History and Discoveries

Preface and Acknowledgments

This project was begun in 1992, with the first two volumes (The Great Archaeologists) being published in 1999. The three volumes that comprise History and Discoveries conclude the Encyclopedia of Archaeology. When this project was first conceived I drew up a very long list of countries, people, sites, techniques, methods, theories, issues, styles and traditions of archaeology that I thought provided a comprehensive picture of the evolution of archaeology. As in most projects of this magnitude, the Encyclopdia of Archaeology of necessity changed during the protracted and often difficult journey to publication. The result retains my initial goals: to provide the most in-depth, authoritative, and through reference work on the history of archaeology.

What I see in all five volumes, but in particular the three that comprise Histories and Discoveries is simply a watershed in the history of archaeology. Never before has it been possible for us to contemplate the unity and diversity of archaeology on this scale. It is now more often being observed (indeed Bruce Trigger does so in these volumes) that the history of archaeology is beginning to play a significant role in debates about archaeological theory and the philosophy of archaeology. The entries in these volumes provide a wonderful source of inspiration and information for those fundamental debates, the outcomes of which will directly affect the ways in which human beings search for an understanding of themselves.

The five volumes represent over a million words of text and the direct and indirect contributions of hundreds of people around the world. It is appropriate to begin these acknowledgments by recognizing the work of the contributors whose names are to be found in the following pages. This encyclopedia is their work. Many of the entries in History and Discoveries were translated into English from French, German, Russian, and Spanish. Although the names of the translators are listed at the end of each relevant entry, it is also important to acknowledge that their work has broadened and deepened this history of archaeology.

A large number of the contributors to these volumes were identified by the very many colleagues who used their networks to track people down. I was often touched by the willingness of colleagues from around the world to help, indeed some who at very short notice came up with superb contributions because those who had originally been contracted failed to deliver. I owe particular debts of gratitude to Peter Bellwood, Ian Hodder, Gordon Willey, Peter Robertshaw, Scott Raymond, Wil Roebroeks, Steve Shennan, Richard Bradley, Mark Leone, T.G.H. James, Barry Cunliffe, Rosemary Joyce, Henry

Introduction

Many of the points I have wanted to make about the importance and value of the history of archaeology have already been made in the introduction to The Great Archaeologists (the first two volumes of the Encyclopedia of Archaeology). In those first volumes I was concerned mainly with exploring the role of biography in writing the history of archaeology, and in coming to grips with the great diversity in approach taken by the contributors to those volumes. The essays in The Great Archaeologists have attracted considerable attention (most of it very good), but one comment made by an eminent historian of archaeology struck a particular chord. Contemplating the richness of new information about something that he felt we knew reasonably well, he was moved to remark that in recent decades the history of archaeology had really come of age.

I think that he meant this in two ways. First, that archaeologists were now sufficiently confident about the value of their discipline and its perspectives to seek a deeper understanding of its history-an understanding that had the clear potential to challenge disciplinary orthodoxies. Second, that the sheer scale of archaeology practiced at a global scale gave rise to many interesting questions about the unity of the discipline. In the early 1980s Bruce Trigger and Ian Glover pursued some of these questions in two editions of the journal World Archaeology that were devoted to the exploration of "regional traditions" in archaeology. What Trigger and Glover (and the contributors to their project) were keen to establish was whether the diversity of experience among archaeologists and the societies they served had led to real differences in approach and purpose among nations or groups of nations such as "Anglo-Saxon" or "Francophone," "First World," "Second World" or "Third World," "Colonialist" or "Postcolonialist."

While the first two volumes of this encyclopedia amply demonstrated the diversity of personal histories among influential archaeologists and antiquarians over the past four centuries, they pointed to significant commonalities as well. This notion that there are questions, issues, and fundamental activities, such as classification, that lie at the heart of a discipline like archaeology supports the view that it is possible for archaeologists to communicate with each other (however imperfectly) and to share knowledge. This theme of unity in diversity (and the ambiguities that arise from it) is even more strongly supported in the final three volumes of the encyclopedia that together comprise History and Discoveries.

In these volumes we have histories of archaeology as it has been practiced in most parts of the world, biographies of significant archaeologists in addition

A

Abercromby, Lord John (1841-1924)

A Scottish antiquary, the secretary of the society of antiquaries of scotland, and its president from 1913 to 1918, Abercromby is most famous for his typological analyses published in *Bronze Age Pottery of Great Britain and Ireland* (1912).

