height. Some are adorned with variety of figures, made of pieces of mother of pearl inlaid: the richer sort, instead of a dome, carry a kind of steeple in the middle; so that, considering the slenderness of the vessel, which is usually 100 or 120 feet long, and scarce six broad, the height of the two ends, and of the steeple, with the load of decorations, it is a kind of miracle they are not overfet.

BALLOON, in the French paper-trade, is a term for a quantity of paper, containing 24 reams.

BALLOON, BALLON, or BALLOT, in the French glass-trade, signifies a certain quantity of glass-plates, smaller or greater, according to their quality. The balloon of white glass contains 25 bundles, of six plates per bundle; but the balloon of coloured glass is only of 12½ bundles, and of three plates to a bundle.

BALLOTA, WHITE MOREHOUND; a genus of the gymnospermia order, belonging to the didymia class of plants. It is a common weed growing on the sides of banks in most parts of England, as also in walk-places near towns and villages in Scotland; so is seldom admitted into gardens. The flowers grow in whorls, upon branched peduncles, and lean on one side of the stalk; they are commonly of a dull red colour, but sometimes white. It was formerly used in hysterical cases, but is now fallen into disuse. The Swedes reckon it almost an universal remedy in the diseases of their

Bal-
lotade
Bal-
fam.

their cattle. Horses, cows, sheep, and goats, refuse to eat it.

BALLOTADE, in the menage, the leap of a horse between two pillars, or upon a straight line, made with justness of time, with the aid of the hand, and the calves of the legs; and in such a manner, that when his fore-feet are in the air, he shews nothing but the fhoes of his hinder-feet without jerking out.

BALLOTING, a method of voting at elections, &c. by means of little balls usually of different colours, by the French called *ballotes*; which are put into a box privately.

BALLS, or **BALLETS**, in heraldry, a frequent bearing in coats of arms, usually denominated, according to their colours, bezants, plates, hurts, &c.

BALLUSTER, a small kind of pillar used for ballustrades.

BALLUSTRADE, a series or row of ballusters, joined by a rail; serving as well for a rest to the elbows, as for a fence or inclosure to balconies, altars, stair-cases, &c. See **ARCHITECTURE**, n° 79, 80.

BALM, in botany. See **MELISSA**.

BALM, or **BALSAM**. See **BALSAM**.

BALM of *Gilead*. See **OPOBALSAM**.

BALNAVES (Henry), a Scottish protestant divine, born in the shire of Fife, in the reign of James V. and educated at the university of St Andrew's. He went afterwards to France in order to finish his studies; and, returning to Scotland, was admitted into the family of the earl of Arran, who at that time governed the kingdom: but in the year 1542 the earl dismissed him for having embraced the Protestant religion. In 1564, he joined, says Mackenzie, the murderers of cardinal Beaton; for which he was declared a traitor, and excommunicated. Whilst that party were besieged in the castle of St Andrew's, they sent Balnaves to England, who returned with a considerable supply of provisions and money: but, being at last obliged to surrender to the French, he was sent with the rest of the garrison to France. He returned to Scotland about the year 1559; and, having joined the congregation, he was appointed one of the commissioners to treat with the duke of Norfolk on the part of queen Elizabeth. In 1563 he was made one of the lords of session, and appointed by the general assembly, with other learned men, to revise the Book of Discipline. Knox, his cotemporary and fellow-labourer, gives him the character of a very learned and pious divine. He died at Edinburgh in the year 1575. He wrote, 1. *A treatise concerning justification*. Edinb. 1550, 8vo. 2. *A catechism, or confession of faith*. Edinb. 1584, 8vo.

BALNEUM, a term used by chemists to signify a vessel filled with some matter, as sand, water, or the like, in which another is placed that requires a more gentle heat than the naked fire.*

BALSA, an ancient town of Lusitania in the Ager Cunnensis; now *Tavira*, capital of Algarva †.

BALSAM, or **NATIVE BALSAM**, an oily, resinous, liquid substance, flowing either spontaneously, or by means of incision, from certain plants. There are a great variety of balsams, generally denominated from the substances from which they are obtained.*

BALSAM of *Copaiba*. } See **MATERIA MEDICA**, 99,
BALSAM of *Peru*. } 100, 101.

ics
Baluz.

Prepared BALSAM; as *Locatelli's*, the *Traumatic*, &c. See **PHARMACY**, n° 432, 800, &c.

BALSAMICS. *Balfamica* is a Latin word which signifies *mitigating*. The term *balsamic* is a very lax one; it includes medicines of very different qualities, as emollients, detergents, restoratives, &c. but in medicines of all these kinds there seems to be this requisite in them, viz. that they be soft, yielding, and adhesive, also that by their smallness they have a ready disposition to motion. Medicines of this tribe are generally required for complaints whose seat is in the viscera; and as they cannot be conveyed there but by the common road of the circulation, it follows that no great effects can be expected from them but by their long continuation. Hoffman calls by the name of *balsamics* those medicines which are hot and acrid, also the natural balsams, gums, &c. by which the vital heat is increased.

BALSORA. See **BASSORA**.

BALTAGI, among the Turks; porters, and hewers of wood, in the court of the grand signior; who also mount on horseback, when the emperor rides out. Part of them also, who, for that purpose, must be castrated, keep watch at the gates of the first and second courts of the seraglio. These last are called *capigi*, and their commander *capigi pascha*.

BALTIC SEA, a great gulph between Germany and Poland; from which run several other gulphs, particularly those of Bothnia, Finland, Livonia, and Dantzick. It is remarkable that this sea neither ebbs nor flows, and there is always a current sets through the sound into the ocean. It is generally frozen over three or four months in the year. Yellow amber is found in plenty on this coast.

BALTIMORE, a town of Ireland in the county of Corke and province of Munster, with the title of a barony. It is seated on a headland which runs into the sea, five miles north-east of Cape Clear. W. Long. 9. 10. N. Lat. 51. 15.

BALTZAR (Thomas), a native of Lubec, was an eminent musical composer, and esteemed the finest performer on the violin of his time. He came into England in the year 1658, and lived about two years in the house of Sir Anthony Cope of Hanwell in Oxfordshire. He was the great competitor of Davis Mell, who, though a clock-maker by trade, was, till Baltzar came hither, allowed to be the finest performer on the violin in England; and after his arrival he divided with him the public applause, it being agreed that Mell excelled in the fineness of his tone and the sweetness of his manner, and Baltzar in the power of execution and command of the instrument. Moreover, it is said of the latter, that he first taught the English the practice of shifting, and the use of the upper part of the finger-board. Baltzar was given to intemperance, and is said to have shortened his days by excessive drinking: he was buried in Westminster-abbey on the 27th day of July 1663.

BALUCLAVO, or **JAMBOL**, a sea-port town of Crimea on the Black Sea, where they build ships for the Grand Signior. E. Long. 35. 15. N. Lat. 44. 50.

BALUZE (Stephen), a French writer, born in 1631, and sometime librarian to M. Colbert. In 1693 he obtained a pension, with the post of director of the royal college, for writing the lives of the popes of Avignon; both which advantages he soon lost in the fluctuation of court-parties. M. Baluze is much more

Motherby's
Med. Dict.

Balyur,
Balzac.

noted for collecting ancient MSS. and illustrating them by notes, than famed for his own compositions.

BALYUR, or **BALIUR**, a sea-port of Africa in the kingdom of Dancali, about 14 hours journey west from Babel-Mandel. It is remarkable only for being the landing place of the Abyssinian Patriarch Alphonus Mendez, with his Jesuits and Portuguese, on April 3^d 1724. The king who had received orders from the Abyssinian emperor to give them a proper reception, dispatched his son to meet them and conduct them to him. The royal palace they found to consist of about half a dozen of tents, and a score of huts, fenced about with a thorn hedge, and shaded by some wild kinds of trees. Near the palace was a river, which was then quite dried up, and no water to be found but what was digged for in the channel. The hall of audience was only a large tent about a musket-shot from the rest. At the upper end was a kind of throne made of stones and clay, covered with a carpet, and two velvet cushions. At the other end was his majesty's horse, with the saddle and other accoutrements hanging on one side; it being the custom of this country for the master and horse to lie together, whether king or subject. Around the hall were about 50 young men sitting cross-legged; and when the Portuguese ambassadors were admitted, they were made to sit down in the same posture. Soon after came the king preceded by some of his domestics, one having an earthen pitcher full of hydromel, another a cup made of porcelain, a third carrying a cocoa shell full of tobacco, and a fourth bringing a silver tobacco-pipe with some fire. Next to them was the king, dressed in a light silk stuff, having on his head a turban, from the rims of which hung a parcel of rings nicely wrought, which dangled before his face. He had in his hand a short kind of javelin, and was followed by all the chief officers of his court and household. The respect paid him at his coming in was by standing on their feet, and squatting down again twice, after which they went forward to kiss his hand.

BALZAC (John Lewis Guez de), born at Angouleme in 1595. Voltaire allows him the merit of having given numbers and harmony to the French prose, but censures his style as somewhat bombast. The critics of his own time gave him no little disquiet; and he gave them no little advantage over him by his fallies of vanity, and some particular propositions which were a little dangerous. Mr Balzac, getting rid of these disputes by his moderation, settled at his country-seat; refined his style and genius; and got by his letters and other writings which he published from time to time, the reputation of being the first writer in France. He was at length drawn from his retirement by the hopes of making his fortune under cardinal Richlieu, who had formerly courted his friendship; but in a few years he retired again, disgusted with the slavish dependence of a court life. All he obtained from the court was a pension of 2000 livres, with the titles of counsellor of state and historiographer of France. He died in 1654; and was buried in the hospital of Notre Dame des Anges, to which he bequeathed 12,000 livres. He left an estate of 100 franks *per ann.* for a gold medal to be bestowed every two years for the best discourse on some moral subject.—Besides his letters, he wrote a work called *Oeuvres Diverses*, i. e. on various

subjects; The Prince; The Christian Socrates, &c. and many other pieces; of all of which have been published in two volumes folio.

BAMBA, a province of the kingdom of Congo in Africa.—It is situated between the rivers of Ambrisi and Loze; the last of which parts it from Pema on the east, and the Ambrisi from the province of Sogno on the north. Along the sea-coasts it extends itself northward to the river Lelunda; and on the south to that of Danda, which parts it from the kingdom of Angola. The governors of this province bear the title of *dukes*, and are always some of the princes of the royal family. They are as despotic and arbitrary as if they were really kings, notwithstanding the care and pains their monarchs have taken to keep them within due bounds. The soil of this province is very fertile; and would produce all the necessaries of life in great plenty, were the inhabitants but industrious in its cultivation. The sea-coasts produce a vast quantity of salt, which could be purified with little trouble, and would yield an extraordinary revenue if the duties were duly paid; but these the governors find means to sink mostly into their own coffers.—Here is also the fishery of the zimbis, or little sea-nail, whose shell is the current coin, not only in this and the neighbouring kingdom, but also in the most distant parts of Africa. Here are also said to be mines of gold, silver, quicksilver, copper, tin, and iron; but none except the iron mines are allowed to be worked.

BAMBERG, a large handsome town of Franconia in Germany, and capital of a bishopric of the same name. It was formerly imperial, but is now subject to the bishop. The country about it produces plenty of corn, fruits, and liquorice. It has an university, founded in 1585; and is situated at the confluence of the rivers Main and Reidnitz. E. Long. 10. 15. N. Lat. 50. 10.

BAMBERG, a town of Bohemia, situated at the foot of a mountain. E. Long. 16. 50. N. Lat. 49. 53.

BAMBOCCIO. See **LAFER**.

BAMBOE, in botany, the trivial name of a species of arundo*.—It is a plant which multiplies very much by its root, from which springs a ramous or branchy tuft, after the manner of the European reeds. The Indian bamboe is the largest kind of cane that is known. It is of an extraordinary height and bigness, when it bears its blossom: each shoot or cane is often, towards the bottom, of the bigness of a man's thigh, and decreases gradually to the top, where it bears a blossom or flower, like our reeds, in their proper season. With these canes of bamboe the Indians build their houses, and make all sorts of furniture, in a very ingenious manner. The wood of these canes is so hard and strong, that they serve very well to make piles for supporting their little houses, built over rivers, which have a gentle course, as if it were over slanting waters. They also make with this wood all sorts of utensils for their kitchens and tables. The thickest bamboes serve to make the sticks and poles with which the slaves or other persons carry those sorts of litters which are called *palanquins*, and are so common in use and so convenient in all the east. They likewise make of that wood a kind of pails, in which the water keeps extremely cool. The walking-canes which we see in Europe, are the first and smallest shoots of the bamboes.—The Ma-

Bamba
Bamboe.* See *A-rundo*.

lays,

bamboe,
bambock.

lays, and those Chinese who are dispersed in the Moluccas and Sunda isles, use the young small shoots of the bamboes preserved in vinegar after their manner, with very strong peppered ingredients. This they call *achiar bamboe*. For they give the name of *achiar* to all that is preserved in vinegar; and, to distinguish it, they add to that name of *achiar* that of the thing preserved *.—Two pieces of bamboe of a certain bigness, being rubbed hard against each other after a certain manner, will produce fire; and, when the Indians cannot get any by other means, they obtain it that way.

BAMBOE-HABIT; a Chinese contrivance by which a person who does not know how to swim may easily keep himself above water. The following account of it is from a letter to the author of the *Seaman's Preservative*. "In the year 1730, I was passenger in a ship from Batavia to China, burden about 400 tons, called the *Pridae*, Francisco Xavier commander, freighted by English, Chinese, and Portuguese. Near the coast of China we met one of those storms called a *Typhoon*, (*Tau song*) or a great wind, which carried away all our masts, bowsprit, and rudder; and in our hold we had six feet of water, expecting every moment the ship would founder.—We consequently were consulting our preservation: the English and Portuguese stood in their shirts only, ready to be thrown off; but the Chinese merchants came upon deck, not in a cork-jacket, but I will call it a *bamboe-habit*, which had lain ready in their chests against such dangers; and it was thus constructed; four bamboes, two before, and two behind their bodies, were placed horizontally, and projected about 23 inches. These were crossed on each side by two others, and the whole properly secured, leaving a space for their body; so that they had only to put it over their heads, and tie the same securely, which was done in two minutes, and we were satisfied they could not possibly sink." The shape is here subjoined.

BAMBUCK, a country of Africa, of which the following account is given by the Abbe Raynal, on the credit of a modern traveller whom he does not name. "In the interior parts of Africa, under the 12th or 13th degree of north latitude, there is, says a modern traveller, a pretty large country, known by the name of *Bambock*. It is not subject to a particular king; but governed by village lords, called *farims*. These hereditary and independent chiefs are all obliged to unite for the defence of the state, when it is either attacked as a community, or only in one of its branches.

"The territory of this aristocratical state is dry and barren. It produces neither maize, rice, nor pulse.

Bamboek,
Bamff.

The insupportable heat it is subject to, proceeds in part from its being surrounded by high mountains, which prevent the wind from refreshing the air. The climate is as unwholesome as it is disagreeable; vapours, which continually issue from the bowels of a soil replete with minerals, render this country unfit to live in, especially to strangers.

"It is gold that hath made this miserable country an object worthy of notice: gold, which in the eyes of the covetous man seems to compensate for all the evils of nature, tho' in reality it increases them all. This metal is so common in this country, that it is found almost indiscriminately every where. To obtain it, sometimes it is sufficient to scrape the surface of the earth, which is clayish, light, and mixed with sand. When the mine is very rich, it is digged only to the depth of a few feet, and never deeper; though it has been observed, that the lower it was digged, the more gold the soil afforded. The miners are too indolent to pursue a toil which constantly becomes more tedious, and too ignorant to perceive the inconveniences it would be attended with. Their negligence and their folly are in this instance so extraordinary, that in washing the gold, in order to separate it from the earth, they only preserve the larger pieces: the light parts pass away with the water, which flows down an inclined plain.

"The inhabitants of Bambock do not work these mines at all times, nor are they at liberty to do it when they please. They are obliged to wait till private or public wants determine the farmers to grant this permission. When it is proclaimed, all who are able to avail themselves of this advantage meet at the appointed place. When their work is finished, a division is made. Half of the gold goes to the lord, and the remainder is equally distributed among the labourers. Those who want gold at any other time than that of the general digging, search for it in the beds of the rivers, where it is very common.

"The French and English have successively been desirous of appropriating to themselves these real or imaginary riches. Some thought they could reach this country by the Niger, others by the Senegal. Far from having succeeded in their attempts of becoming masters of this country, they have not yet ascertained its existence. The unsuccessfulness of past efforts hath redoubled the activity of languine minds: sensible and judicious merchants have chosen to limit themselves to a commerce much more important, which is that of slaves."

BAMFF, a shire of Scotland, comprehending part of Buchan, with the countries of Strathdovern, Boyn, Enzie, Strathaven, and Balvenie, extends 32 miles from east to west, and 13 in breadth from north to south. On the south, it is separated from part of Buchan by the river Ugie; on the east, it is watered by the Doern and the German ocean; on the west, it is bounded by the Spey and the country of Murray; on the south-west, it borders on Badenoch and the Braes of Mar; and on the north, it is confined by the Murray Frith. The face of the country is agreeably diversified with hill and dale, not without woods, well watered with rivers, and exhibiting many seats and plantations. The air is pure and keen, the climate healthy, and the soil fertile, producing plentiful crops

Bamff,
Bamiyan.

of corn. The country of Buchan, extending northwards from the river Ugie to the sea, and westward as far as Dovern, comprehending a tract of 20 miles in length, and nine in breadth, is more free from hills and mountains than any other country of the same extent in the kingdom of Scotland. It is inhabited chiefly by Lowlanders, and gives the title of *Earl* to the chief of the family of Erskine. The country of Bamff abounds with the necessaries and comforts of life. The pasture-grounds yield sheep, cattle, and horses: the arable lands produce plenty of corn; while the rivers and sea supply great quantities of fish. Various minerals have been found in different parts of the shire; and a piece of amber, as large as a horse, was once cast ashore on the beach. In the mountainous district of Balvenie, on the western side of the shire, watered by the Spey, there is a noted rock, which produces hones and whet-stones sufficient to supply the whole island. Here are also veins of allum-stone, and springs of allum-water. Strathallan, another district to the north-east of Balvenie, abounds with such plenty of limestone, that the inhabitants use it as common stone in building their houses; and moreover burn a great quantity of into lime, which they sell to good advantage in the village of Keith, on the river Dovern. Along this whole coast, there are ancient Danish monuments, such as cairns, tumuli, and huge stones standing erect. In Strathaven, a hilly country, lying along the limpid river Avon, which falls into the Spey, we meet with Gordon castle, belonging to the duke of Gordon, the most princely edifice in the north of Scotland, consisting of noble apartments, magnificently furnished, and environed with fine gardens and parks, well stored with fallow-deer. The same nobleman possesses several other seats in this country.

BAMFF, the capital of the shire of that name in Scotland. It is seated at the mouth of the river Dovern, but has no harbour, and consequently little trade except for corn and salmon. W. Long. 2. 5. N. Lat. 57. 40.

BAMIYAN, a city of Asia, situated in the province of Zablestan, 10 days journey from Balkh, and eight from G.azna. It is remarkable only for its dreadful catastrophe when taken by Jenghiz Khan in 1221. At that time the city belonged to sultan Jalalodin, the last of the famous Mahmud Gazni's race. Jenghiz Khan was at that time about to attack Gazna, that prince's capital; but was stopped by the garrison of Gazna, which he had hoped would give him no trouble. In this, however, he was disappointed. The people had for a long time expected an attack; and had therefore ruined the country for five or six leagues round, while the peasants had carried away the stones, and every thing that could be of use to the besiegers. Accordingly, Jenghiz Khan having erected wooden towers, and planted his engines upon them, was in a short time obliged to give over his attacks till millstones and other materials could be brought from a great distance. The walls of the city were very strong, so that the engines of the Moguls made but little impression; and the garrison making frequent and furious sallies cut off whole squadrons of their enemies, and frequently overthrew their towers and engines. This exceedingly chagrined Jenghiz Khan; who one day returning from a fruitless attack, and hearing of the defeat

of one of his generals by Jalalodin, swore to be revenged on Bamiyan. This fury cost the life of one of his grandchildren; who exposing himself too much, to please his grandfather, was slain with an arrow.—At last, however, by the numberless multitude of the Moguls, who continued the attacks without intermission, the city was taken, after its walls had been ruined in many places, and the bravest soldiers and officers of the garrison slain in its defence. The mother of the young prince who had been killed, entering with the troops, and more deserving the name of a fiend than a woman, caused the throats of all the inhabitants to be cut, without excepting one. She even gave orders to rip up the bellies of all the women with child, that not an infant might be left alive. In short, to gratify the rage of this inhuman monster, the buildings were all levelled with the ground; the cattle, and every living creature, destroyed; inasmuch that the hardened Moguls themselves gave this place the name of *Maubalig*, which in their language signifies the *unfortunate city*. A strong castle has since been built out of its ruins.

BAMPTON, a town of Devonshire, situated in a bottom surrounded with high hills. W. Long. 4. 25. N. Lat. 51. 5.

BAN, or **BANS**. See **BANN**.

BAN, in commerce, a sort of smooth fine muslin, which the English import from the East Indies. The piece is almost a yard broad, and runs about 20 yards and a half.

BANANA-TREE, a species of the musa or plantain. See **PLANTAIN**.

BANARES, or **BENARES**, a handsome town of Asia, in the dominions of the Great Mogul, greatly celebrated for its sanctity, and being the university of the Indian bramins. It is seated on the north side of the river Ganges, in E. Long. 82. 30. N. Lat. 26. 20.

BANBURY, a town of Oxfordshire in England, situated on the river Charwell, in W. Long. 1. 20. N. Lat. 52. 0.

BANC, or **BENCA**, in law, denotes a tribunal, or judgment-seat: hence *king's banc* is the same with the *court of king's-bench*, and *common banc* with that of *common pleas* *.

BANCA, an island of Asia, in the East Indies, between Sumatra and Borneo; from the first of which it is separated only by a narrow channel. E. Lon. 105. 10. N. Lat. 13. 25.

BANCALIS, a sea-port town on the east coast of the island of Sumatra, where the Dutch have a settlement. E. Long. 99. 7. N. Lat. 1. 5.

BANCO, an Italian word which signifies *bank*. It is commonly used to signify the *bank of Venice*.

BANCOCK, a town of the kingdom of Siam in Asia, with a fort, which was once in the possession of the French, but they were driven from it in 1688. E. Long. 101. 5. N. Lat. 13. 25.

BAND, in a general sense, some small narrow ligament, wherewith any thing is bound, tied, or fastened.

BAND, in architecture, a general name for any flat, low member, or moulding, that is broad, but not very deep.

BAND of Soldiers, in military affairs, those who fight under the same flag or ensign.

BAND of Pensioners, a company of 120 gentlemen, who

Bampton
Band.* See King's
Bench and
Common
Pleas.

who receive a yearly allowance of 100*l.* for attending on his majesty on solemn occasions.

BAND is also the denomination of a military order in Spain, instituted by Alphonfus XI. king of Castile, for the younger sons of the nobility; who, before their admission, must serve 10 years, at least, either in the army, or at court; and are bound to take up arms for the catholic faith against the infidels.

BAND, in furgery. See **BANDAGE**.

BANDA ISLANDS, the general name of five islands in the East Indies, belonging to the Dutch. Two of them are uncultivated, and almost entirely uninhabited; the other three claim the distinction of being the only islands in the world that produce the nutmeg.

If we except this valuable spice, the islands of Banda, like all the Moluccas, are barren to a dreadful degree. What they produce in superfluities they want in necessities. The land will not bring forth any kind of corn; and the pith of the fago serves the natives of the country instead of bread.

As this food is not sufficient for the Europeans who settle in the Moluccas, they are allowed to fetch provisions from Java, Macassar, or the extremely fertile island of Bali. The company itself carries some merchandize to Banda.

This is the only settlement in the East Indies that can be considered as an European colony; because it is the only one where the Europeans are proprietors of lands. The company finding that the inhabitants of Banda were savage, cruel, and treacherous, because they were impatient under their yoke, resolved to exterminate them. Their possessions were divided among the white people, who got slaves from some of the neighbouring islands to cultivate the lands. These white people are for the most part Creoles, or malecontents who have quitted the service of the company. In the small island of Rosinging, there are likewise several banditti, whom the laws have branded with disgrace; and young men of abandoned principles, whose families wanted to get rid of them: so that Banda is called the *island of correction*. The climate is so unhealthy, that these unhappy men live but a short time. It is on account of the loss of so great a number of hands, that attempts have been made to transfer the culture of the nutmeg to Amboyna; and the company were likewise probably influenced by two other strong motives of interest, as their trade could be carried on with less expence and greater safety. But the experiments that have been made have proved unsuccessful, and matters remain in their former state.

BANDAGE, in furgery, a fillet, roller, or swath, used in dressing and binding up wounds, restraining dangerous hæmorrhages, and in joining fractured and dislocated bones.

BANDALEER, or **BANDELEER**, in military affairs, a large leathern belt, thrown over the right shoulder, and hanging under the left arm; worn by the ancient musqueteers, both for the sustaining of their fire-arms, and for the carriage of their musquet-charges, which being put up in little wooden cases, coated with leather, were hung, to the number of twelve, to each bandaleer.

BANDELET, or **BANDLET**, in architecture, any little band, or flat moulding, as that which crowns the Doric architrave.

BANDER-CONGO, a small sea-port town in Asia, seated on the Persian Gulph. E. Long. 54. 10. N. Lat. 19. 0.

BANDERET, a general, or one of the commanders in chief of the forces.—This appellation is given to the principal commanders of the troops of the canton of Bern in Switzerland, where there are four banderets, who command all the forces of that canton.

BANDEROLL, a little flag, in form of a guidon, extended more in length than in breadth, used to be hung out on the masts of vessels, &c.

BANDITTI, persons proscribed, or, as we call it, *outlawed*; sometimes denominated *banniti*, or *foris-banniti*.

BANDITTI, or **BANDITI**, is also a denomination given to highwaymen, or robbers, who infest the roads in troops, especially in Italy and France. The term is also applied to a sort of freebooters, who pillage in the islands of the Archipelago.

BANDORA, the capital of the island of Salfet, on the west coast of the peninsula on this side the Ganges. It is separated from the island of Bombay by a narrow channel, and subject to the Portuguese. E. Lon. 72. 30. N. Lat. 19. 0.

BANDORA is also the name of an ancient musical instrument, with strings, resembling a lute. See **LUTE**.

BANDY-LEGGED Persons are such whose feet are distorted, turning either inward or outward on either side.

BANE, (from the Sax. *bana*, a murderer), signifies destruction or overthrow. Thus, "I will be the *bane* of such a man," is a common saying. So, when a person receives a mortal injury by any thing, we say, "it was his *bane*;" and he who is the cause of another man's death, is said to be *le bane*, i. e. a malefactor.

BANGHIR, a town of Ireland, in king's county in the province of Leinster, seated on the river Shannon. W. Long. 8. 5. N. Lat. 53. 10.

BANGLE EARS, an imperfection in a horse, remedied in the following manner. Place his ears in such a manner as you would have them stand; bind them with two little boards so fast that they cannot stir, and then clip away all the empty wrinkled skin close by the head.

BANGIUS (Thomas), a Danish divine, and an elegant Latin writer on the origin of languages and a variety of other subjects. He died in 1661.

BANGOR, an episcopal city of Caernarvonshire in North Wales. In ancient times it was so considerable, that it was called *Bangor the Great*, and defended by a strong castle; but it is now a very mean place: the principal buildings being the cathedral, the bishop's palace, and a free school. W. Long. 4. 10. N. Lat. 53. 20.

BANGOR, a town of Ireland, in the county of Down and province of Ulster. It is seated on the fourth shore of the bay of Carrick Fergus, opposite to the town of that name; and sends two members to parliament. W. Long. 6. N. Lat. 54. 42.

BANGUE, a species of opiate, in great use throughout the east, for drowning cares and inspiring joy.—This by the Persians is called *beng*; by the Arabs, *essar*, corruptly *asseral*, and *assarth*; by the Turks, *bengitic*, and vulgarly called *massack*; by the European naturalists, *bangue* or *bange*.—It is the leaf of a kind

Bangu
Banians.

kind of wild hemp, growing in the countries of the Levant; it differs little, either as to leaf or seed, from our hemp, except in fibre. Some have mistaken it for a species of althæa.

There are divers manners of preparing it, in different countries. Plearius describes the method used in Persia. Mr Sale tells us, that, among the Arabs, the leaf is made into pills, or conserves. But the most distinct account is that given by Alexander Maurocordato counsellor and physician of the Ottoman Porte, in a letter to Wedelius. According to this author, bangu is made of the leaves of wild hemp, dried in the shade, then ground to powder; put into a pot wherein butter has been kept; set in an oven till it begin to torrify; then taken out, and pulverized again; thus to be used occasionally, as much at a time as will lie on the point of a knife. Such is the Turkish bangu.—The effects of this drug are, To confound the understanding; set the imagination loose; induce a kind of folly, and forgetfulness, wherein all cares are left, and joy and gaiety take place thereof. Bangu in reality, is a succedaneum to wine, and obtains in those countries where Mahometanism is established; which prohibiting the use of that liquor absolutely, the poor muselmans are forced to have recourse to succedanea, to rouse their spirits. The principal are *opium* and this bangu. As to the opinion among Europeans, that the Turks prepare themselves for battle by a dose of bangu, which rouses their courage, and drives them, with eagerness, to certain death; Dr Maurocordato assures us, that it is a popular error: the Turks think they are then going assuredly to receive the crown of martyrdom; and would not, for any consideration, lose the merit of it, which they would do, by eating the bangu, as being held unlawful by their apostle, among other things which intoxicate.

BANIALUCH, or **BAGNALUCH**, a city of European Turkey, the capital of Bosnia, upon the frontiers of Dalmatia, near the river Setina. E. Long. 18. 20. N. Lat. 44. 20.

BANIANS, a religious sect in the empire of the Mogul, who believe a metempsychosis; and will therefore eat no living creature, nor kill even noxious animals, but endeavour to release them when in the hands of others.—The name of *Banian* is used with some diversity, which has occasioned much confusion, and many mistakes. Sometimes it is taken in a less proper sense, and extended to all the idolaters of India, as contradictorily distinguished from the Mahometans: in which sense, banians include the bramins and other casts. *Banians*, in a more proper sense, is restrained to a peculiar cast, or tribe, of Indians, whose office or profession is trade and merchandize: in which sense, *banians* stand contradictorily distinguished from *bramins*, *catterys*, and *wysse*, the three other casts into which the Indians are divided. The four casts are absolutely separate as to occupation, relation, marriage, &c. though all of the same religion; which is more properly denominated the religion of the bramins, who make the ecclesiastical tribe, than of the *banians*, who make the mercantile. The proper *banians* are called, in the *Shaster*, or book of their law, by the name of *spandery*; under which are comprehended all who live after the manner of merchants, or that deal and transact for others, as brokers; exclusive of the mechanics, or artificers, who

Banians.

make another cast, called *wysse*. These *banians* have no peculiar sect or religion, unless it be, that two of the eight general precepts given by their legislator Breamaw to the Indian nation, are, on account of the profession of the *banians*, supposed more immediately to relate to them, viz. those which enjoin veracity in their words and dealings, and avoiding all practices of circumvention in buying and selling.—Some of the *banians*, quitting their possession, and retiring from the world, commence religious, assume a peculiar habit, and devote themselves more immediately to God, under the denomination of *vertsa*. These, tho' they do not hereby change their cast, are commonly reckoned as bramins of a more devout kind; much as monks in the Romish church, though frequently not in orders, are reputed as a more sacred order than the regular clergy. The name *banian* imports as much, in the bramin language (wherein their law is written), as a people innocent and harmless; void of all guile; and so gentle, that they cannot endure to see even a fly or worm injured; and who, when struck, will patiently bear it, without resisting or returning the blow.—Their mien and appearance is described by Lord†, in terms a little precise, but very significant: “A people presented themselves to my eyes clothed in linen garments, somewhat low descending, of a gesture and garb, as I may say, maidenly and well high effeminate, of a countenance shy and somewhat estranged.”—Gemelli Careri divides the *banians* into 22 tribes, all distinct, and not allowed to marry with each other. Lord assures us they are divided into 82 casts or tribes, correspondent to the casts or divisions of the bramins or priests, under whose discipline they are, as to religious matters; though the generality of the *banians* chuse to be under the direction of the two bramin tribes, the *Visalnagranauagers* and *Vulnagranauagers*.

The *banians* are the great factors, by whom most of the trade of India is managed; in this respect, comparable to the Jews and Armenians, and not behind either, in point of skill and experience, in whatever relates to commerce. Nothing is bought but by their mediation. They seem to claim a kind of *jus divinum* to the administration of the traffic of the nation, grounded on their sacred books, as the bramins do to that of religion. They are dispersed, for this purpose, through all parts of Asia, and abound in Persia, particularly at Ispahan and Gombroon where many of them are extremely rich, yet not above acting as brokers, where a penny is to be got. The chief agents of the English, Dutch, and French East India companies, are of this nation: they are faithful, and are generally trusted with the cast of those companies in their keeping. They act also as bankers, and can give bills of exchange for most cities in the East Indies. Their form of contract in buying and selling, is remarkable; being done without words, in the profoundest silence, only by touching each other's fingers: the buyer loosening his *panerin*, or *girdle*, spreads it on his knee, and both he and the seller having their hands underneath, by the intercourse of the fingers, mark the price of pounds, shillings, &c. demanded, offered, and at length agreed on. When the seller takes the buyer's whole hand, it denotes a thousand; and, as many times as he squeezes it, as many thousand pagods, or roupces, according to the species

† Discov.
Relig. Ba-
nians.

in question, are demanded: when he only takes the five fingers, it denotes five hundred; and when only one, one hundred: taking only half a finger, to the second joint, denotes fifty; the small end of the finger, to the first joint, stands for ten.

BANIER (Anthony), licentiate in laws, member of the academy of inscriptions and belles lettres, and ecclesiastic of the diocese of Clermont in Auvergne; died in November 1741, aged 69. He is principally celebrated for his translation of the *Metamorphoses* of Ovid, with historical remarks and explanations; which was published in 1732, at Amsterdam, in folio, finely ornamented with copperplates, by Picart; and reprinted at Paris 1738, in two vols 4to: and for his *Mythology, or fables of the ancients explained by history*; a work full of the most important information, which was translated into English, and printed at London in 1741, in 4 vols 8vo.

BANISHMENT, exile, among us is of two kinds: the one voluntary, and upon oath; the other by compulsion, for some offence or crime*. The former properly called *abjuration*, is now ceased; the latter is chiefly enjoyed by judgment of parliament. Yet outlawing and transportation may also be considered as species of exile †.

BANISTER (John), a physician and surgeon in the reign of queen Elizabeth, was educated at Oxford, where, says Anthony Wood, he studied logics for a time; but afterwards applied himself solely to physic and surgery. In 1573 he took the degree of bachelor of physic; and, obtaining a licence from the university to practise, settled at Nottingham, where he lived many years in great repute. When or where he died, is not known. There was a long poetical memorial of him in the church of St Olave, Silver-street, London, which is preserved by Stow. He was author of, 1. *A needful, new, and necessary treatise of chirurgery, briefly comprehending the general and particular curation of ulcers*. Lond. 1575, 8vo. 2. *Certain experiments*, of his own invention. 3. *The history of mans, sucked from the sappe of the most approved anatomists*, &c. in nine books. Lond. 1578, thin fol. 4. *Compendious chirurgery, gathered and translated especially out of Wecker*, &c. Lond. 1585, 12mo. 5. *Antidotary chirurgical, containing variety of all sorts of medicines*, &c. Lond. 1589, 8vo. His works were collected and published in 1633, 4to.

BANISTERIA, in botany, a genus of the trigynia order, belonging to the decandria class of plants; of which there are seven

Species. 1. The *angulosa*, with a shrubby climbing stalk, is a native of Jamaica. It twists round the neighbouring trees, raising itself to their very top. It is garnished with leaves as large as those of the bay-tree, and of the same thickness: the flowers are produced in long spikes growing at the end of the branches, and are succeeded by two or three winged seeds like those of the greater maple. 2. The *fulgens*, with smooth oval leaves, is likewise a native of Jamaica and other warm parts of America. It hath slender winding stalks which rise five or six feet high; the flowers grow in a round bunch at the extremity of the branches: they are of a brownish yellow colour; and are also succeeded by winged seeds, but smaller, and with narrower wings, than the former. 3. The *bractiata*, with climbing diffused branches, grows naturally about Carthage

in South America. It sends out many branches which divide again into others, growing without order, and become very bushy upward, sending forth tendrils, by which they fasten themselves to the neighbouring trees and mount to a great height; these have stiff oval leaves ending in a point. The flowers are produced in loose spikes at the end of the branches, and are first of a gold colour, fading afterwards to a scarlet. They are succeeded by seeds of the same shape with the former; but slender, thin, and for the most part single.

4. The *laurifolia* is a native of Campeachy. It hath many irregular climbing stalks, which fasten themselves to the neighbouring trees, and rise to a great height. The leaves are heart-shaped, and hairy on their under side, where they have many transverse ribs. The flowers come out thinly from the side of the branches; they are of a pale yellow colour, and succeeded by large winged seeds which are double. 5. The *aculeata*, with spikes of flowers growing from the sides of the branches, is a native of Tolu in New Spain. It hath strong woody stalks, covered with an ash-coloured bark, and divided into many branches garnished with winged leaves, composed of five or six pair of small ones whitish on their under side: from the wings of the leaves are produced slender bunches of flowers growing in a racemus like those of the currant-bush, and are of a purplish colour. They are succeeded by broad winged seeds growing erect. 6. The *bengalensis* is a native of the East Indies, as also of the warm parts of America. It hath strong woody stalks, which twine round the neighbouring trees, and sometimes rise 20 feet high. It hath oblong pointed leaves, like those of the bay-tree, growing by pairs opposite: from the wings of the leaves the flowers are produced in loose spikes growing upon long footstalks; they are of a blue colour, and are succeeded by slender winged seeds which spread open from each other. 7. The *purpurea* very much resembles the fifth, and is a native of the same country.

Culture. All these plants require to be kept in a bark stove, on account of their being natives of warm climates. They are propagated by seeds, which must be procured from those places where they are natives. The treatment of them differs in nothing material from that of other hot-bed plants.

BANK, in commerce, a common repository, where many persons agree to keep their money, to be always ready at their call or direction: or certain societies or communities, who take the charge of other people's money, either to improve it, or to keep it secure.

The first institution of banks was in Italy, where the Lombard Jews kept benches in the market-places for the exchange of money and bills; and *banco* being the Italian name for *bench*, banks took their title from this word.

Banks are of two principal kinds. 1. One sort is *public*, consisting of a company of monied men, who being duly established, and incorporated by the laws of their country, agree to deposit a considerable fund, or joint stock, to be employed for the use of the society, as lending money upon good security, buying and selling bullion, discounting bills of exchange; &c.: or *private*, i. e. set up by private persons, or partnerships, who deal in the same way as the former upon their own single stock and credit.

The greatest bank of circulation in Europe is the

Bank.

Bank of England. The company was incorporated by parliament in the fifth and sixth years of king William and queen Mary, by the name of *The Governors and Company of the Bank of England*; in consideration of the loan of 1,200,000 l. granted to the government; for which the subscribers received almost 8 per cent. By this charter, the company are not to borrow under their common seal, unless by act of parliament; they are not to trade, or suffer any person in trust for them to trade, in any goods, or merchandize; but they may deal in bills of exchange, in buying or selling bullion, and foreign gold and silver coin, &c.

By an act of parliament passed in the 8th and 9th year of William III. they were impowered to enlarge their capital stock to 2,201,171 l. 10s. It was then also enacted, that bank-stock should be a personal, and not a real estate; that no contract either in word or writing, for buying or selling bank-stock, should be good in law, unless registered in the books of the bank within 7 days; and the stock transferred in 14 days; and that it shall be felony, without benefit of clergy, to counterfeit the common seal of the bank, or any sealed bank-bill, or any bank-note, or to alter or erase such bills or notes. By another act passed in the 7th of queen Anne, the company were impowered to augment their capital to 4,402,343 l. and they then advanced 400,000 l. more to the government; and in 1714, they advanced another loan of 1,500,000 l.

In the third year of the reign of king George I. the interest in their capital stock was reduced to 5 per cent. when the bank agreed to deliver up as many exchequer bills as amounted to 2,000,000 l. and to accept an annuity of 100,000 l. and it was declared lawful for the bank to call for their members, in proportion to their interests in the capital stock, such sums of money as in a general court should be found necessary. If any member should neglect to pay his share of the moneys so called for, at the time appointed by notice in the London Gazette, and fixed upon the Royal Exchange, it should be lawful for the bank, not only to stop the dividend of such member, and to apply it towards payment of the money in question, but also to stop the transfers of the share of such defaulter, and to charge him with an interest of 5 per cent. per annum, for the money so omitted to be paid: and if the principal and interest should be three months unpaid, the bank should then have power to sell so much of the stock belonging to the defaulter as would satisfy the same. After this, the bank reduced the interest of the 2,000,000 l. lent to the government, from 5 to 4 per cent. and purchased several other annuities, which were afterwards redeemed by the government, and the national debt due to the bank reduced to 1,600,000 l. But in 1742, the company engaged to supply the government with 1,600,000 l. at 3 per cent. which is now called the 3 per cent. annuities; so that the government was now indebted to the company 3,200,000 l. the one half carrying 4, and the other 3 per cent.

In the year 1746, the company agreed that the sum of 986,800 l. due to them in the exchequer bills unsatisfied, on the duties for licences to sell spirituous liquors by retail, should be cancelled, and in lieu thereof to accept of an annuity of 39,442 l. the interest of that sum at 4 per cent. The company also agreed to advance the further sum of 1,000,000 l. into the exche-

quer, upon the credit of the duties arising by the malt and land tax, at 4 per cent. for exchequer bills to be issued for that purpose; in consideration of which, the company were enabled to augment their capital with 986,800 l. the interest of which, as well as that of the other annuities, was reduced to 3½ per cent. till the 25th of December 1757, and from that time to carry only 3 per cent.

And in order to enable them to circulate the said exchequer bills, they established what is now called *bank circulation*. The nature of which may be understood from what follows.

The company of the bank are obliged to keep cash sufficient not only to answer the common, but also any extraordinary demand that may be made upon them; and whatever money they have by them, over and above the sum supposed necessary for the purposes, they employ in what may be called the *trade of the company*; that is to say, in discounting bills of exchange, in buying of gold and silver, and in government securities, &c. But when the bank entered into the abovementioned contracts, as they did not keep unemployed a larger sum of money than what they deemed necessary to answer their ordinary and extraordinary demands, they could not conveniently take out of their current cash so large a sum as a million, with which they were obliged to furnish the government, without either lessening that sum they employed in discounting, buying gold and silver, &c. (which would have been very disadvantageous to them), or inventing some method that should answer all the purposes of keeping the million in cash. The method which they chose, and which fully answers their end, was as follows:

They opened a subscription, which they renew annually, for a million of money; wherein the subscribers advance 10 per cent. and enter into a contract to pay the remainder, or any part thereof, whenever the bank shall call upon them, under penalty of forfeiting the 10 per cent. so advanced; in consideration of which, the bank pays the subscribers 4 per cent. interest for the money paid in, and ½ per cent. for the whole sum they agree to furnish; and in case a call shall be made upon them for the whole, or any part thereof, the bank further agrees to pay them at the rate of 5 per cent. per annum for such sum till they repay it, which they are under an obligation to do at the end of the year. By this means the bank obtains all the purposes of keeping a million of money by them; and though the subscribers, if no call is made upon them (which is in general the case), receive 6½ per cent. for the money they advance, yet the company gains the sum of 23,500 l. per annum by the contract; as will appear by the following account.

The bank receives from the government	£.
for the advance of a million	30,000
The bank pays the subscribers who advance	
100,000 l. and engage to pay (when called	} 6,500
for) 900,000 l. more	
The clear gain to the bank therefore is	23,500

This is the state of the case, provided the company should make no call on the subscribers; which they will be very unwilling to do, because it would not only lessen their profit, but affect the public credit in general.

Bank-stock may not improperly be called a *trading stock*, since with this they deal very largely in foreign gold.

Bank.

Bank of England; its establishment, regulations, importance, &c.

Bank.

gold and silver, in discounting bills of exchange, &c. Besides which, they are allowed by the government very considerable sums annually for the management of the annuities paid at their office. All which advantages render a share in their stock very valuable; though it is not equal in value to the East India stock. The company make dividends of the profits half yearly, of which notice is publicly given; when those who have occasion for their money, may readily receive it; but private persons, if they judge convenient, are permitted to continue their funds, and to have their interest added to the principal.

This company is under the direction of a governor, deputy-governor, and 24 directors, who are annually elected by the general court, in the same manner as in the East India company. Thirteen, or more, compose a court of directors for managing the affairs of the company. The officers of this company are very numerous.