In 1904 Abercromby used the term *beaker* to describe the decorated, handleless pottery drinking vessels used all over Europe between 4000 and 2000 b.c. He argued that the appearance of beakers in northern and western Europe could only be understood in relation to changes in similar assemblages from southeast and central Europe. While Abercromby's beaker typology remained unchanged until quite recently, his explanation of their uniform spread has been disproved. Abercromby argued for a putative "Beaker folk" who migrated all over Europe with their pottery. It is now thought that it was the pottery style that migrated alone-that the beakers were an interregional and even international style of artifact that were traded over long distances and were widely recognized male status objects used in drinking rituals. Abercromby argued that cultural uniformity meant social and ethnic uniformity-an argument that was later used by some archaeologists to support Nazi ideology in Germany. Nonetheless Abercromby's "new" approach to archaeological evidence (one that still finds support among some archaeologists) was more international than most approaches to the same evidence in England during this time.

Abercromby's influence was virtually confined to Scotland. His bequest to the University of Edinburgh in 1916 endowed the chair of archaeology that still carries his name. vere gordon childe was the first appointment to the Abercromby Chair in 1927, and stuart piggott succeeded him.

abu simbel

Situated in Lower Nubia (Egypt), the site of abu simbel comprises two temples cut from living rock during the reign of the pharaoh Ramses II, thirteenth century b.c. The temples feature major works of sculpture, in particular seated figures of Ramses II and standing figures of Ramses and his queen, Nefertari.

The integrity of the temples was threatened by rising waters of the Nile River because of the construction of the a new Aswan High Dam and the creation of Lake Nasser in the 1960s. In a model of international cooperation, the United Nations Educational, Scientific, and Cultural Organization (UNESCO) made possible a large-scale survey and excavation of sites that were to be inundated by Lake Nasser and, perhaps more spectacularly, the dismantling and reassembly of the temples at a new site created above the water line. The rescue project lasted from 1960 to 1980.

Abydos

A major site in Upper Egypt, Abydos, which lies west of the Nile near al-Balyana, was a royal burial site of the first two dynasties and later a major place for the worship of the god Osiris. Excavation of Abydos was begun at the end of the nineteenth century by Emile-Clément Amélineau, but the site is most directly associated with sir william matthew flinders petrie. Grave sites from the archaic period and stelae and ritual architecture of the nineteenth dynasty have been discovered, and excavations continued at Abydos throughout the twentieth century.

Acosta's career as an archaeologist lasted nearly fifty years, from 1928 to 1975.

The long list of sites and regions where Acosta did fieldwork is impressive: Zacaleu, guatemala; Mountain Cow, belize (with Thompson); monte albán, Monte Negro, and other centers in Oaxaca; chichén ítza; Uxmal; palenque; Tres Zapotes (Veracruz); Cholul; Ixcateogpan (Guerrero); Tenayuca; and teotihuacán. His most important investigations focused on three ancient cities, Monte Albán, Tula, and Teotihuacán, where he spent years doing research. In the course of other projects he discovered the famous mural sequence of drinking figures inside the Great Pyramid of Cholula and at Uxmal (Yucatán). He directed an architectural restoration program that greatly influenced the theory and practice of cultural patrimony conservation in mexico. He discovered

the ceremonial cave under the Pyramid of the Sun at Teotihuacán that probably played a key role in the founding and the general structural plan of that ancient city. His restoration of the Palace of Quetzalpopalotl at Teotihuacán has been considered excessive by some specialists, but it constituted a major success in making a 1,500-year-old building understandable for thousands of visitors.

Acosta's investigations in Oaxaca with Alfonso Caso and ignacio bernal during three decades were fundamental for the development of Mexican archaeology and produced several classic reports, including *The Ceramics of Monte Albán* (1967) and, on Tula, *Revista Mexicana de Estudios Antropologicos.* While Acosta directed his most consequential field seasons at Tula, he was also the field director of Caso's program at Monte Albán.

On the basis of his work at Tula, Acosta's name can be added to the very short list of archaeologists who have rediscovered major ancient civilizations. Acosta proved that ruins at Tula, in the modern Mexican state of Hidalgo, were in fact those of the legendary city of Tollan, capital of the Toltec Empire during the tenth and eleventh centuries a.d. The major part of Acosta's work at Tula was devoted to the excavation and restoration of many of the buildings on the main plaza. These were some of the best investigations of pre-Hispanic architecture ever conducted in Mexico. Acosta's program at Tula functioned as field training for young archaeologists and anthropologists. He died in Mexico City on March 5, 1975.

Adams, Robert McCormick

(1926-)

Born in Chicago and educated in a progressive environment, Robert McCormick Adams developed an interest in archaeology that can be traced to childhood experiences in the American Southwest. He served in the U.S. Navy during World War II and subsequently enrolled at the University of Chicago to study social sciences. In 1950, Adams, with Linda and robert braidwood, participated in an excavation at jarmo in Iraq. During fieldwork there Adams met the social anthropologist Fredrik Barth, and Barth convinced Adams to continue with graduate school. Important intellectual influences on Adams at the University of Chicago came from the social anthropologist Fred Eggan, with his stress on the comparative method, and from Robert Braidwood, who advocated a multidisciplinary approach to prehistoric archaeology. Adams was also influenced by the work of v. gordon childe and his concern with technology, demography, internal social organization, and social evolution. Another critical influence was the New World archaeologist gordon willey, who had done pioneering reconnaissance surveys in the virú valley of peru, using settlement patterns and demography.

In the field of Near Eastern history, Adams worked with the Danish Sumerologist Thorkild Jacobsen, who had worked on archaeological projects sponsored by the University of Chicago's oriental institute. Jacobsen was not only an expert in third millennium b.c. history and the Sumerian language, he was also

an avid reader and writer in the philosophy of history. Adams's interest and training in ecology came in part from his studies and collegial relationships with Sherwood Washburn and Clark Howell in the Department of Anthropology at Chicago and from Washburn's running argument with the social anthropologist Robert Redfield.

Adams received his M.A. at Chicago in 1952, writing on Jarmo pottery and stone vessel industries, and while he was working toward his doctorate, he was appointed to a combined position divided between the Oriental Institute and the Department of Anthropology. Adams received his Ph.D. in 1956 and held this same combined position for the duration of his academic career at Chicago.

Adams undertook fieldwork in mexico and then returned to fieldwork in Iraq in the 1950s and 1960s, where he continued to work until the 1970s when politics made it impossible to continue

PREV NEXT

book *Heartland of Cities: Surveys of Ancient Settlement and Land Use on the Central Floodplain of the Euphrates* (1981) in which Adams established an almanac of modern and ancient climatic conditions and agricultural productivity in Mesopotamia as a natural and technological setting for further investigation. The interaction between human beings and their environment resulted in an early urbanism in which city-states attempted to achieve stability over an often politically autonomous and resilient countryside. As the larger and more centralized states of late antiquity were able to maximize the production of cereals and other crops, they minimized the flexibility of a pastoralist-urban life and increased the potentialities of salinization, which turned land into swamps and brought about a massive demographic decline. A classic scenario of increasing short-term gains at the expense of long-term survival is played out to a sorrowful end.

Adams's work has shown that in all the superficially mundane activities of locating sites, seriating objects, and connecting them to stratified material and reconstructing settlement patterns-the very stuff of archaeology-the subject of social change could be apprehended. Today, archaeologists devise survey projects of great sophistication and detail and through their work have transformed our knowledge of regions throughout the world. Although Willey in Peru and William Sanders and colleagues in Mexico were also pioneers of systematic settlement surveys, Adams's work has arguably had the greatest impact on this form of research. Adams not only explored the relation between environmental and human social systems better than others but also analyzed and dignified the activities of the archaeological worker in two ways that became critical in the late twentieth century, both to archaeologists and to their colleagues.

First embedded in the intellectual milieu of anthropologists and historians and often regarded more as technicians than as thinkers, archaeologists corporately earned respect through the persuasive intellectuality of Adams's work. His research is judged to be an original contribution to social knowledge and, in particular, to social evolutionary theory. Adams's research emanates from arduous fieldwork and the synthesis of disparate fields of expertise whose breadth no one else has been able to match or, it seems, even imagine. Second, Adams's work has never given the impression of being dispassionate scholarship that is disassociated from the world in which his research was done and that has nothing to say to the people of Iraq or to the makers of modern western policy.