The stability of the bank of England is equal to that of the British government. All that it has advanced to the public must be lost before its creditors can sustain any loss. No other banking company in England can be established by act of parliament, or can consist of more than six members. It acts, not only as an ordinary bank, but (as we have already seen) as a great engine of state; receiving and paying the greater part of the annuities which are due to the creditors of the public; circulating exchequer-bills; and advancing to government the annual amount of the land and malt taxes, which are frequently not paid up till some years thereafter. It likewise has, upon several different occasions, supported the credit of the principal houses, not only in England, but of Hamburg and Holland. Upon one occasion it is said to have advanced for this purpose, in one week, about 1,600,000*l.* a great part of it in bullion.

In Scotland there are two public banks, both at Edinburgh. The one, called *The Bank of Scotland*, was established by act of parliament in 1695; the other, called *The Royal Bank*, by royal charter in 1727.

Within these twenty-five or thirty years there have also been erected private banking companies in almost every considerable town, and even in some villages. Hence the business of the country is almost entirely carried on by paper-currency, *i. e.* by the notes of those different banking companies; with which purchases and payments of all kinds are commonly made. Silver very seldom appears, except in the change of a twenty-shillings bank-note, and gold still feldomer. But though the conduct of all those different companies has not been unexceptionable, and has accordingly required an act of parliament to regulate it; the country, notwithstanding, has evidently derived great benefit from their trade. It has been asserted, that the trade of the city of Glasgow doubled in about 15 years after the first erection of the banks there; and that the trade of Scotland has more than quadrupled since the first erection of the two public banks at Edinburgh. Whether the trade, either of Scotland in general, or of the city of Glasgow in particular, has really increased in so great a proportion, during so short a period, we do not pretend to know. If either of them has increased in this proportion, it seems to be an effect too great to be accounted for by the sole operation of this cause.

Bank.

That the trade and industry of Scotland, however, have increased very considerably during this period, and that the banks have contributed a good deal to this increase, cannot be doubted.

The value of the silver money which circulated in Scotland before the Union, in 1707, and which immediately after it was brought into the bank of Scotland in order to be recoined, amounted to 411,117*l.* 10*s.* 9*d.* sterling. No account has been got of the gold coin; but it appears from the ancient accounts of the mint of Scotland, that the value of the gold annually coined somewhat exceeded that of the silver. There were a good many people too upon this occasion, who, from a diffidence of repayment, did not bring their silver into the bank of Scotland; and there was, besides, some English coin, which was not called in. The whole value of the gold and silver, therefore, which circulated in Scotland before the Union, cannot be estimated at less than a million sterling. It seems to have constituted almost the whole circulation of that country; for though the circulation of the bank of Scotland, which had then no rival, was considerable, it seems to have made but a very small part of the whole. In the present times the whole circulation of Scotland cannot be estimated at less than two millions, of which that part which consists in gold and silver must probably does not amount to half a million. But though the circulating gold and silver of Scotland have suffered so great a diminution during this period, its real riches and prosperity do not appear to have suffered any. Its agriculture, manufactures, and trade, on the contrary, the annual produce of its land and labour, have evidently been augmented.

It is chiefly by discounting bills of exchange, Discounting of bills. *i. e.* by advancing money upon them before they are due, that the greater part of banks and bankers issue their promissory notes. They deduct always, upon whatever sum they advance, the legal interest till the bill shall become due. The payment of the bill, when it becomes due, replaces to the bank the value of what had been advanced, together with a clear profit of the interest. The banker, who advances to the merchant whose bill he discounts, not gold and silver, but his own promissory notes, has the advantage of being able to discount to a greater amount, by the whole value of his promissory notes, which he finds by experience are commonly in circulation. He is thereby enabled to make his clear gain of interest on so much a larger sum.

The commerce of Scotland, which at present is not very great, was still more inconsiderable when the two first banking companies were established; and those companies would have had but little trade, had they confined their business to the discounting of bills of exchange. They invented, therefore, another method of issuing their promissory notes; by granting what they called *cash accounts*, that is, by giving credit to the extent of a certain sum, (2000 or 3000*l.* for example), Cash-accounts. to any individual who could procure two persons of undoubted credit and good landed estate to become surety for him, that whatever money should be advanced to him within the sum for which the credit had been given, should be repaid upon demand, together with the legal interest. Credits of this kind are commonly granted by banks and bankers in all different parts of the world. But the easy terms on which the Scotch banking companies accept of re-payment are peculiar to them,

Smith's Wealth of Nations, Book II. chap. II.

Scotch banks, public and private.

Bank.

them, and have, perhaps, been the principal cause, both of the great trade of those companies, and of the benefit which the country has received from it.

Whoever has a credit of this kind with one of those companies, and borrows 1000l. upon it, for example, may repay this sum piece-meal, by 20 and 30l. at a time, the company discounting a proportionable part of the interest of the great sum from the day on which each of those small sums is paid in, till the whole be in this manner repaid. All merchants, therefore, and almost all men of business, find it convenient to keep such cash-accounts with them; and are thereby interested to promote the trade of those companies, by readily receiving their notes in all payments, and by encouraging all those with whom they have any influence to do the same. The banks, when their customers apply to them for money, generally advance it to them in their own promissory notes. These the merchants pay away to the manufacturers for goods, the manufacturers to the farmers for materials and provisions, the farmers to their landlords for rent, the landlords repay them to the merchants for the conveniencies and luxuries with which they supply them, and the merchants again return them to the banks in order to balance their cash accounts, or to replace what they may have borrowed of them; and thus almost the whole money-business of the country is transacted by means of them. Hence the great trade of those companies.

By means of those cash accounts every merchant can, without imprudence, carry on a greater trade than he otherwise could do. If there are two merchants, one in London, and the other in Edinburgh, who employ equal stocks in the same branch of trade, the Edinburgh merchant can, without imprudence, carry on a greater trade, and give employment to a greater number of people, than the London merchant. The London merchant must always keep by him a considerable sum of money, either in his own coffers, or in those of his banker (who gives him no interest for it), in order to answer the demands continually coming upon him for payment of the goods which he purchases upon credit. Let the ordinary amount of this sum be supposed L. 500. The value of the goods in his warehouse must always be less by L. 500 than it would have been, had he not been obliged to keep such a sum unemployed. Let us suppose that he generally disposes of his whole stock upon hand, or of goods to the value of his whole stock upon hand, once in the year. By being obliged to keep such a great sum unemployed, he must sell in a year L. 500 worth less goods than he might otherwise have done. His annual profits must be less by all that he could have made by the sale of L. 500 worth more goods; and the number of people employed in preparing his goods for the market, must be less by all those that L. 500 more stock could have employed. The merchant in Edinburgh, on the other hand, keeps no money unemployed for answering such occasional demands. When they actually come upon him, he satisfies them from his cash-account with the bank, and gradually replaces the sum borrowed with the money or paper which comes in from the occasional sales of his goods. With the same stock, therefore, he can, without imprudence, have at all times in his warehouse a larger quantity of goods than the London merchant; and can thereby both make a

greater profit himself, and give constant employment to a greater number of industrious people who prepare those goods for the market. Hence the great benefit which the country has derived from this trade.

The late multiplication of banking companies in both parts of the united kingdom, an event by which many people have been much alarmed, instead of diminishing, increases the security of the public. It obliges all of them to be more circumspect in their conduct, and, by not extending their currency beyond its due proportion to their cash, to guard themselves against those malicious runs, which the rivalry of so many competitors is always ready to bring upon them. It restrains the circulation of each particular company within a narrower circle, and reduces their circulating notes to a smaller number. By dividing the whole circulation into a greater number of parts, the failure of any one company, an accident which, in the course of things, must sometimes happen, becomes of less consequence to the public. This free competition too obliges all bankers to be more liberal in their dealings with their customers, lest their rivals should carry them away. In general, if any branch of trade, or any division of labour, be advantageous to the public, the freer and more general the competition, it will always be the more so. See further, the article *PAPER-MONEY*.

2. The other kind of banks consists of such as are instituted wholly on the public account, and are called *Banks of Deposit*; the nature of which not being generally understood, the following particular explanation may not be unacceptable.

The currency of a great state, such as Britain, generally consists almost entirely of its own coin. Should this currency, therefore, be at any time worn, clipped, or otherwise degraded below its standard value, the state by a reformation of its coin can effectually re-establish its currency. But the currency of a small state, such as Genoa or Hamburg, can seldom consist altogether in its own coin, but must be made up, in a great measure, of the coins of all the neighbouring states with which its inhabitants have a continual intercourse. Such a state, therefore, by reforming its coin, will not always be able to reform its currency. If foreign bills of exchange are paid in this currency, the uncertain value of any sum, of what is in its own nature so uncertain, must render the exchange always very much against such a state, its currency being, in all foreign states, necessarily valued even below what it is worth. In order to remedy the inconvenience to which this disadvantageous exchange must have subjected their merchants, such small states, when they began to attend to the interest of trade, have frequently enacted, that foreign bills of exchange of a certain value should be paid, not in common currency, but by an order upon, or by a transfer in the books of, a certain bank, established upon the credit and under the protection of the state; this bank being always obliged to pay, in good and true money, exactly according to the standard of the state. The banks of Venice, Genoa, Amsterdam, Hamburg, and Nuremberg, seem to have been all originally established with this view, though some of them may have afterwards been made subservient to other purposes. The money of such banks, being better than the common currency of the country, necessarily bore an agio, which was greater or smaller, according as the currency was supposed

Bank.

Advantages from thic;

to the banks, and

to the country.

II. Banks of deposit.

Smith's Wealth of Nations, Book IV. chap. iii.

supposed to be more or less degraded below the standard of the state. The agio of the bank of Hamburg, for example, which is said to be commonly about 14 per cent. is the supposed difference between the good standard money of the state, and the clipped, worn, and diminished currency poured into it from all the neighbouring states.

Before 1609, the great quantity of clipped and worn foreign coin, which the extensive trade of Amsterdam brought from all parts of Europe, reduced the value of its currency about 9 per cent. below that of good money fresh from the mint. Such money no sooner appeared, than it was melted down or carried away, as it always is in such circumstances. The merchants, with plenty of currency, could not always find a sufficient quantity of good money to pay their bills of exchange; and the value of those bills, in spite of several regulations which were made to prevent it, became in a great measure uncertain. In order to remedy these inconveniences, a bank was established in 1609 upon the guarantee of the city. The bank received both foreign coin, and the light and worn coin of the country, at its real and intrinsic value in the good standard money of the country, deducting only so much as was necessary for defraying the expence of coinage, and the other necessary expence of management. For the value which remained after this small deduction was made, it gave a credit in its books. This credit was called *bank-money*; which, as it represented money exactly according to the standard of the mint, was always of the same real value, and intrinsically worth more than current money. It was at the same time enacted, that all bills drawn upon or negotiated at Amsterdam of the value of 600 guilders and upwards should be paid in bank-money, which at once took away all uncertainty in the value of those bills. Every merchant, in consequence of this regulation, was obliged to keep an account with the bank in order to pay his foreign bills of exchange, which necessarily occasioned a certain demand for bank-money.

Bank-money, over and above both its intrinsic superiority to currency, and the additional value which this demand necessarily gives it, has likewise some other advantages. It is secure from fire, robbery, and other accidents; the city of Amsterdam is bound for it; it can be paid away by a simple transfer, without the trouble of counting, or the risk of transporting it from one place to another. In consequence of those different advantages, it seems from the beginning to have borne an agio; and it is generally believed that all the money originally deposited in the bank was allowed to remain there, nobody caring to demand payment of a debt which he could sell for a premium in the market. Besides, this money could not be brought from those coffers, as it will appear by and by, without previously paying for the keeping.

Those deposits of coin, or which the bank was bound to restore in coin, constituted the original capital of the bank, or the whole value of what was represented by what is called *bank-money*. At present they are supposed to constitute but a very small part of it. In order to facilitate the trade in bullion, the bank has been for these many years in the practice of giving credit in its books upon deposits of gold and silver bullion. This credit is generally about 5 per cent. below the mint price of such bullion. The bank grants at the same

time what is called a *receipt* or receipt, intitling the person who makes the deposit, or the bearer, to take out the bullion again at any time within six months, upon re-transferring to the bank a quantity of bank-money equal to that for which credit had been given in its books when the deposit was made, and upon paying $\frac{1}{2}$ per cent. for the keeping if the deposit was in silver, and $\frac{1}{4}$ per cent. if it was in gold; but at the same time declaring, that in default of such payment, and upon the expiration of this term, the deposit should belong to the bank at the price at which it had been received, or for which credit had been given in the transfer books. What is thus paid for the keeping of the deposit may be considered as a sort of warehouse rent; and why this warehouse rent should be so much dearer for gold than for silver, several different reasons have been assigned. The fineness of gold, it has been said, is more difficult to be ascertained than that of silver. Frauds are more easily practised, and occasion a greater loss in the more precious metal. Silver, besides, being the standard metal, the state, it has been said, wishes to encourage more the making of deposits of silver than of those of gold.

Deposits of bullion are most commonly made when the price is somewhat lower than ordinary; and they are taken out again when it happens to rise. In Holland the market-price of bullion is generally above the mint-price, for the same reason that it was so in England before the late reformation of the gold coin. The difference is said to be commonly from about six to sixteen silver upon the mark, or eight ounces of silver of eleven parts fine and one part alloy. The bank price, or the credit which the bank gives for deposits of such silver (when made in foreign coin, of which the fineness is well known and ascertained, such as Mexico dollars), is 22 guilders the mark; the mint-price is about 23 guilders; and the market-price is from 23 guilders six, to 23 guilders sixteen silver, or from 2 to 3 per cent. above the mint-price. The proportions between the bank-price, the mint-price, and the market-price of gold bullion are nearly the same. A person can generally sell his receipt for the difference between the mint-price of bullion and the market-price. A receipt for bullion is almost always worth something; and it very seldom happens, therefore, that any body suffers his receipt to expire, or allows his bullion to fall to the bank at the price at which it had been received, either by not taking it out before the end of the six months, or by neglecting to pay the $\frac{1}{2}$ or $\frac{1}{4}$ per cent. in order to obtain a new receipt for another six months. This, however, though it seldom happens, is said to happen sometimes, and more frequently with regard to gold than with regard to silver, on account of the higher warehouse-rent which is paid for the keeping of the more precious metal.

The person who by making a deposit of bullion obtains both a bank-credit and a receipt, pays his bills of exchange as they become due with his bank-credit; and either sells or keeps his receipt, according as he judges that the price of bullion is likely to rise or to fall. The receipt and the bank-credit seldom keep long together, and there is no occasion that they should. The person who has a receipt, and who wants to take out bullion, finds always plenty of bank-credits, or bank-money to buy at the ordinary price; and the person who has

bank-

Bank.

bank-money, and wants to take out bullion, finds receipts always in equal abundance.

The owners of bank-credits and the holders of receipts constitute two different sorts of creditors against the bank. The holder of a receipt cannot draw out the bullion for which it is granted, without re-assigning to the bank a sum of bank-money equal to the price at which the bullion had been received. If he has no bank-money of his own, he must purchase it of those who have it. The owner of bank-money cannot draw out bullion without producing to the bank receipts for the quantity which he wants. If he has none of his own, he must buy them of those who have them. The holder of a receipt, when he purchases bank-money, purchases the power of taking out a quantity of bullion, of which the mint-price is *5 per cent.* above the bank-price. The agio of *5 per cent.* therefore, which he commonly pays for it, is paid, not for an imaginary, but for a real value. The owner of bank-money, when he purchases a receipt, purchases the power of taking out a quantity of bullion of which the market-price is commonly from 2 to 3 *per cent.* above the mint-price. The price which he pays for it, therefore, is paid likewise for a real value. The price of the receipt, and the price of the bank-money, compound or make up between them the full value or price of the bullion.

Upon deposits of the coin current in the country, the bank grants receipts likewise as well as bank-credits; but those receipts are frequently of no value, and will bring no price in the market. Upon ducatoons, for example, which in the currency pass for three gilders three stivers each, the bank gives a credit of three gilders only, or *5 per cent.* below their current value. It grants a receipt likewise intitling the bearer to take out the number of ducatoons deposited at any time within six months, upon paying $\frac{1}{2}$ *per cent.* for the keeping. This receipt will frequently bring no price in the market. Three gilders bank-money generally sell in the market for three gilders three stivers, the full value of the ducatoons if they were taken out of the bank; and before they can be taken out, $\frac{1}{2}$ *per cent.* must be paid for the keeping, which would be mere loss to the holder of the receipt. If the agio of the bank, however, should at any time fall to 3 *per cent.* such receipts might bring some price in the market, and might sell for $1\frac{1}{2}$ *per cent.* But the agio of the bank being now generally about 5 *per cent.* such receipts are frequently allowed to expire, or, as they express it, to fall to the bank. The 5 *per cent.* which the bank gains, when deposits either of coin or bullion are allowed to fall to it, may be considered as the warehouse-rent for the perpetual keeping of such deposits.

The sum of bank-money for which the receipts are expired must be very considerable. It must comprehend the whole original capital of the bank, which, it is generally supposed, has been allowed to remain there from the time it was first deposited, nobody caring either to renew his receipt or to take out his deposit, as, for the reasons already assigned, neither the one nor the other could be done without loss. But whatever may be the amount of this sum, the proportion which it bears to the whole mass of bank-money is supposed to be very small. The bank of Amsterdam has for these many years past been the great warehouse

Bank.

of Europe for bullion, for which the receipts are very seldom allowed to expire, or, as they express it, to fall to the bank. The far greater part of the bank-money, or of the credits upon the books of the bank, is supposed to have been created, for these many years past, by such deposits which the dealers in bullion are continually both making and withdrawing.

No demand can be made upon the bank but by means of a receipt or receipt. The smaller mass of bank money, for which the receipts are expired, is mixed and confounded with the much greater mass for which they are still in force; so that, though there may be a considerable sum of bank-money for which there are no receipts, there is no specific sum or portion of it which may not at any time be demanded by one. The bank cannot be debtor to two persons for the same thing; and the owner of bank-money who has no receipt cannot demand payment of the bank till he buys one. In ordinary and quiet times, he can find no difficulty in getting one to buy at the market-price, which generally corresponds with the price at what he can sell the coin or bullion it intitles him to take out of the bank.

It might be otherwise during a public calamity; an invasion, for example, such as that of the French in 1672. The owners of bank-money being then all eager to draw it out of the bank, in order to have it in their own keeping, the demand for receipts might raise their price to an exorbitant height. The holders of them might form extravagant expectations, and, instead of 2 or 3 *per cent.* demand half the bank-money for which credit had been given upon the deposits that the receipts had respectively been granted for. The enemy, informed of the constitution of the bank, might even buy them up in order to prevent the carrying away of the treasure. In such emergencies, the bank, it is supposed, would break through its ordinary rule of making payment only to the holders of receipts. The holders of receipts, who had no bank-money, must have received within 2 or 3 *per cent.* of the value of the deposit for which their respective receipts had been granted. The bank, therefore, it is said, would in this case make no scruple of paying, either with money or bullion, the full value of what the owners of bank-money who could get no receipts were credited for in its books; paying at the same time 2 or 3 *per cent.* to such holders of receipts as had no bank-money, that being the whole value which in this state of things could justly be supposed due to them.

Even in ordinary and quiet times it is the interest of the holders of receipts to depress the agio, in order either to buy bank-money (and consequently the bullion which their receipts would then enable them to take out of the bank) so much cheaper, or to sell their receipts to those who have bank-money, and who want to take out bullion, so much dearer; the price of a receipt being generally equal to the difference between the market-price of bank-money, and that of the coin or bullion for which the receipt had been granted. It is the interest of the owners of bank-money, on the contrary, to raise the agio, in order either to sell their bank-money so much dearer, or to buy a receipt so much cheaper. To prevent the stock-jobbing tricks which those opposite interests might sometimes occasion, the bank has of late years come to a resolution to sell at all times bank-money for currency, at 5 *per cent.*

agio,

agio, and to buy it again at 4 per cent. agio. In consequence of this resolution, the agio can never either rise above 5 or sink below 4 per cent. and the proportion between the market-price of the bank and that of current money is kept at all times very near to the proportion between their intrinsic values. Before this resolution was taken, the market-price of money used sometimes to rise so high as 9 per cent. agio, and sometimes to sink so low as par, according as opposite interests happened to influence the market.

The bank of Amsterdam professes to lend out no part of what is deposited with it, but, for every guilder for which it gives credit in its books, to keep in its repositories the value of a guilder either in money or bullion. That it keeps in its repositories all the money or bullion for which there are receipts in force, for which it is at all times liable to be called upon, and which, in reality, is continually going from it and returning to it again, cannot well be doubted. But whether it does so likewise with regard to that part of its capital for which the receipts are long ago expired, for which in ordinary and quiet times it cannot be called upon, and which in reality is very likely to remain with it for ever, or as long as the States of the United Provinces subsist, may perhaps appear more uncertain. At Amsterdam, however, no part of faith is better established, than that for every guilder circulated as bank-money there is a correspondent guilder in gold and silver to be found in the treasure of the bank. The city is guaranteed that it should be so. The bank is under the direction of the four reigning burgomasters, who are changed every year. Each new set of burgomasters visits the treasure, compares it with the books, receives it upon oath, and delivers it over, with the same awful solemnity, to the set which succeeds it; and in that sober and religious country oaths are not yet disregarded. A rotation of this kind seems alone a sufficient security against any practices which cannot be avowed. Amidst all the revolutions which faction has ever occasioned in the government of Amsterdam, the prevailing party has at no time accused their predecessors of infidelity in the administration of the bank. No accusation could have affected more deeply the reputation and fortune of the disgraced party; and if such an accusation could have been supported, we may be assured that it would have been brought. In 1672, when the French king was at Utrecht, the bank of Amsterdam paid so readily as left no doubt of the fidelity with which it had observed its engagements. Some of the pieces which were then brought from its repositories appeared to have been scorched with the fire which happened in the town-house soon after the bank was established. Those pieces, therefore, must have lain there from that time.

What may be the amount of the treasure in the bank is a question which has long employed the speculations of the curious. Nothing but conjecture can be offered concerning it. It is generally reckoned, that there are about 2000 people who keep accounts with the bank; and allowing them to have, one with another, the value of 1500l. lying upon their respective accounts, (a very large allowance), the whole quantity of bank-money, and consequently of treasure in the bank, will amount to 3,000,000l. or, at 11 guilders the pound sterling, 33,000,000 of guilders; a great sum, and sufficient to carry on a very extensive circulation, but

vastly below the extravagant ideas which some people have formed of this treasure.

The city of Amsterdam derives a considerable revenue from the bank. Besides what may be called the *ware-houfe-rent* above mentioned, each person, upon first opening an account with the bank, pays a fee of 10 guilders; and for every new account, 3 guilders 3 stivers; for every transfer, 2 stivers; and if the transfer is for less than 300 guilders, 6 stivers, in order to discourage the multiplicity of small transactions. The person who neglects to balance his accounts twice in the year forfeits 25 guilders. The person who orders a transfer for more than is upon his account, is obliged to pay 3 per cent. for the sum overdrawn, and his order is set aside into the bargain. The bank is supposed too to make a considerable profit by the sale of the foreign coin or bullion which sometimes falls to it by the expiring of receipts, and which is always kept till it can be sold with advantage. It makes a profit likewise by selling bank-money at 5 per cent. agio, and buying it in at 4. These different emoluments amount to a good deal more than what is necessary for paying the salaries of officers, and defraying the expence of management. What is paid for the keeping of bullion upon receipts, is alone supposed to amount to a neat annual revenue of between 150,000 and 200,000 guilders. Public utility, however, and not revenue, was the original object of this institution. Its object was to relieve the merchants from the inconvenience of a disadvantageous exchange. The revenue which has arisen from it was unforeseen, and may be considered as accidental.

BANK, in sea-affairs, denotes an elevation of the ground or bottom of the sea, so as sometimes to surmount the surface of the water, or at least to leave the water so shallow as usually not to allow a vessel to remain a-float over it.—In this sense, *bank* amounts to much the same as flat, shoal, &c. There are banks of sand, and others of stone, called also *shelves*, or *rocks*. In the north sea they also speak of banks of ice, which are large pieces of that matter floating.

BANKER, a person who traffics and negotiates in money; who receives and remits money from place to place by commission from correspondents, or by means of bills or letters of exchange, &c.

The ancient bankers were called *argentarii*, and *nummularii*; by the Greeks, *τεραπευται, κολλοβιται, and ερζυραμβοι*. Their chief business was to put out the money of private persons to interest: they had their boards and benches, for this purpose, in all the markets and public places, where they took in the money from some, to lend it to others.

BANKING, the making of banks to oppose the force of the sea, rivers, or the like, and secure the land from being overflowed thereby. With respect to the water which is to be kept out, this is called *banking*; with respect to the land, which is hereby to be defended, *imbanking*.

BANKING is also applied to the keeping a bank, or the employment of a banker. Banking, in this sense, signifies the trading in money, or remitting it from place to place, by means of bills of exchange. This answers to what the French call *faire la banque*. In France, every body is allowed to bank, whether merchant or not; even foreigners are indulged in this kind of traffic. In Italy, banking does not derogate from nobility;

Bankh,
Bankrupt.

nobility, especially in the republic states; whence it is, that most of the younger sons of great families engage in it. In reality, it was the nobility of Venice and Genoa, that, for a long time, were the chief bankers in the other countries of Europe.

BANKISH, a province of the Mogul's dominions, in the north part of the Hither India, lying south-west of the province of Cassimere.

BANKRUPT, (*bancus ruptus*), is so called, because, when the bank or flock is broken or exhausted, the owner is said to be a *bankrupt*. And this word *bankrupt* is derived from the French *banqueroute*, which signifies a breaking or failing in the world: *banque* in French is as much as *mesa* in Latin, and *route* is the same as *vestigium*; and this term is said to be taken originally from the Roman *mensarii*, which were set in public places, and when a tradesman slipped away, with an intention to deceive his creditors, he left only some *vestigia* or signs of his table or shop behind him. But a bankrupt with us, from the several descriptions given of him in our statute-law, may be defined "a trader, who secretes himself, or does certain other acts tending to defraud his creditors." For the better understanding of this article, it will be proper to consider, 1. *Who* may become a bankrupt: 2. *What acts* make a bankrupt: 3. *The proceedings* on a commission of bankruptcy: and, 4. *In what manner* an estate in goods and chattels may be *transferred* by bankruptcy.—But of these, the two last being treated under the article **COMMISSION of Bankruptcy**, the two first only belong to this place.

1. A bankrupt was formerly considered merely in the light of a criminal or offender; and in this spirit we are told by Sir Edward Coke, that we have fetched as well the name, as the wickedness, of bankrupts from foreign nations. But at present the laws of bankruptcy are considered as laws calculated for the benefit of trade, and founded on the principles of humanity as well as justice; and to that end they confer some privileges, not only on the creditors, but also on the bankrupt or debtor himself. On the creditors; by compelling the bankrupt to give up all his effects to their use, without any fraudulent concealment: on the debtor; by exempting him from the rigor of the general law, whereby his person might be confined at the discretion of his creditor, though in reality he has nothing to satisfy the debt; whereas the law of bankrupts, taking into consideration the sudden and unavoidable accidents to which men in trade are liable, has given them the liberty of their persons, and some pecuniary emoluments, upon condition they surrender up their whole estate to be divided among their creditors.

In this respect our legislature seems to have attended to the example of the Roman law. We mean not the terrible law of the twelve tables; whereby the creditors might cut the debtor's body into pieces, and each of them take his proportionable share: if indeed that law, *de debitor in partes secando*, is to be understood in so very butcherly a light; which many learned men have with reason doubted. Nor do we mean those less inhuman laws (if they may be called so, as *their* meaning is indisputably certain), of imprisoning the debtor's person in chains; subjecting him to stripes and hard

labour, at the mercy of his rigid creditor; and sometimes selling him, his wife, and children, to perpetual foreign slavery *trans Tiberim* (A): an oppression, which produced so many popular insurrections, and secessions to the *mons sacer*. But we mean the law of cession, introduced by the Christian emperors; whereby, if a debtor *ceded* or yielded up all his fortune to his creditors, he was secured from being dragged to a gaol, "*omni quoque corporali cruciati semoto*." For, as the emperor justly observes, "*inhumanum erat spoliatum fortunæ suis in solidum damnari*." Thus far was just and reasonable: but, as the departing from one extreme is apt to produce its opposite, we find it afterwards enacted, that if the debtor by any unforeseen accident was reduced to low circumstances, and would swear that he had not sufficient left to pay his debts, he should not be compelled to cede or give up even that which he had in his possession; a law which, under a false notion of humanity, seems to be fertile of perjury, injustice, and absurdity.

The laws of England, more wisely, have steered in the middle between both extremes: providing at once against the inhumanity of the creditor, who is not suffered to confine an honest bankrupt after his effects are delivered up; and at the same time taking care that all his just debts shall be paid, so far as the effects will extend. But still they are cautious of encouraging prodigality and extravagance by this indulgence to debtors: and therefore they allow the benefit of the laws of bankruptcy to none but actual traders; since that set of men are, generally speaking, the only persons liable to accidental losses, and to an inability of paying their debts, without any fault of their own. If persons in other situations of life run in debt without the power of payment, they must take the consequences of their own indiscretion, even though they meet with sudden accidents that may reduce their fortunes: for the law holds it to be an unjustifiable practice, for any person but a trader to encumber himself with debts of any considerable value. If a gentleman, or one in a liberal profession, at the time of contracting his debts, has a sufficient fund to pay them, the delay of payment is a species of dishonesty, and a temporary injustice to his creditor: and if, at such time, he has not sufficient fund, the dishonesty and injustice is the greater. He cannot therefore murmur, if he suffers the punishment which he has voluntarily drawn upon himself. But in mercantile transactions the case is far otherwise. Trade cannot be carried on without mutual credit on both sides: the contracting of debts is therefore here not only justifiable, but necessary. And if by accidental calamities, as by the loss of a ship in a tempest, the failure of brother traders, or by the non-payment of persons out of trade, a merchant or trader becomes incapable of discharging his own debts, it is his misfortune and not his fault. To the misfortunes therefore of debtors, the law has given a compassionate remedy, but denied it to their faults: since, at the same time that it provides for the security of commerce, by enacting that every considerable trader may be declared a bankrupt, for the benefit of his creditors as well as himself, it has also, to discourage extravagance, declared, that

(A) In Pegu, and the adjacent countries in East India, the creditor is entitled to dispose of the debtor himself, and likewise of his wife and children: inasmuch that he may even violate, with impunity, the chastity of the debtor's wife; but then, by so doing, the debt is understood to be discharged.

Blackst.
Comm. II.
472. 8cc.

Bankrupt.

that no one shall be capable of being made a bankrupt, but only a trader; nor capable of receiving the full benefit of the statutes, but only an industrious trader.

In the interpretation of the several statutes made concerning English bankrupts †, it hath been held, that buying only, or selling only, will not qualify a man to be a bankrupt; but it must be both buying and selling, and also getting a livelihood by it: as, by exercising the calling of a merchant, a grocer, a mercer, or, in one general word, a *chapman*, who is one that buys and sells any thing. But no handicraft occupation (where nothing is bought or sold, and therefore an extensive credit, for the stock in trade, is not necessary to be had) will make a man a regular bankrupt; as that of a husbandman, a gardener, and the like, who are paid for their work and labour. Also an inn-keeper cannot, as such, be a bankrupt: for his gain or livelihood does not arise from buying and selling in the way of merchandize, but greatly from the use of his rooms and furniture, his attendance, and the like: and though he may buy corn and victuals, to sell again at a profit, yet that no more makes him a trader, than a schoolmaster or other person is, that keeps a boarding-house, and makes considerable gains by buying and selling what he spends in the house, and such a one is clearly not within the statutes. But where persons buy goods, and make them up into saleable commodities, as shoemakers, smiths, and the like; here, tho' part of the gain is by bodily labour, and not by buying and selling, yet they are within the statutes of bankrupts; for the labour is only in melioration of the commodity, and rendering it more fit for sale.

2. To learn what the *acts* of bankruptcy are which render a man a bankrupt, we must consult the several statutes, and the resolutions formed by the courts thereon. Among these may therefore be reckoned, 1. Departing from the realm, whereby a man withdraws himself from the jurisdiction and coercion of the law, with intent to defraud his creditors. 2. Departing from his own house, with intent to secrete himself and avoid his creditors. 3. Keeping in his own house, privately, (except for just and necessary cause) so as not to be seen or spoken with by his creditors; which is likewise construed to be an intention to defraud his creditors, by avoiding the process of the law. 4. Procuring or suffering himself willingly to be arrested, or outlawed, or imprisoned, without just and lawful cause; which is likewise deemed an attempt to defraud his creditors. 5. Procuring his money, goods, chattels, and effects, to be attached or sequestrated by any legal process; which is another plain and direct endeavour to disappoint his creditors of their security. 6. Making any fraudulent conveyance to a friend, or secret trustee, of his lands, tenements, goods, or chattels; which is an act of the same suspicious nature with the last. 7. Procuring any protection, not being himself privileged by parliament, in order to screen his person from arrests; which also is an endeavour to elude the justice of the law. 8. Endeavouring, or desiring, by any petition to the king, or bill exhibited in any of the king's courts against any creditors, to compel them to take less than their just debts; or to procrastinate the time of payment, originally contracted for; which are an acknowledgment of either his poverty or his knavery. 9. Lying in prison for two months, or more, upon ar-

VOL. II.

rest or other detention for debt, without finding bail, in order to obtain his liberty. For the inability to procure bail argues a strong deficiency in his credit, owing either to his suspected poverty, or ill character; and his neglect to do it, if able, can arise only from a fraudulent intention: in either of which cases, it is high time for his creditors to look to themselves, and compel a distribution of his effects. 10. Escaping from prison after an arrest for a just debt of 100*l.* or upwards. For no man would break prison, that was able and desirous to procure bail; which brings it within the reason of the last case. 11. Neglecting to make satisfaction for any just debt to the amount of 100*l.* within two months after service of legal process, for such debt, upon any trader having privilege of parliament.

These are the several acts of bankruptcy expressly defined by the statutes relating to this article; which being so numerous, and the whole law of bankrupts being an innovation on the common law, our courts of justice have been tender of extending or multiplying acts of bankruptcy by any construction or implication. And therefore Sir John Holt held, that a man's removing his goods privately to prevent their being seized in execution, was no act of bankruptcy. For the statutes mention only fraudulent gifts to third persons, and procuring them to be seized by sham process, in order to defraud creditors: but this, though a palpable fraud, yet, falling within neither of those cases, cannot be adjudged an act of bankruptcy. So also it has been determined expressly, that a banker's stopping or refusing payment is no act of bankruptcy: for it is not within the description of any of the statutes; and there may be good reasons for his so doing, as suspicion of forgery, and the like: and if, in consequence of such refusal, he is arrested, and puts in bail, still it is no act of bankruptcy; but if he goes to prison, and lies there two months, then, and not before, is he become a bankrupt.

As to the consequences resulting from the unhappy situation of a bankrupt, see the article *COMMISSION OF Bankruptcy*.

BANKS (John), a dramatic writer, was bred to the law, and belonged to the society of Gray's Inn; but this profession not suiting his natural disposition, he quitted it for the service of the muses. Here, however, he found his rewards by no means adequate to his deserts. His emoluments at the best were precarious, and the various successes of his pieces too feelingly convinced him of the error in his choice. This however did not prevent him from pursuing with cheerfulness the path he had taken; his thirst of fame, and warmth of poetic enthusiasm, alleviating to his imagination many disagreeable circumstances into which indigence, the too frequent attendant on poetical pursuits, frequently threw him. His turn was entirely to tragedy. His merit in which is of a peculiar kind. For at the same time that his language must be confessed to be extremely unpoetical, and his numbers uncouth and unharmonious; nay, even his characters very far from being strongly marked or distinguished, and his episodes extremely irregular; yet it is impossible to avoid being deeply affected at the representation, and even at the reading, of his tragic pieces. This is owing in the general to an happy choice of his subjects; which are all borrowed from history, either real

Bankrupt.
Banks.

or romantic ; and indeed the most of them from circumstances in the annals of our own country, which, not only from their being familiar to our continual recollection, but even from their having some degree of relation to ourselves, we are apt to receive with a kind of partial prepossession, and a pre-determination to be pleased. He has constantly chosen as the basis of his plays such tales as were in themselves and their well-known catastrophes most truly adapted to the purposes of the drama. He has indeed but little varied from the strictness of historical facts ; yet he seems to have made it his constant rule to keep the scene perpetually alive, and never suffer his characters to droop. His verse is not poetry, but prose run mad. Yet will the false gem sometimes approach so near in glitter to the true one, at least in the eyes of all but the real connoisseurs, (and how small a part of an audience are to be ranked in this class will need no ghost to inform us), that bombast will frequently pass for the true sublime ; and where it is rendered the vehicle of incidents in themselves affecting, and in which the heart is apt to interest itself, it will perhaps be found to have a stronger power on the human passions than even that property to which it is in reality no more than a bare succedaneum. And from these principles it is that we must account for Mr Banks's writings having in the general drawn more tears from, and excited more terror in, even judicious audiences, than those of much more correct and more truly poetical authors. The tragedies he has left behind are, 1. *Albion Queens*. 2. *Cyrus the Great*. 3. *Desolation of Troy*. 4. *Innocent Usurper*. 5. *Island Queens*. This is only the *Albion Queens* altered. 6. *Rival Kings*. 7. *Virtue betrayed*. 8. *Unhappy Favourite*. The *Albion Queens* was rejected by the managers in 1684 ; but was acted by queen Anne's command in 1706, with great applause, and has been several times revived. The *unhappy Favourite* continued, till very lately, a stock tragedy at the theatres ; but gives way at present to the later tragedies from the same story, by Jones and Brooke.—Neither the time of the birth, nor that of the death, of this author, are ascertained. His remains, however, lie interred in the church of St James's, Westminster.

BANKS'S ISLAND, a small island in the fourth sea discovered by captain Cook in 1770, in S. Lat. 53. 32. W. Long. 186. 30. It is of a circular figure, and about 24 leagues in compass : it is sufficiently high to be seen at the distance of 12 or 15 leagues ; and the land has a broken irregular surface, with the appearance of barrenness rather than fertility. It is, however, inhabited, as some straggling savages were observed upon it.

BANN, or **BAN** (from the Brit. *ban*, i. e. clamour), is a proclamation or public notice ; any public summons or edict, whereby a thing is commanded or forbidden. It is a word ordinary among the feudists ; and there is both *banus* and *banum*, which signify two several things.—The word *banns* is particularly used in England in publishing matrimonial contracts ; which is done in the church before marriage, to the end that if any persons can speak against the intention of the parties, either in respect of kindred, precontract, or for other just cause, they may take their exception in time, before the marriage is consummated ; and in the canon law, *Bannæ sunt proclamationes sponsi et sponsæ in ecclesiis fieri solite*. But there may be a faculty or li-

cence for the marriage, and then this ceremony is omitted ; and ministers are not to celebrate matrimony between any persons without a licence, except the bans have been first published three several times, upon pain of suspension, &c. Can. 62.

The use of matrimonial bans is said to have been first introduced in the Gallican church, though something like it obtained even in the primitive times ; and it is this that Tertullian's is supposed to mean by *trinidadina promulgatio*. The council of Lateran first extended, and made the usage general. By the ordinance of Blois, no person could validly contract marriage, without a preceding proclamation of three bans ; nor could any person whatever be dispensed with, except for the two last. But the French themselves have abated much of this severity ; and only minors are now under an absolute necessity of submitting to the formality of bans. For majors, or those of age, after publication of the first bans, the two latter are easily bought off.

BANN is also used to denote proscription, or banishment, for a crime proved ; because anciently published by sound of trumpet ; or, as Vossius thinks, because those who did not appear at the abovementioned summons, were punished by proscription. Hence, to put a prince under the ban of the empire, is to declare him divested of all his dignities. The sentence only denotes an interdict of all intercourse, and offices of humanity, with the offender ; the form of which seems taken from that of the Romans, who banished persons by forbidding them the use of fire and water. Sometimes also cities are put under the imperial ban ; that is, stripped of their rights and privileges.

BANN also denotes a pecuniary mulct, or penalty, laid on a delinquent for offending against a ban.

BANN, or **BANNUS**, a title anciently given to the governor or viceroy of Croatia, Dalmatia, and Slavonia.

BANNUS Episcopalis, was a mulct paid to the bishop by those guilty of sacrilege and other crimes.

BANN, is also used for a solemn anathema, or excommunication, attended with curses, &c. In this sense, we read of *papal banns*, &c.

BANN, in military affairs, a proclamation made in the army by beat of drum, sound of trumpet, &c. requiring the strict observance of discipline, either for the declaring a new officer, or punishing an offender.

BANNER denotes either a square flag, or the principal standard belonging to a prince.

We find a multiplicity of opinions concerning the etymology of the word *banner* ; some deriving it from the Latin *bandum*, a band or flag ; others from the word *bann*, to summons the vassals to appear in arms ; others again from the German *ban*, a field or tenement, because landed men alone were allowed a banner ; and, finally, there arc some who think it is a corruption of *panniere*, from *pannus*, cloth, because banners were originally made of cloth.

The **BANNER of France**, was the largest and richest of all the flags borne by the ancient kings in their great military expeditions. St Martin's cap was in use six hundred years, as the banner of France : it was made of taffety, painted with the image of that saint, and laid one or two days on his tomb to prepare it for use. About the year 1100, came in a more pompous apparatus. The banner royal was fastened to the top of a mast,

room.

maff, or fome tall tree, planted on a fcaffold, borne on a carriage drawn by oxen, covered with velvet houfings, decorated with devices or cyphers of the prince reigning. At the foot of the tree was a prieft, who faid mafs early every morning. Ten knights mounted guard on the fcaffold night and day, and as many trumpets at the foot of the tree never ceafed flourifhing, to animate the troops. This cumbersome machine, the mode of which was brought from Italy, continued in ufe about 130 years. Its poft was in the centre of the army. And here it was that the chief feats were performed, to carry off and defend the royal banner; for there was no victory without it, nor was an army reputed vanquifhed till they had loft this banner.

BANNERET, a very ancient title of honour, faid to derive its institution from the Romans, towards the end of the emperor Gratian's reign. Knights-banneret are called in Latin *militēs vexilliferi*, by Matth. Paris, p. 134; and *militēs vexillati*, by the author of the *Dicte de Trevoux*; their shield was fquare, and they bore their arms in a banner of the fame form.

This was a very honourable order, as it was never conferred but for fome heroic action performed in the field; whereas other orders have frequently been bestowed from favour, or other meaner motives. It is faid to have been firft ufed in England in the time of Edward I. We have had none of this order created fince the time of king Charles I. fo that it is now become extinct among us.

The form of the bannerets creation was this: On a day of battle, the candidate prefented his flag to the king, or general, who cutting off the train or skirt thereof, and making it a fquare, returned it again, being then the proper banner of bannerets, who from hence are fometimes called *knights of the fquare flag*.

BANNOCK, a kind of oat-cake, baked in the embers, or on a ftone placed before the fire: it is common in the northern parts of this kingdom.

BANNUM, in law, fignifies the utmoft bounds of a manor or town.

BANQUET, a feaft or entertainment, where people regale themfelves with pleafant foods, or fruits.

BANQUET, in the menage, that fmall part of the branch of a bridle that is under the eye; which being rounded like a fmall rod, gathers and joins the extremities of the bit to the branch in fuch a manner, that the banquet is not feen, but covered by the cope, or that part of the bit that is next the branch.

BANQUET-Line, an imaginary line drawn, in making a bit, along the banquet, and prolonged up or down, to adjust the defigned force or weaknefs of the branch, in order to make it fiff or eafy.

BANQUET, or **BANQUETTE**, in fortification, a little foot-bank, or elevation of earth, forming a path which runs along the infide of a parapet, upon which the mufqueteers get up, in order to difcover the counter-fcarp, or to fire on the enemy in the moat or in the covert-way.

BANQUETING-ROOM, or **HOUSE**. See **SALOON**. The ancient Romans fupped in the atrium, or vestibule, of their houfes; but, in after-times, magnificent faloons, or banqueting-rooms, were built, for the more commodious and fplendid entertainment of their guefts. Lucullus had feveral of thefe, each diftinguifhed by the name of fome god; and there was a particular rate of

expenfe appropriated to each. Plutarch relates with what magnificence he entertained Cicero and Pompey, who went with defign to furprife him, by telling only a flave who waited, that the cloth fhould be laid in the Apollo. The emperor Claudius, among others, had a fplendid banqueting-room, named *Mercury*. But every thing of this kind was outdone by the luftre of that celebrated banqueting-houfe of Nero, called *dumus aurea*; which, by the circular motion of its partitions, and ceilings, imitated the revolution of the heavens, and represented the different feafons of the year, which changed at every fevice, and flowered down flowers, effences, and perfumes, on the guefts.

BANSTICKLE, in ichthyology. See **GASTEROSTEUS**.

BANTAM, a large town of the ifland of Java, in the East Indies, fituated in E. Long. 105. 16. S. Lat. 6. 20. It is the capital of a kingdom of the fame name, with a good harbour and fortified caftle. It is divided into two towns feparated by a river, and one of them inhabited by the Chinefe. For its hiftory, &c. See **JAVA**.

BANTAM-WORK, a kind of painted or carved work, refembling that of Japan, only more gaudy.