In 1984, at the height of his distinguished career at the University of Chicago-where he had been a professor in the Oriental Institute (and its sometime director), professor of anthropology, dean of the division of social sciences, and provost of the university-Robert Adams became secretary of the smithsonian institution in Washington, D.C., and served in that position until his retirement in 1994. While at the Smithsonian, Adams was also on the staff of the Departments of Near Eastern Studies and Anthropology at Johns Hopkins University. After his retirement from the Smithsonian he became adjunct professor in the Department of Anthropology at the University of California, San Diego.

Africa, East, Later

Research on the later archaeology of East Africa has ranged from the need to understand the late Pleistocene and Holocene artifact traditions and linguistic groups in the region (Bower, Nelson, Waibel, and Wandibba 1977; Isaac, Merrick, and Nelson 1972; L.S.B. Leakey 1931, 1935; M.D. Leakey

1945; M.D. Leakey and L.S.B. Leakey 1950; Phillipson 1977a, 1977b, 1985; Soper 1971a, 1971b; Sutton 1966, 1972), the reconstruction of the environmental changes for the period based on analysis of pollen cores from highland lakes and limnological analysis of lakes in the area (Butzer, Isaac, Richardson, and Washbourne Kamau 1972; Isaac, Merrick, and Nelson 1972; Livingstone 1980; Hamilton 1982; Richardson and Richardson 1972), the techniques of artifact making (Kiriama 1986;

questions of terminal-Stone Age/Iron Age population interactions in East Africa in terms that are determined less by implicit assumptions concerning language, culture, and genetics.

Indigenous Archaeologists

Only Kenyan and Tanzanian universities have active archaeology programs in East Africa, although similar programs are offered by history departments. Most indigenous archaeologists in these countries have concentrated on either the terminal-Stone Age or Iron Age periods (Abungu 1989; Kiriama 1984, 1986, 1992; Masao 1979; Mutoro 1987; Onyango Abuje 1976; Wandibba 1977, 1984). Indigenous archaeologists have concentrated on the later periods because most of the lecturers at the universities were more interested in these periods and they tended to encourage their students to undertake projects in their areas of specialization. It should be noted that, first, despite the prominence of East Africa as a cradle of mankind, none of the people conducting research in the early periods taught at local universities, let alone encouraged local students to undertake study projects in this area. Second, the early period has been seen as not being controversial and as not having enough to do with the history of the local populace and the definition of nation states. Thus, local archaeologists have been encouraged to concentrate on the later periods in an effort to negate colonial and racist propaganda that only began with the intrusion of the white man.

Onyango Abuje (1976) and Onyango Abuje and Wandibba (1979) were the first local archaeologists to argue for the local origins of food production. They also maintained that the term *Neolithic,* discarded as not being fit for African food producing societies, should be retained as food producing societies in eastern Africa had the same characteristics as those in Europe. Onyango Abuje (1976) in particular argued for a total indigenous evolution of the East African Neolithic culture, contending that the populations that independently invested in and developed food producing skills were not Caucasoid immigrants but African in origin. He further argued that these people domesticated some livestock and the majority of the crops that are currently grown in Africa. Wandibba (1977, 1980) undertook a reanalysis of the pottery in the Rift Valley of Kenya and showed that the pottery was particular to the given areas where it was found; thus, there was no likelihood of its importation by immigrants. Karega Munene, on the other hand, used an evolutionary-ecological model to argue for a home-grown Neolithic culture. According to him, the domestication of plants and animals was the result of an adaptive response to stress caused by specific historic situations. In other words, the East African population domesticated plants and animals independently as a response to specific local situations and needs.

Even with regard to the Iron Age, local indigenous archaeologists have been involved in disproving the migrationist theories of earlier archaeologists. S. Lwanga-Lunyiigo (1976), for example, argues that Bantu speakers appeared on the East African scene very early and that the postulated expansion from West Africa never took place. He maintains that it is difficult to spot the exact origin of Bantu speakers, that iron smelting was an independent East African innovation, and that the interlacustrine area was the center from which metallurgy, ceramics, and agricultural techniques spread to central and southern Africa. Kiriama (1986, 1987, 1993), on the other hand, has used a technological and contextual approach to argue for the local invention of ironworking techniques. Analyzing iron slag from an early-Iron Age site in Kenya, Kiriama (1987) has shown that there was preheating of furnaces during the prehistoric period, which enabled the ironworkers to attain high furnace temperatures and thus produce high carbon steel. He has also used a contextual approach (Kiriama 1993) to show that various Bantu speakers used their ceramic and iron implements differently. This work negates the argument for common Bantu origin, and Kiriama proposes that the social realm within which ceramics and iron objects were created and used should be studied if we are to understand the origins and spread of ironworking. The social context within which an item of material culture functions can enable one to

Africa, East, Prehistory

Africa is renowned for its diverse and bountiful fossil record of human and nonhuman ancestors that spans some 50 million years, including Eocene primates from the Fayum deposits of Egypt and a sundry group of hominids (members of the family Hominidae, which is the taxonomic family to which humans and their immediate ancestors belong) that made their evolutionary appearance some 5 million years ago in the Middle Awash of Ethiopia. Tracing humans' ancestral beginnings to this region is but

The History of East African Prehistoric Discoveries

In 1893, geologist J.W. Gregory first recognized the contributive importance of East Africa to better understanding the evolutionary history of ancient technologies when he found evidence of “paleoliths” in and around an ancient lake in Maasai country (Cole 1965). In the twentieth century, German entomologist Kattwinkel noted the presence of fossils in 1911 at a rift escarpment known to the Maasai as Olduway, which shortly led German paleontologist Hans Reck to continue work at Olduway (later called olduvai gorge). Reck noticed that important paleontological localities occur where the Side Gorge meets the Main Gorge. But with World War I beginning, his work came to an abrupt halt. When the war came to an end, extensive archeological research resumed across all of Africa, especially in East Africa. Yet the main scientific quest was not to discover more forgotten material cultures; rather, current scientific interests strove to elucidate past climatic events in order to better understand the chronological framework of the fossil and archaeological records that were already known. This is exactly what prompted E.J. Wayland to survey Uganda while he served as the Director of Geological Survey of Uganda. In 1934, he reported an ancient split-pebble industry based on rolled material taken from the Kafu River in western Uganda, which was later extended to include other Ugandan sites, such as Kagera Valley and Nsongezi, by South African archeologist C. van Riet Lowe. It was the nature of the sedimentary record that led Wayland to describe environmental intervals he called “pluvials,” literally meaning *rains,* that he thought would link Europe's four-glacier concept to Africa. Today, the Kafuan industry is not recognized as a legitimate stone-tool technology because the stone tools (split-pebbles) are the result of natural fractures, most likely caused by the river environment from which they were found, and the pluvial concept is long forgotten. Wayland was also responsible for describing the Sangoan and Magosian Middle Paleolithic industries from type-sites also located near the Kafu River; the Sangoan is still recognized as a legitimate industry, but Magosian tools fall within the range of variation of an Acheulean-Levallois techno-complex.

Prior to the time that the Kafuan industry made its debut, another famous paleoanthropologist and prehistorian, l.s.b. leakey, was working fervently at stone tool sites in Kenya, dinosaur sites in Tanzania (then Tanganyika), and hominid-bearing deposits in South Africa. After getting his field techniques down in Tanzania and describing simple stone tool manufacture and more recent stone tool technologies of Kenya, in 1931 he organized an expedition to Olduvai Gorge with the help of Hans Reck. He quickly recognized the significance of the stone tools found in the layer cake stratigraphy deposits that ranges in date from 1.9 million years ago at the base, to 1.8 million years ago at Bed I, to recent at Bed IV. Before long, Leakey was back at Olduvai, and from 1935 to 1958 he and members of his team had many celebrated accomplishments in terms of collecting fossil mammals and plenty of stone tools, but had discovered no stone tool maker. That wouldn't come until 1959 when his wife, mary leakey, discovered Zinjanthropus (*Australopithecus boisei*), a.k.a. the nutcracker man and, as no surprise, Louis's stone tool maker. Over the decades, the meticulous excavations

Early Paleolithic and Middle Paleolithic Industrial Complexes

Until very recently, African simple flake and small pebble tool technologies were vaguely separated into the Early Stone Age (ESA), while the larger bifacially worked cores and flakes were referred to as the Middle Stone Age (MSA); comparable technologies throughout Europe are known as Early Paleolithic (EP) and Middle Paleolithic (MP), respectively. To lessen confusion, ESA and MSA categories are sometimes interposed with the-just as vague-European system of classification. The only practical classification system is one that critically assesses true industrial complexes (e.g., Oldowan, Karari, Developed Oldowan, and Acheulean) or degree of technological innovation, such as J.D. Clark's Mode 1-5 preparative frameworks.