There are two forts of Bantam, as well as of Japan work. As, in the latter, fome are flat, lying even with the black, and others high and emboffed; fo, in Bantam-work, fome are flat, and others in-cut, or carved into the wood, as we find in many large fcreens: with this difference, that the Japan artifts work chiefly in gold and other metals; and thofe of Bantam generally in colours, with a fmall fprinkling of gold here and there: for the flat Bantam work is done in colours, mixed with gum-water, proper for the thing defigned to be imitated. For the carved, or in-cut kind, the method of performing it is thus defcribed by an ingenious artift: 1. The wood is to be primed with whitening and fize, fo often, till the primer lie near a quarter of an inch thick; then it is to be water-plained, *i. e.* rubbed with a fine wet cloth, and, fome time after, rubbed very fmooth, the blacks laid on, varnifhed up with a good body, and polished well, though with a gentle hand. This done, the defign is to be traced out with vermilion and gum-water, exactly in the manner wherein it is intended to be cut; the figures, trees, buildings, &c. in their due proportion: then the graver is applied, with other tools of proper fhares, differing according to the workman's fancy: with thefe he cuts deep or fhallow, as is found convenient, but never deeper than the whitening lies, the wood being never to feel the edge of the inftrument. Lines, or parts of the black, are fill to be left for the draperies, and other out-lines, and for the diftinction of one thing from another; the rule being to cut where the white is, and leave the black untouched. The carving being finifhed, then take to the pencil, with which the colours are laid into the cut-work: after this, the gold is to be laid in thofe places which the defign requires; for which purpofe, a ftrong thick gum-arabic water is taken, and laid with a pencil on the work; and, while this remains wet, leaf-gold is cut with a fharp fmooth edged knife, in little pieces, fhaped to the bignefs and figure of the places where they are to be laid. Thefe being taken up with a little cotton, they daub them with the fame clofe to the gum-water, which affords a

Banftickle,
Bantam.

rich lustre. The work thus finished, they clear up the black with oil, taking care not to touch the colours. The European workmen ordinarily use brags-dust, which is less bright and beautiful.

BANTRY, a town of Ireland, in the county of Cork, and province of Munster. It is seated on a bay of the same name, in W. Long. 9. 15. N. Lat. 51. 30.

BAOBAB, the name given by Prosper Alpinus to the African calabash-tree, since called ADANSONIA. See that article. But the following more particular account of this most remarkable tree, the largest production of the whole vegetable kingdom, will not, it is hoped, appear superfluous.

The trunk is not above 12 or 15 feet high, but from 65 to 78 feet round. The lowest branches extend almost horizontally; and as they are about 60 feet in length, their own weight bends their extremities to the ground, and thus form an hemispherical mass of verdure of about 120 or 130 feet diameter. The roots extend as far as the branches: that in the middle forms a pivot, which penetrates a great way into the earth; the rest spread near the surface. The flowers are in proportion to the size of the tree; and are followed by an oblong fruit, pointed at both ends, about ten inches long, five or six broad, and covered with a kind of greenish down, under which is a ligneous rind, hard and almost black, marked with rays which divide it lengthwise into fibres. The fruit hangs to the tree by a pedicle two feet long and an inch diameter. It contains a whitish spongy juicy substance; with seeds of a brown colour, and shaped like a kidney-bean. The bark of this tree is nearly an inch thick, of an ash-coloured grey, greasy to the touch, bright, and very smooth: the outside is covered with a kind of varnish; and the inside is green, speckled with red. The wood is white, and very soft; the first shoots of the year are green and downy.

The tree sheds its leaves in November, and new ones begin to appear in June. It flowers in July, and the fruit ripens in October and November. It is very common in Senegal, and the Cape de Verd islands; and is found 100 leagues up the country at Gulam, and upon the sea-coast as far as Sierra-lione.

The age of this tree is perhaps no less remarkable than its enormous size. M. Adanson relates, that in a botanical excursion to the Magdalen Islands, in the neighbourhood of Goree, he discovered some calabash-trees, from five to six feet diameter, on the bark of which were engraved or cut to a considerable depth a number of European names. Two of these names, which he was at the trouble to repair, were dated one the 14th, the other the 15th century. The letters were about six inches long, but in breadth they occupied a very small part only of the circumference of the trunk: from whence he concluded they had not been cut when these trees were young. These inscriptions, however, he thinks sufficient to determine pretty nearly the age which these calabash-trees may attain; for even supposing that those in question were cut in their early years, and that trees grew to the diameter of six feet in two centuries, as the engraved letters evince, how many centuries must be requisite to give them a diameter of 25 feet, which perhaps is not the last term of their growth! The inscribed trees mentioned by this ingenious Frenchman had been seen in 1555, almost

two centuries before, by Thevet, who mentions them in the relation of his voyage to Terra Antartica or Australis. Adanson saw them in 1749.

The virtues and uses of this tree and its fruit, are various. The negroes of Senegal dry the bark and leaves in the shaded air; and then reduce them to powder, which is of a pretty good green colour. This powder they preserve in bags of linen or cotton, and call it *lille*. They use it every day, putting two or three pinches of it into a meal, whatever it happens to be, as we do pepper and salt: but their view is, not to give a relish to their food, but to preserve a perpetual and plentiful perspiration, and to temper the too great heat of the blood; purposes which it certainly answers, as several Europeans have proved by repeated experiments, preserving themselves from the epidemic fever, which, in that country, destroys Europeans like the plague, and generally rages during the months of September and October, when, the rains having suddenly ceased, the sun exhales the water left by them upon the ground, and fills the air with a noxious vapour. M. Adanson, in that critical season, made a light ptisan of the leaves of the baobab, which he had gathered in the August of the preceding year, and had dried in the shade; and drank constantly about a pint of it every morning, either before or after breakfast, and the same quantity of it every evening after the heat of the sun began to abate; he also sometimes took the same quantity in the middle of the day, but this was only when he felt some symptoms of an approaching fever. By this precaution he preserved himself, during the five years he resided at Senegal, from the diarrhoea and fever, which are so fatal there, and which are, however, the only dangerous diseases of the place; and other officers suffered very severely, only one excepted, upon whom M. Adanson prevailed to use this remedy, which for its simplicity was despised by the rest. This ptisan alone also prevents that heat of urine which is common in these parts, from the month of July to November, provided the party abstains from wine.

The fruit is not less useful than the leaves and the bark. The pulp that envelopes the seeds has an agreeable acid taste, and is eaten for pleasure: it is also dried and powdered, and thus used medicinally in pelticent fevers, the dysentery, and bloody flux; the dose is a drachm, passed through a fine sieve, taken either in common water, or in an infusion of the plantain. This powder is brought into Europe under the name of *terra sigillata lemnia*.

The woody bark of the fruit, and the fruit itself when spoiled, helps to supply the negroes with an excellent soap, which they make by drawing a ley from the ashes, and boiling it with palm-oil that begins to be rancid.

The trunks of such of these trees as are decayed, the negroes hollow out into burying places for their poets, musicians, buffoons: persons of these characters they esteem greatly while they live, supposing them to derive their superior talents from sorcery or a commerce with demons; but they regard their bodies with a kind of horror when dead, and will not give them burial in the usual manner, neither suffering them to be put into the ground, nor thrown into the sea or any river, because they imagine that the water would not then nourish

Baptism.

Bapaume
Baptism.

rish the fish, nor the earth produce its fruits. The bodies flut up in these trunks become perfectly dry without rotting, and form a kind of mummies without the help of embalment.

The baobab is very distinct from the calabash-tree of America, with which it has been confounded by father Labat. See CRESCENTIA.

BAPAUME, a strong town of Artois in the French Netherlands. It has been in the possession of the French ever since the year 1641; and is seated in a dry spot, in E. Long. 3. 1. N. Lat. 50. 6.

BAPTĒ, in antiquity, an effeminate, voluptuous kind of priests, at Athens, belonging to the goddess Cotyttus; thus called from their staid dippings and washings, by way of purification. Their rites were performed in the night, and consisted chiefly of lascivious dances, and other abominations. Eupolis having composed a comedy to expose them, entitled *BAPTĒ*, they threw him into the sea, to be revenged; and the same fate is also said to have befallen Cratinus, another Athenian poet, who had written a comedy against the *Baptæ*, under the same title.

BAPTISM, in matters of religion, the ceremony of washing; or a sacrament, by which a person is initiated into the Christian church.—The word is formed from the Greek *βαπτίζω*, of *βαπτο* to dip or wash. Baptism is known, in ecclesiastical writers, by divers other names and titles. Sometimes it is called *palinogenesis*, or *laver of regeneration*; sometimes *salus*, or *life and salvation*; sometimes *σφραγις*, *signaculum Domini*, and *signaculum fidei*, or *the seal of faith*; sometimes absolutely *mysterium*, and *sacramentum*; sometimes *the sacrament of faith*; sometimes *viaticum*, from its use to departing persons; sometimes *sacerdotium laici*, or *the lay priesthood*, because allowed, in cases of necessity, to be conferred by laymen: sometimes it is called the *great circumcision*, by reason it succeeds in the room of circumcision, and is the seal of the Christian covenant, as that was the seal of the covenant made with Abraham: so, in regard that baptism had Christ for its author, and not man, it was anciently known by the name of *Δουρον* and *χαρισμα Κυριου*, *the gift of the Lord*: sometimes it was simply called *δουρον*, without any other addition, by way of eminence, because it was both a gratuitous and singular gift of Christ: in reference to the making men complete members of Christ's body, the church, it had the name of *τελειωσις*, and *τελειωσις*, the *consecration*, and *consummation*; because it gave men the perfection of Christians, and a right to partake of the *Το Τειλαιον*, which was the *Lord's Supper*: it had also the name of *μυστικη* and *μυσταγωγια*, *the initiation*, because it was the admittance of men to all the sacred rites and mysteries of the Christian religion.

Various names given to baptism.

Bingham's Orig. Eccles.

Its origin, &c.

Baptism had its origin from the Jewish church, where it was the practice, long before Christ's time, to baptize proselytes or converts to their faith, as part of the ceremony of their admission; a practice which obtains among them to this day: a person turning Jew, is first circumcised, and, when healed, is bathed, or baptized in water, in presence of their rabbins; after which he is reputed a good Jew.

Grotius is of opinion, that the rite of baptism had its original from the time of the deluge; immediately after which, he thinks, it was instituted in memory of the world having been purged by water. Some learned

men think it was added to circumcision, soon after the Samaritan schism, as a mark of distinction to the orthodox Jews. Spencer, who is fond of deriving the rites of the Jewish religion from the ceremonies of the Pagans, lays it down as a probable supposition, that the Jews received the baptism of proselytes from the neighbouring nations, who were wont to prepare candidates for the more sacred functions of their religion by a solemn ablution; that, by this affinity of sacred rites, they might draw the Gentiles to embrace their religion, and the proselytes (in gaining of whom they were extremely diligent) might the more easily comply with the transition from Gentilism to Judaism. In confirmation of this opinion, he observes, first, that there is no divine precept for the baptism of proselytes, God having enjoined only the rite of circumcision for the admission of strangers into the Jewish religion. Secondly, that, among foreign nations, the Egyptians, Persians, Greeks, Romans, and others, it was customary that those who were to be initiated into their mysteries, or sacred rites, should be first purified by dipping their whole body in water. That learned writer adds, as a further confirmation of his opinion, that the cup of blessing likewise, added to the paschal supper, seems plainly to have been derived from a pagan original: for the Greeks, at their feasts, had one cup, called *σπονγης αγαθου δαιμονου*, *the cup of the good demon or god*, which they drank at the conclusion of their entertainment, when the table was removed. Since, then, a rite of Gentile origin was added to one of the Jewish sacraments, viz. the passover, there can be no absurdity in supposing, that baptism, which was added to the other sacrament, namely circumcision, might be derived from the same source. In the last place, he observes, that Christ, in the institution of his sacraments, paid a peculiar regard to those rites which were borrowed from the Gentiles: for, rejecting circumcision and the paschal supper, he adopted into his religion baptism and the sacred cup; thus preparing the way for the conversion and reception of the Gentiles into his church.

The design of the Jewish baptism is supposed to be, to import a regeneration, whereby the proselyte is rendered a new man, and of a slave becomes free. The effect of it is, to cancel all former relations; so that those, who were before akin to the person, after the ceremony ceased to be so. It is to this ceremony Christ is supposed to have alluded, in his expression to Nicodemus, that it was necessary he should be born again, in order to become his disciple.—The necessity of baptism to salvation, is grounded on those two sayings of our Saviour: *He that believeth, and is baptized, shall be saved; and, Except a man be born of water and of the Spirit, he cannot enter into the kingdom of God.*—The ancients did not generally think the mere want of baptism, where the procuring it was impracticable, excluded men absolutely from the benefit of church-communion, or the hopes of eternal salvation. Some few of them, indeed, are pretty severe upon infants dying without baptism; and some others seem also, in general terms, to deny eternal life to adult persons dying without it: but when they interpret themselves, and speak more distinctly, they make few allowances, and except several cases, in which the want of baptism may be supplied with other means. Such are, martyrdom, which commonly goes by the name of *second baptism*.

Opinions concerning the necessity of Baptism to salvation.

Baptism.

baptism in mens own blood, in the writings of the ancients; because of the power and efficacy it was thought to have, to save men by the invisible baptism of the spirit, without the external element of water. Faith, and repentance, were also esteemed a supplement to the want of baptism, in such catechumens as died while they were piously preparing themselves for baptism. Constantly communicating with the church, was thought to supply the want of baptism, in persons who had been admitted to communion, on a presumption of their being duly baptized, though the contrary afterwards appeared. For infants dying without baptism, the case was thought more dangerous; as here, no personal faith, repentance, or the like, could be pleaded, to supply the defect, and wash away original sin: on this account, they who spoke most favourably of them, as Greg. Nazianzen, and Severus bishop of Antioch, only assigned them a middle state, neither in heaven nor hell. But the Latins, as St Augustin, Fulgentius, Marius Mercator, &c. who never received the opinion of a middle state, concluded, as they could not be received into heaven, they must go to hell. Pelagius, and his followers, who denied original sin, asserted, that they might be admitted to eternal life and salvation, though not to the kingdom of heaven; between which they distinguished. Where the fault was not on the side of the child, nor his parents, but of the minister, or where any unavoidable accident rendered baptism absolutely impossible, Hincmar, and others, make an exception, in holding the child saved without baptism.—The receiving baptism is not limited to any time, or age of life. Some contend for its being administered like circumcision, precisely on the eighth day, as Greg. Nazianzen; and others would have it deferred till the child is three years of age, and able to hear the mytic words, and make answer thereto, though they do not understand them. In the canon law we find divers injunctions against deferring the baptism of infants beyond the 37th day, 30th day, and the 9th day; some of them under pecuniary forfeitures.

Salmasius, and Suicerus from him, deliver it as authentic history, that, for the two first ages, no one received baptism, who was not first instructed in the faith and doctrine of Christ, so as to be able to answer for himself, that he believed; because of those words, *He that believeth, and is baptized*: which, in effect, is to say, that no infant, for the first two ages, was ever admitted to Christian baptism. But, afterwards, they own, that pædo-baptism came in, upon the opinion that baptism was necessary to salvation. But Vossius, Dr Forbes, Dr Hammond, Mr Walker, and especially Mr Wall, who has exactly considered the testimony and authority of almost every ancient writer that has said any thing upon this subject, endeavour to evince, that infants were baptized even in the apostolical age. It is certain, Tertullian pleads strongly against giving baptism to infants; which shews, at least, that there was some such practice in his age, tho' he disapproved of it. It is certain, the ordinary subjects of this sacrament, in the first ages, were converts from Judaism and Gentilism, who, before they could be admitted to baptism, were obliged to spend some time in the state of catechumens, to qualify them to make their professions of faith, and a Christian life, in their own persons: for, without such personal pro-

Baptism.

essions, there was ordinarily no admission of them to the privilege of baptism.—Those baptized in their sick-beds were called *clinici*; and were held in some reproach, as not being reputed true Christians. Hence several censures, in councils and ecclesiastical writers, of clinic baptism. This clinic baptism was not sufficient to qualify the person, in case of recovery, for ordination. Some had their baptism put off by way of punishment, when they fell into gross and scandalous crimes, which were to be expiated by a longer course of discipline and repentance. This was sometimes 5, 10, 20 years, or more; even all their lives, to the hour of death, when their crimes were very flagrant.

In the earliest ages of the church, there was no fixed time or place for the reception of baptism. Afterwards, Easter, Whitstundie, and Epiphany, became solemn seasons, out of which baptism was not administered, except in cases of necessity. The catechumens, who were to receive it at these times, were called *competentes*; and to these it is that St Cyril addresses his catecheses. In the apostolical age, and some time after, before churches and baptiseries were generally erected, they baptized in any place where they had convenience; as John baptized in Jordan, and Philip baptized the eunuch in the wilderness, and Paul the jailor in his own house. But, in after-ages, baptiseries were built adjoining to the church; and then rules were made, that baptism should ordinarily be administered no where but in these buildings. Justinian, in one of his novels, refers to ancient laws, appointing that none of the sacred mysteries of the church should be celebrated in private houses. Men might have private oratories for prayer in their own houses; but they were not to administer baptism or the eucharist in them, unless by a particular licence from the bishop of the place. Such baptiseries are frequently condemned in the ancient councils, under the name *παρεβατικῶν μαρίων*, *baptiseries in private conventicles*.

As to the attendant ceremonies and manner of baptism in the ancient church: The person to be baptized, if an adult, was first examined by the bishop, or officiating priest, who put some questions to him; as, first, Whether he abjured the devil and all his works; secondly, Whether he gave a firm assent to all the articles of the Christian faith: to both which he answered in the affirmative. If the person to be baptized was an infant, these interrogatories were answered by his *sponsors*, or god-fathers. Whether the use of sponsors was as old as the apostles days, is uncertain: perhaps it was not, since Justin Martyr, speaking of the method and form of baptism, says not a word of them.—After the questions and answers, followed exorcism; the manner and end of which was this: The minister laid his hands on the person's head, and breathed in his face, implying thereby the driving away, or expelling, of the devil from him, and preparing him for baptism, by which the good and holy spirit was to be conferred upon him.—After exorcism, followed baptism itself: and first the minister, by prayer, consecrated the water for that use. Tertullian says, "any waters may be applied to that use; but then God must be first invoked, and then the Holy Ghost presently comes down from heaven, and moves upon them, and sanctifies them." The water being consecrated, the person was baptized "in the name of the Father, and of

Baptism.

“ the Son, and of the Holy Ghost ;” by which “ dedication of him to the blessed Trinity, the person “ (says Clemens Alexandrianus) is delivered from the “ corrupt trinity, the devil, the world, and the flesh.” In performing the ceremony of baptism, the usual custom, (except in clinical cases, or where there was scarcity of water), was to immerse and dip the whole body. Thus St Barnabas, describing a baptized person, says, “ We go down into the water full of sin “ and filth, but we ascend bearing fruit in our hearts.” And this practice of baptizing naked was so general, that we find no exceptions made in respect either to the tenderness of infants, or the bashfulness of the other sex, unless in case of sickness or other disability. But, to prevent any indecency, men and women were baptized apart. To which end, either the baptisteries were divided into two apartments, one for the men, the other for the women, as Bingham has observed; or the men were baptized at one time, and the women at another, as is shewn by Vossius, from the *Ordo Romanus*, Gregory’s *Sacramentarius*, &c. Add, that there was anciently an order of deaconesses, one part of whose business was to assist at the baptism of women. After immersion, followed the unction; by which (says St Cyril) was signified, that they were now cut off from the wild olive, and were ingrafted into Christ, the true olive-tree; or else to shew, that they were now to be champions for the gospel, and were anointed thereto, as the old athlete were against their solemn games. With this anointing was joined the sign of the cross, made upon the forehead of the person baptized; which being done, he had a white garment given him, to denote his being washed from the defilements of sin, or in allusion to that of the apostle, “ as many as are “ baptized into Christ have put on Christ.” From this custom the feast of Pentecost, which was one of the annual seasons of baptism, came to be called *Whitsunday*, i. e. *White-sunday*. This garment was afterwards laid up in the church, that it might be an evidence against such persons as violated or denied that faith which they had owned in baptism.—When the baptism was performed, the person baptized, according to Justin Martyr, “ was received into the number of the faithful, who then sent up their public prayers to God, “ for all men, for themselves, and for those who had “ been baptized.”

The ordinary ministers, who had the right of administering this sacrament, that is, of applying the water to the body, and pronouncing the formula, were presbyters, or bishops; though on extraordinary occasions, laymen were admitted to perform the same.

As to the present forms of administering baptism, the church of Rome uses the following. When a child is to be baptized, the persons who bring it, wait for the priest at the door of the church, who comes thither in his surplice and purple stole, attended by his clerks. He begins with questioning the god-fathers, whether they promise, in the child’s name, to live and die in the true catholic and apostolic faith, and what name they would give the child. Then follows an exhortation to the sponsors; after which the priest, calling the child by its name, asks it as follows: *What dost thou demand of the church?* The god-father answers, *Eternal life*. The priest goes on: *If you are desirous of obtaining eternal life, keep God’s commandments,*

thou shalt love the Lord thy God, &c. After which he breathes three times in the child’s face, saying, *Come out of this child, thou evil spirit, and make room for the Holy Ghost*. This said, he makes the sign of the cross on the child’s forehead and breast, saying, *Receive the sign of the cross, on thy forehead, and in thy heart*. Then, taking off his cap, he repeats a short prayer; and, laying his hand gently on the child’s head, repeats a second prayer: which ended, he blesses foam salt; and, putting a little of it into the child’s mouth, pronounces these words, *Receive the salt of wisdom*. All this is performed at the church-door. The priest, with the god-fathers and god-mothers, coming into the church, and advancing towards the font, repeat the apostles-creed and the Lord’s-prayer. Being come to the font, the priest exorcises the evil spirit again; and taking a little of his own spittle, with the thumb of his right-hand rubs it on the child’s ears and nostrils, repeating, as he touches the right ear, the same word (*Ephatha, be thou opened*) which our Saviour made use of to the man born deaf and dumb. Lastly, they pull off its swaddling-cloaths, or strip it below the shoulders, during which the priest prepares the oils, &c. The sponsors then hold the child directly over the font, observing to turn it due east and west: whereupon the priest asks the child, *Whether he renounces the devil and all his works*; and, the god-father having answered in the affirmative, the priest anoints the child between the shoulders in the form of a cross. Then taking some of the consecrated water, he pours part of it three on the child’s head, at each perfusion calling on one of the Persons of the Holy Trinity. The priest concludes the ceremony of baptism with an exhortation.—The Romish church allows midwives, in cases of danger, to baptize a child before it is come entirely out of its mother’s womb: where it is to be observed, that some part of the body of the child must appear before it can be baptized, and that it is baptized on the part which first appears: if it be the head, it is not necessary to rebaptize the child; but if only a foot or hand appears, it is necessary to repeat baptism. A still-born child, thus baptized, may be buried in consecrated ground.

The Greek church differs from the Romish, as to the rite of baptism, chiefly, in performing it by immersion, or plunging the infant all over in the water, which the relations of the child take care to have warmed, and throw into it a collection of the most odoriferous flowers.

The forms of administering baptism among us being too well known to require a particular description, we shall only mention one or two of the more material differences between the form, as it stood in the first liturgy of King Edward, and that in the English Common-Prayer Book at present. First, the form of consecrating the water did not make a part of the office, in King Edward’s liturgy, as it does in the present, because the water in the font was changed, and consecrated, but once a month. The form likewise itself was something different from that now used; and was introduced with a short prayer, that *Jesus Christ, upon whom (when he was baptized) the Holy Ghost came down in the likeness of a dove, would send down the same Holy Spirit, to sanctify the fountain of baptism*; which prayer was afterwards left out, at the second review.—By King Edward’s first book, the minister is to dip the child

Baptism.

In the Greek church.

English form in the liturgy of K. Edw.

Modern forms. In the church of Rome.

Baptism.

child in the water thrice ; first, dipping the right side ; secondly, the left ; the third time, dipping the face toward the font. This trine immersion was a very ancient practice in the Christian church, and used in honour of the Holy Trinity ; though some later writers say, it was done to represent the death, burial, and resurrection, of Christ, together with his three days continuance in the grave. Afterwards, the Arians making an ill use of it, by persuading the people that it was used to denote that the three Persons in the Trinity were three distinct substances, the orthodox left it off, and used only one single immersion.

By the first common-prayer of king Edward, after the child was baptized, the godfathers and godmothers were to lay their hands upon it, and the minister was to put on him the white vestment commonly called the *chrysome*, and to say, " Take this white vesture, as a token of the innocency, which, by God's grace, in this holy sacrament of baptism, is given unto thee ; and for a sign, whereby thou art admonished, so long as thou livest, to give thyself to innocency of living, that after this transitory life thou mayest be partaker of the life everlasting. Amen." As soon as he had pronounced these words, he was to anoint the infant on the head, saying, " Almighty God, the father of our Lord Jesus Christ, who hath regenerated thee by water and the Holy Ghost, and hath given unto thee remission of all thy sins ; may he vouchsafe to anoint thee with the unction of his Holy Spirit, and bring thee to the inheritance of everlasting life. Amen." This was manifestly done in imitation of the practice of the primitive church.

The custom of sprinkling children, instead of dipping them in the font, which at first was allowed in case of the weakness or sickness of the infant, has so far prevailed, that immersion is at length quite excluded. What principally tended to confirm the practice of affusion or sprinkling, was, that several of our Protestant divines, flying into Germany and Switzerland during the bloody reign of queen Mary, and returning home when queen Elizabeth came to the crown, brought back with them a great zeal for the Protestant churches beyond sea, where they had been sheltered and received ; and having observed, that, at Geneva and some other places, baptism was administered by sprinkling, they thought they could not do the church of England a greater piece of service than by introducing a practice dictated by so great an oracle as Calvin. This, together with the coldness of our northern climate, was what contributed to banish entirely the practice of dipping infants in the font.

Notions concerning the effects of baptism.

Many different notions have been entertained concerning the effects of baptism, which it would be endless to enumerate.—The Remonstrants and Socinians reduce baptism to a mere sign of divine grace. The Romanists, on the contrary, exalt its power ; holding, that all sin is entirely taken away by it ; that it absolutely confers the grace of justification, and consequently grace *ex opere operato*. Some also speak of an indelible character impressed on the soul by it, called *character dominicus*, and *character regius* : but this is held, by others, a mere spectre ; for that the spiritual character, conferred in regeneration, may easily be effaced by mortal sins. Dodwell maintained, that it is by baptism the soul is made immortal ; so that those

Baptism.

who die without it will not rise again. It must be added, he restrains this effect to episcopal baptism alone. From the effects ordinarily ascribed to baptism, even by ancient writers, it should seem, that the ceremony is as much of heathen as Jewish origin ; since Christians do not restrain the use of it, like the Jews, to the admission of new members into the church, but hold, with the heathens, a virtue in it for remitting and washing away sins. The brahmins are still said to baptize with this latter view, at certain seasons, in the river Ganges ; to the waters whereof they have annexed a cleansing or sanctifying quality ; and hence it is that they flock from all parts, even of Tartary, driven by the expectation of their being eased of their load of sins. But, in this point, many Christians seem to have gone beyond the folly of the heathens. It was only the smaller sins of infirmity which these latter held to be expiable by washing ; for crimes of a blacker dye, they allowed no water could efface them, no purgation could discharge them. The Christian doctrine of a total remission of sins by baptism could not fail, therefore, to scandalize many among the heathens, and furnished Julian an occasion of satyrizing Christianity itself : Whoever, says he, is guilty of rapes, murders, sacrilege, or any abominable crime, let him be washed with water, and he will become pure and holy.

In the ancient church, baptism was frequently conferred on Jews by violence : but the church itself never seems to have allowed of force on this occasion. By a canon of the fourth council of Toledo, it is expressly forbid to baptize any against their wills. That which looks most like force, in this case, allowed by law, were two orders of Justinian ; one of which appoints the heathens, and the other Samaritans, to be baptized, with their wives and children, and servants, under pain of confiscation. By the ancient laws, baptism was not to be conferred on image-makers, stage-players, gladiators, *aurige* or public drivers, magicians, or even strolling beggars, till they quitted such professions. Slaves were not allowed the privilege of baptism without the testimony and consent of their masters ; excepting the slaves of Jews, heathens, and heretics, who were not only admitted to baptism, but, in consequence thereof, had their freedom. Vossius has a learned and elaborate work, *De Baptismo* ; wherein he accurately discusses all the questions concerning baptism, according to the doctrine of the ancient.

§ 4. l. 8.
c. 11. § 17.

BAPTISM by Fire, spoken of by St John the Baptist, has occasioned much conjecture. The generality of the fathers held, that believers, ere they enter paradise, are to pass through a certain fire, which is to purify them from all pollutions remaining on them unexpiated. Others, with St Basil, understand it of the fire of hell ; others, of that of tribulation and temptation. Others, with St Chryostom, will have it denote an abundance of graces. Others suppose it to mean the descent of the Holy Ghost on the apostles, in form of fiery tongues. Lastly, others maintain, that the word *fire*, here, is an interpolation ; and that we are only to read the text, *He that shall come after me will baptize you with the Holy Ghost*. In reality, it is not found in divers manuscript copies of St Matthew.

The ancient Seleucians and Hermians, understanding the passage literally, maintained, that material fire

Baptism.

was necessary in the administration of baptism. But we do not find how, or to what part of the body, they applied it, or whether they were satisfied with obliging the person baptized to pass through the fire. Valentinus re-baptized all who had received water-baptism, and conferred on them the baptism of fire.

Bis docuit tingi, iradibitque corpore flamma.

TERTULL. *Carm. contr. Marc. l. 1.*

Heraclion, cited by Clemens Alexandrinus, says, that he soon applied a red-hot iron to the ears of the person baptized, as if to impress some mark upon him.

BAPTISM of the Dead; a custom which anciently prevailed among some people in Africa, of giving baptism to the dead. The third council of Carthage speaks of it as a thing that ignorant Christians were fond of. Gregory Nazianzen also takes notice of the same superstitious opinion prevailing among some who delayed to be baptized. In his address to this kind of men, he asks, whether they staid to be baptized after death? Philastrius also notes it as the general error of the Montanists or Cataphrygians, that they baptized men after death. The practice seems to be grounded on a vain opinion, that, when men had neglected to receive baptism in their life-time, some compensation might be made for this default by receiving it after death.

BAPTISM of the Dead was also a sort of vicarious baptism, formerly in use, where a person dying without baptism, another was baptized in his stead.

St Chrysostom tells us, this was practised among the Marcionites with a great deal of ridiculous ceremony; which he thus describes: After any catechumen was dead, they hid a living man under the bed of the deceased; then coming to the dead man, they asked him, whether he would receive baptism? and he making no answer, the other answered for him, and said, he would be baptized in his stead: and so they baptized the living for the dead.

Epiphanius assures us, the like was also practised among the Corinthians. This practice they pretended to found on the apostle's authority; alleging that text of St Paul for it, *If the dead rise not at all, what shall they do who are baptized for the dead?* A text which has given occasion to a great variety of different systems and explications. Bofius enumerates no less than nine different opinions, among learned divines, concerning the sense of the phrase being baptized for the dead.

St Ambrose, and Walafrid Strabo, seem clearly of opinion, that the apostle had respect to such a custom then in being; and several moderns have given into the same opinion, as Baronius, Jos. Scaliger, Justellus, and Grotius.

Several among the Roman-catholics, as Bellarmine, Salmeron, Menochius, and a number of schoolmen, understand it of the baptism of tears, and penance, and prayers, which the living undergo for the dead; and thus allege it as a proof of the belief of purgatory in St Paul's days.

Hypothetical BAPTISM, that formerly administered in certain doubtful cases, with this formula: *If thou art baptized, I do not rebaptize; if thou art not, I baptize thee in the name of the Father, &c.* This sort of baptism, enjoined by some ancient constitutions of the English church, is now fallen into disuse.

Solemn BAPTISM, that conferred at stated seasons; such, in the ancient church, were the *Paschal baptism,*

VOL. II.

and that at Whitfuntide. This is sometimes also called *general baptism.*

Lay-BAPTISM, we find to have been permitted by both the Common-Prayer Books of King Edward, and that of Queen Elizabeth, when an infant is in immediate danger of death, and a lawful minister cannot be had. This was founded upon the mistaken notion of the impossibility of salvation without the sacrament of baptism: but afterwards, when they came to have clearer notions of the sacraments, it was unanimously resolved in a convocation, held in the year 1575, that even private baptism, in a case of necessity, was only to be administered by a lawful minister.

BAPTISM is also applied, abusively, to certain ceremonies used in giving names to things inanimate.

The ancients knew nothing of the custom of giving baptism to inanimate things, as bells, ships, and the like, by a superstitious consecration of them. The first notice we have of this is in the Capitulars of Charles the Great, where it is only mentioned to be censured: but, afterwards, it crept into the Roman offices by degrees. Baronius carries its antiquity no higher than the year 968, when the greatest bell of the church of Lateran was christened by Pope John III. At last it grew to that superstitious height, as to be thought proper to be complained of in the *Centum Gravamina* of the German nation, drawn up in the public diet of the empire held at Norimberg anno 1581; where (after having described the ceremony of baptizing a bell, with god-fathers, who make responses as in baptism, and give it a name, and clothe it with a new garment as Christians were used to be clothed, and all this to make it capable of driving away tempests and devils), they conclude against it, as not only a superstitious practice, but contrary to the Christian religion, and a mere seduction of the simple people.

BAPTISM, in the sea-language, a ceremony in long voyages on board merchant ships, practised both on persons and vessels who pass the tropic or line for the first time. The baptizing the vessel is simple, and consists only in washing them throughout with sea-water; that of the passengers is more mysterious. The oldest of the crew, that has past the tropic or line, comes with his face blacked, a grotesque cap on his head, and some sea-book in his hand, followed by the rest of the seamen dressed like himself, each having some kitchen utensil in his hand, with drums beating; he places himself on a seat on the deck, at the foot of the main mast. At the tribunal of this mock magistrate, each passenger not yet initiated, swears he will take care the same ceremony be observed, whenever he is in the like circumstances: Then, by giving a little money by way of gratification, he is discharged with a little sprinkling of water; otherwise he is heartily drenched with streams of water poured upon him: and the ship-boys are inclosed in a cage, and ducked at discretion.—The seamen, on the baptizing a ship, pretend to a right of cutting off the beak-head, unless redeemed by the captain.

BAPTISMAL, something belonging to baptism; thus, we say, baptismal vow, presents, &c.

BAPTISMAL Vow, or *Covenant*, a profession of obedience to the laws of Christ, which persons in the ancient church made before baptism. It was an indispensable part of the obligation on catechumens, before

6 K

they

Baptism.
Baptismal.

Baptismal
Bar.

they were admitted to the ceremony of regeneration. It was made by turning to the East; for what mystical reasons, is not well agreed on.

BAPTISMAL Presents are in use in Germany, made by the sponsors for the infant, consisting of money, plate, or even sometimes fiefs of lands; which by the laws of the country are to be kept for the child till of age, the parents having only the trust, not the right of disposing of them. An anonymous author has published a discourse exprefs on this occasion, entitled, *De pecunia Infancia*.

BAPTISTS, in church history, the name by which the Anabaptists love to distinguish themselves *.

BAPTISTERY, in ecclesiastical writers, a place in which the ceremony of baptism is performed.

In the ancient church it was one of the exedre or buildings distinct from the church itself; and consisted of a porch or anti-room where the persons to be baptized made their confession of faith, and an inner room where the ceremony of baptism was performed. Thus it continued till the sixth century, when the baptisteries began to be taken into the church-porch, and afterwards into the church itself.

The ancient baptisteries were commonly called *pho-terias*, *photisteria*, q. d. places of illumination; an appellation sometimes given to baptism. Or, they might have the name for another reason, because they were the places of an illumination, or instruction, preceding baptism: for here the catechumens seem to have been trained up, and instructed in the first rudiments of the Christian faith.

Those baptisteries were anciently very capacious; because, as Dr Cave observes, the stated times of baptism returning but seldom, there were usually great multitudes to be baptized at the same time: and then the manner of baptizing, by immersion, or dipping under water, made it necessary to have a large font likewise. In *Venantius Fortunatus*, it is called *aula baptismatis*, the large hall of baptism; which was indeed so capacious, that we sometimes read of councils meeting and sitting therein. This hall, or chapel, was always kept shut during Lent, and the door sealed up with the bishop's seal, not to be opened till Maunday-Thurs'day.

The baptistry was always reputed a sacred place. In the Roman order, we find the ceremonies used in the consecration of the baptisteries: they were to be built of a round figure, and distinguished with the image of St John the Baptist; over the basin or font was a figure of a dove in gold or silver, to represent the Holy Ghost.

The name *baptistry* is sometimes also given to a kind of chapel in a large church, which served for the same office. It is an observation of some learned men, that anciently there was but one baptistry in a city, and that at the bishop's church; and that afterwards they were set up in parish churches, with the special allowance however of the bishop.

BAR, in a general sense, denotes a slender piece of wood, or iron, for keeping things close together.

BAR, in courts of justice, an inclosure made with a strong partition of timber, where the council are placed to plead causes. It is also applied to the benches where the lawyers or advocates are seated, because anciently there was a bar to separate the pleaders from

the attorneys and others. Hence our lawyers who are called to the bar, or licensed to plead, are termed *bar-risters*, an appellation equivalent to licentiate in other countries.

BAR, or *Barra*, (Latin *barra*, and in French *barre*), in a legal sense, is a plea or peremptory exception of a defendant, sufficient to destroy the plaintiff's action. And it is divided into bar to common intendment, and bar special; bar temporary, and perpetual. Bar to a common intendment is an ordinary or general bar, which usually disableth the declaration of the plaintiff; bar special is that which is more than ordinary, and falls out upon some special circumstance of the fact as to the case in hand. Terms de Ley. Bar temporary is such a bar as is good for the present, but may afterwards fail; and bar perpetual is that which overthrows the action of the plaintiff for ever.

BAR, in heraldry, an ordinary in form of the fefs, but much less. See **HERALDRY**, n^o 22.

BAR, in the menage, the highest part of that place of a horse's mouth situated between the grinders and tushes, so that the part of the mouth which lies under and at the side of the bars retains the name of the gum. A horse with sensible bars has a fine light mouth, with an even and firm appui. See **APPUI**.

To BAR a Vein, in farricry, is an operation performed upon the veins of the legs of a horse and other parts, with intent to stop the malignant humours. It is done by opening the skin above it, disengaging it, and tying it both above and below, and striking between the two ligatures.

BAR, in music, a stroke drawn perpendicularly across the lines of a piece of music, including between each two a certain quantity or measure of time, which is various as the time of the music is either triple or common. In common time, between each two bars is included the measure of four crotchets; in triple, three. The principal use of bars is to regulate the beating of time in a concert. The use of bars is not to be traced higher than the time when the English translation of Adrian le Roy's book on the Tablature was published, viz. the year 1574; and it was some time after that, before the use of bars became general. To come nearer to the point, Bernard's cathedral music, printed in 1641, is without bars: but bars are to be found throughout in the *Ayres and Dialogues* of Henry Lawes published in 1653; from whence it may be conjectured that we owe to Lawes this improvement.

BAR, in hydrography, denotes a bank of sand, or other matter, whereby the mouth of a river is in a manner choaked up.

The term *bar* is also used for a strong beam whereby the entrance of a harbour is secured: This is more commonly called *boom*.

BAR, among printers, denotes a piece of iron with a wooden handle, whereby the screw of the press is turned in printing. See **PRINTING**.

Bars of Iron, are made of the metal of the fows and pigs as they come from the furnace. These pass thro' two forges called the *finery* and the *chaufery*; where, undergoing five several heats, they are formed into bars.

BAR, a very strong city of Podolia in Poland upon the river Kiow. E. Long. 28. 30. N. Lat. 50. 6.

BAR, a duchy of France, bounded on the east by **Lorraine**,

* See *Ana-
baptists*.

Bar
Baranwahr.

Lorrain, on the north by Luxembourg, on the west by Champagne, on the south by part of the same country and by Franche Compté. It is crossed by the river Meuse from north to south, and watered by several other rivers, which render it very fertile. It is divided into four bailiwicks, viz. Bassilyni, Bar, St Michael, and Clermont. The chief towns are Bar-le-duc, Clermont, St Michael, Longuey, Pont a Mousson, and Stenay. In 1736, it was given to Stanislaus then king of Poland.

BAR-le-Duc, the capital of the duchy of Bar, seated on the declivity of a hill. It is divided into the higher and lower town: the lower is watered by the rivulet Orney, which abounds with excellent trouts. The vines are excellent, and not inferior to those of Champagne. E. Long. 5. 30. N. Lat. 48. 35.

BAR-le-Mont, a town of the French Netherlands, in Hainault, situated on the river Sambre. E. Long. 3. 40. N. Lat. 50. 10.

BAR sur Aube, an ancient town of France, seated at the foot of a mountain. E. Long. 4. 50. N. Lat. 48. 14.

BAR sur Seine, a town of France, in the duchy of Burgundy, seated between a mountain which covers it on the west, and the river Seine, which runs on the east. E. Long. 4. 30. N. Lat. 48. 5.

BAR-Master, among miners, the person who keeps the gage, or dish, for measuring the ore.

BARABINZIANS, a tribe of Tartars, living on both sides the river Irty. They seem to derive their name from the *Barabaian* desert, whose lakes supply them abundantly with fish, on which, and their cattle, they chiefly subsist. They have plenty of game and wild-fowl of every kind, particularly ducks and puffins. Most of them are heathens, but Mahometanism daily gains ground among them. Some of them pay tribute to the emperors of Russia, and others to the Khan Taisha.

BARACOA, a town in the north-east part of the island of Cuba. W. Long. 76. 10. N. Lat. 21. 5.

BARALIPTON, among logicians, a term denoting the first indirect mode of the first figure of syllogism. A syllogism in baralipon, is when the two first propositions are general, and the third particular, the middle term being the subject in the first proposition, and the predicate in the second. The following is of this kind:

- B A. Every evil ought to be feared;
R A. Every violent passion is an evil;
L I P. Therefore something that ought to be feared is a violent passion.

BARALLOTS, in church-history, a sect of heretics at Bologna in Italy, who had all things in common, even their wives and children.—Their facility in complying with all manner of debauchery made them get the name *obedientes*, compliers.

BARANCA DE MALAMBO, a town of Terra Firma in America, with a bishop's see, and a good haven. It is a place of great trade, and is seated on the river Magdalcine. W. Long. 75. 30. N. Lat. 11. 10.

BARANGI, officers among the Greeks of the lower empire. Cujas calls them in Latin *protectores*, and others give them the name of *securigeri*. It was their business to keep the keys of the city-gates, where the emperor resided.

BARANWAHR, a town of Lower Hungary, in

a county of the same name, taken by the emperor of Germany from the Turks in 1684. It is seated between Buda and Belgrade, in E. Long. 20. 5. N. Lat. 46. 0.

BARATHRUM, in antiquity, a deep dark pit at Athens, into which condemned persons were cast headlong. It had sharp spikes at the top, that no man might escape out; and others at the bottom, to pierce and torment such as were cast in.

BARATZ, (Turkish), letters-patent granted by the Turkish emperors to the Greek patriarch, bishops, &c. for the exercise of their ecclesiastical functions. This *Baratz* gives the bishops full power and authority to establish and depose the inferior clergy, and all other religious persons; to grant licences for marriages, and issue out divorces; to collect the revenues belonging to the churches; to receive the pious legacies bequeathed to them; in short, to enjoy all the privileges and advantages belonging to their high station: and all this (as it is expressed in the *baratz itself*) according to the vain and idle ceremonies of the Christians.

BARB, or **BARBE**, a horie brought from Barbary*. * See *Equus*.
BARBA, in botany, a species of *pubes*, or down, with which the surface of some plants is covered. The term was invented by Linnæus, and made its appearance in the *Delineatio Plantæ*, without any explanation. Its meaning, therefore, has not been accurately ascertained: though, by its application in the *Species Plantarum*, it seems to signify a tuft or bunch of strong hairs terminating the leaves. *Mesembryanthemum barbatum*, furnishes an example.

The word is also often used in composition with some other, to form the trivial names of several plants, as *barba jovis*, *barba capræ*, &c.

BARBACAN, or **BARBICAN**, an outer defence or fortification to a city or castle, used especially as a fence to the city or walls; also, an aperture made in the wall of a fortress, to fire through upon the enemy.

BARBACAN is also used to denote a fort at the entrance of a bridge, or the outlet of a city, having a double wall with towers.

BARBADOES, the most easterly of all the Caribbee Islands, subject to Great Britain, and, according to the best geographers, lying between 59. 50. and 60. 2. of west longitude, and between 12. 56. and 13. 16. of north latitude. Its extent is not certainly known: the most general opinion is, that it is 25 miles from north to south, and 15 from east to west; but these mensurations are subject to so many difficulties and uncertainties, that it will perhaps convey a more adequate idea of this island, to tell the reader, that in reality it does not contain above 107,000 acres. The climate is hot, but not unwholesome, the heat being qualified by sea-breezes; and a temperate regimen renders this island as safe to live in, as any climate south of Great Britain; and, according to the opinion of many, as even Great Britain itself. This island has on its east side two streams that are called *rivers*, and in the middle is said to have a bituminous spring which sends forth a liquor like tar, and serves for the same uses as pitch or lamp-oil. The island abounds in wells of good water, and has several reservoirs for rain-water. Some parts of the soil are said to be hollowed into caves, some of them capable of containing 300 people. These are imagined to have been the lurking places of runaway

Barathrum
Barbadoes.

negroes, but may as probably be natural excavations. The woods that formerly grew upon the island have been all cut down, and the ground converted into sugar plantations. When those plantations were first formed, the soil was prodigiously fertile, but has since been worn out, inasmuch, that about the year 1730, the planters were obliged to raise cattle for the sake of their dung, by which means the profit of their plantations was reduced to less than a tenth of its usual value. Notwithstanding the smallness of Barbadoes, its soil is different; being in some places sandy and light, in others rich, and in others spongy; but all of it is cultivated according to its proper nature, so that the island presents to the eye the most beautiful appearance that can be imagined. Oranges and lemons grow in Barbadoes in great plenty, and in their utmost perfection. The lemon juice here has a peculiar fragrance. The citrons of Barbadoes afford the best drams and sweetmeats of any in the world, the Barbadoes ladies excelling in the art of preserving the rind of the citron fruit. The juice of the limes, or dwarf lemons, is the most agreeable souring we know, and great quantities of it have of late been imported into Britain and Ireland. The pine apple is also a native of Barbadoes, and grows there to much greater perfection than it can be made to do in Europe by any artificial means. A vast number of different trees peculiar to the climate are also found to flourish in Barbadoes in great perfection; such as the aloe, mangrove, calabash, cedar, cotton, mastic, &c. Here likewise are produced some sensitive plants, with a good deal of garden stuff, which is common in other places. In short, a native of the finest, the richest, and most diversified country in Europe, can hardly form an idea of the variety of delicious and at the same time nutritive vegetable productions with which this island abounds.

When Barbadoes was first discovered by the English, few or no quadrupeds were found upon it, except hogs, which had been left there by the Portuguese. For convenience of carriage to the sea-side, some of the planters at first procured camels; which undoubtedly would in all respects have been preferable to horses for their sugar and other works; but the nature of the climate disagreeing with that animal, it was found impossible to preserve the breed. They then applied for horses to Old and New England: from the former they had those that were fit for shew and draughts; from the latter those that were proper for mounting their militia, and for the saddle. They had likewise some of an inferior breed from Curacao, and other settlements. They are reported to have had their first breed of black cattle from Bonavilla and the isle of May; they now breed upon the island, and often do the work of horses. Their asses are very serviceable in carrying burdens to and from the plantations. The hogs of Barbadoes are finer eating than those of Britain, but the few sheep they have are not near so good. They likewise have goats, which when young are excellent food. Racoons and monkeys are also found here in great abundance. A variety of birds are produced on Barbadoes, of which the humming bird is the most remarkable. Wild fowl do not often frequent this island; but sometimes teal are found near their ponds. A bird which they call the *man of war*, is said to meet ships at 20 leagues from land, and their

return is, to the inhabitants, a sure sign of the arrival of these ships. When the wind blows from the south and south-west, they have flocks of curlews, plovers, snipes, wild pigeons, and wild ducks. The wild pigeons are very fat and plentiful at such seasons, and rather larger than those of England. The tame pigeons, pullets, ducks, and poultry of all kinds, that are bred at Barbadoes, have also a fine flavour, and are accounted more delicious than those of Europe. Their rabbits are scarce; they have no hares; and if they have deer of any kind, they are kept as curiosities. The insects of Barbadoes are not venomous, nor do either their snakes or scorpions ever sting. The musketoons are troublesome, and bite; but are more tolerable in Barbadoes than on the continent. Various other insects are found on the island, some of which are troublesome, but in no greater degree than those that are produced by every warm summer in England. Barbadoes is well supplied with fish; and some caught in the sea surrounding it are almost peculiar to itself; such as the parrot-fish, snappers, grey cavallos, turbot, and coney-fish. The mullets, lobsters, and crabs, caught here are excellent; and the green turtle is perhaps the greatest delicacy that ancient or modern luxury can boast of. At Barbadoes this delicious shell-fish seldom sells for less than a shilling a pound, and often for more. There is found in this island a kind of land-crab which eats herbs wherever it can find them, and shelters itself in houses and hollows of trees. According to report, they are a shell-fish of passage; for in March they travel to the sea in great numbers. See *CANCER*.

The inhabitants may be reduced to three classes, viz. the masters, the white servants, and the blacks. The former are either English, Scots, or Irish: but the great encouragement given by government to the peopling of this and other West India islands induced some Dutch, French, Portuguese, and Jews, to settle among them with their estates; by which, after a certain time, they acquire the rights of naturalization in Great Britain. The white servants, whether by covenant or purchase, lead more easy lives than the day-labourers in England; and when they come to be overseers, their wages and other allowances are considerable. As to the treatment of the negro slaves in this and the other islands, that falls to be spoken of under the articles *NEGRO, SLAVE, WEST-INDIES*; which see. The manners of the white inhabitants, in general, are the same as in most polite towns and countries in Europe. The capital of the island is called *Bridge-Town*; see that article.

As the history of this island furnishes no very remarkable events, the following short hints concerning it may suffice.

When the English, some time after the year 1625, first landed here, they found it the most savage and desolate place they had hitherto visited. It had not the least appearance of ever having been peopled even by savages. There was no kind of beads of pasture or of prey, no fruit, no herb, nor root fit for supporting the life of man. Yet as the climate was so good, and the soil appeared fertile, some gentlemen of small fortune in England resolved to become adventurers thither. The trees were so large, and of a wood so hard and stubborn, that it was with great difficulty they could clear as much ground as was necessary for their subsistence.

Barbadoes
||
Barbarism.

subsistence. By unremitting perseverance, however, they brought it to yield them a tolerable support; and they found that cotton and indigo agreed well with the soil; and that tobacco, which was beginning to come into repute in England, answered tolerably. These prospects, together with the storm between the king and parliament, which was beginning to break out in England, induced many new adventurers to transport themselves into this island. And what is extremely remarkable, so great was the increase of people in Barbadoes, 25 years after its first settlement, that in 1650 it contained more than 50,000 whites, and a much greater number of negro and Indian slaves. The latter they acquired by means not at all to their honour: for they seized upon all those unhappy men, without any pretence, in the neighbouring islands, and carried them into slavery; a practice, which has rendered the Caribbee Indians irreconcilable to us ever since. They had begun a little before this, to cultivate sugar, which soon rendered them extremely wealthy. The number of slaves, therefore, was still augmented; and in 1676 it is supposed that their number amounted to 100,000, which, together with 50,000 whites, make 150,000 on this small spot: a degree of population unknown in Holland, in China, or any other part of the world most renowned for numbers. At this time Barbadoes employed 400 sail of ships, one with another, of 150 tons in their trade. Their annual exports in sugar, indigo, ginger, cotton, and citron-water, were above 350,000 l. and their circulating cash at home was 200,000 l. Such was the increase of population, trade, and wealth, in the course of 50 years. But since that time this island has been much on the decline; which is to be attributed partly to the growth of the French sugar-colonies, and partly to our own establishments in the neighbouring isles. Their numbers at present are said to be 20,000 whites, and 100,000 slaves. Their commerce consists of the same articles as formerly, though they deal in them to less extent.

BARBADOES-Tar, a mineral fluid of the nature of the thicker fluid bitumens, of a nauseous bitterish taste, very strong and disagreeable smell, found in many parts of America trickling down the sides of the mountains, and sometimes floating on the surface of the waters. It has been greatly recommended in coughs, and other disorders of the breast and lungs.

BARBARA, among logicians, the first mode of the first figure of syllogisms. A syllogism in barbara is one whereof all the propositions are universal and affirmative; the middle term being the subject of the first proposition, and attribute in the second. For example:

BAR. Every wicked man is miserable;

BA. All tyrants are wicked men;

RA. Therefore all tyrants are miserable.

BARBARIAN, a name given by the ancient Greeks and Romans to all who were not of their own country, or were not initiated in their language, manners, and customs.—In this sense, the word signified with them no more than foreigner; not signifying, as among us, a wild, rude, or uncivilized person.

BARBARISM, in a general sense, a rudeness of language or behaviour.

BARBARISM, in grammar, an offence against the purity of style or language; or an ungrammatical way

of speaking or writing, contrary to the true idiom of any particular language.

BARBARIUM, (anc. geogr), a promontory of Lusitania, to the fourth of the mouth of the Tagus; now called *Cabo de Espichel*. W. Long. 6°. N. Lat. 37°.

BARBAROSSA, (Aruch, and Hayradin), two famous corsairs, the sons of a potter in the isle of Lesbos; who, turning pirates, carried on their depredations with such success and conduct, that they were soon possessed of twelve galleys beside smaller vessels. Of this fleet Aruch the elder brother, called *Barbarossa* from the redness of his beard, was admiral, and Hayradin the second in command: they called themselves the *friends of the sea*, and the *enemies of all who sailed upon it*; and their names became terrible from the fruits of Dardanelles to those of Gibraltar. With such a power they wanted an establishment; and the opportunity of settling themselves offered in 1516, by the inconsiderate application of Eutemi king of Algiers to them for assistance against the Spaniards. Aruch, leaving his brother to command the fleet, carried 5000 men to Algiers, where he was received as their deliverer; and secretly murdering the prince he came to aid, caused himself to be proclaimed king in his stead. To this usurpation he added the conquest of Tremecen; when his exploits and piracies induced the emperor Charles V. to furnish the marquis de Gomarez governor of Oran with troops to suppress him; by whom he was defeated and killed near Tremecen. His brother Hayradin, known also by the name of *Barbarossa*, assumed the sceptre at Algiers with the same abilities, and with better fortune; for the Spaniards, sufficiently employed in Europe, giving him no disturbance, he regulated the interior police of his kingdom with great prudence, carried on his naval operations with vigour, and extended his conquests on the continent of Africa. He put his dominions under the protection of the Grand Signior, Solyman the Magnificent; and obtained the command of the Turkish fleet. With so powerful a protector, he acquired the kingdom of Tunis in a manner similar to that by which his brother gained Algiers. Since the time of the Barbarossa's, Algiers has been understood to be dependent on the Porte; but this dependence is now little more than merely nominal*.

BARBARUS (Francis), a noble Venetian, was a man of great fame in the 15th century, not only for learning, but likewise for a skillful address in the management of public affairs. He is author of a book *De Re Uxoribus*, and some speeches.

BARBARUS (Hermolaus), grandson of the preceding, one of the most learned men in the 15th century. The public employments he was entrusted with early, did not prevent him from cultivating polite learning with great application. As he was very skillful in the Greek, he undertook the most difficult translations, and began with a famous paraphrase upon Aristotle. He then attempted Diocorides, whose text he corrected, gave a translation of him, and added a commentary. But of all his works, there is none which has gained him so much reputation as that which he made upon Pliny; he corrected in him above 5000 passages, and occasionally restored 300 in Pomponius Mela. Pope Innocent VIII. to whom he was ambassador, conferred the patriarchate of Aquileia upon him. He was so imprudent as to accept of it without waiting for the consent of

his superiors: though he could not be ignorant that the republic of Venice had made laws to forbid all the ministers they sent to the court of Rome to accept any benefice. His superiors were inflexible; and not being able to gain any thing upon them either by his flattery or his father's interest, the father died of grief, and the son soon followed him.

BARBARUS (Daniel), of the same family with the preceding, was patriarch of Aquileia, and famous for his learning. He was ambassador from Venice to England; and was one of the fathers of the council of Trent, where he acted with great zeal for the interest of the pope. He wrote, 1. A commentary upon Viruvius. 2. *Catena Græcorum Patrum in quinguingenta Psalmos Latine versa.* 3. *La Prattica della Perseffiva.* He died in 1569, at 41 years of age.

Extent, &c.

BARBARY, a kingdom of Africa, including the states of Algiers, Morocco, Tripoli, and Tunis; (see those articles). This country contains almost the whole of what the Romans possessed of the continent of Africa, excepting Egypt. It stretches itself in length from east to west, beginning at the southern limits of Egypt, to the straits of Gibraltar full 35 degrees of longitude; and from thence to Santa Cruz, the utmost western edge of it, about six more, in all 41 degrees: so that the utmost length of Barbary from east to west is computed at above 759 German leagues. On the south, indeed, it is confined within much narrower bounds, extending no farther than from 27 to 35½ degrees of north latitude; so that its utmost breadth from north to south, does not exceed 128 German miles. More particularly, Barbary begins on the west of the famed mount Atlas, called by the Arabs *Ay Duacal*, or *Al Duacal*, inclosing the ancient kingdoms of Suez and Dela, now provinces of Morocco; thence stretching north-eastward along the Atlantic to the pillars of Hercules at Cape Finister, then along the coast of the Mediterranean, it is at last bounded by the city of Alexandria in Egypt.

Whence named.

Concerning the origin of the name *Barbary*, there are many conjectures. According to some, the Romans, after they had conquered this large country, gave it that name out of contempt and dislike to the barbarous manners of the natives, according to their custom of calling all other people but themselves *Barbarians*. Marmol, on the contrary, derives the word *Barbary* from *Berber*, a name which the Arabs gave to its ancient inhabitants, and which they retain to this day in many parts of the country, especially along the great ridge of the mountains of Atlas; and which name was given them on account of the barrenness of their country. According to Leo Africanus, the name of Barbary was given by the Arabs on account of the strange language of the natives, which appeared to them more like a murmur or grumbling of some brute animals than articulate sounds. Others, however, derive it from the Arabic word *bar*, signifying a desert, twice repeated; which was given by one *Isrik* or *Africus*, a king of Arabia, from whom the whole continent of Africa is pretended to have taken its name. According to them, this king being driven out of his own dominions, and closely pursued by his enemies, some of his retinue called out to him *bar bar*; that is, *To the desert, To the desert*; from which the country was afterwards called *Barbary*.

Barbary.

3
Subject to the Romans.

4
Bonifacius calls in the Vandals.

Among the Romans this country was divided into the provinces of Mauritania, Africa Propria, &c. and they continued absolute masters of it from the time of Julius Cæsar till the year of Christ 428. At that time Bonifacius the Roman governor of these provinces, having through the treachery of Ætius been forced to revolt, called in to his assistance Genserik king of the Vandals, who had been some time settled in Spain. The terms offered, according to Procopius, were, that Genserik should have two thirds, and Bonifacius one third, of Africa, provided they could maintain themselves against the Roman power; and to accomplish this they were to assist each other to the utmost—This proposal was instantly complied with; and Genserik set sail from Spain in May 428, with an army of 80,000 men, according to some, or only 24,000 according to others, together with their wives, children, and all their effects. In the mean time, however, the Empress Placidia, having discovered the true cause of Bonifacius's revolt, wrote a most kind and obliging letter to him, in which she assured him of her favour and protection for the future, exhorting him to return to his duty, and exert his usual zeal for the welfare of the empire, by driving out the barbarians whom the malice of his enemies had obliged him to call in for his own safety and preservation.

Bonifacius readily complied with this request, and offered the Vandals considerable sums if they would retire out of Africa and return to Spain. But Genserik, already master of the greatest part of the country, first returned a scoffing answer, and then, falling unexpectedly on him, cut most of his men in pieces, and obliged Bonifacius himself to fly to Hippos, which place he invested in May 430. The siege lasted till the month of July the following year; when the Vandals were forced, by a famine that began to rage in their camp, to drop the enterprize, and retire. Soon after, Bonifacius having received two reinforcements, one from Rome, and the other, under the conduct of the celebrated Aspar, from Constantinople, a resolution was taken by the Roman generals to offer the enemy battle. The Vandals readily accepting the challenge, a bloody engagement ensued, in which the Romans were utterly defeated, a prodigious number of them taken, and the rest obliged to shelter themselves among the rocks and mountains. Aspar, who commanded the eastern troops, escaped with difficulty to Constantinople, and Bonifacius was recalled to Italy. Upon their departure, the Vandals over-ran all Africa, committing every where the most terrible ravages; which struck the inhabitants of Hippos with such terror, that they abandoned their city, which was first plundered, and then set on fire by the victorious enemy; so that Cirthea and Carthage were now the only strong places possessed by the Romans.

5
Endeavour unsuccessfully to persuade them to return.

6
Romans defeated by Genserik king of the Vandals.

In 435, Genserik, probably being afraid of an attack by the united forces of the eastern and western empires, concluded a peace with the Romans, who yielded to him part of Numidia, the province of Proconularis, and likewise Byzacene; for which, according to Prosper, he was to pay a yearly tribute to the emperor of the east. Genserik delivered up his son Hannerik by way of hostage; but so great was the confidence which the Romans placed in this barbarian, that some time after they sent him back his son. Of

Genferic's
treachery.

this they soon had reason to repent; for in 439, the Romans being engaged in a war with the Goths in Gaul, Genferic laid hold of that opportunity to seize upon the city of Carthage; by which he considerably enlarged his African dominions. Valentinian, the Roman emperor, however, maintained as long as he lived, the two Mauritanias, with Tripolitana, Tingitana, and that part of Numidia where Ciritha stood.

On the taking of Carthage, Genferic made it the feat of his empire; and in 440 made a descent on the island of Sicily, where he ravaged the open country, and even laid siege to Palermo. Not being able, however, to reduce that place, he soon returned to Africa, with an immense booty and a vast number of captives. Being now become formidable to both empires, Theodosius emperor of the east resolved to assist Valentinian against so powerful an enemy. Accordingly he fitted out a fleet consisting of 1100 large ships; and putting on board of it the flower of his army, under the conduct of Arcovindas, Ansilus, and Germanus, he ordered them to land in Africa, and, joining the western forces there, to drive Genferic out of the countries he had seized. But Genferic in the mean time pretending a desire to be reconciled with both empires, amused the Roman general with proposals of peace, till the season for action was over; and, next year, Theodosius being obliged to recall his forces to oppose the Huns, Valentinian found it necessary to conclude a peace with the Vandals; and this he could obtain on no other terms than yielding to them the quiet possession of the countries they had seized.

So powerful was Genferic now become, or rather so low was the Roman empire by this time reduced, that in 455, he took and plundered the city of Rome itself, as is fully related under the article *ROME*; and, after his return to Africa, made himself master of the remaining countries held by the Romans in that part of the world. Hercupon Avitus, who had succeeded Valentinian in the empire, dispatched ambassadors to Genferic, putting him in mind of the treaty he had concluded with the empire in 442; and threatening, if he did not observe the articles at that time agreed upon, to make war upon him not only with his own forces, but with those of his allies the Visigoths, who were ready to pass over into Africa. To this Genferic was so far from paying any regard, that he immediately put to sea with a fleet of 60 ships; but being attacked by the Roman fleet under Ricimer, he was utterly defeated, and forced to fly back into Africa: he returned, however, soon after with a more powerful fleet, committing great ravages on the coast of Italy: but in a second expedition he was not attended with so good success; the Romans falling unexpectedly upon his men while busied in plundering the country, put great numbers of them to the sword, and among the rest the brother-in-law of Genferic himself. Not content with this small advantage, Majorianus, at that time emperor, resolved to pass over into Africa, and attempt the recovery of that country. For this purpose he made great preparations; but his fleet being surprized and defeated by the Vandals, thro' the treachery, it is said, of some of his commanders, the enterprize miscarried.

Notwithstanding this misfortune, however, Majorianus persisted in his resolution; and would in all like-

hood have accomplished his purpose, had not he himself been murdered soon after by Ricimer. After his death, Genferic committed what ravages he pleased in the poor remains of the western empire, and even made descents on Peloponnesus and the islands belonging to the emperor of Constantinople. To revenge this affront, Leo made vast preparations for the invasion of Africa, inasmuch, that, according to Procopius, he laid out 130,000 pounds weight of gold in the equipment of his army and navy. The forces employed on this occasion were sufficient for expelling the Vandals, had they been much more powerful than they were; but the command being given to Basiliscus a covetous and ambitious man, the fleet was utterly defeated through his treachery, and all the vast preparations came to nothing. By this last defeat the power of the Vandals in Africa was fully established, and Genferic made himself master of Sicily, as well as of all the other islands between Italy and Africa, without opposition from the western emperors, whose power was entirely taken away in the year 476.

Thus was the Vandalic monarchy in Barbary founded by Genferic, between the years 428 and 468. If we take a view of that prince's government in his new dominions, it presents no very agreeable prospect. Being himself an absolute barbarian in the strictest sense of the word, and an utter stranger to every useful art, he did not fail to shew his own prowess by the destruction of all the monuments of Roman greatness which were so numerous in the country he had conquered. Accordingly, instead of improving his country, he laid it waste, by demolishing all the stately structures both public and private, and all other valuable and sumptuous works with which those proud conquerors had adorned this part of their dominions. So that, whatever monuments the Romans had been at such an immense expence to erect, in order to eternize their own glory, the barbarous Vandals were now at no less pains to reduce into heaps of ruins. Besides this kind of devastation, Genferic made his dominions a scene of blood and slaughter, by persecuting the orthodox Christians; being himself, as well as most of his countrymen, a zealous Arian; and for this his long reign is chiefly remarkable. He died in 477, after a reign of 60 years; and was succeeded by his son Hunneric.

The new king proved yet a greater tyrant than his father, persecuting the orthodox with the utmost fury; and, during his short reign of seven years and an half, destroyed more of them than Genferic had done in all his lifetime. He is said to have died in the same manner as the herefarch Arius †; before which time his flesh had been rotting upon his bones, and crawling with worms, so that he looked more like a dead carcase than a living man. Concerning his successors Gutamund, Thrafasmund, and Hilderic, we find nothing remarkable, except that they sometimes persecuted, and sometimes were favourable to, the orthodox; and by his favour for them the last king was ruined. For, having unadvisedly published, in the beginning of his reign, a manifesto, wherein he repealed all the acts of his predecessors against the orthodox, a rebellion was the immediate consequence. At the head of the malcontents was one Glimmer, or Gildemar, a prince of the blood-royal, who by degrees became so powerful, as to depose Hilderic in the seventh year of his reign:

Barbary. after which he caused the unhappy monarch with all his family to be closely confined, and was himself crowned king of the Vandals at Carthage.

Gilmer proved a greater tyrant than any that had gone before him. He not only cruelly persecuted the orthodox, but horribly oppressed all the rest, so that he was held in universal abhorrence and detestation when the Greek emperor Justinian projected an invasion of Africa. This expedition of Justinian's is said to have been occasioned by an apparition of Lætus an African bishop, who had been murdered some time before, but now commanded the emperor to attempt the recovery of Africa, and assured him of success. Accordingly, this, or some other motive, prevailed upon Justinian so far, that notwithstanding his being at that time engaged in a war with Persia, he sent a powerful fleet and army to Africa, under the command of the celebrated general Belisarius, who was for that reason recalled from Persia.

So much was Gilmer, all this time, taken up with his own pleasures, or with oppressing his subjects, that he knew little or nothing of the formidable preparations that were making against him. On the arrival of Belisarius, however, he was constrained to put himself into a posture of defence. The management of his army he committed to his two brothers Gundimer and Gelamund, who accordingly attacked the Romans at the head of a numerous force. The engagement was long and bloody; but at last the Vandals were defeated, and the two princes slain. Gilmer, grown desperate at this news, sallied out at the head of his corps de reserve, with full purpose to renew the attack with the utmost vigour; but by his own indiscretion lost a fair opportunity of defeating the Romans. For no sooner did they perceive Gilmer hastening after them at the head of a fresh army, than they betook themselves to flight; and the greatest part were dispersed in such a manner, that, had the king followed them close, they must have been totally cut off. Instead of this, however, stumbling unfortunately on the body of one of his slain brothers, the sight of it made him lose all thoughts about the enemy; and instead of pursuing them, he spent part of his time in idle lamentations, and part in burying the corpse with suitable pomp and dignity. By this means Belisarius had an opportunity of rallying his men; which he did so effectually, that, coming unexpectedly upon Gilmer, he easily gained a new and complete victory over him.

This defeat was followed by the loss of Carthage, which the barbarians had been at no pains to put into a posture of defence. After which Gilmer, having in vain endeavoured to obtain assistance from the Moors and Goths, was obliged to recal his brother Tzafon from Sardinia. The meeting between the two brothers was very mournful; but they soon came to a resolution of making one desperate attempt to regain the lost kingdom, or at least recover their captives out of the hands of the enemy. The consequence of this resolution was another engagement, in which Tzafon was killed with 800 of his choicest men, while the Romans lost no more than 50; after which Belisarius moving suddenly forward at the head of all his army, fell upon the camp of the Vandals. This Gilmer was no sooner apprised of, than, without staying to give any more orders to the rest of his army, he fled towards Numidia in the

utmost consternation. His flight was not immediately known among his troops; but when it was, such an universal confusion ensued, that they abandoned their camp to the Romans, who had now nothing to do but plunder it; and not content with this, they massacred all the men found in it, carrying away the women captives.

Thus a total end was put to the power of the Vandals in Barbary, and the Romans once more became masters of this country. The Vandal inhabitants were permitted to remain as they were, on condition of exchanging the heresy of Arius for the orthodox faith. As for Gilmer, he fled with the utmost expedition to Medamus, a town situated on the top of the Pappian mountain, and almost inaccessible by reason of its height and ruggedness. The siege of this place was committed to Pharas, an officer of great experience, who having shut up all avenues to the town, the unhappy Gilmer was reduced to the greatest straits for want of provisions. Pharas being soon apprised of the distress he was in, wrote him a most friendly and pathetic letter, earnestly exhorting him to put an end to the distress of himself and his friends by a surrender. This Gilmer declined; but at the same time concluded his answer with a most submissive request, that Pharas would do far pity his great distress as to send him a loaf of bread, a sponge, and a lute. This strange request greatly surprised Pharas; but at last it was explained by the messenger, who told him that the king had not tasted any baked bread since his arrival on that mountain, and earnestly longed to eat a morsel of it before he died: the sponge he wanted to allay a tumour that was fallen on one of his eyes; and the lute, on which he had learned to play, was to assist him in setting some elegiac verses he had composed on the subject of his misfortunes to a suitable tune. At this mournful report Pharas could not refrain from tears, and immediately dispatched the messenger with the things he wanted.

Gilmer had spent near three winter-months on the summit of this inhospitable mountain, his misery hardening him still more against the thoughts of surrendering, when a melancholy scene in his own family at once reconciled him to it. This was a bloody struggle between two boys, one of them his sister's son, about a flat bit of dough, laid on the coals; which the one seized upon, burning hot as it was, and clapped it into his mouth; but the other by dint of blows forced it out, and eat it from him. This quarrel, which might have ended fatally had not Gilmer interposed, made so deep an impression upon him, that he immediately dispatched a messenger to Pharas, acquainting him that he was willing to surrender himself and all his effects upon the conditions he had offered, as soon as he was assured that they were embraced by Belisarius. Pharas lost no time to get them ratified and sent back to him; after which he was conducted to Belisarius, who gave him a very kind reception. Gilmer was afterwards brought before Justinian in golden chains, whom he besought in the most submissive manner to spare his life. This was readily granted by the emperor; who also allowed him a handsome yearly pension to live upon as a private gentleman. But his mind and heart were too much unsettled and broken to enjoy the sweets of a private state; so that Gilmer, oppressed with grief,

died

died in the year 534, the first of his captivity, and five years after he had been raised to the throne.

Barbary being thus again reduced under the power of the Romans, its history falls to be taken notice of under that of Rome. In the khalifat of Omar, this country was reduced by the Saracens, as we have already related under the article ARABIA. It continued subject to the khalifs of Arabia and Bagdad till the reign of Harun Al Rashid, who having appointed Ibrahim Ebn Aglab governor of the western parts of his empire, that prefect took the opportunity, first of assuming greater powers to himself than had been granted by the khalif, and then erecting a principality altogether independent of the khalifs. The race of Aglab continued to enjoy their new principality peaceably till the year of the Hegira 297 or 298, during which time they made several descents on the island of Sicily, and conquered part of it. About this time, however, one Obeidallah rebelled against the house of Aglab, and assumed the title of khalif of *Kairwan* (the ancient Cyrene, and residence of the Aglabite princes). To give the greater weight to his pretensions he also took the surname of Al Mohdi, or Al Mahedi, the *director*. According to some, also, he pretended to be descended in a right line from Ali Ebn Abu Taleb, and Fatema the daughter of Mahomet; for which reason, say they, the Arabs called him and his descendants *Fatimites*. He likewise encouraged himself and his followers by a traditional prophecy of Mahomet, that at the end of 300 years the sun should rise out of the west. Having at length driven the Aglabites into Egypt, where they became known by the name of *Magrebbians*, he extended his dominions in Africa and Sicily, making Kairwan the place of his residence.

In the 300th year of the Hegira, Habbafah, one of Al Mohdi's generals, overthrew the khalif Al Moktader's forces in the neighbourhood of Barca, and made himself master of that city. After which he reduced Alexandria itself; and was making great progress in the conquest of the whole country, when Al Moktader dispatched against him his two generals Takin and Al Kafem, with an army of 100,000 men. Habbafah being informed that the khalif's troops were in motion, advanced at the head of his army to give them battle, and at last came up with them in an island called by the Arabs *Ard Al Khamfin*. Here he attacked them with incredible bravery, notwithstanding their force was much superior to his; but the approach of night obliged both generals to found a retreat.—The action therefore was by no means decisive, tho' extremely bloody, the khalif's generals having lost 20,000, and Habbafah 10,000. The latter, however, durst not renew the fight next morning; but stole off in the night, and returned home, so that Al Moktader in effect gained a victory. In the 302^d year of the Hegira, however, Habbafah returned, possessed himself of Alexandria a second time, defeated a body of the khalif's forces, and killed 7000 of them upon the spot. What further progress he made at that time we are not certainly told; but in the 307th year of the Hegira, Abul Kafem, son to the Fatemite khalif Al Mohdi, again entered Egypt with an army of 100,000 men. At first he met with extraordinary success, and over-ran a considerable part of that fine country. He made himself

master of Alexandria, Al Tayum, Al Baknafa, and the isle of Al Alhimariy, penetrating even to Al Jizah, where the khalif's army under the command of Munes was posted in order to oppose him. In this country he found means to maintain himself till the 308th year of the Hegira. This year, however, he was entirely defeated by Munes, who made himself master of all his baggage, as well as of the plunder he had acquired; and this blow obliged him to fly to Kairwan with the shattered remains of his army, where he remained without making any further attempt on Egypt.

Al Mohdi reigned 24 years; and was succeeded by his son Abul Kafem abovementioned, who then took the surname of *Al Kayem Mohdi*. During his reign we read of nothing remarkable, except the revolt of one Yezid Ebn Condat, a man of mean extraction, but who, having been raised to the dignity of chancellor, found means to raise such a strong party, that the khalif was obliged to shut himself up in the castle of Mohedia. Yezid, being then at the head of a powerful army, soon reduced the capital of Kairwan, the cities of Al Rakkada and Tunis, and several other fortresses. He was no less successful in defeating a considerable number of troops which Al Kayem had raised and sent against him, after which he closely besieged the khalif himself in the castle where he had shut himself up. The siege continued seven months; during which time the place was reduced to such straits, that the khalif must either have surrendered it or been starved, when death put an end to his anxiety in the 12th year of his reign, and 334th of the Hegira.

Al Kayem was succeeded by his son Ishmael, who immediately took upon himself the title of *Al Mansur*. This khalif thought proper to conceal the death of his father till he had made the preparations necessary for reducing the rebels. In this he was so successful, that he obliged Yezid to raise the siege of Mohedia the same year; and in the following gave him two great overthrows, obliging him to shut himself up in the fortresses of Kothama, or Cutama, where he besieged him in his turn. Yezid defended the place a long time with desperate bravery; but finding the garrison at last obliged to capitulate, he made shift to escape privately. Al Mansur immediately dispatched a body of forces in pursuit of him; who overtook, and brought him back in fetters; but not till after a vigorous defence, in which Yezid received several dangerous wounds, of which he died in prison. After his death, Al Mansur caused his body to be flayed, and his skin stuffed and exposed to public view. Of Al Mansur's exploits in Sicily an account is given under that article. Nothing farther remarkable happened in his African dominions; and he died after a reign of seven years and 16 days, in the 341st of the Hegira.

Al Mansur was succeeded by his son Abu Zammin Moad, who assumed the surname of *Al Moez Ledinillah*. He proved a very warlike prince, and maintained a bloody contest with Abdalrahman, khalif of Andalusia; for a particular account of which see the article SPAIN. In the 347th year of the Hegira, beginning March 25th 958, Al Moez sent a powerful army to the western extremity of Africa, under the command of Abul Hasan Jawhar, one of his slaves, whom he had advanced to the dignity of Vizir. Jawhar first advanced to a city called *Tabart*, which he besieged for some time

ineffectually. From thence he marched to Fez, and made the proper dispositions for attacking that city. But finding that Ahmed Ebn Beer, the Emir of the place, was resolved to defend it to the last, he thought proper to abandon the enterprize. However, having traversed all the tract between that capital and the Atlantic ocean, he again sat down before Fez, and took it by storm the following year.

But the greatest achievement performed by this khalif was his conquest of Egypt, and removal of the khalifat to that country. This conquest, though long projected, he did not attempt till the year of the Hegira 358. Having then made all necessary preparations for it, he committed the care of that expedition to a faithful and experienced general called *Giasfar*, or *Jaa-sar*; but in the mean time, this enterprize did not divert Al Moezz from the care of his other conquests, particularly those of Sicily and Sardinia: to the last of which he failed in the year of the Hegira 361, continuing a whole year in it, and leaving the care of his African dominions to an experienced officer named *Tuff Ben Zeiri*. He failed thence the following year for Tripoli in Barbary, where he had not staid long before he received the agreeable news that his general had made himself master of Alexandria. He lost no time, but immediately embarked for it, leaving the government of his old African dominions in the hands of his trusty servant Yusef abovementioned, and arriving safely at that port was received with all the demonstrations of joy. Here he began to lay the foundations of his new Egyptian dynasty, which was to put a final end to the old one of Kairwan after it had continued about 65 years.

Al Moezz preserved all his old dominions of Kairwan or Africa Proper. But the ambition or avarice of the governors whom he appointed suffered them to run quickly to a shameful decay; particularly the new and opulent metropolis of Mohedia, on which immense sums had been lavished, as well as labour and care, so as to render it not only one of the richest and stateliest, but one of the strongest, cities in the world: so that we may truly say, the wealth and splendor of this once famed, though short-lived state, took their final leave of it with the departure of the khalif Al Moezz, seeing the whole maritime tract from the Egyptian confines to the straits of Gibraltar hath since become the nest of the most odious piratical crew that can be imagined.

Under the article ALGIERS we have given a short account of the erection of a new kingdom in Barbary by Texeffin; which, however, is there no farther continued than is necessary for the proper understanding the history of that country. A general history might here be given of the whole country of Barbary; but as that would necessarily occasion repetitions under the articles MOROCCO, TRIPOLI, TUNIS, &c. we chuse to refer to those articles for the historical part, as well as for an account of the climate, inhabitants, &c.

BARBE, or BARB. See BARB.

BARBE, in the military art. To fire in barbe, means to fire the cannon over the parapet, instead of firing through the embrasures; in which case, the parapet must not be above three feet and a half high.

BARBE, or BARDE, is an old word, denoting the armour of the horses of the ancient knights and soldiers, who were accoutred at all points. It is said to have

been an armour of iron and leather, wherewith the neck, breast, and shoulders of the horse were covered.

BARBE (St.) a town of Biscay in Mexico, near which are rich silver mines. W. Long. 109. 55. N. Lat. 26. 0.

BARBED, in a general sense, bearded like a fish-hook, set with barbs; also shaved or trimmed.

BARBED, and *Crested*, in heraldry, an appellation given to the combs and gills of a cock, when particularized for being of a different tincture from the body.

A *barbed cross*, is a cross, the extremities whereof are like the barbed irons used for striking of fish.

BARBEL, in ichthyology. See CYPRINUS.

BARBELICOTÆ, an ancient sect of gnostics, spoken of by Theodoret. Their doctrines were absurd, and their ceremonies abominable.

BARBER, one who makes a trade of shaving or trimming the beards of other men for money. Anciently, a lute or viol, or some such musical instrument, was part of the furniture of a barber's shop, which was used then to be frequented by persons above the ordinary level of the people, who resorted to the barber either for the cure of wounds, or to undergo some chirurgic operations, or, as it was then called, to be *trimmed*, a word that signified either shaving or cutting and curling the hair; these, together with letting blood, were the ancient occupations of the barber-furgeon. As to the other important branch of surgery, the setting of fractured limbs, that was practised by another class of men called *bone-setters*, of whom there are hardly any now remaining. The musical instruments in his shop were for the entertainment of waiting customers; and answered the end of a news-paper, with which at this day those who wait for their turn at the barber's amuse themselves.

BARBERINI (Francis), one of the most excellent poets of his age, was born at Barberino, in Tuscany, in the year 1264. As his mother was of Florence, he settled in that city; where his profession of the law, but especially the beauty of his poetry, raised him a very considerable character. The greatest part of his works are lost; but that which is intitled the *Precepts of Love*, which is a moral poem calculated to instruct those in their duty who have a regard for glory, virtue, and eternity, has had a better fate. It was published at Rome, adorned with beautiful figures, in 1640, by Frederic Ubal dini: he prefixed the author's life; and, as there are in the poem many words which are grown obsolete, he added a glossary to explain them, which illustrates the sense by the authority of contemporary poets.

BARBERINO, a town of Tuscany in Italy, situated at the foot of the Appennine mountains, in E. Long. 12. 15. N. Lat. 43. 40.

BARBERRY, in botany. See *Berberis*.

BARBESUL, (anc. geog.) a town and river of Bætica, and a colony in the resort of the Conventus Gaditanus in Spain: now *Marbella* in Granada. * See *Marbella*.

BARBET, in natural history, a name given by M. Reaumur, and other of the French writers, to a peculiar species of the worms which feed on the pucerons, or aphides. See APHIS.

This worm is more particularly called *bar bet blanc*, as also *herisson blanc*, or white hedgehog, from its being covered with oblong white tufts of filaments, which stand

33
He con-
quers E-
gypt.34
And trans-
fers the seat
of govern-
ment to that
country.

Barbet.

stand in the manner of the quills of a hedgehog or porcupine. M. Reaumur calls these tufts of filaments, *spines*; not to signify that they are capable of pricking, for they have no such power; but to express their manner of arrangement on the body of the animal.

This creature is of the size of a small fly without its wings; but this tufted covering so much increases the bigness, that it appears of the size of a fly of the largest kind.

These tufts have neither the hardness of spines, nor the consistence of hairs; but they resemble, in their spongy texture, a filament of cotton. All these spines or tufts of cotton are arranged in six lines, as evenly parallel to one another as the shape of the animal's body will permit. Each of these lines reaches over the whole upper part of the body, following the course of one of the rings. The several spines, which compose each line, almost touch one another at their bases; but as they all stand perpendicular, and are placed on a convex surface, they are considerably distant from one another at the points. The tufts on different insects of this species are of different lengths. In the common kinds, they are short, and stand perfectly erect; but in some they are so long, as not to be able to support their own weight, but bend into hooks. In all the species, every single tuft has its irregularities, and is seen to be composed of several cottony filaments of unequal lengths, which are knotty and rough in several places; and when touched, they feel soft like cotton. It is also very remarkable, that, on being touched, they always adhere to the fingers; and are so loosely connected with the body of the animal, that, on rubbing the finger over it ever so lightly, they all come off, and leave it naked. The creature then appears green, and of a very different figure from what it had before; and the tufts lose their figure, and appear only a congeries of round grains of a cottony matter. The sudden change in size and appearance in the creature, makes it look as if it had undergone a transformation.

It is evident from observation, that the matter of which the tufts, which cover the body of this animal, are made, is of a very different nature and formation from the silky filaments which caterpillars and other insects spin out of their entrails. They have all peculiar organs for the spinning it, and all draw it out to any length they please; but this matter, on the contrary, has a determinate length, which it cannot exceed; and is only formed of the matter perspired through certain parts of the body of the creature, which hardens as it remains in the air. As it is so easy to divest these creatures of their downy covering, it will be readily conceived, that nature must have made its reparation to the animal very easy; and this is indeed the case: for if the animal be wholly made naked, by drawing the finger three or four times over it, it loses its fine green colour in half an hour afterwards, appearing as if dusted over with flour; and, in fine, within the space of twelve hours, is furnished with tufts as long, and every way as large, as those it lost. When the tufts have been rubbed off from one of these animals, and its body is left naked, if it be then examined by a microscope, there will be found a number of small hollows or depressions in the skin, exactly answering in place and number to the cottony tufts that are to succeed the lost ones. It is to be conceived, that, within each of

these hollows, there are a great number of fine apertures, through which the matter that is to form the new tufts is to pass; but these are not distinguishable by the most powerful glasses: if the tufts, however, be examined while forming, they will be found to consist of a vast number of regular filaments, placed close by one another, and each running distinctly the whole length of the tuft: this appearance is, however, wholly lost afterwards, the fine threads sticking to, and intermingling with, one another, and many of them breaking in several places; so that the whole tuft resembles a coarse and single filament.

These barbets are found in great plenty on the leaves of the plum-tree in the months of June and July. The puceron of this tree seems more to their taste than any other kind; and they are often found in numbers on every leaf of the tree where these little animals are. The matter of their tufts seems analogous to the downy covering of some of the pucerons, and to no other substance in the animal world. The puceron of the beech-tree has this downy matter running into much longer filaments even than this animal; and, in the several other species, it is found growing to the different lengths from this to a mere downy powder. The barbet lives about a fortnight in that form, and then becomes a chrysalis; from which, after a month, there comes out a small beetle of a dusky brown colour.

BARBETS, the name of the inhabitants of several valleys in Piedmont, particularly those of Lucerna, Angrona, Perugia, and St Martin.

BARBEYRAC (John), was born in Besiers in Lower Languedoc in 1674. He was made professor of law and history at Lausanne in 1710; which he enjoyed for seven years, and during that time was three times rector: in 1717, he was professor of public and private law at Groningen. He translated into French the two celebrated works of Puffendorf, his *Law of Nature and Nations*, and his *Duties of a Man and a Citizen*; to both which he wrote excellent notes, and to the former an introductory preface. He translated also Grotius's treatise *De Jure Belli ac Pacis*, with large and excellent notes; and several of Tillotson's sermons. He wrote a work intitled *Traite de Dieu*, 2 vols 8vo.

BARBEZIEUX, a town of Saintonge in France, with the title of a marquissate. It hath a manufacture of linen cloth; and lies in W. Long. o. 5. N. Lat. 45. 23.

BARBICAN, or BARBACAN. See BARBACAN.

BARBITOS, or BARBITON, an ancient instrument of music, mounted with three, others say seven, strings; much used by Sappho and Alceus, whence it is also denominated *Lebounn*.

BARBLES, or BARBS, in farriery, the knots or superfluous flesh that grow up in the channels of a horse's mouth; that is, in the intervals that separate the bars, and lie under tongue.

BARBOUR (John), arch-deacon of Aberdeen, was esteemed an elegant poet in the reign of David I. He wrote the history of Robert the Bruce, in an heroic poem, which is still extant, and which contains many facts and anecdotes omitted by other historians. The latest edition of this book is that of Glasgow, 8vo, printed in the year 1672. It is entitled, "The acts and life of the most victorious conqueror Robert Bruce king of Scotland; wherein also are contained the mar-

Barbet
Barbonn.

Barbuda,
Barca.

tial deeds of the valiant princes Edward Bruce, Sir James Dowglafs, Earl Thomas Randal, Walter Stewart, and sundry others." In one paffage, he calls it a *romance*; but that word was then of good reputation: every body knows that the 'Romant of romaunts' has been innocently applied to true history; as well as the 'Ballad of ballads' to a sacred fong.

BARBUDA, one of the British Caribbee iflands, about 20 miles long and 12 broad. It is low land, but fruitful and pretty populous. The inhabitants addit themselves to husbandry, and find always a ready market for their corn and cattle in the fugar iflands. Barbuda is the property of the Codrington family, who have great numbers of negroes here as well as in Barbadoes. It lies in W. Long. 61. 3. N. Lat. 18. 5.

BARCA, a large country of Africa, lying on the coasts of the Mediterranean fea, between the kingdoms of Egypt and Tripoli, extending itself in length from east to west from the 39th to the 46th degree of east longitude, and in breadth from north to south about 30 leagues, as is generally fuppofed. It is for the most part, especially in the middle, a dry sandy defart; on which account the Arabs call it *Sabart*, or *Ceyart Barka*, that is, the defart or road of whirlwinds or hurricanes. It labours almost every where under a great scarcity of water; and except in the neighbourhood of towns and villages, where the ground produces some small quantities of grain, such as millet, and some maize, the rest is in a manner quite barren and uncultivated, or, to speak more properly, uncultivable: and even that small quantity which those few spots produce, the poor inhabitants are obliged to exchange some part with their indigent neighbours, for dates, sheep, and camels, which they stand in greater need of than they, by reason of their great scarcity of grafs and other proper food; for want of which, those that are brought to them seldom thrive or live long. In this country stood the famed temple of Jupiter Ammon; and notwithstanding the pleafantness of the spot where it stood, this part of the country is said to have been the most dangerous of any, being furrounded with such quick and burning sands as are very detrimental to travellers; not only as they sink under their feet, but being light, and heated by the rays of the sun, are easily raised by every breath of wind; which, if it chance to be in their faces, almost burns their eyes out, and stifles them for want of breath; or, if vehement, often overwhelms whole caravans. Against this temple Cambyfes king of Persia difpatched an army of 50,000 men. They fet out from Thebes in upper Egypt, and under the conduct of proper guides reached the city of Oasis seven days journey from that place: but what was their fate afterwards is uncertain; for they never returned either to Egypt, or to their own country. The Ammonians informed Herodotus, that, after the army had entered the sandy defart which lies beyond Oasis, a violent wind began to blow from the south at the time of their dinner, and raised the sand to such a degree, that the whole army was overwhelmed and buried alive.