Early Paleolithic (ca. 2.5 million-250,000 years ago; e.g., Oldowan, Developed Oldowan, Karari, Acheulean, Mode 1, and Mode 2)

The earliest flaked stone technology consisting of split cobbles and simple flakes made mostly of trachyte, rhyolite, basalt, and quartz come from the Gona sequence of Ethiopia dated at 2.6 million years ago and the Hadar sequence, both within the Kada Hadar Member of the Hadar Formation, dated at 2.3 million years ago. Although Gona has the oldest known stone tools, the Kada Hadar stone flakes were recovered on surface and in situ where the A.L. 666 maxilla (upper jaw) attributed to early *Homo* was discovered (Kimbel et al. 1996). In addition, stone tools dated at 2.3 million years ago have also been recovered from the Omo deposits in southern Ethiopia and at Lokalalei, West Turkana, from the Nachukui Formation.

Oldowan Industrial Complex-Early Oldowan is a lithic industry based upon artifact assemblages from Bed 1 and Bed 2 at Olduvai Gorge (Leakey 1971). Overall the Oldowan complex consists of modified (deliberate flaked) pieces of stone or battered cobbles that are classified into several types: hammerstones, choppers, scrapers, discoids, polyhedrons, spheroids, subspheroids, burins, and protobifaces. Overall assemblages are classified by artifact type and relative frequency. For instance, typical Oldowan assemblages are localized and consist of 28 to 79 percent choppers made from varied resources (e.g., quartzite and chert) and in proximity to raw sources. Less than 28 percent of choppers for all tools/cores in assemblages may be indicative of a more progressive lithic complex. Two examples that are thought to lead to the Acheulean Industry are:

(1) Developed Oldowan A-Lithic industry based upon artifact assemblages from upper Bed I, lower Bed II at Olduvai Gorge. Artifact assemblages have low frequency of choppers, and a greater abundance of spheroids, subspheroids, and small scrapers. In addition, protobifaces (a small core not extensively worked on both sides) appear in the record.

(2) Developed Oldowan B-Lithic industry based upon artifact assemblages from lower Bed II through middle Bed III at Olduvai Gorge (Leakey and Roe 1994) and from Melka Kontouré of Central Ethiopia ca. 1.7 to 0.1 million years ago. Artifact assemblages have a greater frequency of core forms (discoids and choppers), and the first appearance of a small bifaces (albeit few in number). Many have argued that this industry can be subsumed in the Acheulean industry; however, Mary Leakey maintained that the Developed Oldowan B is consistent with Oldowan tool traditions.

Acheulean Industry-Lithic industry originally based upon large bifaces found at St. Acheul (France), but in Africa this industry is based upon artifact assemblages from upper Bed II at Olduvai Gorge and at Konso (Ethiopia), Olorgesailie, and Melka Kontouré-to name a few of the more important sites. Artifact assemblages are composed of large bifaces, like handaxes, picks, and cleavers, and all show a high degree of standardization, something that was missing form earlier flake stone techno-complexes. Isaac (1977) suggests that African Acheulean is characterized by the use of very large flakes (less than 10

centimeters in length). Earlier Acheulean at Olduvai utilized smaller cores when preparing bifaces.

Middle Paleolithic (ca. 200-35 thousand years ago; Levalloisian-type cores, Mode 3 preparation)

Levallois-type cores are prepared by an elaborate

Isaac (1977) suggests that African Acheulean is characterized by the use of very large flakes (less than 10

centimeters in length). Earlier Acheulean at Olduvai utilized smaller cores when preparing bifaces.

Middle Paleolithic (ca. 200-35 thousand years ago; Levalloisian-type cores, Mode 3 preparation)

Levallois-type cores are prepared by an elaborate

technique named after a Parisian suburb where flakes of this kind were first recognized. Levalloisian cores take a lot of core preparation to get the perfect striking platform in order to generate a flake with a predetermined shape. Typically, Levalloisian flakes are very thin. In addition, there is an increase in retouched flake tools in the Middle Paleolithic. This industrial period also bears witness to improved hunting techniques as reflected by faunal remains. Sites include Gademotta (Ethiopia), Diré-Dawa (Port-Epic, Ethiopia), Katanda (Congo), and Kapthurin (Kenya).