Concerning the government or commerce of this country we know nothing certain. Most probably the maritime towns are under the protection of the Porte: but whether under the basha of Egypt or Tripoli, or whether they have formed themselves into independent

flates like those of Algiers and Tunis, we cannot say; only we are told that the inhabitants of the maritime towns are more civilized than those that dwell in the inland parts. The first profets Mahometanism, and have imbibed some notions of humanity and justice; whilst the latter, who have neither religion, nor any sign of worship among them, are altogether savage and brutish. They are a sort of Arabs, and like them live entirely upon theft and plunder. By them this tract, which before was a continued defart, was first inhabited. At their first coming in, they settled themselves in one of the best places of the country; but as they multiplied, and had frequent wars with one another, the strongest drove the weakest out of the best spots, and sent them to wander in the defart parts, where they live in the most miserable manner, their country hardly affording one single necessary of life. Hence it is that they are said to be the ugliest of all the Arabs: their bodies having scarcely any thing but skin and bone, their faces meagre, with fierce ravenous looks; their garb, which is commonly what they take from the passengers who go through these parts, tattered with long wearing; while the poorest of them have scarce a rag to cover their nakedness. They are most expert and resolute robbers, that being their chief employment and livelihood; but the travellers in these parts are so few, that the Barcans are often necessitated to make distant excursions into Numidia, Libya, and other southern countries. Those that fall into their hands are made to drink plenty of warm milk: then they hang them up by the feet, and shake them, in order to make them vomit up any money they think they have swallowed; after which, they strip them of all their clothes, even to the last rag: but, with all this inhumanity, they commonly spare their life, which is more than the other African robbers do. Yet, notwithstanding every artifice they can use, the Barcans are so poor, that they commonly let, pledge, or even sell, their children to the Sicilians and others from whom they have their corn, especially before they fet out on any long excursion.

BARCALON, an appellation given to the prime minister of the king of Siam. The barcalon has in his department every thing relating to commerce, both at home and abroad. He is likewise superintendent of the king's magazines.

BARCELONA, a handsome, rich, and strong city of Spain, in the province of Catalonia, of which it is the capital. This city was originally founded by Hamilcar Barcas, and from him called *Barcino*. It was reduced by the Romans, and continued subject to them till the kingdom of Spain was over-run by the Goths and Vandals, and afterwards by the Saracens or Moors. In the beginning of the 9th century, Barcelona was in the hands of the Moors, and under the government of one *Zade*. This governor having more than once abused the clemency of Charlemagne, at last irritated Lewis king of Aquitain, and son to Charles, to such a degree, that he gave orders to his generals to invest the city, and not to rise from before it till they had put Zade into his hands. The Moor made a most obstinate resistance, so that the siege lasted many months: at last, finding it impossible to preserve the city much longer, and being destitute of all hopes of relief, he determined, or rather was compelled by the inhabitants, to go to the

Barca
|
Barcelona

Christian

Christian camp, and implore the emperor's mercy; but here he was no sooner arrived than he was arrested, and sent prisoner to Charlemagne, who condemned him to perpetual banishment. The people gaining nothing by this expedient, continued to hold out for six weeks longer, when the king of Aquitain himself took the command of the siege. To him they made a proposal, that if he would allow them to march out, and go where they pleased, they would surrender the place. Lewis having agreed to this, made his public entry into Barcelona, where he formed a design of extending his father's dominions as far as the Ebro; but being recalled before he could put his design in execution, he appointed one Bera count of Barcelona. The city continued subject to him and his successors, who still enjoyed the title of *counts of Barcelona*, from the year 802 to 1131; during which time we find nothing remarkable, except that the city was once taken by the Moors, but soon after retaken by the assistance of Lewis IV. king of France. In 1131, it was united to the crown of Arragon by the marriage of Don Raymond V. count of Barcelona with the daughter of Don Ramiro the Monk, king of Arragon. In 1465, the Catalonians revolted against Don Juan II. king of Arragon, out of hatred to his queen Donna Juanna; the consequence of which was, that Barcelona was besieged by that monarch in 1471. Various efforts were made by Lewis XI. of France, and the duke of Lorraine, in order to raise the siege, but without effect. Things at length were brought to the utmost extremity, when the king offered to pardon them all, without the smallest punishment either in person or property, provided they would submit: but these terms they rejected, chiefly through the influence of the count de Pailhars, who had been pardoned the year before. The army, on the other hand, was very earnest in being led on to the assault, in hopes of plunder. The king, however, wrote a letter to the citizens, dated the 6th of October, in terms as affectionate as if he had been writing to his children, bewailing the miseries they had brought on themselves, and concluding with a protestation, that they, and not he, must be answerable for the consequences. Upon this, at the persuasion of a priest who had a reputation for sanctity, they sent deputies to the king, and made a capitulation on the 17th of the same month. In this the king acknowledged they had taken up arms on just motives; and forgave every body except Pailhars, who was, however, suffered to escape. On the 22^d of October the king made his entry into the city, and confirmed all their ancient privileges. In 1697, Barcelona was taken by the French, after a bloody siege of 52 days; and the loss of this city had a considerable effect in disposing the Spaniards to agree to the treaty of Ryfwick. In Queen Anne's time it was taken by the allies under the earl of Peterborough; but being afterwards shamefully denied assistance by the English ministry, was obliged to submit to Philip V. by whom the whole province was deprived of its ancient privileges; for a particular account of which, see the article SPAIN.

Barcelona is situated by the sea-side, of a form between a square and an oval; it is surrounded with a good brick wall, round which is another, with 14 bastions, horn-works, ramparts, and ditches; the ramparts are high, broad, and spacious, inasmuch that an hundred coaches may be seen every evening driving thereon for pleasure.

The city is divided into two parts, the Old and the New, which are separated from each other by a wall and a large ditch; the streets are handsome, well paved with large stones, wide, and very clean. It is the residence of a viceroys, is a bishop's see, has a fine university, a mint, a good port, and is adorned with handsome buildings. Here is a court of inquisition, which the inhabitants look upon as an advantage. The remarkable buildings are the cathedral, which is large, handsome, and adorned with two high towers, the church of the Virgin Mary, the palace of the bishop, that of the inquisition, and several religious houses: add to these the palace of the viceroys; the arsenal, which contains arms for 1000 men; the exchange, where the merchants meet; the *terfana*, where they build the galleys; and the palace where the nobility of the country meet, called *La Casa de la Deputation*. This last is built with fine large free stone, and adorned with columns of marble: there is in it a large hall, with a gilt ceiling, and a handsome portico, wherein persons may either walk or sit; the hall is adorned with the portraits of all the counts of Barcelona. There are several fine squares, particularly that of St Michael, into which all the great streets run. The port is wide, spacious, deep, and safe; defended on the one side by a great mole, and on the other sheltered from the west wind by two mountains, that advance into the sea, and form a kind of promontory: the mole is 750 paces long, with a quay, at the end of which is a light-house, and a small fort. One of the mountains, called *Mount Joy*, is very high, and rises in the middle of the plain near the city: it is covered with gardens, vineyards, groves of trees, and has a strong fort for the defence of the city: this mountain being a rock, yields an inexhaustible quarry of fine hard free stone. Barcelona is a place of great trade, on account of the conveniency of its harbour; and it has a manufacture of knives greatly esteemed in Spain, as also of blankets. Here are also several glass-houses. The inhabitants are diligent, and equally fit for labour and trade; they are also very civil to strangers. The women are well shaped, and as handsome as any in Spain; they are brisk and lively in their conversation, and more free and unrestrained in their behaviour than in other parts of Spain. E. Long. 2. 5. N. Lat. 41. 26.

BARCELONETTA, a town of France in the government of Dauphiny, and capital of the valley of its own name. It belonged to the duke of Savoy, and was ceded to France by the treaty of Utrecht in 1712. E. Long. 6. 40. N. Lat. 44. 26.

BARCELOR, a town of Asia, in the East Indies, on the coast of Malabar. It is a Dutch factory, where they carry on a considerable trade in pepper. E. Long. 74. 15. N. Lat. 13. 45.

BARCELOS, a town of Portugal, with the title of a duchy. It is seated on the river Cavado, over which there is a handsome bridge. W. Long. 7. 00. N. Lat. 41. 20.

BARCINO, (anc. geogr.) a town of the Terraconensis in Spain, and capital of the Laleatani. Now *Barcelona*. See that article.

BARCLAY (Alexander), a learned monk in the reign of Henry VIII. Where he was born, though of no great importance, was nevertheless a matter of virulent contention among his former biographers.

Bale.

Barclay.

Bale, who was his cotemporary, is of opinion he was born in Somersetshire. There is indeed a village of his name, and a numerous family, in that county. Pits thinks he was born in Devonshire. Mackenzie is positive he was a Scotchman; but without proof, unless we admit as such his name, *Alexander*. He was, however, educated in Oriel college, Oxford. After leaving the university, he went abroad, and continued some time in France, Italy, and Germany, where he acquired a competent knowledge of the languages of those countries, as appears from several translations of books, which he afterwards published. On his return to England, he was made chaplain to his patron the bishop of Tyne, who likewise appointed him a priest of St Mary, at the college of Ottery in Devonshire, founded by Grandison bishop of Exeter. After the death of his patron, he became a Benedictine monk of Ely. On the dissolution of that monastery, he first obtained the vicarage of St Matthew at Wokey, in Somersetshire; and, in 1549, being then doctor of divinity, was presented to the vicarage of Much Badew in Essex. In 1552, he was appointed rector of Allhallows, Lombardstreet, which he lived to enjoy but a very short time. He died at Croydon in Surrey, in June 1552. He is generally allowed to have improved the English language, and to have been one of the politest writers of his time. He composed several original works; but was chiefly remarkable for his translations from the Latin, Italian, French, and German languages. His version from Sallust of the war of Jugurtha is accurate, and not without elegance. His lives of several saints, in heroic verse, are still unpublished. His *Stultifera navis*, or *The ship of fools*, is the most singular of his performances. It was printed by Richard Pynson at London 1509, in folio; and contains a variety of wooden plates, which are worthy the inspection of the curious.

BARCLAY (William), a learned Civilian, was born in Aberdeenshire in the year 1541. He spent the early part of his life, and much of his fortune, at the court of Mary Queen of Scots, from whose favour he had reason to expect preferment. In 1573, he went over to France, and at Bourges commenced student of civil law under the famous Cujacius. He continued some years in that seminary, where he took a doctor's degree; and was soon after appointed professor of civil law in the university of Pont-à-Mousson, then first founded by the duke of Lorraine. That prince afterwards made him counsellor of state, and master of requests. Barclay, in the year 1581, married Ann de Malla-ville, a French lady, by whom he had a son, who became a celebrated author, and of whom the reader will find an account in the next article. This youth the Jesuits would gladly have received into their society. His father refused his consent, and for that reason these disciples of Jesus found contrived to ruin him with the duke his patron. Barclay now embarked for Britain, where king James I. offered him considerable preferment, provided he would become a member of the church of England: but, not chusing to comply, he returned to France in 1604; and, soon after his arrival, was appointed professor of civil law in the university of Angers, where he died the year following, and was buried in the Franciscan church. He was esteemed a learned civilian; and wrote elaborately in defence of the divine right of kings, in answer to Buchanan and others.

The titles of his works are, 1. *De regno et regali potestate*, &c. 2. *Commentarius in tit. pandectarum de rebus creditis, et de jurejurando*. 3. *De potestate papæ*, &c. 4. *Præmetia in vitam Agricola*.

BARCLAY (John), son of the former, was, as we have above mentioned, so great a favourite of the Jesuits, that they used all their efforts to engage him in their society. His father would not consent, and carried his son with him into England, who was already an author, for he had published *A commentary upon the Thebais of Statius*, and a Latin poem on the coronation of King James, and the first part of *Euphormio*, 1603. He returned to France with his father; and after his father's death went to Paris, and soon after came back to London: he was there in 1606. He published *The History of the Gun-powder Plot*, a pamphlet of six leaves, printed at Amsterdam. He published at London, in 1610, *An Apology for the Euphormio*, and his father's treatise *De potestate papæ*. And at Paris, 1612, he published a book intitled *Pietas*, in answer to cardinal Bellarmin, who had written against William Barclay's book concerning the power of the Pope. Two years after, he published *Icon Animorum*. He was invited to Rome by Pope Paul V. and received a great deal of civility from cardinal Bellarmin, though he had written against him. He died at Rome in 1621, while his *Argenis* was printing at Paris. This celebrated work has since gone through a great number of editions, and has been translated into most languages. M. de Peirese, who had the care of the first edition, caused the effigies of the author to be placed before the book; and the following distich, written by Grotius, was put under it:

*Genæ Caledonius, Gallus natalibus, hic est,
Romam Romano qui docet ore loqui.*

BARCLAY (Robert), one of the most eminent among the Quakers, the son of colonel David Barclay, descended of the ancient family of Barclays, was born at Edinburgh in 1648. He was educated under an uncle at Paris, where the Papists used all their efforts to draw him over to their religion. He joined the Quakers in 1669, and distinguished himself by his zeal and abilities in defence of their doctrines. In 1676, he published in Latin at Amsterdam his *Apology for the Quakers*; which is the most celebrated of his works, and esteemed the standard of the doctrine of the Quakers. The *Theses Theologicae*, which were the foundation of this work, and addressed to the clergy of what fort however, were published before the writing of the *Apology*, and printed in Latin, French, High-Dutch, Low-Dutch, and English. The dedication of his *Apology* to king Charles II. is very remarkable for the uncommon frankness and simplicity with which it is written. Amongst many other extraordinary passages, we meet with the following: "There is no king in the world, who can so experimentally testify of God's providence and goodness; neither is there any who rules so many free people, so many true Christians; which thing renders thy government more honourable, thyself more considerable, than the accession of many nations filled with slavish and superstitious souls. Thou hast tasted of prosperity and adversity; thou knowest what it is to be banished thy native country, to be over-ruled as well as to rule and sit upon the throne; and being oppressed, thou hast reason to know how hateful the oppressor is."

both.

both to God and man : if, after all those warnings and advertisements, thou dost not turn unto the Lord with all thy heart, but forget him who remembered thee in thy distress, and give up thyself to follow lust and vanity, surely great will be thy condemnation."—He travelled with the famous Mr William Penn, through the greatest part of England, Holland, and Germany, and was every where received with the highest respect; for though both his conversation and behaviour were suitable to his principles, yet there was such liveliness and spirit in his discourse, and such serenity and cheerfulness in his deportment, as rendered him extremely agreeable to all sorts of people. When he returned to his native country, he spent the remainder of his life in a quiet and retired manner. He died at his own house at Ury, on the 3^d of October, 1690, in the 42^d year of his age.

BARCOCHEBAS, or rather **BARCOCHAB**, a Jewish impostor, whose real name was *Akiba*; but he took that of *Barcochab*, which signifies the *Son of a Star*; in allusion to the prophecy of Balaam, "There shall a star arise out of Jacob." He proclaimed himself the Messiah; and talking of nothing but wars, victories, and triumphs, made his countrymen rise against the Romans, by which means he was the author of a thousand disorders: he ravaged many places, took a great number of fortresses, and massacred an infinite multitude of people, and particularly the Christians. The emperor sent troops to Rufus, governor of Judea, to suppress the sedition. Rufus, in obedience, exercised a thousand cruelties, but could not finish his attempt. The emperor was therefore obliged to send Julius Severus, the greatest general of that time; who attained his end without a direct battle: he fell on them separately; cut off their provisions; and at last the whole contest was reduced to the siege of Bitter, in the 18th year of Hadrian. The impostor perished there. This war cost the Romans a great deal of blood.

BARDANA, or **BURDOCK**. See **ARCTIUM**.

BARDAS, the brother of the empress Theodora; and uncle of the famous Photius, is said to have had no other good quality besides that of loving the sciences and polite literature, which he established in the Eastern empire; for he was treacherous, cruel, and ambitious. In the year 856, he assassinated Theoctistes, general of the emperor Michael's forces, and obtained his post. At length he caused the disgrace of the empress Theodora; and St Ignatius, patriarch of Constantinople, reproaching him for his vices, he had him deposed in 858, in order to make room for Photius. Bardas was assassinated by Basilus the Macedonian, in 866.

BARDED, in heraldry, the same with caparisoned. **BARDESANISTS**, a sect of ancient heretics, thus denominated from their leader Bardesanes, a Syrian of Edessa in Mesopotamia. Bardesanes, born in the middle of the second century, became eminent, after his conversion to Christianity, for his zeal against heretics; against whom, we are informed, by St Jerome and Eusebius, he wrote a multitude of books: yet had he the misfortune to fall, himself, into the errors of Valentinus, to which he added some others of his own. He taught, that the actions of men depend altogether on fate, and that God himself is subject to necessity. His followers went further, and denied the resurrection of the body, and the incarnation and death of our Sa-

viour; holding that these were only apparent or phantastical.

BARDEWICK, a town of Germany, in the circle of Lower Saxony and duchy of Lunenburg; formerly a very large place; but being ruined in 1189, by the duke of Saxony, has never yet recovered itself. It is seated on the river Ilmeneau, in E. Long. 10. 6. N. Lat. 53. 40.

BARDS. The word *bard* being a primitive noun, neither derived nor compounded, it can neither be traced to its root, nor resolved into its parts. It signified one who was a poet by his genius and profession; and "who sung of the battles of heroes, or the heaving "breasts of love."*

The curiosity of man is great with respect to the transactions of his own species; and when such transactions are described in verse, accompanied with music, the performance is enchanting. An ear, a voice, skill in instrumental music, and, above all, a poetical genius, are requisite to excel in that complicated art. As such talents are rare, the few that possessed them were highly esteemed; and hence the profession of a bard, which, beside natural talents, required more culture and exercise than any other known art. Bards were capital persons at every festival and at every solemnity. Their songs, which, by recording the achievements of kings and heroes, animated every hearer, must have been the entertainment of every warlike nation. We have Heoid's authority, that in his time bards were as common as potters or joiners, and as liable to envy. Demodocus is mentioned by Homer as a celebrated bard; and Phemius, another bard, is introduced by him deprecating the wrath of Ulysses in the following words:

- "O King! to mercy be thy soul inclin'd,
"And spare the poet's ever-gentle kind.
"A deed like this thy future fame would wrong,
"For dear to gods and men is sacred song.
"Self-taught I sing; by heav'n, and heav'n alone,
"The genuine feels of poetry are foun;
"And (what the gods bestow) the lofty lay,
"To gods alone, and godlike worth, we pay.
"Save then the poet, and thyself reward;
"Tis thine to merit, mine is to record." *ODYSSEY*, viii.

Cicero reports, that at Roman festivals, anciently, the virtues and exploits of their great men were sung. The same custom prevailed in Peru and Mexico, as we learn from Garcilasso and other authors. We have for our authority Father Gobien, that even the inhabitants of the Marian islands have bards, who are greatly admired, because in their songs are celebrated the feats of their ancestors.

But in no part of the world did the profession of bard appear with such lustre as in Gaul, in Britain, and in Ireland. Wherever the Celtæ or Gauls are mentioned by ancient writers, we seldom fail to hear of their druids and their bards; the institution of which two orders, was the capital distinction of their manners and policy. The druids were their philosophers and priests; the bards, their poets and recorders of heroic actions: and both these orders of men seem to have subsisted among them, as chief members of the state, from time immemorial. The Celtæ possessed, from very remote ages, a formed system of discipline and manners, which appears to have had a deep and lasting influence. Ammianus Marcellinus † gives them this express testimony, that there flourished among them the study of the most laudable arts; introduced

Bardewick, Bards.

Bards.

by the bards, whose office it was to sing in heroic verse the gallant actions of illustrious men; and by the druids, who lived together in colleges or societies, upon the Pythagorean manner, and, philosophizing upon the highest subjects, asserted the immortality of the human soul. Tho' Julius Cæsar, in his account of Gaul, does not expressly mention the bards; yet it is plain, that, under the title of *Druids*, he comprehends that whole college or order; of which the bards, who, it is probable, were the disciples of the druids, undoubtedly made a part. It deserves remark, that, according to his account, the druidical institution first took rise in Britain, and passed from thence into Gaul; so that they who were apt to be thorough masters of that learning were wont to resort to Britain. He adds too, that such as were to be initiated among the druids, were obliged to commit to their memory a great number of verses, inasmuch that some employed twenty years in this course of education; and that they did not think it lawful to record these poems in writing, but sacredly handed them down by tradition from race to race.

So strong was the attachment of the Celtic nations to their poetry and their bards, that amidst all the changes of their government and manners, even long after the order of the druids was extinct, and the national religion altered, the bards continued to flourish; not as a set of strolling songsters, like the Greek *ᾠδοὶ* or *rhapsodists*, in Homer's time, but as an order of men highly respected in the state, and supported by a public establishment. We find them, according to the testimonies of Strabo and Diodorus, before the age of Augustus Cæsar; and we find them remaining under the same name, and exercising the same functions as of old, in Ireland, and in the north of Scotland, almost down to our own times. It is well known, that, in both these countries, every *regulus* or chief had his own bard, who was considered as an officer of rank in his court.

Of the honour in which the bards were held, many instances occur in Ossian's poems. On all important occasions, they were the ambassadors between contending chiefs; and their persons were held sacred. " Cairbor feared to stretch his sword to the bards, tho' his soul was dark. Loose the bards, (said his brother Cathmor), they are the sons of other times. Their voice shall be heard in other ages, when the kings of Temora have failed."—The bards, as well as the druids, were exempted from taxes and military services, even in times of the greatest danger; and when they attended their patrons in the field, to record and celebrate their great actions, they had a guard assigned them for their protection. At all festivals and public assemblies they were seated near the person of the king or chieftain, and sometimes even above the greatest nobility and chief officers of the court. Nor was the profession of the bards less lucrative than it was honourable. For, besides the valuable presents which they occasionally received from their patrons when they gave them uncommon pleasure by their performances, they had estates in land allotted for their support. Nay, so great was the veneration which the princes of these times entertained for the persons of their poets, and so highly were they charmed and delighted with their tuneful strains, that they sometimes pardoned even their capital crimes for a song.

We may very reasonably suppose, that a profession that was at once so honourable and advantageous, and enjoyed so many flattering distinctions and desirable immunities, would not be deserted. It was indeed very much crowded; and the accounts which we have of the numbers of the bards in some countries, particularly in Ireland, are hardly credible. We often read, in the poems of Ossian, of a hundred bards belonging to one prince, singing and playing in concert for his entertainment. Every chief bard, who was called *Allah Redan*, or *doctor in poetry*, was allowed to have 30 bards of inferior note constantly about his person; and every bard of the second rank was allowed a retinue of 15 poetical disciples.

Though the ancient Britons of the southern parts of this island had originally the same taste and genius for poetry with those of the north, yet none of their poetical compositions of this period have been preserved. Nor have we any reason to be surprized at this. For after the provincial Britons had submitted quietly to the Roman government, yielded up their arms, and had lost their free and martial spirit, they could take little pleasure in hearing or repeating the songs of their bards in honour of the glorious achievements of their brave ancestors. The Romans too, if they did not practise the same barbarous policy which was long after practised by Edward I. of putting the bards to death, would at least discourage them, and discountenance the repetition of their poems, for very obvious reasons. These sons of the song being thus persecuted by their conquerors, and neglected by their countrymen, either abandoned their country or their profession; and their songs being no longer heard, were soon forgotten.

It is probable that the ancient Britons, as well as many other nations of antiquity, had no idea of poems that were made only to be repeated, and not to be sung to the sound of musical instruments. In the first stages of society in all countries, the two sister-arts of poetry and music seem to have been always united; every poet was a musician, and sung his own verses to the sound of some musical instrument. This, we are directly told by two writers of undoubted credit, was the case in Gaul, and consequently in Britain, in this period.

" The bards (says Diodorus Siculus) sung their poems † Lib. v. to the sound of an instrument not unlike a lyre." sect. 31.
 " The bards, (according to Ammianus Marcellinus *, * Lib. xv. c. 9. as above hinted), celebrated the brave actions of illustrious men in heroic poems, which they sung to the sweet sounds of the lyre." This account of these Greek and Latin writers is confirmed by the general strain, and by many particular passages, of the poems of Ossian.
 " Beneath his own tree, at intervals, each bard sat down with his harp. They raised the song, and touched the string, each to the chief he loved †." † Vol. II. p. 112, 113

The invention of writing made a considerable change in the bard profession. It is now an agreed point, that no poetry is fit to be accompanied with music, but what is simple: a complicated thought or description requires the utmost attention, and leaves none for the music; or, if it divide the attention, it makes but a faint impression †. The simple operas of Quinault bear away the palm from every thing of the kind composed by Boileau or Racine. But when a language, in its progress to maturity, is enriched with variety of phrases fit to express the most elevated thoughts, men of genius aspired

Dr. Bel. Gal. l. 6.

Ossian, 11. 22.

Henry's History, Vol. I. p. 365.

Kaim's Sketches, ubi supra.

† See the article Attention.

aspired to the higher strains of poetry, leaving music and song to the bards: which distinguished the profession of a poet from that of a bard. Homer, in a lax sense, may be termed a bard; for in that character he strolled from feast to feast. But he was not a bard in the original sense: he, indeed, recited his poems to crowded audiences; but his poems are too complex for music, and he probably did not sing them, nor accompany them with the lyre. The Trovadores of Provence were bards in the original sense; and made a capital figure in the days of ignorance, when few could read, and fewer write. In later times, the songs of the bards were taken down in writing, which gave every one access to them without a bard; and the profession sunk by degrees into oblivion. Among the Highlanders of Scotland, reading and writing in their own tongue is not common even at present; and that circumstance supported long the bard-profession among them, after being forgot among the neighbouring nations.

BARDT, a strong and rich town of Germany, in the duchy of Pomerania, with a castle and spacious harbour. It is subject to the Swedes; and is situated near the Baltic sea, in E. Long. 13. 20. N. Lat. 54. 23.

BARE, in a general sense, signifies *not covered*. Hence we say bare-headed, bare-footed, &c.

The Roman women, in times of public distress and mourning, went *bare-headed*, with their hair loose.—Among both Greeks, Romans, and Barbarians, we find a feast called *Nudipedalia*.—The Abyssinians never enter their churches, nor the palaces of kings and great men, but *bare-footed*.

BARE-foot Carmelites and Augustines, are religious of the order of St Carmel and St Austin, who live under a strict observance, and go without shoes, like the capuchins. There are also barefoot fathers of mercy. Formerly there were barefoot dominicans, and even barefoot nuns of the order of St Augustin.

BAREITH, a town of Germany in Franconia, in the margravate of Culembach, with a famous college belonging to the margrave of Brandenburg Bareith. E. Long. 11. 50. N. Lat. 50. 0.

BARENT (Diteric), an excellent painter, was born at Amsterdam, and was the son of a very industrious painter. He studied in Italy, and became the favourite disciple of Titian, with whom he lived a long time; but at length returned to Amsterdam, where he performed many extraordinary pieces. He died in 1582, aged 48.

BARFLEUR, a town of France, in Normandy, on the continent. It was ruined, and had its harbour filled up by the English in 1346. The Cape of that name is 12 miles east of Cherbourg, and near it part of the French fleet was destroyed in 1692. W. Long. 1. 6. N. Lat. 49. 40.

BARGAIN AND SALE, a species of conveyance in the English law. It is a kind of a real contract, whereby the bargainer for some pecuniary consideration bargains and sells, that is, contracts to convey, the land of the bargainee; and becomes by such bargain a trustee for, or seized to the use of, the bargainee; and then the statute of uses completes the purchase: or, as it hath been well expressed, the bargain first vests the use, and then the statute vests the possession. But as

it was foreseen that conveyances, thus made, would want all those benefits of notoriety which the old common-law assurances were calculated to give; to prevent therefore clandestine conveyances of freeholds, it was enacted in the same session of parliament by statute 27 Hen. VIII. c. 16. that such bargains and sales should not enure to pass a freehold, unless the same be made by indenture, and enrolled within six months in one of the courts of Westminster-hall, or with the *custos rotulorum* of the county. Clandestine bargains and sales of chattel interests, or leases for years, were thought not worth regarding, as such interests were very precarious till about six years before; which also occasioned them to be overlooked in framing the statute of uses: and therefore such bargains and sales are not directed to be enrolled. But how impossible is it to foresee, and provide against, all the consequences of innovations! This omission has given rise to the species of conveyance by lease and release.*

BARGE (*bargie*, Dutch), a vessel or boat of state, furnished with elegant apartments, canopies, and cushions; equipped with a band of rowers, and decorated with flags and streamers: they are generally used for processions on the water, by noblemen, officers of state, or magistrates of great cities. Of this sort, too, we may naturally suppose the famous barge or galley of Cleopatra, which, according to Shalkepear,

Like a burnish'd throne
Burnt on the water: the poop was beaten gold:
Purple her sails; and so perfumed, that
The winds were love-sick with them: the oars were silver,
Which to the tune of flutes kept time, and made
The water which they beat to follow faster,
As amorous of their strokes—
At the helm
A seeming mermaid steer'd: the silken tackles
Swell'd with the touches of those flower-soft hands
That yarely form'd their office.

There are likewise other barges of a smaller kind, for the use of admirals and captains of ships of war. These are of a lighter frame, and may be easily hoisted into, and out of, the ships to which they occasionally belong.

BARGE, is also the name of a flat-bottomed vessel of burden, for lading and discharging ships, and removing their cargoes from place to place in a harbour.

BARGE-Couples, in architecture, a beam mortised into another, to strengthen the building.

BARGE-Course, with bricklayers, a term used for that part of the tiling which projects over without the principal rafters, in all sorts of buildings where there is either a gable or a kirkin-head.

BARGHMASTER, **BARMER**, or **BAR-MASTER**, in the royal mines, the steward or judge of the barmote.—The bar-master is to keep two great courts of barmote yearly; and every week a small one, as occasion requires.

BARGHMOTE, or **BARMOTE**, a court which takes cognizance of causes and disputes between miners.—By the custom of the mines, no person is to sue any miner for ore-debt, or for ore, or for any ground in variance, but only in the court of barmote, on penalty of forfeiting the debt, and paying the charges at law.

BARI, a very handsome and rich town of Italy, in the kingdom of Naples; the capital of Terra di Bari, and an archbishop's see. It is well fortified, is seated

Barge
Bari.

* See Lease
and Release.

Bari
Bark.

on the gulph of Venice, and had formerly a good harbour, but it was destroyed by the Venetians. E. Long. 17. 40. N. Lat. 41. 31.

BARİ, or *Terra di Bari*, a territory of Italy in the kingdom of Naples, of which the abovementioned city is the capital. It is bounded on the north by the Capitanata, on the north-west by the Ulterior Principato, on the south by the Basilicata, on the south-east by the Terra de Otranto, and on the north-east by the gulph of Venice. It has no considerable river except the Ofanto, which separates it from the Capitanata. The air is temperate; and the soil produces plenty of corn, fruit, and saffron: but there are a great many serpents, and spiders called *tarantulas* *. The principal towns are Bari the capital, Frani, Andria, Bavo, Bilonto, Converfano, Monopoli, Polignano, Barletta, and Malfetto. The two first are archiepiscopal, and all the rest episcopal.

BARILLIA, in the glass-trade, a sort of potashes imported from Spain, inferior in goodness to that of the Levant; called *polverine*, when loose, small, and in powder; and *rochetta*, when in hard rockylumps.—The fritt made of these makes fine and clear crystal glass, especially that from the rochetta, or the polverine in lumps; but the barillia of Spain, though it be usually fatter, yet makes not a glass so white, but usually inclining a little to a bluish colour.

BARING OF TREES, in agriculture, the taking away some of the earth about the roots, that the winter-rain and snow-water may penetrate farther into the roots. This is frequently practised in the autumn.

BARJOLS, a small populous town of Provence, in France. E. Long. 5. 23. N. Lat. 43. 35.

BARIIUM, (anc. geogr.) a town of Apulia on the Adriatic; so called from the founders, who being expelled from the island Bora, built this town. It is now called *Bari*; see that article.

BARK, in the anatomy of plants, the exterior part of trees, corresponding to the skin of an animal. For its organization, texture, &c. see the article **PLANTS**.

As animals are furnished with a panniculus adiposus, usually replete with fat, which invests and covers all the fleshy parts, and screens them from external cold; plants are encompassed with a bark replete with fatty juices, by means whereof the cold is kept out, and in winter-time the spiculæ of ice prevented from fixing and freezing the juices in the vessels: whence it is, that some sorts of trees remain ever-green the year round, by reason their barks contain more oil than can be spent and exhaled by the sun, &c.

The bark has its peculiar diseases, and is infected with insects peculiar to it.—It appears from the experiments of M. Buffon, that trees stripped of their bark the whole length of their stems, die in about three or four years. But it is very remarkable, that trees thus stripped in the time of the sap, and suffered to die, afford timber heavier, more uniformly dense, stronger, and fitter for service, than if the tree had been cut down in its healthy state. Something of a like nature has been observed by Vitruvius and Evelyn.

The ancients wrote their books on bark, especially

of the ash and lime-tree, not on the exterior, but on the inner and finer bark called *philyra*.

There are a great many kinds of barks in use in the several arts. Some in agriculture, and in tanning leather, as the oak-bark (A); some in physic, as the *quinquina* or jesuit's bark, mace, &c.; others in dyeing, as the bark of alder and walnut trees; others in spicery, as cinnamon, cassia lignea, &c.; and others for divers uses, as the bark of the cork-tree, &c.

In the East Indies, they prepare the bark of a certain tree so as to spin like hemp. After it has been beat and steeped in water, they extract long threads from it, which are something between silk and common thread; being neither so soft nor so glossy as silk, nor so rough and hard as hemp. They mix silk with it in some stuffs; and these are called *nillaes*, and *cherquemelles*.

Of the bark of a species of mulberry-tree the Japanese make their paper. See **MORUS**.

In the island of O-Tahcite, the natives make their cloth, which is of three kinds, of the bark of three different trees, the paper-mulberry above-mentioned, the bread-fruit tree, and the cocoa tree. (See **MORUS**, **BREAD-FRUIT TREE**, and **COCOS**.) That made of the mulberry is the finest and whitest, and worn chiefly by the principal people. It is manufactured in the following manner. When the trees are of a proper size, they are drawn up, and stripped of their branches; after which, the roots and tops are cut off; the bark of these rods being then slit up longitudinally, is easily drawn off; and, when a proper quantity has been procured, it is carried down to some running water, in which it is deposited to soak, and secured from floating away by heavy stones: when it is supposed to be sufficiently softened, the women servants go down to the brook, and, stripping themselves, sit down in the water, to separate the inner bark from the green part on the outside: to do this, they place the under side upon a flat smooth board, and with a kind of shell scrape it very carefully, dipping it continually in the water till nothing remains but the fine fibres of the inner coat. Being thus prepared in the afternoon, they are spread out upon plantain leaves in the evening; they are placed in lengths of about 11 or 12 yards, one by the side of another, till they are about a foot broad, and two or three layers are also laid one upon the other: care is taken that the cloth shall be in all parts of an equal thickness, so that if the bark happens to be thinner in any one particular part of one layer than the rest, a piece that is somewhat thicker is picked out to be laid over it in the next. In this state it remains till the morning, when great part of the water which it contained when it was laid out is either drained off or evaporated, and the several fibres adhere together, so as that the whole may be raised from the ground in one piece. It is then taken away, and laid upon the smooth side of a long piece of wood prepared for the purpose, and beaten by the women servants. The instrument used for this purpose is a square wooden club, having each of its four sides or faces marked, lengthways, with small grooves, or furrows, of different degrees

Bark.

See A-
rantes.

(A) The bark of the oak has been long used in tanning leather, and even thought essential to that operation: but a different substance has been lately discovered, which answers the purpose full as well, and may be procured at a much cheaper rate; we mean oak saw-dust, or the chips of oak reduced to powder. This valuable secret was lately purchased by the society for the encouragement of arts, &c.

grees of fineness; those on one side being of a width and depth sufficient to receive a small pack-thread, and the others finer in a regular gradation, so that the last are not more than equal to sewing silk. They beat it first with the coarsest side of this mallet, keeping time like our smiths; it spreads very fast under the strokes, chiefly however in the breadth, and the grooves in the mallet mark it with the appearance of threads; it is successively beaten with the other sides, last with the finest, and is then fit for use. Of this cloth there are several sorts, of different degrees of fineness, in proportion as it is more or less beaten. The other cloth also differs in proportion as it is beaten; but they differ from each other in consequence of the different materials of which they are made. The bark of the bread-fruit is not taken till the trees are considerably longer and thicker than those of the mulberry; the process afterwards is the same.—Of the bark, too, of a tree which they call *poorou*, they manufacture excellent matting; but a coarse sort which serves them to sleep upon, and a finer to wear in wet weather. Of the same bark they also make ropes and lines, from the thickness of an inch to the size of a small pack-thread.

BARK, of *Jesuit's Bark*, is a name given by way of eminence to the quinquina, or cinchona.

BARK, in navigation, a general name given to small ships; it is however peculiarly appropriated by seamen to those which carry three masts without a mizen top-sail. Our northern mariners, who are trained in the coal-trade, apply this distinction to a broad-sterned ship which carries no ornamental figure on the stern or prow.

Water-BARKS, are little vessels used in Holland for the carriage of fresh-water to places where it is wanting, as well as for the fetching sea-water to make salt of. They have a deck, and are filled with water up to the deck.

BARK-Binding, a distemper incident to trees; cured by slitting the bark, or cutting along the grain.

BARK-Galling, is when the trees are galled with thorns, &c. It is cured by binding clay on the galled places.

BARK-Longue, or *Barca Longa*, a small low sharp-built, but very long, vessel without a deck. It goes with sails and oars, and is very common in Spain.

BARKHAMSTEAD, or *BERKHAMSTEAD*, a town of Hertfordshire in England; formerly of more note than at present. It had formerly a strong castle built by the Normans, but it has been long since demolished. *W. Long. c. 35. N. Lat. 45. 49.*

BARKING, a town of Essex in England, seated on the river Roding, not far from the Thames, in a very unwholesome air. It has been chiefly noted for a large monastery, now in ruins; there being nothing left standing but a small part of the walls, and a gatehouse. *E. Long. c. 13. N. Lat. 51. 30.*

BARKING of Trees; the peeling off the rind or bark. This must be done, in our climate, in the month of May, because at that time the sap of the tree separates the bark from the wood. It would be very difficult to perform it at any other time of the year, unless the season was extremely wet and rainy; for heat and dryness are a very great hindrance to it.

By the French laws, all dealers are forbid to bark their wood while growing, on the penalty of 500 livres.

This law was the result of ignorance; it being now found, that barking of trees, and letting them die, increases the strength of timber.

BARKLEY, a town of Gloucestershire in England, seated on a branch of the river Severn. It was formerly of some note for a nunnery, and has still the title of a barony. *W. Long. 2. 30. N. Lat. 51. 40.*

BARKWAY, a town of Hertfordshire in England, on the great road from London to York. *W. Long. c. 5. N. Lat. 52.*

BARLÆUS (*Gaspard*), professor of philosophy at Amsterdam, and one of the best Latin poets of the 17th century. There was scarce any thing great that happened in the world while he lived, but he made a pompous elogy upon it, when reasons of state were no obstacle to it. He was a great defender of Arminius; and shewed his abilities in history by his relation of what passed in Brazil during the government of count Maurice of Nassau, published 1647. He died the year after.

BARLERIA, (from *Jacobus Barlier* at Paris, a famous botanist), *SNAP-DRAGON*; a genus of the angiospermia order, belonging to the didynamia class of plants.

Species. 1. The *folanifolia*, with spear-shaped indented leaves, rises with upright square stalks three feet high, garnished with two leaves at every joint; above which the flowers come out in whorls surrounding the stalks; and under each whorl there are six sharp spines, which are as long as the empalement of the flowers. The joints are about three inches distance, and the flowers are blue. *2.* The *prionites*, with spines growing by fours on the side of the branches, has been long in the gardens of the curious in Holland, but is only introduced into Britain of late. This sends out many slender stems from the root, which rise eight or nine feet high, garnished with oval pointed leaves, two growing opposite at each joint, which are attended by four long spines standing crosswise. This plant hath not yet flowered in England, though there are large plants of it in Chelsea garden. *3.* The *buxifolia*, with roundish entire leaves, is a native of Jamaica. It hath shrubby stalks rising five or six feet high, garnished with roundish entire leaves placed opposite, under which are placed strong spines: the flowers are produced in whorls towards the upper part of the stalk, and are succeeded by short seed-vessels, containing three or four flat seeds. *4.* The *Coccinea* is a native of the warm parts of America. The stalks are smooth, rise to the height of four feet, and are garnished with two oval indented leaves standing opposite; the flowers are of a scarlet colour, and placed in whorls at the joints of the stalks. They appear in July, August, and September, and are succeeded by short pods inclosing flat seeds.

Culture. All these plants, being natives of very warm countries, require to be kept in a stove, and must be treated like other tender exotics. The roots of the first species will continue three or four years; but after the second year, the plants grow too ranking, and the lower parts of the branches become naked; they should therefore be turned out every two years. This species is propagated by seeds. The second hath flexible perennial stalks, which if cut off during the summer months, and made into lengths of six or eight inches,

will soon put out roots when planted. The other two are propagated by seeds, and require no particular direction for their culture.

BARLETTA, a handsome and strong town of Italy, in the kingdom of Naples, and in the Terra di Bari, with a bishop's see. It is situated on the gulph of Venice, in E. Long. 16. 32. N. Lat. 41. 30.

BARLEY, in botany. See **HORDEUM**; and **AGRICULTURE**, n^o 118.

The principal use of barley among us is for making beer; in order to which, it is first malted. See the article **BEER**.

The Spaniards, among whom malt-liquors are little known, feed their horses with barley, as we do with oats. In Scotland, barley is a common ingredient in broths; and the consumpt of it for that purpose is very considerable, *barley-broth* being a dish as frequent there, as that of *soup* in France.

Barley has likewise its use in medicine, on account of its cooling and absterfive qualities: hence, a decoction of barley, especially if a little nitre be dissolved in it, is greatly recommended in slow fevers.

BARLEY-CORN, the least of our long measures, being the third of an inch.

BARLOW (William), bishop of Chichester, descended of an ancient family in Wales, was born in the county of Essex. In his youth he favoured the reformation; and travelled to Germany to be instructed by Luther, and other preachers of the new doctrine. How long he continued a Protestant is uncertain: but from his letter to king Henry VIII. quoted below, it appears that he wrote several books against the church of Rome. However, he was a regular canon in the Augustine monastery of St Osth in the county of Essex, and studied some time at Oxford with the brothers of that order, where he took the degree of doctor in divinity. He was then made prior of the convent at Bisham in Berkshire; and afterwards succeeded to the several priories of Blackmore, Typtree, Lega, Bromhole, and Haverford-west. On the dissolution of abbeyes, he resigned not only with a good grace, but persuaded several other abbots to follow his example. King Henry was so pleased with his ready obedience on this occasion, that he sent him, in 1535, on an embassy to Scotland; in the same year, made him bishop of St Asaph; in two months after, translated him to the see of St David's, and in 1547 to that of Bath and Wells. During this time, our good bishop, as appears from the following epistle to the king, was, or pretended to be, a staunch Papist; it was written in 1533. "Prayse be to God, who of his infynyte goodnes and mercy inestimable hath brought me out of darknes into light, and from deadly ignorance into the quick knowledge of the truth. From the whiche, through the fiend's mitigation and false persuasion, I have greatly sverved.—In so much that I have made certayn bokes, and have soffred them to be emprinted, as the tretise of the *buryall of the masse*, &c. In these tretises I perceive and acknowledge myself grievously to have erred, namely against the blessed sacrament of the altare; disallowing the masse and denying purgatory, with slanderous infamy of the pope and my lord cardinal, and outrageous raylying against the clergy; which I have forsaken and utterly renounced.—Asks par-

“don, *William Barlow*.” However, when Edward VI. came to the crown, he was again a Protestant; and for that reason, on queen Mary's accession, was deprived of his bishoprick, and sent prisoner to the fleet, where he continued some time. At length he found means to escape, and immediately joined the other English Protestants in Germany. When queen Elizabeth ascended the throne, our prelate was raised to the see of Chichester, and soon after made first prebendary of the collegiate church of Westminster. He died in 1568, and was buried in the cathedral at Chichester. He had five daughters, each of which married a bishop. He wrote, 1. *The buryall of the masse*. 2. *The climbing up of fryers and religious persons portred with figures*. 3. *Christian homilies*. 4. *A book upon Cosmography*. 5. *The godly and pious institution of a Christian man, commonly called the bishop's book*; and several other works. He is said to be the translator of the apocrypha as far as the book of Wisdom. His letters to M. Parker are in manuscript in Corpus Christi college Cambridge, Misc. i. 445.

BARLOW (William), a mathematician and divine, the son of the bishop of Chichester, was born in Pembrokeshire whilst his father was bishop of St David's. In 1560, he was entered commoner of Balliol college in Oxford; and in 1564, took a degree in arts, which having completed by determination, he left the university and went to sea; but in what capacity is uncertain: however, he acquired considerable knowledge in the art of navigation. About the year 1573, he entered into orders; and became prebendary of Winchester, and rector of Easton near that city. In 1588, he was made prebendary of Litchfield, which he exchanged for the place of treasurer of that church. Some years after, he was made chaplain to prince Henry, the son of king James I.; and in 1614, archdeacon of Salisbury. He was the first writer on the nature and properties of the magnet. Barlow died in the year 1625, and was buried in the church at Easton. His works are, 1. *The navigator's supply, containing many things of principal importance belonging to navigation, and use of diverse instruments framed chiefly for that purpose*. Lond. 1597, 4to. Dedicated to Robert earl of Essex. 2. *Magnetical advertisements, or diverse pertinent observations and approved experiments concerning the nature and properties of the loadstone*. Lond. 1616, 4to. 3. *A brief discovery of the idle animadversions of Mark Ridley, M. D. upon a treatise entitled Magnetical advertisements*. Lond. 1618, 4to.

BARLOW (Thomas), born in 1607, was appointed fellow of Queen's college in Oxford in 1633; and two years after was chosen reader of metaphysics to the university. He was keeper of the Bodleian library, and in 1657 was chosen provost of Queen's college. After the restoration of king Charles II. he was nominated one of the commissioners for restoring the members unjustly expelled in 1648. He wrote at that time *The case of Toleration in matters of Religion*, to Mr R. Boyle. In 1675, he was made bishop of Lincoln. After the popish plot, he published several tracts against the Roman-catholic religion; in which he shews an uncommon extent of learning, and skill in polemical divinity. Nevertheless, when the duke of York was proclaimed king, he took all opportunities of expressing his affection toward him; but after the revolution he as readily voted

voted that the king had abdicated his kingdom; and was very vigorous in excluding those of the clergy who refused the oaths, from their benefices.

Mr Granger observes, that "this learned prelate, whom nature designed for a scholar, and who acted in conformity with the bent of nature, was perhaps as great a master of the learned languages, and of the works of the celebrated authors who have written in those languages, as any man of his age. The greatest part of his writings, of which Mr Wood has given us a catalogue, are against Popery; and his conduct for some time, like that of other Calvinists, appeared to be in direct opposition to the church of Rome. But after James ascended the throne, he seemed to approach much nearer to Popery than he ever did before. He sent the king an address of thanks for his declaration for liberty of conscience, and is said to have written reasons for reading that declaration. His compliances were much the same after the revolution. His moderation, to call it by the softest name, was very great; indeed too great, as to bring the firmness of his character in question. But casuistry, which was his most distinguished talent, not only reconciles seeming contradictions, but has also been known to admit contradictions themselves. He was, abstracted from this laxity of principles, a very great and worthy man." He died at Buckden, in Huntingdonshire, on the 8th of October 1691, in the 85th year of his age.

BARLOW (Francis), an eminent English painter, was born in Lincolnshire. On his coming to London, he was placed with one Shepherd, a limner; but his genius led him chiefly to drawing of birds, fish, and other animals. There are six books of animals from his drawings, and he painted some ceilings with birds for noblemen and gentlemen in the country.—His etchings are numerous; his illustration of Elop is his greatest work. He died in 1702.—There is something pleasing in the composition and manner of this master, though neither is excellent. His drawing too is very indifferent; nor does he characterize any animal justly. His birds in general are better than his beasts.

BARM, the same with yeast. See YEAST.—Barm is said to have been first used by the Celts in the composition of bread. About the time of Agricola's entrance into Lancashire, a new sort of loaf had been introduced at Rome; which was formed only of water and flour, and much esteemed for its lightness; and it was called the *water cake* from its simple composition, and the *Parthian roll* from its original inventors. But even this was not comparable to the French or Spanish bread for its lightness. The use of curmi †, and the knowledge of brewing, had acquainted the Celts with an ingredient for their bread, which was much better calculated to render it light and pleasing, than the leaven, the eggs, the milk, or the wine and honey, of other nations. This was the fume which arose on the surface of their curw in fermentation, and which the Welch denominate *burn*, and we *burn*. The Celtes of Gaul, of Spain, and most probably therefore of South-Britain, had long used it; and their bread was, in consequence of this, superior in lightness to that of any other nation in the world*. See the articles BAKING and BREAD.

BARMAS, an East Indian people, who in 1515 possessed all the coast extending from Bengal to Pegu.

It appears also, that they were formerly masters of Ava, the dominions of which extended as far as China; and of consequence the Barmas were masters of most of the northern part of the peninsula beyond the Ganges. Their dominions, however, were afterwards reduced to very narrow bounds, and their king became tributary to him of Pegu; but by degrees they not only recovered their former empire, but conquered the kingdoms of Pegu, Siam, and several others. By the latest accounts, their kingdom extends from the province of Yun-nan in China, about 800 miles in length from north to south, and 250 in breadth from east to west. See the article PEGU.

St BARNABAS'S DAY, a Christian festival, celebrated on the 11th of June.—St Barnabas was born at Cyprus, and descended of the tribe of Levi, whose Jewish ancestors are thought to have retired thither to secure themselves from violence during the troublesome times in Judea. His proper name was *Josias*; to which, after his conversion to Christianity, the apostles added that of *Barnabas*, signifying either the *son of prophecy*, or the *son of consolation*; the first respecting his eminent prophetic gifts, the other his great charity in selling his estate for the comfort and relief of the poor Christians. He was educated at Jerusalem, under the great Jewish doctor Gamaliel; which might probably lay the foundation of that intimate friendship which was afterwards contracted between this apostle and St Paul. The time of his conversion is uncertain; but he is generally esteemed one of the seventy disciples chosen by our Saviour himself*.

At Antioch, St Paul and St Barnabas had a contest, which ended in their separation: but what followed it, with respect to St Barnabas, is not related in the *Acts of the Apostles*. Some say, he went into Italy, and founded a church at Milan. At Salamis, we are told, he suffered martyrdom; whither some Jews, being come out of Syria, set upon him, as he was disputing in the synagogue, and stoned him to death. He was buried, by his kinsman Mark, whom he had taken with him, in a cave near that city. The remains of his body are said to have been discovered in the reign of the emperor Zeno, together with a copy of St Matthew's gospel, written with his own hand, and lying on his breast.

St BARNABAS'S *Epistle*, an apocryphal work ascribed to St Barnabas, and frequently cited by St Clement of Alexandria and Origen.—It was first published in Greek, from a copy of father Hugh Menard a Benedictine monk. An ancient version of it was found in a manuscript of the abbey of Coebey, near a thousand years old. Vossius published it, in the year 1656, together with the epistles of St Ignatius.

St BARNABAS'S *Gospel*, another apocryphal work, ascribed to St Barnabas the apostle, wherein the history of Jesus Christ is related in a manner very different from the account given us by the four Evangelists. The Mahometans have this gospel in Arabic, and it corresponds very well with those traditions which Mahomet followed in his Koran. It was, probably, a forgery of some nominal Christians; and afterwards altered and interpolated by the Mahometans, the better to serve their purpose.

BARNABITES, a religious order, founded in the 16th century by three Italian gentlemen, who had been advised

Barnabas,
Barnabites.

* See further
Acts
ix. xi. xiii.
xiv. xv.

See Act.

Pliny, lib.
iii. c. 7.

advised by a famous preacher of those days to read carefully the epistles of St Paul. Hence they were called *clerks of St Paul*; and *Barnabites*, because they performed their first exercise in a church of St Barnabas at Milan. Their habit is black; and their office is to instruct, catechise, and serve in mission.

* See Anas.

BARNACLE, in ornithology, a species of goose *. **BANACLES**, in fariery, an instrument composed of two branches joined at one end with a hinge, to put upon horses noses when they will not stand quietly to be shod, blooded, or dressed.

BARNARD, or **BERNARD**, (John), the son of John Barnard, gent. was born at Castor, in Lincolnshire, and educated at Cambridge. After several preferments, he was made a prebendary of the church of Lincoln. He wrote *Censura Clerici*, against scandalous ministers not fit to be restored to church livings; the *Life of Dr Heylyn*; and a few other works. He died at Newark, August 17. 1683.

BARNARD-CASTLE, a town of the county of Durham, in England, seated on the river Tees. It is indifferently large, and has a manufacture of stockings. W. Long. 1. 45. N. Lat. 54. 35.

BARNES (Joshua), professor of the Greek language at Cambridge, in the beginning of the 18th century. He was chosen queen's professor of Greek in 1695, a language he wrote and spoke with the utmost facility. His first publication was a whimsical tract, intitled *Gerania*, or a new Discovery of the little sort of people called *Pignies*. After that appeared his *Life of Edward III.* in which he introduces his hero making long and elaborate speeches.—In the year 1700, when he published many of his works, Mrs Mason, of Hemmingford, in Huntingdonshire, a widow lady of between 40 and 50, with a jointure of L. 200 *per annum*, who had been for some time a great admirer of him, came to Cambridge, and desired leave to settle L. 100 a-year upon him after her death; which he politely refused, unless she would likewise condescend to make him happy with her person, which was not very engaging. The lady was too obliging to refuse any thing to Joshua, for whom, she said, “the sun stood still;” and they were accordingly married. Mr Barnes wrote several other books besides those abovementioned, particularly, *Sacred poems*; *The Life of Oliver Cromwell, the Tyrant*; *several dramatic pieces*; *A poetical Paraphrase on the History of Esther, in Greek verse*, with a Latin translation, &c.; and he published editions of *Euripides*, *Aræon*, and *Homer's Iliad and Odyssey*, with notes and a Latin translation. He wrote with greater ease in Greek than even in English, and yet is generally allowed not to have understood the delicacies of that language. He was of such a humane disposition, and so unacquainted with the world, that he gave his only coat to a vagrant begging at his door. This excellent man died on the 3^d of August 1712, in the 58th year of his age.

BARNEVELDT (John d' Olden), the celebrated Dutch statesman, and one of the founders of the civil liberty of Holland. His patriotic zeal inducing him to limit the authority of Maurice prince of Orange the second stadtholder of Holland, the partisans of that prince falsely accused him of a design to deliver his country into the hands of the Spanish monarch. On this absurd charge he was tried by 26 commissaries

deputed from the seven provinces, condemned, and beheaded in 1619. His sons William and René, with a view of revenging their father's death, formed a conspiracy against the stadtholder, which was discovered. William fled: but René was taken and condemned to die; which fatal circumstance has immortalized the memory of his mother, of whom the following anecdote is recorded. She solicited a pardon for René; upon which Maurice expressed his surprize that she should do that for her son, which she had refused for her husband. To this remark, she replied with indignation, “I would not ask a pardon for my husband, because he was innocent. I solicit it for my son, because he is guilty.”

BARNET, a town partly in Middlesex, and partly in Hertfordshire. It is a great thorough-fare, and the market is very remarkable for hogs. W. Long. o. 5. N. Lat. 51. 42.

BARNSELEY, or **BLACK BARNSELEY**, a town of the west riding of Yorkshire, seated on the side of a hill, and five furlongs in length. W. Long. 1. 20. N. Lat. 53. 35.

BARNSTABLE, a sea-port town of Devonshire, seated on the river Tau, over which there is a good bridge. It is a corporation town, and sends two members to Parliament. W. Long. 4. 5. N. Lat. 51. 15.

BARO, or **BARON**, (Peter), professor of divinity in the university of Cambridge, in the 16th century, was born at Estampes in France, and educated in the university of Bourges, where he was admitted a licentiate in the law: but being of the Protestant religion, he was obliged to leave his native country to avoid persecution; and, withdrawing into England, was kindly entertained by lord Burleigh. He afterwards settled at Cambridge; and, by the recommendation of his noble patron, was, in 1574, chosen lady Margaret's professor there. For some years he quietly enjoyed his professorship: but there was at last raised a restless faction against him, by his opposing the doctrine of absolute predestination; which rendered his place so uneasy to him, that he chose to leave the university, and to settle in London. He wrote, 1. *In Jonam Prophetam Prælectiones* xxxix. 2. *De Præstantia & Dignitate Divinæ Legis*; and other pieces. He died in London, about the year 1600.

BAROCCI (Frederic), a celebrated painter, was born at Urbino, where the genius of Raphael inspired him. In his early youth he travelled to Rome; where he painted several things in fresco. He then returned to Urbino; and giving himself up to intense study, acquired a great name in painting. His genius particularly led him to religious subjects. At his leisure hours, he etched a few prints from his own designs; which are highly finished, and executed with great softness and delicacy. The *salutation* is his capital performance; of which we seldom meet with any impressions, but those taken from the retouched plate, which are very harsh. He died at Urbino in 1612, aged 84.

BAROCHE, a town of Cambaya, in the dominions of the Great Mogul; it is walled round, and was formerly a place of great trade. It is now inhabited by weavers, and such mechanics as manufacture cotton cloth. Here they have the best cotton in the world, and of consequence the best bastas are manufactured in this place. The English and Dutch had formerly factories

factories

ories here, which are now abandoned. E. Long. 72. 5. N. Lat. 22. 15.

BAROCO, in logic, a term given to the fourth mode of the second figure of syllogisms. A syllogism in baroco has the first proposition universal and affirmative, but the second and third particular and negative, and the middle term is the predicate in the two first propositions. For example,

Nullus homo non est bipes:

Non omne animal est bipes:

Non omne animal est homo.

BAROMETER, (from βαρῶν *weight*, and μέτρον *measure*), an instrument for measuring the weight of the atmosphere, and of use in foretelling the changes of the weather, and also for measuring the height of mountains, &c.

The common barometer consists of a glass tube hermetically sealed at one end, and filled with quicksilver well defecated and purged of its air. The finger being then placed on the open end, in immediate contact with the mercury, so as not to admit the least particle of air, the tube is inverted, and the lower end plunged into a basin of the same prepared mercury; then, upon removing the finger, the mercury in the tube will join that in the basin, and the mercurial column in the tube will subside to the height of 29 or 30 inches, according to the state of the atmosphere at that time. This is the principle on which all barometers are constructed. Of their invention, the different kinds of them, and the theories by which their phenomena are solved, we shall proceed to give an historical account.

In the beginning of the last century, when the doctrine of a plenum was in vogue, philosophers were of opinion, that the ascent of water in pumps was owing to the abhorrence of a vacuum; and that, by means of suction, fluids might be raised to any height whatever. But Galileo, who flourished about that time, discovered that water would not ascend in a pump unless the sucker reached within 33 feet of its surface in the well. From hence he concluded, that not the power of suction, but the pressure of the atmosphere was the cause of the ascent of water in pumps; that a column of water 33 feet high was a counterpoise to one of air of an equal base, whose height extended to the top of the atmosphere; and that for this reason the water would not follow the sucker any farther. From this Torricelli, Galileo's disciple, took the hint; and considered, that if a column of water of about 33 feet in height was equal in weight to one of air having the same base, a column of mercury no longer than about 29½ inches would be so too, because, mercury being about 14 times heavier than water, a column of mercury must be 14 times shorter than one of water equally heavy. Accordingly, having filled a glass tube with mercury, and inverted it into a basin of the same, he found the mercury in the tube to descend till it stood about 29½ inches above the surface of that in the basin.

Notwithstanding this clear proof of the pressure of the atmosphere, however, the assertors of a plenum left no means untried to solve the phenomena of the Torricellian experiment by some other hypothesis. The most ridiculous solution, and which at the same time gave the adverse party the greatest difficulty to overthrow it, was that of Linus. He contended, that, in the upper part of the tube, there is a film, or *rope of mercury*, ex-

tended through the seeming vacancy; and that, by this rope, the rest of the mercury was suspended, and kept from falling into the basin. Even this so absurd hypothesis he pretended to confirm by the following experiments. Take, says he, a small tube, open at both ends, suppose about 20 inches long; fill this tube with mercury, stopping the lower orifice with your thumb: Then closing the upper end with your finger, and immersing the lower in stagnant mercury, you shall perceive, upon the removal of your thumb, a manifest suction of your finger into the tube; and the tube and mercury will both stick so close to it, that you may carry them about the room. Therefore, says he, the internal cylinder of mercury in the tube is not held up by the preponderant air without; for if so, whence comes so strong a suction, and so firm an adhesion of the tube to the finger?—The same effect follows, though the tube be not quite filled with mercury; for if a little space of air is left at the top, after the tube is immersed in the stagnant mercury, there will be a considerable suction as before.

These experiments, which are themselves clear proofs of the pressure of the air, supported for some time the *funicular* hypothesis, as it was called, of Linus. But when it was discovered, that if the tube was carried to the top of an high mountain the mercury stood lower than on the plain, and that if removed into the vacuum of an air-pump it fell out altogether, the hypothesis of Linus was rejected by every body.—There are, however, two experiments which create a considerable difficulty. One is mentioned by Mr Huygens, viz. that if a glass tube 75 inches long, or perhaps longer, is filled with mercury well purged of its air, and then inverted, the whole will remain suspended; whereas, according to the Torricellian experiment, it ought to subside immediately to the height of 29 or 30 inches. It is true indeed, that, upon shaking the tube, the mercury presently subsides to that height; but why it should remain suspended at all, more than twice the height to which it can be raised by the pressure of the most dense atmosphere, seems not easily accounted for; and accordingly, in the Philosophical Transactions, we find attempts to account for it by the pressure of a medium more subtle than the common air, and capable of pervading both the mercury and glass. We find there also another very surprising fact of the same kind mentioned; viz. that a pretty large tube under 29 inches in length, filled with mercury, and inverted into a basin of the same, will remain full, though there be a small hole in the top. This, too, is there accounted for by the pressure of a medium more subtle than common air; but by no means in a satisfactory manner. Mr Rowning, who mentions the phenomenon of the 75 inch tube, accounts for it in the following manner. “The cause of this phenomenon seems to be, that by the great weight of so long a column of mercury, it was pressed into so close contact with the glass in pouring in, that, by the mutual attraction of cohesion between the mercury and the glass, the whole column was sustained after the tube was inverted.”—Here, however, we must observe, that this solution seems equally unsatisfactory with that of the subtle medium already mentioned; because it is only one end of the column which sustains so great a pressure from the weight of the mercury; and therefore, though five or six inches of the upper part of

Barometer.

The tube, where the pressure had been strongest, might thus remain full of mercury, yet the rest ought to fall down. Besides, it is only the outside of the mercurial column that is in contact with the glass, and consequently these parts only ought to be attracted. Therefore, even granting the pressure to be equally violent, on the inversion of the tube, all the way from 29 to 75 inches, yet the glass ought to be only as it were silvered over by a very thin film of mercury, while the middle parts of the column ought to fall out by reason of their fluidity.

10
Another
experiment
with si-
phons.

The other experiment hinted at, is with regard to siphons: which though it belongs more properly to the article HYDROSTATICS, yet seems necessary to be mentioned here. It is this: That a siphon, once set a running, will continue to do so though set under the receiver of an air-pump and the air exhausted in the most perfect manner; or if a siphon is filled, and then set under a receiver and the air exhausted, if by any contrivance the end of the lower leg is opened, it will immediately begin to run, and discharge the water of any vessel in which the other leg is placed, as though it was in the open air. The cause of this phenomenon, as well as the former, seems very difficult to be investigated. In Chambers's Dictionary, under the word *Siphon*, we have a solution something similar to the funicular hypothesis of Linus abovementioned; namely, that "fluids in siphons seem as it were to form one continued body; so that the heavier part, descending, like a chain pulls the lighter after it." This might be deemed a sufficient explication, if the siphon was only to empty the water it at first contains in itself: but when we consider that the water in the vessel, which much exceeds the quantity contained in the siphon, is likewise evacuated, Mr Chambers's hypothesis can by no means be admitted; because this would be like the lighter part of a chain pulling the heavier after it.

11
Solution by
Mr Cham-
bers.

12
Insufficient.

Concerning the cause of these singular phenomena, we can only offer the following conjecture. The existence of a medium much more subtle than air, and which pervades the vacuum of an air-pump with the utmost facility, is now sufficiently ascertained in the phenomena of electricity. It is also well known, that this fluid surrounds the whole earth to an indeterminate height. If therefore this fluid either is the power of gravity itself, or is acted upon by that power, it must necessarily press upon all terrestrial bodies in a manner similar to the pressure of the atmosphere. If then we could from any vessel entirely exclude this subtle fluid, and form an electrical vacuum, as well as we can do an aerial one by means of the air-pump, we would in that case see fluids as evidently raised by the pressure of the electric matter, as we now see them raised by that of the air. But tho' this cannot be done, we are assured that there are certain substances, of which glass is one, through which the electric matter cannot pass but with difficulty. We are likewise certain, that tho' the electric matter passes through the pores of water, metals, &c. with very great facility, yet it still must meet with some resistance from their solid and impenetrable parts, which cannot be pervaded by any material substance. We know also, that all substances do naturally contain a certain quantity of this electric matter, which they are not always ready to part with; and when by any means the fluid they contain is set in mo-

13
Another
solution
from the
action of
electricity.

tion, they are then said to be *electricified*. Now, though we are certain, that the friction of glass by mercury does set in motion the electric fluid contained in the mercury, or in the glass; yet, when the tube is filled with the metallic fluid, whatever quantity has been extricated, either from the glass or mercury, during the time of filling, will be reabsorbed by the metal, and conveyed to the earth, during the time of inversion; and consequently the mercurial tube, when inverted, will not be electricified, but both glass and mercury will be in their natural state. Here, then, the pressure of the electrical fluid is kept off in some measure from the upper part of the mercury by the glass, which it cannot penetrate, easily at least. To the mercury in the basin it has free access, and therefore presses more upon the lower than the upper part; the consequence of which is a suspension of the mercury. It is true, this fluid very easily penetrates the metallic matter; but it must be considered, that the electric fluid itself is in some measure entangled in the particles of the quicksilver, and cannot be extricated without motion. As soon therefore as the tube is shaken, some part of the electricity is extricated, and the mercury begins to descend. The subtilty of the medium is such, that no sooner has it begun to extricate itself, than, by the motion of the metal downwards, it issues forth in great quantities, so as to become visible, like a blue flame, in the dark. The equilibrium is therefore destroyed in an instant, as it would be were we to admit air to the top of the barometer; nay, in a more effectual manner. For if a small quantity of air was admitted to the top of a barometer, the mercury would only descend in proportion to the quantity of air admitted; but here, no sooner is a quantity of electric matter admitted, than it procures admission for a vast deal more, and consequently the mercury descends with accelerated velocity.—On this principle the ascent of water in the siphon while *in vacuo* is so easily accounted for, that we need not take up time in explaining it farther.—But why an inverted glass tube should remain full of mercury when it has a hole either great or small in the top, is more difficult to be accounted for, and requires this farther circumstance to be taken into consideration, viz. that though all solid bodies will, by the action of gravity, or by any other impulse, easily approach very near to one another, yet they cannot be brought into absolute contact without a very considerable force, much greater than is sufficient to overcome their gravity; and thus it appears from some experiments, that the links of a chain are by no means in contact with one another, till the chain has a considerable weight appended to it. This may be the case with the tube in question. The air by its gravity descends upon it, and is ready to enter the small hole in the top; but, by a repulsive power from the glass, its action is prevented, so that the mercury cannot fall.

It was, however, some time after the Torricellian experiment had been made, and even after it had been universally agreed that the suspension of the mercury was owing to the weight of the atmosphere, before it was discovered that this pressure of the air was different at different times though the tube was kept in the same place. But the variations of altitude in the mercurial column were too obvious to remain long unobserved; and accordingly philosophers soon became careful

14

er used for
prognostic-
ating the
weather.

fid

ful enough to mark them. When this was done, it was impossible to avoid observing also, that the changes in the height of the mercury were accompanied, or very quickly succeeded, by changes in the weather. Hence the instrument obtained the name of the *weather-glass*; and was generally made use of with a view to the foreknowledge of the weather. In this character, its principal phenomena are as follow.

1. The rising of the mercury presages, in general, fair weather; and its falling, foul weather, as rain, snow, high winds, and storms.

2. In very hot weather, the falling of the mercury foretells thunder.

3. In winter, the rising presages frost; and in frosty weather, if the mercury falls three or four divisions, there will *certainly* follow a thaw. But in a continued frost, if the mercury rises, it will *certainly* snow.

4. When foul weather happens soon after the falling of the mercury, expect but little of it; and, on the contrary, expect but little fair weather when it proves fair shortly after the mercury has risen.

5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes; then expect a great deal of wet, and probably high winds.

7. The unsettled motion of the mercury denotes uncertain and changeable weather.

8. You are not so strictly to observe the words engraved on the plates, (though in general it will agree with them) as the mercury's *rising* and *falling*. For if it stands at *much rain*, and then rises up to *changeable*, it presages fair weather; though not to continue so long as if the mercury had risen higher: and so, on the contrary, if the mercury stood at *fair*, and falls to *changeable*, it presages foul weather; though not so much of it as if it had sunk lower.

These are the observations of Mr Patrick, on which Mr Rowning makes the following remarks. "From these observations it appears, That it is not so much the height of the mercury in the tube, that indicates the weather, as the motion of it up and down: wherefore, in order to pass a right judgment of what weather is to be expected, we ought to know whether the mercury is actually rising or falling; to which end the following rules are of use.

1. "If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is generally a sign that the mercury is then rising.

2. "If the surface is concave, it is then sinking; and,

3. "If it is plain, the mercury is stationary, or rather if it is a little convex; for mercury being put into a glass tube, especially a small one, will naturally have its surface a little convex, because the particles of mercury attract one another more forcibly than they are attracted by glass. Further,

4. "If the glass is small, shake the tube; and if the air is grown heavier, the mercury will rise about half the tenth of an inch higher than it stood before; if it is grown lighter, it will sink as much. This proceeds from the mercury's sticking to the sides of the

tube, which prevents the free motion of it till it is disengaged by the shock: and therefore, when an observation is to be made with such a tube, it ought always to be shaken first; for sometimes the mercury will not vary of its own accord, till the weather it ought to have indicated is present."

Here we must observe, that the abovementioned phenomena are peculiar to places lying at a considerable distance from the equator; for, in the torrid zone, the mercury in the barometer seldom either rises or falls much. In Jamaica, it is observed by Sir William Beeston*, that the mercury in the morning constantly stood at one degree below *changeable*, and at noon sunk to one degree above *rain*; so that the whole scale of variation there was only $\frac{1}{10}$ of an inch. At St Helena, too, where Dr Halley made his observations, he found the mercury to remain mostly stationary whatever weather happened. Of these phenomena, their causes, and why the barometer indicates an approaching change of weather, the Doctor gives us the following account.

"1. In calm weather, when the air is inclined to rain, the mercury is commonly low.

"2. In serene, good, and settled weather, the mercury is generally high.

"3. Upon very great winds, though they be not accompanied with rain, the mercury sinks lowest of all, with relation to the point of the compass the wind blows upon.

"4. *Ceteris paribus*, the greatest heights of the mercury are found upon easterly, or north-easterly winds.

"5. In calm frosty weather, the mercury generally stands high.

"6. After very great storms of wind, when the mercury has been very low, it generally rises again very fast.

"7. The more northerly places have greater alterations of the barometer than the more southerly.

"8. Within the tropics, and near them, those accounts we have had from others, and my own observations at St Helena, make very little or no variation of the height of the mercury in all weathers.

"Hence I conceive that the principal cause of the rise and fall of the mercury is from the variable winds which are found in the temperate zone, and whose great inconsistency, here in England, is notorious.

"A second cause is, the uncertain exhalation and precipitation of the vapours lodging in the air, whereby it comes to be at one time much more crowded than at another, and consequently heavier; but this latter depends in a great measure upon the former. Now from these principles I shall endeavour to explicate the several phenomena of the barometer, taking them in the same order I have laid them down. Thus,

"1. The mercury's being low inclines it to rain, because the air being light, the vapours are no longer supported thereby, being become specifically heavier than the medium wherein they floated; so that they descend towards the earth, and, in their fall, meeting with other aqueous particles, they incorporate together, and form little drops of rain: but the mercury's being at one time lower than another, is the effect of two contrary winds blowing from the place where the barometer stands; whereby the air of that place is carried both ways from it, and consequently the incumbent

Barometer. cylinder of air is diminished, and accordingly the mercury sinks: As, for instance, if in the German ocean it should blow a gale of westerly wind, and, at the same time, an easterly wind in the Irish Sea; or, if in France it should blow a northerly wind, and in Scotland a southerly; it must be granted, that that part of the atmosphere impendant over England would thereby be exhausted and attenuated, and the mercury would subside, and the vapours which before floated in these parts of the air of equal gravity with themselves would sink to the earth.

“ 2. The greater height of the barometer is occasioned by two contrary winds blowing towards the place of observation, whereby the air of other places is brought thither and accumulated; so that the incumbent cylinder of air being increased both in height and weight, the mercury pressed thereby must needs stand high, as long as the winds continue so to blow; and then the air being specifically heavier, the vapours are better kept suspended, so that they have no inclination to precipitate and fall down in drops, which is the reason of the serene good weather which attends the greater heights of the mercury.

“ 3. The mercury sinks the lowest of all by the very rapid motion of the air in storms of winds. For the tract or region of the earth's surface, wherein the winds rage, not extending all round the globe, that stagnant air which is left behind, as likewise that on the sides, cannot come in so fast as to supply the evacuation made by so swift a current, so that the air must necessarily be attenuated, when and where the said winds continue to blow, and that more or less according to their violence: add to which, that the horizontal motion of the air being so quick as it is, may in all probability take off some part of the perpendicular pressure thereof; and the great agitation of its particles is the reason why the vapours are dissipated, and do not condense into drops so as to form rain, otherwise the natural consequence of the air's rarefaction.

“ 4. The mercury stands highest upon the easterly and north-easterly wind; because in the great Atlantic ocean, on this side the 35th degree of north latitude, the winds are almost always westerly or south-westerly; so that whenever here the wind comes up at east and north-east, it is sure to be checked by a contrary gale as soon as it reaches the ocean; wherefore, according to our second remark, the air must needs be heaped over this island, and consequently the mercury must stand high, as often as these winds blow. This holds true in this country; but is not a general rule for others, where the winds are under different circumstances: and I have sometimes seen the mercury here as low as 29 inches upon an easterly wind; but then it blew exceedingly hard, and so comes to be accounted for by what was observed in the third remark.

“ 5. In calm frosty weather the mercury generally stands high; because (as I conceive) it seldom freezes but when the winds come out of the northern and north-eastern quarters: or at least, unless those winds blow at no great distance off. For the north parts of Germany, Denmark, Sweden, Norway, and all that tract from whence north-eastern winds come, are subject to almost continual frost all the winter: and thereby the lower air is very much condensed, and in that state is brought hitherward by those winds, and, being accumu-

lated by the opposition of the westerly wind blowing in the ocean, the mercury must needs be pressed to a more than ordinary height; and as a concurring cause, the shrinking of the lower parts of the air into lesser room by cold, must needs cause a descent of the upper parts of the atmosphere, to reduce the cavity made by this contraction to an equilibrium.

“ 6. After great storms, when the mercury has been very low, it generally rises again very fast: I once observed it to rise one inch and an half in less than six hours after a long continued storm of south-west wind. The reason is, because the air being very much rarefied by the great evacuations which such continued storms make thereof, the neighbouring air runs in the more swiftly to bring it to an equilibrium; as we see water runs the faster for having a greater declivity.

“ 7. The variations are greater in the more northerly places, as at Stockholm greater than at Paris (compared by M Pafchal); because the more northerly parts have usually greater storms of wind than the more southerly, whereby the mercury should sink lower in that extreme; and then the northerly winds bringing in the more dense and ponderous air from the neighbourhood of the pole, and that again being checked by a southerly wind at no great distance, and so heaped, must of necessity make the mercury in such case stand higher in the other extreme.

“ 8. Lastly, this remark, that there is little or no variation near the equinoctial, does above all others confirm the hypothesis of the variable winds being the cause of these variations of the height of the mercury; for in the places above named, there is always an easy gale of wind blowing nearly upon the same point, viz. E. N. E. at Barbadoes, and E. S. E. at St Helena, so that there being no contrary currents of air to exhaust or accumulate it, the atmosphere continues much in the same state: however, upon hurricanes, the most violent of storms, the mercury has been observed very low; but this is but once in two or three years, and it soon recovers its settled state, about 29 $\frac{1}{2}$ inches.”

This theory we find controverted by Mr Chambers, in his Dictionary, under the word **BAROMETER**. The principal objections are, That if the wind was the sole agent in raising or depressing the mercury, the alterations of its height in the barometer would be only relative or topical; there would still be the same quantity supported at several places taken collectively: thus what a tube at London lost, another at Paris, Pisa, or Zurich, &c. would gain. But the contrary is found to be the case; for, from all the observations hitherto made, the barometers in several distant parts of the globe rise and fall together. This is a very surprising fact; and deserves to be well examined. Again, setting aside all other objections, it is impossible, on Dr Hally's hypothesis, to explain the mercury's fall before, and rise after, rain. For suppose two contrary winds sweeping the air from over London; we know that few if any of the winds reach above a mile high; all therefore they can do will be to cut off a certain part of the column of air over London: if the consequence of this be the fall of the mercury, yet there is no apparent reason for the rains following it. The vapours indeed may be let lower; but it will only be till they come into an air of the same specific gravity with themselves, and there they will stick as before. Lastly, it

is impossible, according to the laws of fluids, that the air above any place could be exhausted by the blowing of two contrary winds from it: for, suppose a north-east and south-west wind both blow from London at the same time, there will be two others at the same time blowing towards it from opposite points, viz. a N. W. and S. E. one, which will every moment restore the equilibrium, so that it can never be lost in any considerable degree at least.

Mr Leibnitz accounted for the sinking of the mercury before rain upon another principle, viz. That as a body specifically lighter than a fluid, while it is suspended by it, adds more weight to that fluid, than when, by being reduced in its bulk, it becomes specifically heavier, and descends; so the vapour, after it is reduced into the form of clouds, and descends, adds less weight to the air than before; and therefore the mercury falls. To which it is answered, 1. That when a body descends in a fluid, its motion in a very little time becomes uniform, or nearly so, a farther acceleration of it being prevented by the resistance of the fluid; and then, by the third law of nature, it forces the fluid downwards with a force equal to that whereby it tends to be farther accelerated, that is, with a force equal to its whole weight. 2. The mercury by its descent foretells rain a much longer time before it comes, than the vapour after it is condensed into clouds can be supposed to take up in falling. 3. Supposing that as many vapours as fall in rain during a whole year were at once to be condensed into clouds, and even quite cease to gravitate upon the air, its gravity would scarce be diminished thereby so much as is equivalent to the descent of two inches of mercury in the barometer. Besides, in many places between the tropics, the rains fall at certain seasons in very great quantities, and yet the barometer shews there very little or no alteration in the weight of the atmosphere.

Mr Chambers gives an hypothesis somewhat similar to that of Leibnitz: but as it is liable to the objections just now mentioned, especially the last, we forbear to give any particular account of it; and shall attempt, upon other principles, to give a satisfactory solution of this phenomenon.

The necessary preliminaries to our hypothesis are, 1. That vapour is formed by an intimate union between the element of fire and that of water, by which the fire or heat is so totally enveloped, and its action so entirely suspended by the watery particles, that it not only loses its properties of giving light and burning, but becomes incapable of affecting the most sensible thermometer; in which case, it is said by Dr Black, the author of this theory, to be in a latent state. For the proofs of this, see the articles EVAPORATION, COLD, CONGELATION, &c. 2. If the atmosphere is affected by any unusual degree of heat, it thence becomes incapable of supporting so long a column of mercury as before, for which reason that in the barometer sinks. This appears from the observations of Sir William Beclton already mentioned; and likewise from those of De Luc, which shall be afterwards taken notice of.

These axioms being established, it thence follows, that as vapour is formed by an union of fire with water, or if we please to call it an *elastic* attraction between them, or solution of the water in the fire, it is impos-

sible that the vapour can be condensed until this union, attraction, or solution, be at an end. The beginning of the condensation of the vapour then, or the first symptoms of an approaching rain, must be the separation of the fire which lies hid in the vapour. This may be at first slow and partial, or it may be sudden and violent: in the first case, the rain will come on slowly, and after a considerable interval; and in the other, it will be very quick, and in great quantity. But Dr Black hath proved, that when fire quits its latent state, however long it may have lain dormant and insensible, it always assumes its proper qualities again, and affects the thermometer as though it had never been absorbed. The consequence of this must be, that in proportion as the latent heat is discharged from the vapour, it must sensibly affect those parts of the atmosphere into which it is discharged; and in proportion to the heat communicated to these, they will become specifically lighter, and the mercury sink of course. Neither are we to imagine that the quantity of heat discharged by the vapour is inconsiderable; for Dr Black hath shewn, that when any quantity of water, a pound for instance, is condensed from the vapour of a common still, as much heat is communicated to the head and refrigeratory as would have been sufficient to heat the pound of water red hot, could it have born that degree of sensible heat.

The causes by which this separation between the fire and water is, or may be, effected, come to be considered under the articles RAIN, CONDENSATION, VAPOUR, &c. Here we have only to observe, that as the separation may be gradual and slow, the barometer may indicate rain for a considerable time before it happens: or if the sensible heat communicated from the vapour to the atmosphere shall be absorbed by the colder parts, or by any unknown means carried off, or prevented from affecting the specific gravity of the air, the barometer will not be affected; and yet the water being deprived of the heat necessary to sustain it, must descend in rain; and thus it is found that the indications of the barometer do not always hold true. Hence also it appears, that tho' the specific gravity of the air is diminished, unless that diminution proceeds from a discharge of the latent heat contained in the vapours, no rain will follow; and thus the sinking of the barometer may prognosticate wind as well as rain, or sometimes nothing at all.

The difficulty, however, on this hypothesis, is to account for the barometer being stationary in all weathers between the tropics; whereas it ought to move up and down there as well as here, only more suddenly, as the changes of weather there are more sudden than here. But it must be considered, that in these climates, during the day-time, the action of the sun's rays is so violent, that what is gained by the discharge of latent heat from the vapour, is lost by the interposition of the clouds betwixt the sun and earth; and in the night, the cold of the atmosphere is so much increased, that it absorbs the heat as fast as the vapour discharges it, so that no sensible effect can be produced; for in warm climates, tho' the day is excessively hot, the night is observed to be vastly colder in proportion than it is with us. This, however, does not prevent the barometer from being affected by other causes, as well as with us; for Dr Halley observes, that in the time of

Barometer. hurricanes it sinks very low.

24
Different
kinds of
barometers
described.

Plate LVI.

Having thus given an account of the several phenomena of the barometer considered as a weather-glass, and likewise endeavoured to account for them in the most satisfactory manner, we now proceed to give a particular description of the barometers most commonly made use of, with various schemes for their improvement.

Fig. V. N^o 1. represents the common barometer, such as was invented by Torricelli, and such as we have already given a general description of. AB represents a tube of glass, a quarter of an inch in diameter, and 34 inches long, hermetically sealed at A. This tube being supposed to be filled with mercury, is then inverted into the basin CD; upon which the mercury in the tube falls down to GH, somewhat above 28 inches, while that in the basin rises to CF. The lowest station of the mercury in this country is found to be 28 inches, and the highest 31. From the surface of the mercury CF, therefore, 28 inches are to be measured on the tube AB, which suppose to reach to the point K. This point, therefore, is the lowest of the scale of variation, and in the common barometers is marked *Stormy*. In like manner, the highest point of the scale of variation I, is placed 31 inches above EF; and is marked *very dry* on one side for the summer, and *very hard frost* on the other for the winter. The next half inch below is marked *set fair* on the one side, and *set frost* on the other. At 30 inches from CF is marked the word *fair* on one side, and *frost* on the other. Half an inch below that, is wrote the word *changeable*, which answers both for summer and winter. At 29 inches is *rain* on the one side, and *snow* on the other; and at 28½, are the words *much rain* on the one side, and *much snow* on the other. Each of these large divisions is usually subdivided into ten; and there is a small sliding index fitted to the instrument, by which the ascent or descent of the mercury to any number of divisions is pointed out.

This kind of barometer is the most common, and perhaps the most useful of any that hath yet been invented; but as the scale of variation here is only three inches, and it is naturally wished to discover more minute variations than can thus be perceived, several improvements have been thought of.

The improvement most generally adopted is the diagonal barometer represented N^o 2. in which the scale of variation, instead of three inches, may be made as many feet, by bending the tube so as to make the upper part of it the diagonal of a parallelogram of which the shortest side is the three-inches scale of variation of the common barometer. This, however, has a very great inconvenience: for not only is the friction of the mercury upon the glass so much increased that the height doth not vary with every slight change of air; but the column of mercury is apt to break in the tube, and part of it to be left behind, upon any considerable descent.

N^o 3. is the rectangular barometer; where AC represents a pretty wide cylinder of glass, from which proceeds the tube CDF bent into a right angle at D. Suppose now the cylinder AC to be four times larger than the tube CD, so that every inch of the cylinder from C to A should be equal in capacity to four inches of the tube CD. The whole being then filled with mercury, and inverted, the mercury will subside from

A to B, at the same time that it cannot run out at the open orifice F, because the air presses in that way. If any alteration then happens in the weight of the air, suppose such as would be sufficient to raise the mercury an inch from B towards A, it is evident that this could not be done without the mercury in the horizontal leg retiring four inches from E towards D; and thus the scale of variation counted on the horizontal leg would be 12 inches. But the inconveniences of friction are much greater here than in the diagonal barometer; and besides, by the least accident the mercury is apt to be driven out at the open orifice F.

The pendant barometer (N^o 4.) consists of a single tube, suspended by a string fastened to the end A. This tube is of a conical or tapering figure, the end A being somewhat less than the end B. It is hermetically sealed at A, and filled with mercury: then will the mercury sink to its common station, and admit of a length of altitude CD, equal to that in the common barometers. But from the conical bore of the tube the mercury will descend as the air grows lighter, till it reaches its lowest altitude, when the mercury will stand from the lower part of the tube B to E, so that BE will be equal to 28 inches: consequently the mercury will, in such a tube, move from A to E, or 32 inches, if the tube be five feet, or 60 inches; and therefore the scale AE is here above ten times greater than in the common barometer: but the fault of this barometer is, that the tube being of a very small bore, the friction will be considerable, and prevent its moving freely; and if the tube is made of a wider bore, the mercury will be apt to fall on.

N^o 5. is an invention of Mr Rowning, by which the scale of variation may be increased to any length, or even become infinite. ABC is a compound tube hermetically sealed at A, and open at C, empty from A to D, filled with mercury from thence to B, and from thence to E with water. Let GBH be a horizontal line; then it is plain from the nature of the syphon, that all the compound fluid contained in the part from H to G, will be always *in equilibrio* with itself, be the weight of the air what it will, because the pressure at H and G must be equal. Whence it is evident, that the column of mercury DH is *in equilibrio* with the column of water GE, and a column of air taken conjointly, and will therefore vary with the sum of the variations of these. That the variation in this barometer may be infinite, will appear from the following computation. Let the proportion between the bores of the tube AF and FC be such, that when HD, the difference of the legs wherein the mercury is contained, is augmented one inch, GE, the difference of the legs wherein the water is contained, shall be diminished 14: then, as much as the pressure of the mercury is augmented, that of the water will be diminished, and so the pressure of both taken together will remain as it was; and consequently, after it has begun to rise, it will have the same tendency to rise on, without ever coming to an equilibrium with the air.

N^o 6. represents Dr Hook's wheel-barometer. Here ACDG is a glass tube, having a large round head at A, and turned up at the lower end F. Upon the surface of the mercury in the bent leg is an iron ball G, with a string going over a pulley CD. To the other end of the string is fastened a smaller ball H, which as

Baromete

the

meter. the mercury rises in the leg FG, turns the index KL from N towards M, on the graduated circle MNOP; as it rises in the other leg, the index is carried the contrary way by the defect of the heavier ball G, along with the mercury. The friction of this machine, however, unless it is made with very great accuracy, renders it useless.