Summary

East Africa is the birthplace of our earliest ancestors and the oldest known stone technology, but, more importantly, this region provides the earliest evidence of a creative pulse that catapulted our ancestors on a evolutionary trajectory never before witnessed in the history of life. It is not surprising that with the formal acquaintance of different hominid groups sharing ecological niches within the rapidly changing environments of East Africa, groups were forced to compete amongst one another and other animals for available resources. It would only be a question of time until the advent of a flaked stone technology would spawn a crucial advantage for the maker and users of the stone tools to out-compete one other and other primates for food (and water) by expanding dietary breadths and significantly contributing to their survival during times of environmental stress. The significance of flaked stone technologies, however, lies not within the corpus of edification that results when one bashes two pebbles together, but the necessary mental faculties and imaginative capabilities of first conceptualizing stones that possess the mechanical properties that facilitate knapping. When this happened, the overall hominid bauplan was changing course. Encephalization in the Family took off, and nothing short of a major hominid radiation occurred throughout Africa. With the bashing of two rocks a few million years ago, it seems our evolutionary path was reflexively set in stone.

Historical self-criticism has seldom been strong among French prehistorians. A rare instance is F. Audouze and andré leroi-gourhan's article (1981) entitled "France: A Continental Insularity,"

that France has perhaps never fully recovered from its loss of talent in World War I and that that war broke colonial efforts into two segments. A third phase of investigations is the postindependence emergence of African national research aspirations.

Pre-1914: Africa Intrudes upon the Prehistorian's Consciousness

The Maghrebian states of Algeria, Morocco, and Tunisia are the exception to the rule of marginalization even during the pre-1914 period. Large corps of colonial amateurs scoured the countryside around the major cities of Constantine, Tebessa, Oran, and Tunis. They established societies of *prehistoire* (Stone Age) and *archeologie* (classical archaeology), and each had its own publications, the first of which, the *Journal de la Societe Archeologique de Constantine*, was founded in 1894. Exceptionally, French professionals were attracted to North Africa, and one of them, P. Pallary, published the first monographic regional synthesis in 1909. For decades, the attraction for amateur, professional, and the whole of the metropolitan establishment was the so-called Capsian-Aurignacian debate.

Resemblances between the blade component of the Maghrebian Capsian and the European Aurignacian periods were remarked upon as early as 1890. It was, however, the professional prehistorian Jacques de Morgan who started the debate by claiming that the similarities were the result of independent development under similar environmental conditions. This position was consistent with the cultural evolutionist, paleoethnological school of gabriel de mortillet, but de Morgan was immediately criticized by some professional archaeologists such as Louis Capitan. De Morgan was particularly criticized by local amateur archaeologists who argued not only that a land bridge had once spanned the Mediterranean but also that North Africa was the source of the technological advances made during the Upper Paleolithic period. Breuil himself provisionally accepted the position of de Morgan's opponents in 1912. Most influential among these amateurs was Albert Debruge, who described what he believed to be Neanderthaloid skeletal remains as “ancient Aurignacian.” These remains were found during his 1912, 1914, and 1923 excavations at the important site of Mechta El Arbi.

It was not until the 1940s that the Capsian was finally accepted as being much more recent than the Aurignacian. Significantly absent from the debate was the question of the advisability of classifying local assemblages in terms of the dominant tool typology of France. The bane of francophone African archaeology until very recently was this modified evolutionary presumption, that the stages of the French Paleolithic period anticipated identical or analogous stages elsewhere and that such stages could be recognized by a relatively few type tools *(fossiles directeurs)*.

A racist view of the world lay behind the making of highly subjective surface collections of “belles pieces” in the forested lowland basin of central Africa. Bored stones and fine-ground stone axes had been carried back to French-occupied territory by early explorers (e.g., H.M. Stanley and G. Schweinfurth), and this tradition was continued by the administrators and engineers of the early days of French and Belgian colonialism. These collections of artifacts became primary evidence for the theories of cultural evolutionists such as E. Dupont, the head of the Belgian Royal Institute of Natural Sciences. These evolutionists argued that all people throughout the world went through the same stages in the manufacturing of implements and tools, based on the similarity of African stone tools and those found in Europe. They also argued that different people passed from manufacturing stage to manufacturing stage at a faster or a slower rate determined by their race, their environment, or both. Well into the twentieth century, ethnographies of stone tools using “contemporary ancestors, such the forest Pygmies,” were used to illustrate the lifestyles of Paleolithic peoples.