N^o 7. is another barometer invented by Mr Rowning, in which also the scale may be infinite. ABCD is a cylindrical vessel, filled with a fluid to the height W, in which is immersed the barometer SP consisting of the following parts: The principal one is the glass tube TP, (represented separately at *tp*), whose upper end T is hermetically sealed: this end does not appear to the eye, being received into the lower end of a tin pipe GH, which in its other end G receives a cylindrical rod or tube ST, and thus fixes it to the tube TP. This rod ST may be taken off, in order to put in its stead a larger or a lesser as occasion requires. S is a star at the top of the rod ST; and serves as an index by pointing to the graduated scale LA, which is fixed to the cover of the vessel ABCD. MN is a large cylindrical tube made of tin, (represented separately at *mn*), which receives in its cavity the smaller part of the tube TP, and is well cemented to it at both ends, that none of the fluid may get in. The tube TP, with this apparatus, being filled with mercury, and plunged into the basin MP, which hangs by two or more wires upon the lower end of the tube MN, must be so poised as to float in the liquor contained in the vessel ABCD; and then the whole machine rises when the atmosphere becomes lighter, and *vice versa*. Let it now be supposed, that the fluid made use of is water; that the given variation in the weight of the atmosphere is such, that, by pressing upon the surface of the water at W, the surface of the mercury at X may be raised an inch higher, (measuring from its surface at P), than before; and that the breadth of the cavity of the tube at X, and of the basin at P, are such, that, by this ascent of the mercury, there may be a cubic inch of it in the cavity X more than before, and consequently in the basin a cubic inch less. Now, upon this supposition, there will be a cubic inch of water in the basin more than there was before; because the water will succeed the mercury, to fill up its place. Upon this account the whole machine will be rendered heavier than before by the weight of a cubic inch of water; and therefore will sink, according to the laws of hydrostatics, till a cubic inch of that part of the rod WS, which was above the surface of the water at W, comes under it. Then, if we suppose this rod so small, that a cubic inch of it shall be 14 inches in length, the whole machine will sink 14 inches lower into the fluid than before; and consequently the surface of the mercury in the basin will be pressed, more than it was before, by a column of water 14 inches high. But the pressure of 14 inches of water is equivalent to one of mercury; this additional pressure will make the mercury ascend at X as much as the supposed variation in the weight of the air did at first. This ascent will give room for a second cubic inch of water to enter the basin; the machine will therefore be again rendered so much heavier, and will subside 14 inches farther, and so on *in infinitum*. If the rod was so small that more than fourteen inches of it were required to make a cubic inch, the

variation of this machine would be negative with respect to the common barometer; and instead of coming nearer to an equilibrium with the air by its ascent or descent, it would continually recede farther from it: but if less than 14 inches of rod were required to make a cubic inch, the scale of variation would be finite, and might be made in any proportion to the common one. Neither this nor the other infinite barometer have ever been tried, so that how far they would answer the purposes of a barometer is as yet unknown.

N^o 8. represents another contrivance for enlarging the scale of the barometer to any size.—AB is the tube of a common barometer open at B and sealed at A, suspended at the end of the lever which moves on the fulcrum E.—CD is a fixt glass tube, which serves in place of the cistern. This last tube must be so wide as to allow the tube AB to play up and down within it.—AB being filled with mercury, is nearly counterbalanced by the long end of the lever. When the atmosphere becomes lighter, the mercury descends in the long tube, and the surface of the mercury rising in the cistern pushes up the tube AB, which at the same time becoming lighter, the lever preponderates, and points out the most minute variations. Here too the friction occasions inconveniences; but this may be in some measure remedied by a small shake of the apparatus at each inspection.

In the Philosophical Transactions, Mr Caswell gives the following account of a barometer, which is recommended by Mr Chambers as the most exact hitherto invented. "Let ABCD (N^o 9.) represent a bucket of water, in which is the barometer *erezosm*, which consists of a body *ersm*, and a tube *ezyo*: the body and tube are both concave cylinders communicating with one another, and made of tin: the bottom of the tube *zy*, has a lead weight to sink it so that the top of the body may just swim even with the surface of the water by the addition of some grain weights on the top. The water, when the instrument is forced with its mouth downwards, gets up into the tube to the height *yu*. There is added on the top a small concave cylinder, which I call the *pipe* to distinguish it from the bottom small cylinder which I call the *tube*. This pipe is to sustain the instrument from sinking to the bottom: *md* is a wire; *ms, ds*, are two threads oblique to the surface of the water, which threads perform the office of diagonals: for that while the instrument sinks more or less by the attraction of the gravity of the air, there where the surface of the water cuts the thread, is formed a small bubble; which bubble ascends up the thread, as the mercury in the common barometer ascends."

The dimensions of this instrument given there are, 21 inches for the circumference of the body, the altitude 4, each base having a convexity of $6\frac{1}{2}$ inches. The inner circumference of the tube is 5.14 inches, and its length $4\frac{1}{2}$; so that the whole body and tube will contain almost $2\frac{1}{2}$ quarts. The circumference of the pipe, that the machine may not go to the bottom on every small alteration of the gravity of the air, is 2.14 inches; according to which dimensions, he calculates that it will require 44 grains to sink the body to the bottom, allowing it only four inches to descend; at the same time that it is evident, that the fewer grains that are required to sink it to this depth, the more nice the barometer will be. He also calculates, that

Barometer.

when the mercury in the common barometer is 30½ inches high, the body with a weight of 44 grains on its top will be kept in *æquilibrio* with the water; but when the mercury stands at 28 inches, only 19 grains can be supported: and lastly, by computing the lengths of the diagonal threads, &c. he finds, that his instrument is 1200 times more exact than the common barometer. The following are his observations on the use of it.

25
Mr Caswell's observations with his barometer.

“ 1. While the mercury of the common barometer is often known to be stationary 24 hours together, the bubble of the new barometer is rarely found to stand still one minute.

“ 2. Suppose the air's gravity increasing, and accordingly the bubble ascending; during the time that it ascends 20 inches, it will have many short descents of the quantity of half an inch, one, two, three, or more inches; each of which being over, it will ascend again. These retrocessions are frequent, and of all varieties in quantity and duration, so that there is no judging of the general course of the bubble by a single inspection, though you see it moving, but by waiting a little time.

“ 3. A small blast of wind will make the bubble descend; a blast that cannot be heard in a chamber of the town will sensibly force the bubble downward. The blasts of wind sensible abroad, cause many of the above-mentioned retrocessions, or accelerations in the general course; as I found by carrying my barometer to a place where the wind was perceptible.

“ 4. Clouds make the bubble descend. A small cloud approaching the zenith, works more than a great cloud near the horizon. In cloudy weather, the bubble descending, a break of the clouds (or clear place) approaching to the zenith, has made the bubble to ascend; and after that break had passed the zenith a considerable space, the bubble again descended.

“ 5. All clouds (except one) hitherto by me observed, have made the bubble to descend. But the other day, the wind being north, and the course of the bubble descending, I saw to the windward a large thick cloud near the horizon, and the bubble still descended: but as the cloud drew near the zenith, it turned the way of the bubble, making it to ascend; and the bubble continued ascending till the cloud was all passed, after which it resumed its former descent. It was a cloud that yielded a cold shower of small hail.”

These are the most remarkable contrivances for the improvement of the common barometer: and indeed we must agree with Mr Chambers, that the last, on account of its being so exceedingly sensible, and likewise easy of construction, and portable, seems to deserve attention much more than the others, which are always the more unexact, and the less easily moved, according to the enlargement of their scale; whereas this is seemingly subject to no such inconvenience. It is evident, however, that none of these could be used at sea, on account of the unsteady motion of the ship: for which reason Dr Hook thought of constructing a barometer upon other principles.

26
Marine barometer by Mr Hook.

His contrivance was no other than two thermometers. The one was the common spirit-of-wine thermometer, which is affected only by the warmth of the air: the other, which acts by the expansion of a bubble of air included, is affected not only by the external

warmth, but by the various weight of the atmosphere. Therefore, keeping the spirit thermometer as a standard, the excess of the ascent or descent of the other above it would point out the increase or decrease of the specific gravity of the atmosphere. This instrument is recommended by Dr Halley, who speaks of it as follows. “ It has been observed by some, that, in long keeping this instrument, the air included either finds a means to escape, or deposits some vapours mixed with it, or else for some other cause becomes less elastic, whereby in process of time it gives the height of the mercury somewhat greater than it ought; but this, if it should happen in some of them, hinders not the usefulness thereof, for that it may at any time very easily be corrected by experiment, and the rising and falling thereof are the things chiefly remarkable in it, the just height being barely a curiosity.

“ I had one of these barometers with me in my late southern voyage, and it never failed to prognosticate and give early notice of all the bad weather we had, so that I depended thereon, and made provision accordingly; and from my own experience I conclude, that a more useful contrivance hath not for this long time been offered for the benefit of navigation.”

A new kind of marine barometer hath lately been invented by Mr Nairne. It differs from the common one in having the bore of the tube small for about two feet in its lower part; but above that height it is enlarged to the common size. Through the small part of the instrument, the mercury is prevented from ascending too hastily by the motion of the ship; and the motion of the mercury in the upper wide part is consequently lessened. Much is found to depend on the proper suspension of this instrument; and Mr Nairne has since found, by experiment, the point from which it may be suspended so as not to be affected by the motion of the ship.

We must now speak of the barometer in its second character, namely, as an instrument for measuring accessible altitudes. This method was first proposed by M. Pascal; and succeeding philosophers have been at no small pains to ascertain the proportion between the sinking of the mercury, and the height to which it is carried. For this purpose, however, a new improvement in the barometer became necessary, viz. the making of it easily portable from one place to another, without danger of its being broken by the motion of the mercury in the tube. The common portable barometer is constructed as follows.

The tube containing the mercury, instead of having its lower end immersed in a vessel of that fluid, has it tied up in a leathern bag not quite full of mercury; and though the external air cannot get into the bag to suspend the mercury in the tube by pressing on its surface as in the common one; yet it has the same effect, by pressing on the outside of the bag; which being pliant, yields to the pressure, and keeps the mercury suspended in the tube at its proper height. This bag is generally inclosed in a little box, through the bottom of which passes a screw: with this screw the bag may be compressed so as to force the mercury up to the top of the tube; which keeps it steady, and hinders it from breaking the tube by dashing against the top when it is carried about, which it is otherwise apt to do.

Among the number of portable barometers we may

perhaps reckon what Mr Boyle called his *Statical* barometer. It consisted of a glass bubble, about the size of a large orange, and blown very thin, so as to weigh only 70 grains. This being counterpoised by brass weights in a pair of scales that would turn with the thirtieth part of a grain, was found to act as a barometer. The reason of this was, that the surface of the bubble was opposed to a vastly larger portion of air than that of the brass weight; and consequently behaved to be affected by the various specific gravity of the atmosphere: thus when the air became specifically light, the bubble descended, and *vice versa*; and thus, he says, he could have perceived variations of the atmosphere no greater than would have been sufficient to raise or lower the mercury in the common barometer an eighth part of an inch.

The portable barometer, as already observed, has long been in use for the mensuration of accessible altitudes; and, in small heights, was found to be more exact than a trigonometrical calculation, the mercury descending at the rate of about one inch for 800 feet of height to which it was carried: but, in great heights, the most unaccountable differences were found between the calculations of the most accurate observers; so that the same mountain would sometimes have been made thousands of feet higher by one person than another; nay, by the same person at different times. All these anomalies M. de Luc of Geneva undertook to account for, and to remove; and in this undertaking he persisted with incredible patience for 20 years. The result of his labour is as follows.

The first cause of irregularity observed was a fault in the barometer itself. M. de Luc found, that two barometers, though perfectly alike in their appearance, did not correspond in their action. This was owing to air contained in the tube. The air was expelled by boiling the mercury in them; after which, the motions of both became perfectly consonant. That the tubes may bear boiling, they must not be very thick, the thickness of the glass not above half a line, and the diameter of the bore ought to be from two and an half to three lines. The operation is performed in the following manner; A chafing dish with burning coals is placed on a table; the tube, hermetically sealed at one end, is inverted and filled with mercury within two inches of the top; the tube is gradually brought near the fire, moving it obliquely up and down, that the whole length of it may be heated; and advancing it nearer and nearer, till it is actually in the flame, the globules of air begin to move visibly towards the top. The boiling at last commences; and it is easy to make it take place from one end to the other, by causing the several parts of the tube successively pass with rapidity through the flame.

The next cause of variation, was a difference of temperature. To discover the effects of heat on the mercury, several barometers were chosen that for a long time had been perfectly consonant in their motions. One of these was placed in an apartment by itself, to mark the change in the external air, if any should happen. The rest were situated in another apartment, along with three thermometers, graduated according to the scale of M. De Reaumur, and exactly correspondent with one another. The point at which the mercury stood when the experiment began, was care-

fully noted, and also the precise height of the thermometers. The latter apartment then was gradually heated; and with so much uniformity, that the thermometers continued still to agree. When the heat had been augmented as much as possible, the altitudes both of the barometers and thermometers were again accurately marked, to ascertain the differences that corresponded to one another. This experiment was repeated several times with next to no variation; and from the barometer in the first apartment it appeared, that no sensible alteration had taken place in the external air. Hence M. De Luc found, that an increase of heat sufficient to raise the thermometer from the point of melting ice to that of boiling water, augments the height of the mercury in the barometer precisely six lines; and therefore, dividing the distance between these two points on the thermometer into 96 equal parts, there will be $\frac{1}{16}$ th of a line to add to, or subtract from, the height of the mercury in the barometer, for every degree of variation of the thermometer so graduated. A scale of this kind, continued above boiling or below freezing water, accompanies his portable barometer and thermometer.—So accurate, he says, did long practice make him in barometrical observations, that he could distinguish a variation of $\frac{1}{12}$ of a line in the height of the mercury. He allows of no inclination of the tube, or other means to augment the scale, as all these methods diminish the accuracy of the instrument. Two observations are always required to measure the altitude of a mountain: one with a barometer left on the plain, and another on the summit; and both must be accompanied with a thermometer.

His portable barometer consists of two tubes, one of 34 French inches in length; and from the top, for this length, perfectly straight; but, below this, it is bent round, so that the lower end turns up for a short space, parallel to the straight part. On this open end is fixed a cock; and on the upper side of this cock, is placed another tube, of the same diameter with the former, eight inches in length, open at both ends, and communicating with the long tube, through the cock. When the barometer is carried from one place to another, it is inverted very slowly, to hinder any air getting in; the quicksilver retires into the long tube on which the key of the cock is turned; and to preserve the cock from too great pressure of the mercury, the barometer is conveyed about in this inverted posture. When an observation is to be made, the cock is first opened; the tube is then turned upright, very slowly, to prevent, as much as possible, all vibration of the mercury, which disturbs the observation; and, according to the weight of the atmosphere, the mercury falls in the longer branch, and rises up through the cock, into the shorter.

The whole of the cock is made of ivory, except the key. The extremities of the tubes are wrapped round with the membrane employed by the gold-beaters, done over with fish-glue, in order to fix them tight, the one in the lower, and the other in the upper, end of the perpendicular canal of the cock. The part of the key that moves within the cock is of cork, and the outward part or the handle is of ivory. The cork is fastened firmly to the ivory by means of a broad thin plate of steel, which cuts both the ivory and cork, length-wise, through the centre, and reaches inward

Barometer.

36
M. De
Luc's port-
able baro-
meter.

to the hole of the key. This plate also counteracts the flexibility of the cork, and makes it obey the motion of the handle, notwithstanding it is very considerably compressed by the ivory, to render it tight. That this compression may not abridge the diameter of the hole of the key, it is lined with a thin hollow ivory cylinder, of the same diameter with the tubes.

On the upper end of the shorter tube is fixed, in the intervals of observation, a kind of funnel, with a small hole in it, which is shut with an ivory stopple. The use of it is to keep the tube clean, to replace the mercury that may have made its way thro' the cock in consequence of any dilatation, and likewise to replace the mercury taken out of the shorter tube, after shutting the cock, on finishing an observation; because, when the mercury is left exposed to the air, it contracts a dark pellicle on its surface, that sullies both itself and the tube. The shorter tube should be wiped from time to time, by a little brush of sponge fixed on the end of a wire.

The barometer, thus constructed, is placed in a long box of fir, the two ends of which are lined on the inside with cushions of cotton, covered with leather. This box may be carried on a man's back, like a quiver, either walking or riding; and should have a cover of wax-cloth, to defend it against rain. It should be kept at some distance from the body of the man, and be protected from the sun by an umbrella, when near the place of observation, to prevent its being affected by any undue degree of heat. The barometer should, farther, be attended with a plummet, to determine the perpendicular position of it; and a tripod, to support it firm in that position at the time of observation.

The scale of the barometer begins on the long tube, at a point on a level with the upper end of the short one; and rises, in the natural order of the numbers, to 21 inches. Below the above point, the scale is transferred to the short tube; and descends on it, in the natural order of the numbers, to 7 inches. The whole length of the scale is 28 French inches; and since, as the mercury falls in the one tube, it must rise in the other; the total altitude will always be found by adding that part of the scale, which the mercury occupies in the long tube, to that part of it which the mercury does not occupy in the short one. In estimating, however, the total fall or rise on the long tube, every space must be reckoned twice; because, of barometers of this construction, half the real variation only appears in one of the branches.

Near the middle of the greater tube, is placed the thermometer abovementioned, for ascertaining the corrections to be made on the altitude of the mercury, in consequence of any change in the temperature of the air. It is placed about the middle of the barometer, that it may partake as much as possible of its mean heat. The ball is nearly of the same diameter with the tube of the barometer, that the dilatations or condensations of the fluids they contain may more exactly correspond. The scale is divided into 96 parts; between the points of boiling water and melting ice, and the term of 0, is placed one eighth part of this interval above the lower point; so that there are 12 degrees below, and 84 above, it. The reason for placing 0 here is, that, as 27 French inches are about the mean height of the barometer, so the 12th degree above freezing is nearly the mean altitude of the thermometer. Hence,

by taking these two points, the one for the mean altitude, and the other for the mean heat, there will be fewer corrections necessary to reduce all observations to the same state, than if any higher or lower points had been fixed upon.

If then the barometer remain at 27 inches, and the thermometer at 0, there are no corrections whatever to be made. But if, while the barometer continues at 27 inches, the thermometer shall rise any number of degrees above 0, so many sixteenths of a line must be subtracted from the 27 inches, to obtain the true height of the barometer, produced by the weight of the atmosphere, and to reduce this observation to the state of the common temperature. If, on the other hand, the thermometer shall fall any number of degrees below 0, while the barometer still stands at 27 inches, so many sixteenths must be added to that height, to obtain the true altitude.

Nothing is more simple than these corrections, when the barometer is at or near 27 inches of height. If, however, it fall several inches below this point, as the portable barometer very frequently must, the dilatations will no longer keep pace with the degrees of heat, after the rate of $\frac{1}{12}$ of a line for every degree of the thermometer; because, the columns of mercury being shortened, the quantity of fluid to be dilated will be diminished. The truth is, the quantity of the dilatations for the same degree of heat is just as much diminished as the column is shortened. If, then, it shall still be found convenient to reckon the dilatations by sixteenths of a line, these sixteenths must be counted on a scale, of which the degrees shall be as much longer than the degrees of the first scale, as the shortened column of mercury is less than 27 inches, the height to which the length of the degrees of the first scale was adapted. For instance, let the mercury descend to $13\frac{1}{2}$ inches, half the mean column, and let the thermometer ascend 10 degrees above the mean heat; 10 sixteenths should be deducted from the mean column, for this temperature, according to the rule; but 10 half-sixteenths only, or 5 whole sixteenths, must be subtracted from the column of $13\frac{1}{2}$ inches, because the sum of its dilatations will be half that of the former, the quantities of fluid being to one another in that proportion.

It would cause considerable embarrassment if the sixteenths of correction were always to be subdivided into less fractions, proportional to every half inch of descent of the barometer; and the same end is obtained in a very easy manner, by reckoning the corrections on different scales of the same length, but of which the degrees are longer according as the columns of the barometer are shorter. For example, the degrees of correction on the scale applicable to the column of $13\frac{1}{2}$ inches, will be double in length what the same degrees are for the column of 27 inches; and, of course, the number of corrections will be reduced likewise one half, which we have seen by the rule they ought to be.

The author constructed, on a piece of vellum, scales with these properties, for no less than 23 columns of mercury, being all those between 18 inches and 29 inclusive, counting from half inch to half inch; within which extremes, every practical case will be comprehended. He wrapped this vellum on a small hollow cylinder, including a spring, like a spring-curtain, and

fixed

ometer. fixed it on the right side of the thermometer. The velleum is made of pafs from right to left, behind the tube of the thermometer, and to graze along its surface. The observer, to find the corrections to be made, pulls out the vellum till the scale corresponding to the observed altitude of the barometer comes to touch the thermometer, and on that scale he counts them. The vellum is then let go, and the screw gently furls it up.

The author having now, as he imagined, completely finished the instruments necessary for the accurate mensuration of heights; proceeded to establish, by experiment, the altitudes corresponding to the different descents of the mercury. Much had been written, and many rules had been given, on this subject, by different eminent philosophers, since the days of Pascal, who first broached it: but these disagreed so much with one another, and presented so little good reason why any one of them should be preferred, that no conclusion could, with confidence, be deduced from them. It became requisite, therefore, to lay them all aside, and to endeavour to discover, by practice, what could not be ascertained by theory. Salève, a mountain near Geneva, was chosen for the scene of these operations. This mountain is near 3000 French feet high. The height of it was twice measured by levelling, and the results of the mensurations differed only 10½ inches; tho' there intervened six months between them, and the total altitude was so considerable. On this mountain were chosen no less than 15 different stations, rising after the rate of 200 feet, one above another, as nearly as the ground would admit. At these stations, it was proposed to make such a number of observations as might be a good foundation, either for establishing a new rule of proportion between the heights of places and the descents of the mercury, or for preferring some one of those formerly discovered.

Little progress was made in this plan, when a phenomenon, altogether unexpected, presented itself. The barometer being observed, at one of the stations, twice in one day, was found to stand higher in the latter observation than in the former. This alteration gave little surprisè, because it was naturally imputed to a change of the weight of the atmosphere, which would affect the barometer on the plain in the same manner. But it produced a degree of astonishment, when, on examining the state of the latter, it was found, instead of corresponding with the motions of the former, to have held an opposite course, and to have fallen while the other rose. This difference could not proceed from any inaccuracy in the observations, which had been taken with all imaginable care; and it was so considerable as to destroy all hopes of success, should the cause not be detected and compensated.

The experiment was repeated several times, at intervals, that no material circumstance might escape notice. An observer on the mountain, and another on the plain, took their respective stations at the rising of the sun, and continued to mark an observation, every quarter of an hour, till it set. It was found, that the lower barometer gradually descended for the first three quarters of the day, after which it re-ascended, till, in the evening, it stood at nearly the same height as in the morning; that the higher barometer ascended for the first three fourths of the day, and then descended, so as to regain likewise, about sunset, the altitude of the

morning.

The following theory seems to account in a satisfactory manner for this phenomenon. When the sun rises above the horizon of any place, his beams penetrate the whole of the section of the atmosphere of which that horizon is the base. They fall, however, very obliquely on the greater part of it, communicate little heat to it, and consequently produce little dilatation of its air. As the sun advances, the rays become more direct, and the heat and rarefaction of course increase. But the greatest heat of the day is not felt even when the rays are most direct, and the sun is in the meridian. It increases while the place receives more rays than it loses, which it will do for a considerable time after mid-day; in like manner, as the tide attains not its highest altitude till the moon has advanced a considerable way to the west of the meridian. The heat of the atmosphere is greatest at the surface of the earth, and seems not to ascend to any great distance above it. The dilatations, for this reason, of the air, produced by the sun, will be found chiefly, if not solely, near the earth. A motion must take place, in all directions, of the adjacent air, to allow the heated air to expand itself. The heated columns extending themselves vertically, will become longer, and at the same time specifically lighter, in consequence of the rarefaction of their inferior parts. The motion of air, till it rises into wind, is not rapid; these lengthened columns, therefore, will take some time to dissipate their summits among the adjacent less rarefied columns that are not so high; at least, they will not do this as fast as their length is increased by the rarefaction of their bases.

The reader, we presume, anticipates the application of this theory to the solution of the phenomenon in question. The barometer on the plain begins to fall a little after morning, because the column of air that supports it becomes specifically lighter on account of the rarefaction arising from the heat of the sun. It continues to fall for the first three quarters of the day; because, during that time, the heat, and consequently the rarefaction, are gradually increasing. It rises again, after this period; because the cold, and of course the condensation, coming on, the specific gravity is augmented by the rushing in of the adjacent air. The equilibrium is restored, and the mercury returns to the altitude of the morning.

The barometer on the eminence rises after morning, and continues to do so for three fourths of the day, for two reasons. The density of the columns of air is greatest near the earth, and decreases as the distance from it increases. The higher, for this reason, we ascend in the atmosphere, we meet with air specifically lighter. But by the rarefaction of the base of the column that supports the mercury of the barometer on the eminence, the denser parts of that column are raised higher than naturally they would be if left to the operation of their own gravity. On this account, the higher barometer is pressed with a weight, nearly as great as it would sustain, were it brought down, in the atmosphere, to the natural place of that denser air now raised above it by the prolongation of the base of the column. The other reason is, that as the rarefaction does not take place at any great distance from the earth, little change is produced in the specific gravity

Barometer.

of the portion of the column that presses on the higher barometer, and the summit of that column dissipates itself more slowly than it increases. Thus, we see how this barometer must ascend during the first three fourths of the day, and pursue a course the reverse of that on the plain. The condensations returning after this time, the denser air subsides, the equilibrium takes place, and the mercury descends to its first position.

40
Render another pair of thermometers necessary.

This phenomenon prompted the idea of a second pair of thermometers, to measure the mean heat of the column of air intercepted between the barometers. These thermometers are extremely delicate and sensible. The tubes are the finest capillary, the glass very thin, and the diameters of the balls only three lines. The balls are insulated, or detached from the scales, which are fixed to the tubes only, by ligatures of fine brass-wire covered with silk. The air, by this contrivance, has free communication with the balls on all sides; and, if the direct rays of the sun be intercepted at some distance by a bit of paper, or even the leaf of a tree, the thermometers will quickly mark the true temperature of the air.

41
Method of computing the altitudes.

The reader, perhaps, will ask here, Could not this end have been gained by the first pair of thermometers? But we must request him to suspend his judgment, till we have explained the theory of computing the altitudes from the descents of the mercury. He will then find the scales of these thermometers so different, that neither of them could, without much inconvenience, serve the purpose of the other.

The altitudes are computed by logarithms. A table of logarithms contains two series of numbers, running parallel to one another. The first has its terms in geometrical progression, and the second its terms in arithmetical. The natural numbers 1, 2, 3, 4, &c. form the first series; which, though in arithmetical progression when standing detached, are in geometrical in regard of the second series; whose terms are in arithmetical progression, and are called *logarithms*, because they express the distance of their correspondent terms of the geometrical progression from the beginning of the series.

To apply this table to the present purpose: let us suppose the whole atmosphere divided into concentric spherical sections, whose common centre is that of the earth. Suppose, also, all these sections of equal thickness, namely, 12.497 toises, which is found to be the thickness of the lowest section, and balances a line of mercury, when the barometer stands at 348 lines or 29 inches. Add, then, all these sections together; and we shall have the total altitude of the atmosphere expressed in an arithmetical progression, whose common difference is 12.497 toises. Consequently, in this view, the heights are proportional to the logarithms.

It remains only to find the descents of the mercury, which measures the weights of the respective sections, in geometrical proportion, in order to justify the application of the logarithmic table to the computation of the altitudes. Now, it is easy to prove, in a very satisfactory manner, that the mean densities of these sections, which are in proportion of their weights, must be in geometrical progression, when the altitudes are in arithmetical; consequently, it is with great propriety and convenience that the logarithms are employed in

Baromet.

the computation of the altitudes corresponding to the descents of the mercury. For, to find the vertical distance between two barometers, at different heights, no more is necessary than to look, in a table of logarithms, for the numbers that express in lines, or sixteenths of a line, the altitudes of the two columns of mercury, and take the logarithms of these numbers, whose difference will give this distance accurately, in thousandth parts of a toise. Multiply the toises by 6, which will furnish the altitudes in French feet.

The author made about 500 different observations at the several stations on the mountain of Saleve, which both suggested and verified the computation by logarithms. Many, however, of these observations, produced conclusions that deviated considerably from the results of the actual mensuration, on account of the different temperatures in which they were taken. It was the design of the second pair of thermometers to point out the corrections of these deviations. In setting the scales necessary for this end, the first object was, to mark the temperature of all the observations where the logarithms gave the altitudes exactly, or nearly equal to what they were found to be by levelling. This temperature corresponded to $16\frac{1}{2}$ on the scale of Reaumur, and to 70 on that of Fahrenheit, and at it was fixed the term 0. The next step was, to determine the corrections of the heights that became necessary, according as the state of the air was warmer or colder than the fixed point. With this view, all the remaining observations were collected, and compared with the different temperatures in which they were taken; and from an attentive examination of these circumstances, it was discovered, that for every 215 feet of height furnished by the logarithms, one foot of correction must be added or subtracted, for every degree of the thermometer, according as it stood above or below the term 0.

The scale of Reaumur did not conveniently express this correction of 1 to 215. The author wished to adopt the ratio of 1 to 1000, in forming a new scale for that purpose; but the divisions would have been too small. He employed, therefore, that of 1 to 500; because, by doubling the degrees of the higher thermometer above or below 0; or, which amounted nearly to the same thing, by doubling the mean heat of the column of air in taking the sum of the degrees of both thermometers, there resulted the ratio of 1 to 1000. The new scale, then, was divided by the following proportion: As 215, the last term of the ratio found by Reaumur's scale, is to 500, the last term of the ratio to be applied on the new scale; so is 80, the parts between the fixed points of the first scale, to 186, the number of parts between the same points on the second. And as 80 is to 186, so is $16\frac{1}{2}$, the point on Reaumur's scale at which the logarithms give the altitudes without correction, to 39, the point at which they give them on the new scale. The term 0 is placed at this point, 39 at melting ice, and 147 at that of boiling water. To reduce all observations to the same temperature by this scale, nothing more is necessary than to multiply the heights found from the logarithms, by the sum of the degrees of both thermometers above or below 0, and to divide the product by 1000. The quotient must be added to, or subtracted from, the logarithmic height, according as the temperature is positive or negative.

rometer,
baron.

As a specimen of the author's method, we shall now present our readers with the result of his operations at the 15 stations on Saleve. In one column are marked the heights found by levelling, and opposite to them the same heights found by the barometer; to the latter are prefixed the number of observations of which they are the mean.

Stations.	Heights by levelling.		Number of observations.	Heights by barometer.
	feet.	inches.		feet.
1	216	2	12	230 $\frac{1}{2}$
2	428	10	13	435 $\frac{1}{4}$
3	586	0	13	591 $\frac{1}{4}$
4	728	8	21	732 $\frac{1}{4}$
5	917	0	24	919 $\frac{1}{4}$
6	1218	8	27	1221 $\frac{1}{4}$
7	1420	0	23	1418 $\frac{1}{4}$
8	1800	0	17	1798 $\frac{3}{4}$
9	1965	3	17	1962 $\frac{1}{4}$
10	2211	0	17	2210
11	2333	0	17	2331 $\frac{1}{4}$
12	2582	4	16	2583 $\frac{1}{5}$
13	2700	0	15	2703 $\frac{1}{4}$
14	2742	0	10	2741 $\frac{1}{4}$
15	2926	0	11	2924 $\frac{1}{2}$

From this table, we presume the reader will be inclined to entertain the most favourable opinion of the abilities and industry of the author; but his barometer is probably susceptible of improvement. It seems too bulky and complex, and liable to accidents, and will require long practice to render other observers equally accurate and dextrous with him in its use. We hear, however, that the ingenious Mr Ramfden of London, optician, has actually invented and constructed a portable barometer, as simple and light, almost, as the common stationary one. It is little apt to be disarranged by motion; and is capable, by the help of a Nonius index, to mark distinctly a variation of the mercury to the thousandth part of an inch, which corresponds, on the surface of the earth, to nearly 6 inches of height.

BARON, a degree next below a viscount, and the lowest of nobility. See NOBILITY.

A baron's is the most general and universal title of nobility; for originally every one of the peers of superior rank had also a barony annexed to his other titles. But it hath sometimes happened, that, when an ancient baron hath been raised to a new degree of peerage, in the course of a few generations the two titles have descended differently; one perhaps to the male descendants, the other to the heirs general; whereby the earldom or other superior title hath subsisted without a barony: and there are also modern instances, where earls and viscounts have been created without annexing a barony to their other honours: so that now the rule doth not hold universally, that all peers are barons. The original and antiquity of baronies has occasioned great inquiries among our English antiquarians. The most probable opinion seems to be, that they were the same with our present lords of manors; to which the name of *court baron* (which is the lord's court, and incident to every manor) gives some countenance. It may be collected from king John's *magna charta*, that originally all lords of manors, or barons, that held of the king *in capite*, had seats in the great council or

parliament: till about the reign of that prince the conflux of them became so large and troublesome, that the king was obliged to divide them, and summon only the greater barons in person; leaving the small ones to be summoned by the sheriff, and (as it is said) to sit by representation in another house; which gave rise to the separation of the two houses of parliament. By degrees the title came to be confined to the greater barons, or lords of parliament only; and there were no other barons among the peerage but such as were summoned by writ, in respect of the tenure of their lands or baronies, till Richard II. first made it a mere title of honour, by conferring it on divers persons by his letters patent. See LAW, Part III. N^o clviii. 12, 13, 14.

BARON by Tenure, one who held certain territories of the king, who still retained the tenure in chief to himself.

BARONS of the Exchequer, the four judges to whom the administration of justice is committed, in causes between the king and his subjects, relating to matters concerning the revenue. They were formerly barons of the realm, but of late are generally persons learned in the laws. Their office is also to look into the accounts of the king, for which reason they have auditors under them. See AUDITOR.

BARONS of the Cinque-ports are members of the house of commons, elected by the five ports, two for each port. See the article CINQUE-PORTS.

BARON and Feme, in the English law, a term used for husband and wife, in relation to each other: and they are deemed but one person; so that a wife cannot be witness for or against her husband, nor he for or against his wife, except in cases of high treason.

BARON and Feme, in heraldry, is when the coats of arms of a man and his wife are borne par pale in the same escutcheon, the man's being always on the dexter side, and the woman's on the sinister; but here the woman is supposed not an heiress, for then her coat must be borne by the husband on an escutcheon of pretence*.

BARON (Robert), a dramatic author, who lived during the reign of Charles I. and the Protectorship of Oliver Cromwell. He received the earlier parts of his education at Cambridge, after which he became a member of the honourable society of Gray's-Inn. During his residence at the university, he wrote a novel called the *Cyprian Academy*, in which he introduced the two first of the dramatic pieces mentioned below. The third of them is a much more regular and perfect play, and was probably written when the author had attained a riper age. The names of them are, 1. *Dessein Dona*, a masque. 2. *Griphus and Hegio*, a pastoral. 3. *Mirza*, a tragedy. Mr Baron had a great intimacy with the celebrated Mr James Howell, the great traveller, in whose collections of Letters* there is one to this gentleman, who was at that time at Paris. To Mr Howel in particular, and to all the ladies and gentlewomen in England in general, he has dedicated his romance.

BARON (Michael), an excellent comedian of Paris, was the son of Michael Baron another comedian who was a native of Iffoudun. He wrote some poems, and several theatrical pieces, which are printed together in 2 vols 12mo. He died at Paris in 1729, aged 77.

BARONET. This is a modern degree of honour, instituted by king James I. on the 22^d of May, 1611;

* See Pale, and Escutcheon of Pretence.

* Vol. III. Let. 418.

Baronet,
Baroni.

and the 9th year of his reign; who made it hereditary in the male line, as an encouragement to those of his subjects who assisted in the reduction of the province of Ulster in Ireland. The number of baronets was first restricted to 200; but it is now enlarged at the king's pleasure, without limitation. The title of *baronet* is conferred by patent under the great seal; and, like other knights, he is distinguished by the appellation *Sir*, prefixed to his Christian name, in speaking and writing.

No person could be admitted into this order, unless he was a gentleman of unblemished morals, and possessed of an yearly income of 1000*l.* in land; and the express condition of his admission was, that he should pay 1095*l.* for the maintenance of 30 soldiers, for three years on the military establishment of Ireland. As an armorial badge of distinction, a baronet wears, in a canton or escutcheon, the arms of Ulster, viz. *Argent, a Sniſter Hand couped at the wrist, Gules.*

BARONET of Scotland. The order of baronets in Scotland was also projected by king James I. for the plantation and cultivation of the province of Nova Scotia, in America; and his son king Charles I. executed his royal father's plan by instituting this order soon after his accession to the throne: the first person dignified with this title was Sir Robert Gordon, of Gordonstone, a younger son of the earl of Sutherland, whose patent bears date the 28th of May 1625. — His majesty king Charles I. was so desirous of adding every mark of dignity to this his favourite order, that, four years after its institution, he issued a royal warrant, granting them the privilege of wearing an orange ribbon and a medal; which last was presented to each of them by the king himself, according to the words of the warrant. All the privileges of the order, particularly this of wearing the medal, were confirmed at the king's request by the Convention of Estates, in the year 1630; and in order to establish them on the most solid foundation, they were again confirmed by an act of the parliament of Scotland, in the year 1633. This mark of distinction fell to the ground with all the other honours of this country, during the usurpation of the long parliament and of Oliver Cromwell. It continued in general, though not total, disuse, after the Restoration. There have been former meetings of the order to revive the use of it, one in the year 1721, and another in 1734. These meetings proved ineffectual, because the proper steps towards its revival were not taken; but, under the auspices of our illustrious monarch George III. such measures were concerted in the year 1775, as have effectually established this honourable dignity.

BARONET of Ireland. This order was likewise instituted by king James I. in the 18th year of his reign, for the same purpose and with the same privileges within the kingdom of Ireland, as he had conferred on the like order in England; for which the Irish baronets paid the same fees into the treasury of Ireland. The first of that kingdom that was advanced to this hereditary dignity was Sir Francis Blundell, then secretary for the affairs of Ireland. Since his time, several have been created, no number being limited.

BARONI (Leonora), a celebrated singer and composer, was born at Naples, but spent the greatest part of her life at Rome. She was daughter of Adriana Baroni of Mantua, baroness of Pian-caretta; a lady also

Baroni
Baroni.

distinguished for her musical talents, and for her beauty firamed the *fair*. Leonora had less beauty than her mother; but excelled her in her profound skill in music, the fineness of her voice, and the charmingness of her manner. She is said by Mr Bayle to have been one of the finest singers in the world. She was, as well as her mother, celebrated by the wits, who strove to excel each other in recording her praises; and in 1639 there was published, at Bracciano, a collection of Latin, Greek, Italian, Spanish, and French poems made upon her, under this title, *Applausi Poetici alle Glorie della Signora Leonora Baroni*. Among the Latin poems of Milton are no fewer than three entitled 'Ad Leonoram Romæ canentem,' wherein this lady is celebrated for her singing, with an allusion to her mother's exquisite performance on the lute. A fine eulogium on this accomplished woman is contained in a discourse of the Music of the Italians, printed with the life of Malherbe, and some other treatises at Paris, 1672, in 12mo. This discourse was composed by Mr Maugars, prior of St Peter de Mac, the king's interpreter of the English language, and besides so famous a performer on the viol, that the king of Spain and several other sovereign princes of Europe desired to hear him. The character given by this person of Leonora Baroni is as follows: "She is endowed with fine parts; she has a very good judgment to distinguish good from bad music; she understands it perfectly well; and even composes, which makes her absolute mistress of what she sings, and gives her the most exact pronunciation and expression of the sense of her words. She does not pretend to beauty, neither is she disagreeable, or a coquet. She sings with a bold and generous modesty, and an agreeable gravity; her voice reaches a large compass of notes, and is exact, loud, and harmonious; she softens and raises it without straining or making grimaces. Her raptures and sighs are not lascivious; her looks have nothing impudent, nor does she transgress a virgin modesty in her gestures. In passing from one key to another, she shews sometimes the divisions of the enharmonic and chromatic kind with so much art and sweetness, that every body is ravished with that fine and difficult method of singing. She has no need of any person to assist her with a theorbo or viol, one of which is necessary to make her singing complete; for she plays perfectly well herself on both these instruments. In short, I have had the good fortune to hear her sing several times above 30 different airs, with second and third stanzas composed by herself. I must not forget to tell you, that one day she did me the particular favour to sing with her mother and her sister. Her mother played upon the lute, her sister upon the harp, and herself upon the theorbo. This concert, composed of three fine voices, and of three different instruments, so powerfully transported my senses, and threw me into such raptures, that I forgot my mortality, and thought myself already among the angels enjoying the felicity of the blessed."

BARONIUS (Cæsar), a pious and learned cardinal, was born at Sore in 1538. He studied at Rome, and put himself under the discipline of St Philip de Neri. In 1593, he was made general of the congregation of the Oratory by the resignation of the founder Philip de Neri. Pope Clement VIII. made him his confessor, and created him a cardinal in 1596. He was afterwards

wards made Librarian to the Vatican; and died in 1605, at 68 years of age. He wrote several works, the principal of which is his *Annales Ecclesiastici*, from A. D. 1 to 1198, in 12 vols folio; which has been abridged by several persons, particularly by Henry Spondzeus, Bzovius, and Ludovico Aurelio.

BARONY, the honour and territory which gives title to a baron, whether he be a layman or a bishop.

BARRA, in commerce, a long-measure used in Portugal and some parts of Spain, to measure woollen cloths, linen cloths, and serges. There are three sorts; the barra of Valencia, 13 of which make 12 $\frac{1}{2}$ yards English measure; the barra of Castile, 7 of which make 6 $\frac{1}{2}$ yards; and the barra of Aragon, 3 of which make 2 $\frac{1}{2}$ yards English.

BARRABA, (defart of); a tract of land in Siberia, lying between the rivers Irtis and Oby, in the province of Tobolsk. It is uninhabited, but not thro' any deficiency of the soil; for that is excellent for tillage, and part of it might also be laid out in meadows and pastures. It is interspersed with a great number of lakes, which abound with a species of carp called by the neighbouring people *karawtschen*; and the country produces great numbers of elks, deer, foxes, ermine, and squirrels. Between the Irtis and Oby are some rich copper-mines; particularly on a mountain called *Pitowua*, from the *pitwa* or white firs that grow upon it. Every hundred weight of the ore found here yields 12 pounds of pure copper; and there is no occasion for digging deep in order to come at it. Most of these ores, besides being very rich in copper, yield a great deal of silver, which affords so much gold as makes rich returns for the trouble and expence of extracting it.

BARRACAN, in commerce, a sort of stuff, not diapered, something like camblet, but of a coarser grain. It is used to make cloaks, furots, and such other garments, to keep off the rain.—The cities where the most barracans are made in France are, Valenciennes, Lisle, Abbeville, Amiens, and Roan. Those of Valenciennes are the most valued; they are all of wool, both the warp and the woof.

BARRACKS, or **BARACKS**, places for soldiers to lodge in, especially in garrisons.—Barracks, when damp, are greatly prejudicial to the health of the soldiers lodged in them; occasioning dysenteries, intermitting fevers, coughs, rheumatic pains, &c. For which reason, quarter-masters ought to be careful in examining every barrack offered by the magistrates of a place; rejecting all ground-floors in houses that have either been uninhabited, or have any signs of moisture.

BARRATIERE (Philip), a most extraordinary instance of the early and rapid exertion of mental faculties. This surprising genius was the son of Francis Barratiere, minister of the French church at Schwobach near Nuremberg, where he was born Jan. 10th 1721. The French was his mother tongue, together with some words of High Dutch; but by means of his father insensibly talking Latin to him, it became as familiar to him as the rest; so that, without knowing the rules of grammar, he at four years of age talked French to his mother, Latin to his father, High Dutch to the maid or neighbouring children; and all this without mixing or confounding the respective languages. About the middle of his fifth year he acquired Greek in like manner; so that in 15 months he perfectly understood all

the Greek books in the Old and New Testament, which he readily translated into Latin. When he was five years and eight months old, he entered upon Hebrew; and in three years time was so expert in the Hebrew text, that from a bible without points, he could give the sense of the original in Latin or French; or translate extempore the Latin or French versions into Hebrew, almost word for word; and had all the Hebrew psalms by heart. He composed at this time a dictionary of rare and difficult Hebrew words, with critical remarks and philological observations, in about 400 pages in 4to; and, about his tenth year, amused himself for twelve months with the rabbinical writers. With these he intermixed a knowledge of the Chaldaic, Syriac, and Arabic; and acquired a taste for divinity and ecclesiastical antiquity, by studying the Greek fathers, and councils of the first four ages of the church. In the midst of these occupations, a pair of globes coming into his possession, he could in 8 or 10 days time resolve all the problems on them; and in about three months, in Jan. 1735, devised his project for the discovery of the longitude, which he communicated to the Royal Society at London and the Royal Academy of Sciences at Berlin. In June 1731, he was matriculated in the university of Altorf; and at the close of the year 1732, he was presented by his father at the meeting of the reformed churches of the circle of Franconia; who, astonished at his wonderful talents, admitted him to assist in the deliberations of the synod: and to preserve the memory of so singular an event, it was ordered to be registered in their acts. In 1734, the Margrave of Brandenburg Anspach granted this young scholar the use of whatever books he wanted from the Anspach library, together with a pension of 50 florins, which he enjoyed three years; and his father receiving a call to the French church at Stetin in Pomerania, young Barratiere was, on the journey, admitted master of arts, with universal applause, at the university of Hall: at Berlin he was honoured with several conversations with the king of Prussia, and was received into the royal academy. Towards the close of his life he acquired a taste for medals, inscriptions, and antiquities; metaphysical inquiries, and experimental philosophy; intervening occasionally between these studies. He wrote several essays and dissertations; made astronomical remarks, and laborious calculations; took great pains toward a history of the heresies of the anti-trinitarians, and of the 30 years war in Germany: his last publication, which appeared in 1740, was on the succession of the bishops of Rome. The final work he engaged in, for which he had gathered large materials, was *Inquiries concerning the Egyptian Antiquities*. But the substance of this blazing meteor was now almost exhausted: he was always weak and sickly; and died October 5. 1740, aged 19 years 8 months and 16 days. He published eleven different pieces, and left 26 MSS. on various subjects, the contents of which may be seen in his life written by M. Formey professor of philosophy at Berlin.

BARRATOR, or **BARRETOR**, in law, a person guilty of barretry. See **BARRETRY**.

Lambert derives the word *barretor* from the Latin *balatro*, a vile knave: but the proper derivation is from the French *barrateur*, i. e. a deceiver; and this agrees with the description of a common barretor in my Lord Coke's

Barratry
Barratry.

Coke's report, viz. that he is a common mover and maintainer of suits in disturbance of the peace, and in taking and detaining the possession of houses and lands or goods by false inventions, &c. And therefore it was adjudged, that the indictment against him ought to be in these words, viz. That he is *communis malefactor, calumniator et seminator litium et discordiarum inter vicinos suos, et pacis regis perturbator*, &c. And there it is said that a common barrator is the most dangerous oppressor in the law, for he oppresseth the innocent by colour of law, which was made to protect them from oppression.

BARRATRY, in law. See BARRETRY.

BARRATRY, in a shipmaster, is his cheating the owners. If goods delivered on ship-board are embezzled, all the mariners ought to contribute to the satisfaction of the party that lost his goods, by the maritime law; and the cause is to be tried in the admiralty. In a case where a ship was insured against the barratry of the master, &c. and the jury found that the ship was lost by the fraud and negligence of the master, the court agreed, that the fraud was barratry, tho' not named in the covenant; but that negligence was not.

BARRAUX, a fortress of Dauphiny belonging to France. It stands in the valley of Grefivaudan, and was built by a duke of Savoy in 1597. The French took it in 1598, and have kept it ever since. It is seated on the river Iser, in E. Long. 4. 35. N. Lat. 45. 0.

BARRAY, one of the Hebrides, or Western isles of Scotland, situated in W. Long. 6. 30. N. Lat. 56. 55.—Of this island Mr Smollet gives the following description. "About two leagues and a half to the south-west of South Vift appears the isle of Barray, or Barra, five miles in length and three in breadth, partly mountainous, and partly capable of cultivation, having the advantage of a commodious harbour on the east side, and a good fishery of cod, ling, and salmon; which last are speckled, surprisingly nimble and shy, inasmuch that the fishermen are obliged to use three nets within one another, that, if the fish springs over two, it may be caught in the third. In the fourth end of Barray, there is an orchard planted with fruit-trees, though few of them produce fruit: but all sorts of pot-herbs and roots grow here in great perfection; nay, the natives even raised tobacco; but it never answered their purpose or expectation. This island, together with the adjacent smaller isles, belongs to the laird of Macneil, said to be the 36th in lineal descent from him of the same name who first possessed this estate. He holds it, however, in vassalage, from Macdonald of Slate, to whom he pays a yearly quit-rent. In the little isle of Kermul, about a quarter of a mile to the southward of Barry, is the family-seat, furnished with a watch-tower, and surrounded by a kind of fortification. The cockman, or watchman, is constantly on the tower to reconnoitre and prevent surprize; and the government of the castle is vested in a constable, who is very cautious of admitting any stranger in the absence of Macneil or his lady. The church of this island is dedicated to St Barr, a wooden image of whom stands on the altar, and of this patron they recite a legend of miracles: hard by is a little chapel in which Macneil and his descendants are interred. The inhabitants are very courteous and hospitable: as soon as any stranger

lands on the island, they oblige him to eat, on the supposition that the keen air of the ocean must have sharpened his appetite. When three or four guests arrive, each, by ancient custom, is lodged in a separate house; and thus man and wife are very often parted. The natives chiefly employ themselves in fishing, and climbing rocks for eggs and sea-fowl. The chief climber is distinguished by the name of *gingich*, or *hero*; and pays dear for his pre-eminence. When the boat approaches the rock, the *gingich* first leaps upon it, and, with the assistance of an horse-hair rope, draws his companions after him from one precipice to another. At their return to the boats with their booty of eggs and fowls, the *gingich*, at the hazard of his life, jumps into the vessel, which is generally tossed by a violent agitation of the sea, and keeps her steady to the rock, until the rest enter: in compensation for his courage and dexterity, he is gratified with a larger proportion of their plunder.

When a tenant's wife dies, the husband makes application to Macneil, desiring him to recommend another helpmate, and his request is immediately granted: then he visits her, carrying along with him a bottle of strong waters for the celebration of the marriage, which is consummated without further ceremony. When the husband dies, the widow presents the same petition, and is accommodated in the same manner. Should a tenant lose his milk cows by the severity of the season, or any other misfortune, Macneil is obliged to supply him with the like number; and when an old man is past his labour, the laird maintains him in his own family, for the remaining part of his life.

BARRE (Louis Francois Joseph de la) of Tournay, author of several works printed at Paris. Amongst others, *Imper. Orientale, Recueil des Medailles, des empereurs*, "Memoirs for the history of France, &c." He died in 1738.

BARREL, in commerce, a round vessel, extending more in length than in breadth, made of wood, in form of a little tun. It serves for holding several sorts of merchandize.

BARREL is also a measure of liquids. The English barrel, wine-measure, contains the eighth part of a tun, the fourth part of a pipe, and one half of a hog-head; that is to say, it contains 31½ gallons: a barrel, beer-measure, contains 36 gallons; and, ale-measure, 32 gallons. The barrel of beer, vinegar, or liquor preparing for vinegar, ought to contain 34 gallons, according to the standard of the ale-quart.

BARREL also denotes a certain weight of several merchandizes, which differs according to the several commodities. A barrel of Essex butter weighs 106 pounds; and of Suffolk butter, 256 pounds. The barrel of herrings ought to contain 32 gallons wine-measure, which amount to about 28 gallons old standard, containing about 1000 herrings. The barrel of salmon must contain 42 gallons; the barrel of eels the same. The barrel of soap must weigh 256 lb.

BARREL, in mechanics, a term given by watch-makers to the cylinder about which the spring is wrapped; and by gun-smiths to the cylindrical tube of a gun, pistol, &c. through which the ball is discharged.

BARREL, in anatomy, a pretty large cavity behind the tympanum of the ear, about four or five lines deep, and five or six wide.

Thus-

Thundering BARRELS, in the military art, are filled with bombs, grenades, and other fire-works, to be rolled down a breach.

BARRENESS, the fame with sterility *.

BARRETRY, in law, is the offence of frequently exciting and stirring up suits and quarrels between his majesty's subjects, either at law or otherwise. The punishment for this offence, in a common person, is by fine and imprisonment: but if the offender (as is too frequently the case) belongs to the profession of the law, a barrer who is thus able as well as willing to do mischief ought also to be disabled from practising for the future. And indeed it is enacted by statute 12 Geo. I. c. 29. that if any one, who hath been convicted of forgery, perjury, subornation of perjury, or common barrety, shall practise as an attorney, solicitor, or agent, in any suit; the court, upon complaint, shall examine it in a summary way; and, if proved, shall direct the offender to be transported for seven years. Hereunto also may be referred another offence, of equal malignity and audaciousness; that of suing another in the name of a fictitious plaintiff, either one not in being at all, or one who is ignorant of the suit. This offence, if committed in any of the king's superior courts, is left, as a high contempt, to be punished at their discretion. But in courts of a lower degree, where the crime is equally pernicious, but the authority of the judges not equally extensive, it is directed by statute 8 Eliz. c. 2. to be punished by six months imprisonment, and treble damages to the party injured.

BARRICADE, or *BARRICADO*, a military term for a fence formed in haste with vessels, baskets of earth, trees, pallisades, or the like, to preserve an army from the shot or assault of the enemy.—The most usual materials for barricades consist of pales or stakes, crossed with battoons, and shod with iron at the feet; usually set up in passages or breaches.

BARRICADE, in naval architecture, a strong wooden rail, supported by stanchions, extending across the foremost part of the quarter-deck. In a vessel of war, the vacant spaces between the stanchions are commonly filled with rope-matts, cork, or pieces of old cable; and the upper part, which contains a double rope-netting above the rail, is stuffed with full hammocks to intercept the motion, and prevent the execution of small-shot in time of battle.

BARRIER, in fortification, a kind of fence made at a passage, retrenchment, &c. to stop up the entry thereof. It is composed of great stakes, about four or five feet high, placed at the distance of eight or ten feet from one another, with transoms, or over-thwart rafters, to stop either horse and foot, that would enter or rush in with violence: in the middle is a moveable bar of wood, that opens or shuts at pleasure. A barrier is commonly set up in a void space, between the citadel and the town, in half moons, &c.

BARREERS, signifies that which the French call *jeu de barres*, i. e. *palestra*; a martial exercise of men armed and fighting together with short swords, within certain bars or rails which separated them from the spectators: it is now disused in this country.

BARRING A VEIN, in farriery, an operation performed upon the veins of a horse's legs, and other parts of his body, with intent to stop the course, and lessen the quantity, of the malignant humours that pre-

vail there.

BARRINGTON. See *SHUTE*.

BARRISTER, is a counsellor learned in the law, admitted to plead at the bar, and there to take upon him the protection and defence of clients. They are termed *jurisconsulti*; and in other countries called *licentiati in jure*: and anciently barristers at law were called *apprentices* of the law, in Latin *apprenticij juris nobilitores*. The time before they ought to be called to the bar, by the ancient orders, was eight years, now reduced to five; and the exercises done by them (if they were not called *ex gratia*) were twelve grand moots performed in the inns of Chancery in the time of the grand readings, and 24 petty moots in the term times, before the readers of the respective inns: and a barrister newly called is to attend the six (or four) next long vacations the exercise of the house, *viz.* in Lent and Summer, and is thereupon for those three (or two) years styled a *vacation barrister*. After they are called *utter barristers*, i. e. pleaders *ouster* the bar, to distinguish them from benchers, or those that have been readers, who are sometimes admitted to plead within the bar, as the king, queen, or prince's counsel are.

BARROS (John), a celebrated Portuguese historian, born at Visco, in 1496. He was educated at the court of king Emanuel, among the princes of the blood, and made a great progress in Greek and Latin. The Infant John, to whom he attached himself, and became preceptor, having succeeded the king his father in 1521, Barros obtained a place in this prince's household; and in 1522, was made governor of St George del Mina, on the coast of Guinea. Three years after, the king having recalled him to court, made him treasurer of the Indies, and this post inspired him with the thought of writing his history; for which purpose he retired to Pompos, where he died, in 1570. His history of Asia and the Indies is divided into decades; the first of which he published in 1552, the second in 1553, and the third in 1563; but the fourth decade was not published till the year 1615, when it appeared by order of King Philip III. who had the manuscript purchased of the heirs of John Barros. Several authors have continued it, so that we have at present 12 decades. He left many other works; some of which have been printed, and others remain in manuscript.

BARROW (Isaac), an eminent mathematician and divine, of the last century, was the son of Mr Thomas Barrow a linen draper in London, where he was born, in 1630. He was at first placed at the charter-house school, for two or three years; where his behaviour afforded but little hopes of success in the profession of a scholar, he being fond of fighting, and promoting it among his school-fellows: but being removed from thence, his disposition took a happier turn; and having soon made a great progress in learning, he was admitted a pensioner of Peter house, in Cambridge. He now applied himself with great diligence to the study of all parts of literature, especially to that of natural philosophy. He afterwards turned his thoughts to the profession of physic, and made a considerable progress in anatomy, botany, and chemistry; after this he studied chronology, astronomy, and geometry. He then travelled into France and Italy, and in a voy-

Barrow.

Barrow.

age from Leghorn to Smyrna, gave a proof of his bravery; for the ship being attacked by an Algerine pirate, he staid upon deck, and with the greatest intrepidity fought, till the pirate, perceiving the stout resistance the ship made, sheered off and left her (a).

At Smyrna he met with a most kind reception from Mr Bretton, the English consul, upon whose death he afterwards wrote a Latin elegy. From thence he proceeded to Constantinople, where he received the like civilities from Sir Thomas Bendish the English ambassador, and Sir Jonathan Dawes, with whom he afterwards preserved an intimate friendship. At Constantinople he read over the works of St Chryostom, once bishop of that see, whom he preferred to all the other fathers. When he had been in Turkey somewhat more than a year, he returned to Venice. From thence he came home in 1659, through Germany and Holland; and was episcopally ordained by bishop Brownrig. In 1660, he was chosen to the Greek professorship at Cambridge. When he entered upon this province, he intended to have read upon the tragedies of Sophocles; but he altered his intention, and made choice of Aristotle's rhetoric. These lectures having been lent to a friend who never returned them, are irrecoverably lost. July the 16th, 1662, he was elected professor of geometry in Gresham college, by the recommendation of Dr Wilkins, master of Trinity college, and afterwards bishop of Chester. Upon the 20th of May, 1663, he was elected a fellow of the Royal Society, in the first choice made by the council after their charter. The same year the executors of Mr Lucas having, according to his appointment, founded a mathematical lecture at Cambridge, they fixed upon Mr Barrow for the first professor; and tho' his two professorships were not inconsistent with each other, he chose to resign that of Gresham college, which he did May the 20th, 1664. In 1669, he resigned his mathematical chair to his learned friend Mr Isaac Newton, being now determined to give up the study of mathematics for that of divinity. Upon quitting his professorship, he was only a fellow of Trinity college, till his uncle gave him a small sinecure in Wales, and Dr Seth Ward bishop of Salisbury conferred upon him a prebend in his church. In the year 1670, he was created doctor in divinity by mandate; and, upon the promotion of Dr Pearson master of Trinity college to the see of Chester, he was appointed to succeed him by the king's patent bearing date the 13th of February 1672. When the king advanced him to this dignity, he was pleased to say, "he had given it to the best scholar in England." His majesty did not speak from report, but from his own knowledge; the doctor being then his chaplain, he used often to converse with him, and in his humorous way, to call him an "unfair preacher," because he exhausted

every subject, and left no room for others to come after him. In 1675, he was chosen vicechancellor of the university.—The doctor's works are very numerous, and such as do honour to the English nation. They are, 1. Euclid's Elements. 2. Euclid's Data. 3. Optical Letters, read in the public school of Cambridge. 4. Thirteen Geometrical Letters. 5. The Works of Archimedes, the four Books of Apollonius's Conic Sections, and Theodorus's Spherics explained in a new Method. 6. A Lecture, in which Archimedes's Theorems of the Sphere and Cylinder are investigated and briefly demonstrated. 7. Mathematical Lectures, read in the public schools of the university of Cambridge; the above were all printed in Latin; and as to his English works, they are printed together in four volumes folio.—"The name of Dr Barrow (says the reverend and learned Mr Grauger) will ever be illustrious for a strength of mind, and a compass of knowledge that did honour to his country. He was unrivalled in mathematical learning, and especially in the sublime geometry; in which he has been excelled only by one man, and that man was his pupil, the great Sir Isaac Newton. The same genius that seemed to be born only to bring hidden truths to light, to rise to the heights or descend to the depths of science, would sometimes amuse itself in the flowery paths of poetry, and he composed verses both in Greek and Latin. He at length gave himself up entirely to divinity; and particularly to the most useful part of it, that which has a tendency to make men wiser and better. He has, in his excellent sermons on the Creed, solved every difficulty and removed every obstacle that opposed itself to our faith, and made divine revelation as clear as the demonstrations in his own Euclid. In his sermons he knew not how to leave off writing till he had exhausted his subject; and his admirable Discourse on the Duty and Reward of Bounty to the Poor, took him up three hours and an half in preaching. This excellent person, who was a bright example of Christian virtue, as well as a prodigy of learning, died on the 4th of May 1677, in the 47th year of his age;" and was interred in Westminster abbey, where a monument, adorned with his bust, was soon after erected, by the contribution of his friends.

BARROWS, in British topography, artificial hills or mounds, met with in many parts of Britain, and supposed to have been Roman tumuli, or sepulchral monuments of the ancient Britons. They are either of stones heaped up, or of earth. For the former, more generally known by the name of *cairns*, see CAIRNS.—Of the latter Dr Plott takes notice of two forts in Oxfordshire: one placed on the military ways; the other in the fields, meadows, or woods; the first fort doubtless of Roman erection, the other more probably erected by the Britons or Danes. We have an

exa-

(a) There is another anecdote told of him, which not only shewed his intrepidity, but an uncommon goodness of disposition, in circumstances where an ordinary share of it would have been probably extinguished. He was once in a gentleman's house in the country, where the necessary was at the end of a long garden, and consequently at a great distance from the room where he lodged: as he was going to it before day, for he was a very early riser, a fierce mastiff, who used to be chained up all day, and let loose at night for the security of the house, perceiving a strange person in the garden at that unseasonable time, set upon him with great fury. The doctor caught him by the throat, threw him, and lay upon him; and whilst he kept him down, considered what he should do in that exigence: once he had a mind to kill him; but he altered this resolution, upon recollecting that this would be unjust, since the dog did only his duty, and he himself was in fault for rambling out of his room before it was light. At length he called out so loud, that he was heard by some of the house, who came presently out, and freed the doctor and the dog from the danger they were both in.

examination of the barrows in Cornwall by Dr Williams, in the Phil. Trans. N^o 458. from whose observations we find that they are composed of foreign or adventitious earth; that is, such as does not rise on the place, but is fetched from some distance. Monuments of this kind are also very frequent in Scotland. On digging into the barrows, urns have been found in some of them, made of calcined earth, and containing burnt bones and ashes; in others, stone chests containing bones entire; in others, bones neither lodged in chests nor deposited in urns. These tumuli are round, not greatly elevated, and generally at their basis surrounded with a foss. They are of different sizes; in proportion, it is supposed, to the greatnefs, rank, and power, of the deceased person.

Ancient Greece and Latium concurred in the same practice with the natives of this island. Patroclus among the Greeks, and Hector among the Trojans, received but the same funeral honours with our Caledonian heroes; and the ashes of Dercennus the Laurentine monarch had the same simple protection. The urn and pall of the Trojan warrior might perhaps be more superb than those of a British leader: the rising monument of each had the common materials from our mother earth.

The snowy bones his friends and brothers place,
With tears collected, in a golden vase.
The golden vase in purple palls they roll'd
Of softest texture and inwrought with gold.
Last o'er the urn the sacred earth they spread,
And rais'd a tomb, memorial of the dead.

Pope's Homer's Iliad, xxiv. 1003.

Or, as it is more strongly expressed by the same elegant translator, in the account of the funeral of Patroclus;

High in the midst they heap the swelling bed
Of rising earth, memorial of the dead. *Ib. xxiii. 319.*

BARROW, in the salt-works, are wicker-cases, almost in the shape of a fugar-loaf, wherein the salt is put to drain.

BARRULET, in heraldry, the fourth part of the bar, or the one half of the closet: is an usual bearing in coat-armour.

BARRULY, in heraldry, is when the field is divided bar-ways, that is, across from side to side, into several parts.

BARRY (Girald), commonly called *Giraldus Cambrensis*, i. e. *Girald of Wales*, an historian and ecclesiastic in the reigns of Henry II. and Richard I. was born at the castle of Mainarper, near Pembroke, A. D. 1146. By his mother he was descended from the princes of South Wales; and his father, William Barry, was one of the chief men of that principality. Being a younger brother, and intended for the church, he was sent to St David's, and educated in the family of his uncle, who was bishop of that see. He acknowledges, in his history of his own life and actions, that in his early youth he was too playful; but being severely reproached for it by his preceptors, he became a very hard student, and greatly excelled all his school-fellows in learning. When he was about 20 years of age, he was sent, A. D. 1166, for his further improvement, to the university of Paris; where he continued three years, and became, according to his own account, a most excellent rhetorician; which rendered him very famous.

VOL. II.

On his return into Britain, he entered into holy orders, and obtained several benefices both in England and Wales. Observing, with much concern, that his countrymen, the Welsh, were very backward in paying the tithes of wool and cheefe, which he was afraid would involve them in eternal damnation, he applied to Richard archbishop of Canterbury, and was appointed his legate in Wales for rectifying that disorder, and for other purposes. He executed this commission with great spirit; excommunicating all, without distinction, who refused to save their souls by surrendering the tithes of their cheefe and wool. Not satisfied with enriching, he also attempted to reform, the clergy; and dilated the archdeacon of Brechin to the archbishop, for the unpardonable crime of matrimony; and the poor old man, refusing to put away his wife, was deprived of his archdeaconry; which was bestowed upon our zealous legate. In discharging the duties of this new office, he acted with great vigour, which involved him in many quarrels; but, if we may believe himself, he was always in the right, and always victorious. His uncle, the bishop of St David's, dying A. D. 1176, he was elected his successor by the chapter: but this election having been made without the permission, and contrary to the inclination of Henry II. our author prudently declined to insist upon it, and went again to Paris to prosecute his studies, particularly in the civil and canon law, and theology. He speaks with great raptures of the prodigious fame he acquired by his eloquent declamations in the schools, and of the crowded audiences who attended them, who were at a loss to know whether the sweetness of his voice, the beauty of his language, or the irresistible force of his arguments, were most to be admired. Having spent about four years at Paris, he returned to St David's; where he found every thing in confusion; and the bishop being expelled by the people, he was appointed administrator by the archbishop of Canterbury, and governed the diocese in that capacity to A. D. 1184, when the bishop was restored. About the same time he was called to court by Henry II. appointed one of his chaplains, and sent into Ireland, A. D. 1185, with Prince John. By this prince he was offered the united bishoprics of Femes and Leighlin; but declined them, and employed his time in collecting materials for his Topography of Ireland, and his History of the conquest of that island. Having finished his Topography, which consisted of three books, he published it at Oxford, A. D. 1187, in the following manner, in three days. On the first day he read the first book to a great concourse of people, and afterwards entertained all the poor of the town; on the second day he read the second book, and entertained all the doctors and chief scholars; and, on third day, he read the third book, and entertained the younger scholars, soldiers, and burgeses. "A most glorious spectacle! (says he) which revived the ancient times of the poets, and of which no example had been seen in England." He attended Baldwin archbishop of Canterbury, in his progress through Wales, A. D. 1186, in preaching a croisade for the recovery of the Holy Land; in which, he tells us, he was far more successful than the primate; and particularly, that the people were prodigiously affected with his Latin sermons, which they did not understand, melting into tears, and coming in crowds to take the cross. Barfalli.Barfalli
Barfalli

though Henry II. as our author assures us, entertained the highest opinion of his virtues and abilities; yet he never would advance him to any higher dignity in the church, on account of his relation to the princes and great men of Wales. But on the accession of Richard I. (A. D. 1189), his prospects of preferment became better: for he was sent for by that prince into Wales to preserve the peace of that country, and was even joined in commission with William Longchamp, bishop of Ely, as one of the regents of the kingdom. He did not, however, improve this favourable opportunity; refusing the bishoprick of Bangor in A. D. 1190, and that of Landaff the year after, having fixed his heart on the see of St David's, the bishop of which was very old and infirm. In A. D. 1192, the state of public affairs, and the course of interest at court, became so unfavourable to our author's views, that he determined to retire. At first he resolved to return to Paris to prosecute his studies; but meeting with some difficulties in this, he went to Lincoln, where William de Monte read lectures in theology with great applause. Here he spent about six years in the study of divinity, and in composing several works. The see of St David's, which had long been the great object of his ambition, became vacant, A. D. 1198, and brought him again upon the stage. He was unanimously elected by the chapter; but met with so powerful an adversary in Hubert archbishop of Canterbury, (who opposed his promotion with great violence), that it involved him in a litigation, which lasted five years, cost him three journeys to Rome, at a great expence, and in which he was at last defeated, A. D. 1203. Soon after this he retired from the world, and spent the last 17 years of his life in a studious privacy, composing many books, of which we have a very correct catalogue in the *Biographia Britannica*. That Girald of Wales was a man of uncommon activity, genius, and learning, is undeniable; but these and his other good qualities were much tarnished by his insufferable vanity, which must have been very offensive to his contemporaries, as it is highly disgusting to his readers.

BARRY, in heraldry, is when an escutcheon is divided bar-ways, that is, across from side to side, into an even number of partitions, consisting of two or more tinctures, interchangeably disposed: it is to be expressed in the blazon by the word *barry*, and the number of pieces must be specified; but if the divisions be odd, the field must be first named, and the number of bars expressed.

BARRY-Bendy is when an escutcheon is divided evenly, bar and bend-ways, by lines drawn transverse and diagonal, interchangeably varying the tinctures of which it consists.

BARRY-Pily is when a coat is divided by several lines drawn obliquely from side to side, where they form acute angles.

BARSALE, a kingdom of Africa, bordering on the river Gambia, inhabited by a tribe of negroes called *Jalaffi*. The government of this kingdom is a most despotic monarchy; all people being obliged to prostrate themselves on the earth when any of the royal family makes his appearance. In time of war, every soldier has his share of the booty, and the king but a certain proportion, which is moderate, considering that if he pleased he might keep the whole. The kingdom

is divided into a number of provinces, over which governors called *bumeys* are appointed by the king. These bumeys are absolute within their jurisdictions; but they seldom carry their prerogative so far as to incur the dislike of the people, which would quickly prove fatal to them. The Mahometan religion is professed by the king and his court; though little regard is paid to that part of the impostor's creed which forbids the use of wine; for the king cannot live without brandy, nor is he ever more devout than when he is drunk. When his majesty is in want of brandy or other necessaries, he sends to beg of the governor of James-fort that he will dispatch a boat with the merchandize he has occasion for; and to purchase this he plunders the neighbouring towns, and seizes a certain number of his subjects whom he sells for slaves to the Europeans in exchange for their commodities. This is his method of supplying himself if he happens to be at peace with his neighbours; for which reason the people are never so happy as when at war; and hence they pursue war with great vigour, and continue it with obstinacy.—The general dress of the people is a kind of loose callicoe surplice, that hangs down below the knee; which they sometimes plait about the waist in a very agreeable manner. They wear a great number of gold trinkets in their hair, ears, noses, and round their necks, arms, and legs; but the women especially are fond of these ornaments. The king of Barfalli, whom Moore saw in 1732, had a prodigious number of women: but when he went abroad he was seldom attended by more than two, who seemed to be dressed out in the whole finery and jewels of the seraglio. He had likewise a number of brethren; but it was seldom that he deigned to speak to them: if ever he did them that honour, they were forced to treat him with the same respect as other subjects, and fall prostrate on the earth the moment they came into his presence, notwithstanding they were the presumptive heirs of the crown. It is indeed usual for the king's children to dispute the right of succession with his brethren, and the longest sword generally carries away the prize.

BARSANTI (Francisco), an eminent musical performer and composer, was born at Lucca about the year 1690. He studied the civil law in the university of Padua; but, after a short stay there, chose music for his profession. Accordingly he put himself under the tuition of some of the ablest masters in Italy; and having attained to a considerable degree of proficiency in the science of practical composition, took a resolution to settle in England, and came thither with Geminiani, who was also a Luccese, in the year 1714. He was a good performer on the hautboy, and also on the flute; in the former capacity he found employment in the opera band, and in the latter derived considerable advantages by teaching. He published, with a dedication to the earl of Burlington, six solos for a flute with a thorough-bass, and afterwards six solos for a German flute and a bass. He also made into sonatas, for two violins and a bass, the first six solos of Geminiani. He continued many years a performer at the opera-house: at length, reflecting that there was a prospect of advantage for one of his profession in Scotland, he went thither; and, with greater truth than the same is asserted of David Rizzo, may be said to have meliorated the music of this country, by collecting

ting and making basses to a great number of the most popular Scots tunes. About the year 1750 Barfanti returned to England; but, being advanced in years, he was glad to be taken into the opera band as a performer on the tenor violin; and in the summer season into that of Vauxhall. At this time he published 12 concertos for violins; and shortly after, *Sci Antifone*, in which he endeavoured to imitate the style of Palestrina, and the old composers of motets: but from these publications so little profit resulted, that, towards the end of his life, the industry and economy of an excellent wife, whom he had married in Scotland, and the studies and labours of a daughter, whom he had qualified for the profession of a singer, but who is now an actress at Covent-Garden, were his chief support.

BARTAS (William de Saluste du), a French poet, who lived in the 16th century. He was employed by Henry IV. of France in England, Denmark, and Scotland; and commanded a troop of horse in Gascony, under the *marchal de Martignan*. He was a Calvinist; and died in 1590, aged 46. He wrote a great number of poems; the most famous of which are, 1. *The Week*, or the Creation of the World, in seven books. 2. *The Poem of Judith*; and 3. *The Battle of Ivry*, gained by Henry IV. in 1590. Du Bartas wrote in a bombast style.

BARTER, or **TRUCK**, is the exchanging of one commodity for another. The word comes from the Spanish *barator*, to deceive or circumvent in bargaining, perhaps because those who deal this way usually endeavour to over-reach one another.

To transact properly, the price of one of the commodities, and an equivalent quantity of the other, must be found either by practice, or by the rule of three.

Quest. 1. How many pounds of cotton, at 9 d. per lb. must be given in barter for 13 C. 3 Q. 14 lb. of pepper, at 2 l. 16s. per C.?

The value or price of the goods received and delivered in barter being always equal, it is obvious that the product of the quantities received and delivered, multiplied in their respective rates, will be equal.

Hence arises a rule which may be used with advantage in working several questions; namely, Multiply the given quantity and rate of the one commodity, and the product divided by the rate of the other commodity quotes the quantity sought; or divided by the quantity quotes the rate.

Quest. 2. How many yards of linen, at 4 s. per yard, should I have in barter for 120 yards of velvet, at 15 s. 6d.?

BARTH, or **BART** (John), a brave fisherman of Dunkirk, who rose to the rank of an admiral; and is celebrated for his signal valour and naval exploits, in the annals of France. He died in 1702, aged 51.

BARTHIUS (Gaspard), a very learned and copious writer, born at Cultrin in Brandenburg, the 22^d of June 1576. Mr Baillet has inserted him in his *Eruditionis Celebres*; where he tells us, that at 12 years of age he translated David's Psalms into Latin verse of every measure, and published several Latin poems. Upon the death of his father (who was professor of civil law at Francfort, counsellor to the elector of Brandenburg, and his chancellor at Cultrin), he was sent to Gotha, then to Eisenach, and afterwards, according to custom, went through all the different universities in Germany. When he had finished his studies, he began his travels; he visited Italy, France, Spain, England, and Holland, improving himself by the conversation and works of the learned in every country. He studied the modern as well as ancient languages, and his translations from the Spanish and French shew that he was not content with a superficial knowledge. Upon his return to Germany, he took up his residence at Leipzig, where he led a retired life, his passion for study having made him renounce all sort of employment. He wrote a vast number of books; the principal of which are, 1. His *Adversaria*, a large volume in folio; the second and third volumes of which he left in manuscript. 2. A Translation of *Aeneas Gazæus*. 3. A large volume of Notes upon Claudian, in 4to. 4. Three large volumes upon Statius; &c. He died at Leipzig, in 1658, aged 71.

BARTHOLINUS (Caspar), a learned physician and anatomist in the 17th century, was born at Malmoe,

Bartholomew.

a town in the province of Schonen, which then belonged to Denmark. At three years of age he had such a quick capacity, that in 14 days he learned to read; and in his 13th year he composed Greek and Latin orations, and pronounced them in public. When he was about 18, he went to the university of Copenhagen, and afterwards studied at Rostock and Wirtemberg. He next set out upon his travels; during which he neglected no opportunity of improving himself at the different universities to which he came, and every where receiving marks of respect. He was in 1613 chosen professor of physic in that university, which he enjoyed 11 years; when, falling into a dangerous illness, he made a vow, that if it should please God to restore him, he would solely apply himself to the study of divinity. He recovered, and kept his word; and soon after obtained the professorship of divinity, and the canonry of Roschild. He died on the 13th of July 1629, after having written several small works, chiefly on metaphysics, logic, and rhetoric.

BARTHOLINUS (Thomas), a celebrated physician, son of the former, was born at Copenhagen in 1616. After studying some years in his own country, he in 1637 went to Leyden, where he studied physic during three years. He then travelled into France; and resided two years at Paris and Montpellier, in order to improve himself under the famous physicians of those universities. Afterwards going to Italy, he continued three years at Padua; and at length went to Basil, where he obtained the degree of doctor of philosophy. Soon after, he returned to Copenhagen; where, in 1647, he was appointed professor of the mathematics; and next year was nominated to the anatomical chair, an employment better suited to his genius and inclination; which he discharged with great assiduity for 13 years, and distinguished himself by making several discoveries with respect to the lacteal veins and lymphatic vessels. His close application, however, having rendered his constitution very infirm, he, in 1661, resigned his chair; but the king of Denmark allowed him the title of *honorary professor*. He now retired to a little estate he had purchased at Hagested, near Copenhagen, where he hoped to have spent the remainder of his days in peace and tranquillity; but his house being burnt in 1650, his library, with all his books and manuscripts, was destroyed. In consideration of this loss the king appointed him his physician, with a handsome salary, and exempted his land from all taxes; the university of Copenhagen also appointed him their librarian; and, in 1675, the king did him the honour to give him a seat in the grand council of Denmark. He wrote, 1. *Anatomia Caspari Bartholini Parentis novis Observationibus privum locupletata*, 8vo. 2. *De Morbis in Natura & Medicina*, 4to. 3. *De Armillis Veterum, præsertim Danorum Schedion*, 8vo; and several other works. This great man died on the 4th of December 1680.

St BARTHOLOMEW'S DAY, a festival of the Christian church, celebrated on the 24th of August. St Bartholomew was one of the twelve Apostles; and is esteemed to be the same as Nathanael, one of the first disciples that came to Christ.

It is thought this apostle travelled as far as India, to propagate the gospel; for Eusebius relates, that a famous philosopher and Christian, named *Pantenus*,

desiring to imitate the apostolical zeal in propagating the faith, and travelling for that purpose as far as India, found there, among those who yet retained the knowledge of Christ, the gospel of St Matthew, written, as the tradition asserts, by St Bartholomew, one of the twelve apostles, when he preached the gospel in that country. From thence he returned to the more northern and western parts of Asia, and preached to the people of Hierapolis; then in Lycaonia; and lastly at Albania, a city upon the Caspian Sea; where his endeavours to reclaim the people from idolatry were crowned with martyrdom, he being (according to some writers) slain alive, and crucified with his head downwards.—There is mention made of a Gospel of St Bartholomew, in the preface to Origen's Homilies on St Luke, and in the preface to St Jerom's commentary on St Matthew: but it is generally looked upon as spurious, and is placed by pope Gelasius among the apocryphal books.

BARTHOLOMEW (St), one of the Caribbee islands belonging to the French, who sent a colony thither in 1648. It is about 24 miles in compass, and has a good haven. W. Long. 62. 15. N. Lat. 18. 6.

BARTHOLOMITES, a religious order founded at Genoa in the year 1307; but the monks leading very irregular lives, the order was suppressed by pope Innocent X. in 1650, and their effects were confiscated. In the church of the monastery of this order at Genoa is preserved the image which it is pretended Christ sent to king Abgarus. See **ABGARUS**.

BARTOLOCCI (Julius), a learned monk, and professor of Hebrew at Rome, was born at Celano, in 1613; and distinguished himself by writing an excellent Hebrew and Latin catalogue of the Hebrew writers and writings, in 4 vols folio, a continuation of which was performed by Imbonati his disciple. He died in 1687.

BARTOLOMEO (Francisco), a celebrated painter, born at Savignano, a village 10 miles from Florence, in the year 1469, was the disciple of Cosimo Rosselli, but was much more beholden to the works of Leonarda da Vinci for his extraordinary skill in painting. He was well versed in the fundamentals of design. Raphael, after quitting the school of Perugino, applied to this master; and under him studied the rules of perspective, with the art of managing and uniting his colours. In the year 1500, he turned Dominican friar; and some time after was sent by his superiors to the convent of St Martin, in Florence. He painted both portraits and histories; but his scrupulous conscience would hardly ever suffer him to draw naked figures, though no body understood them better. He died in 1517, aged 48.

BARTON, a town of Lincolnshire, seated on the river Humber, where there is a considerable ferry to pass over into Yorkshire. W. Long. 0. 10. N. Lat. 53. 40.

BARTSIA, **PAINTED CUP**; a genus of the angiospermia order, belonging to the didymia class of plants. Of this there are two species: the viscosa, or marshy; and the alpina. The first, called also *yellow marsh eye-bright*, was found by Mr Lightfoot in bogs and marshy places about Loch-Goyl, near Loch-Long in the district of Cowal in Argyleshire. The plant is about ten or twelve inches high, with an erect stalk downy and unbranched: the leaves are sessile, spear-shaped, and

Bartholomew
Bartholomew

uch
lites.

a little viscous; the flowers are yellow, and the plant dries black. It is likewise found in marshy places in Cornwall in England. The alpina, or mountain eye-bright cow-wheat, hath heart-shaped leaves placed opposite, and bluntly ferrated, with purple blossoms in leafy spikes. It is likewise a native of Britain, and is found near rivulets in hilly countries. Sheep and goats eat it.

BARUCH (the prophecy of), one of the apocryphal books, subjoined to the canon of the Old Testament. Baruch was the son of Neriah, who was the disciple and amanuensis of the prophet Jeremiah. It has been reckoned part of Jeremiah's prophecy, and is often cited by the ancient fathers as such. Josephus tells us, Baruch was descended of a noble family; and it is said, in the book itself, that he wrote this prophecy at Babylon; but at what time is uncertain. It is difficult to determine in what language this prophecy was originally written. There are extant three copies of it; one in Greek, the other two in Syriac; but which of these, or whether any one of them, be the original, is uncertain.

BARULES, in church-history, certain heretics, who held, that the Son of God had only a phantom of a body; that souls were created before the world, and that they lived all at one time.

BARUTH, an ancient town of Turkey in Syria, with a Christian church of the Nestorian persuasion. It is situated in a fine fertile soil, but is inconsiderable now to what it was formerly. E. Long, 34. 20. N. Lat. 33. 30.

BARUTH, an Indian measure, containing 17 gantans: It ought to weigh about three pounds and an half English avoirdupois.

BARYTONUM, in the Greek grammar, denotes a verb, which having no accent marked on the last syllable, a grave accent is to be understood. In Italian music, *barytono* answers to our common pitch of bass.

BAS CHEVALIER. See **BACHELOR**.

BAS-Relief. See **BASSO-Relievo**.

BASALTES, in natural history, is a heavy hard stone, chiefly black or green, consisting of prismatic crystals, the number of the sides of which is uncertain. It is called by English miners *cockle*, and by Germans *fehrl*. Its specific gravity is to that of water, as 3000 or upwards to 1000. It is considered by Wallerius as a species of the *cornues*, or *horn-rock*. Cronstedt enumerates it among the earths which he called *garnet earths*. Basaltes frequently contains iron; and consists either of particles of an indeterminate figure, or of a sparry, striated, or fibrous texture. Black basaltes is called *lapis lydianus*, and is used as a touchstone to shew the colours of metals. Basaltes has a stinty hardness, is insoluble by acids, and is fusible by fire.—The most remarkable quality of this is its figure, being never found in strata, like other marbles; but always standing up in the form of regular angular columns, composed of a number of joints, one placed on and nicely fitted to another, as if formed by the hands of a skilful workman. See Plate LV. fig. 9. The basaltes was originally found in columns in Ethiopia, in fragments in the river Tmolus, and some other places: we now have it frequently, both in columns and small pieces, in Spain, Russia, Poland, near Dresden, and in Silesia; but the noblest store in the world seem to be

Basaltes,
Basan.

that called the *Giant's Causeway*, in Ireland; and Staffa, one of the Western isles of Scotland. In Ireland it rises far up in the country, runs into the sea, crosses its bottom, and rises again on the opposite land. See **GIANTS Causeway**, and **STAFFA**.

The origin and formation of basaltes has much puzzled the world; but we may consider, that many of the known fossil bodies have a property, like salts, of arranging themselves into different figures at the time of their first coalescence into a mass. This is from the same laws in nature with that of salts; and we are well assured by daily experience, that crystal and spar, according to this natural determination, ever form regularly angular figures, when all the proper accidents have concurred to their concretion. The most common figures of crystals are the hexangular columns; and those of spar, either trigonal columns or parallelepipeds. The combinations and mixture of these, in different degrees, may naturally produce mixed figures, according to these degrees; and a third substance, though in itself not disposed by nature to assume or arrange itself into any particular figure, if mixed with these, may be able to spread, extend, and enlarge the figures they concreate into, or otherwise alter them. A mixture of three bodies is, therefore, capable of producing a fourth, of a figure different from any one of the three above; and we find also, by many parallel instances, that the quicker or slower passing off of the fluid from whence bodies are concreted, is capable of altering their figures.

The marble of the Giants-causeway, or any other columns of basaltes, is found to be composed of an admixture of crystal, spar, and earth. The spar may be procured in its own form; and the remaining mass, after the separation of the spar, is found to be pure crystal, and an earth of the clay kind, seeming the same with the black pipe-clay of Northamptonshire and some other places, only much blacker. We know very well what would be the figures of these bodies concreted alone; and may thence deduce what may be the possible consequences of their union, and the different accidents attending their concretions. But the opinion which seems most likely to prevail at present is, that this substance is a crystallization from some kinds of volcanic lava. See **VOLCANO**.

BASAN, (anc. geog.), a territory beyond Jordan, mentioned in scripture. By Josephus, Eusebius, and Jerom, it is called *Batanea*. On the entering of the Israelites into the land of Canaan, the whole of the country beyond Jordan, from that of the Moabites, or Arabia, as far as mount Hermon and Lebanon, was divided into two kingdoms, viz. that of Sihon king of the Amorites, and of Og king of Basan or *Balsan*; the former to the south, and the latter to the north. The kingdom of Sihon extended from the river Arnon and the country of Moab, to the river Jabok; which running in an oblique course from the east, was at the same time the boundary of the Ammonites, as appears from Numb. xxi. 24. and Deuteron. ii. 37. and iii. 16. The kingdom of Sihon fell to the lot of the Reubenites and Gadites, and Basan to the half-tribe of Manasseh. To this was annexed a part of the hilly country of Gilead, and the district of Argob; yet so that Basan continued to be the principal and greatest part: but, after the Babylonish captivity, Basan was subdivided;

Gar-

vided; ſo that only a part was called *Batanea*, or *Baſan*, another *Trachonitis*, a third *Aurunitis*, or *Iturea*, and ſome part alſo *Gaulonitis*; but to ſettle the limits of each of theſe parts is a thing now impoſſible.—Baſhan was a country famous for its paſtures and breed of large cattle.

BASARTSCHICK, a conſiderable town of Romania in Turkey of Europe. It is pretty well built, and hath clean and broad ſtreets; has a great trade; and is ſituated on the river Meritz, in E. Long. 24. 30. N. Lat. 41. 49.

BASARUCO, in commerce, a ſmall baſe coin in the Eaſt Indies, being made only of very bad tin. There are, however, two ſorts of this coin, a good and a bad; the bad is one ſixth in value lower than the good.

BASE, in geometry, the loweſt ſide of the perimeter of a figure: Thus, the baſe of a triangle may be ſaid of any of its ſides, but more properly of the loweſt, or that which is parallel to the horizon. In reſtangled triangles, the baſe is properly that ſide oppoſite to the right angle.

Base of a Solid Figure, the loweſt ſide, or that on which it ſtands.

Base of a Conic Section, a right line in the hyperbola and parabola, ariſing from the common interſection of the ſcant plain and the baſe of the cone.

BASE, in architecture, is uſed for any body which bears another, but particularly for the lower part of a column and pedefal.—The ancients, in the early times of architecture, uſed no baſes. The Doric columns in the temple of Minerva at Athens have none, but ſtand immediately upon the floor of the porch. Columns afterwards came to be ſupported on ſquare pieces called *plinths*, and after that on pedefals. When we ſee a column, of whatever order, on a pedefal, the baſe is that part which comes between the top of the pedefal and the bottom of the ſhaft of the column; when there is no pedefal, it is the part between the bottom of the column and the plinth: ſome have included the plinth as a part of the baſe; but it is properly the piece on which the baſe ſtands, as the column ſtands upon that.—The pedefal alſo has its baſe as well as the column, and the piſaſter. The baſe of columns is differently formed in the different orders; but in general it is compoſed of certain ſpires or circles, and was thence in early times called the *ſpire of a column*. Theſe circles were in this caſe ſuppoſed to represent the folds of a ſnake as it lies rolled up; but they are properly the representations of ſeveral larger and ſmaller rings or circles of iron, with which the trunk of trees which were the ancient columns were ſurrounded to prevent their burſting: theſe were rude and irregular, but the ſculptor who imitated them in ſtone found the way to make them elegant.

BASE, in fortification, the exterior ſide of the polygon, or that imaginary line which is drawn from the flanked angle of a baſtion to the angle oppoſite to it.

BASE, in gunnery, the leaſt ſort of ordnance, the diameter of whoſe bore is $1\frac{1}{4}$ inch, weight 200 pound, length 4 feet, load 5 pound, ſhot $1\frac{1}{2}$ pound wt. and diameter $1\frac{1}{2}$ inch.

BASE, in chemistry. See **BASIS**.

BASE, in law. *Baſe eſtate*, ſuch as baſe tenants have in their hands. *Baſe tenure*, the holding by vil-