Stone and metal tools were displayed in the Central African Geological Exhibition at King Leopold II's imperialistic showpiece, the 1897 Brussels International Exhibition. Two years later, one of the

geologists responsible, X. Stainier, published *L'Âge de la Pierre au Congo,* in which he sought to demonstrate the backwardness of the African peoples. For Stainier, African prehistory simply replicated (albeit more recently

without history by demonstrating the importance of West African cities and their great empires. His efforts led the Académie des Inscriptions et Belles Lettres to cosponsor Desplagnes at El Oualdgi and to send Bonnel de Mezieres to the presumed capital of Ghana. Still, the interpretive paradigm (of outside stimulation leading to the emergence of historical states and cities) was fixed and remained unchallenged during the following post-World War I period; indeed, it underlay much of postindependence research. This paradigm described the area's history as unprogressive local populations forming advanced political forms and urban centers only after contact with traders or colonists from the “centers of radiation” across the Sahara.

High Colonialism: Local Particularism from World War I to 1960

The paradigm of Arab cultural stimulation provided a backdoor for the legitimacy and, incidentally, the professionalization of West African prehistory that began in the 1930s. Although on the extreme periphery of the areas covered by Gabriel Camps's prehistory and history of North Africa (1980), the towns and states of the southern desert and the Sahel were, nevertheless, worthy of attention as legitimate parts of the Islamic Arab-Berber world.

It is important to note that the purpose of archaeological work at those sites was to confirm a particular location as a place named in the Arabic chronicles, to recover (cross-datable) North African imports, and to expose monumental stone-built structures (especially mosques). Major “medieval” sites investigated during this period include, in Mauritania, Azugi (by Theodore Monod and Raymond Mauny), Tegdaoust in Mauritania (by Mauny), and the presumed capital of Ghana, Koumbi Saleh (by Lazartigues, Thomassey, and Mauny; Mauny and Szumowski); in Mali, Gao (by le Pontois, Kikoine, and Michel; Bartoli; Mauny), Teghaza (by Langlais and Bessac; de Beauchene; Bourgrat), Tadmekka (by Lhote; Mauny), Timbuktu (by Mauny); in Guinea, the presumed capital of Mali, Niani (by Cooley and Binger; Vidal; Gaillard; Montrat; Mauny); and in Niger, Takedda (by Lieutenant Roy; Lombard; Lhote; Mauny). Raymond Mauny pulled together these disparate archaeological efforts, along with Arab and European documentary sources and oral traditions, in his masterly *Tableau Géographique de l'Ouest Africain au Moyen Age* [A Geography of West Africa during the Middle Ages, 1961], which remains the prime secondary source on the latest prehistory and early history of West Africa.

Mauny's career is illustrative of the professional winds tugging at all of francophone Africa. Trained as a lawyer-administrator, he arrived in Senegal in 1938, the founding year of the premier African research center, the Institut Français d'Afrique Noire (IFAN). By 1947, an avocational historical bent had matured, and he headed the prehistory and proto-history (“metal age and medieval”) department at IFAN. Mauny took a polymath's interest in all periods (lithics and rock art included), visited most known sites, hounded amateur excavators for their unpublished field notes, compiled answers to questionnaires sent to administrators, and displayed his exceptionally interdisciplinary vision in over 220 articles and several synthetic monographs.

If not brilliant, Mauny's excavations were at least up to the standards of most other professionals in francophone Africa (and no worse than even some today). Mauny recruited George Szumowski for IFAN at Bamako (Mali), and he dug innumerable (and poorly published) *petits sondages* (test pits dug nonstratigraphically) in the many habitation sites of the middle Niger (Mema, Mopti), near Segou, and in many rock-shelter deposits near Bamako. Similar work was done, for example, by P. Jouenne and J. Joire on the megalithic and earthen monuments of Senegal and by Mauny and a host of administrators on the tells and tumuli in the lakes region of the middle Niger. Were these efforts better than amateur scratchings? Stratigraphic excavation was the exception, no ceramic sequences or formal pottery typologies were developed, and the recording of the Sahara's prolific rock art was generally inadequate (except by Monod). And in lithic studies, with the exception of Laforgue and Hubert, there was no

critique of the continuing reliance upon haphazard surface collections and *fossiles directeurs* derived from the European sequences.

PREV NEXT

active local research societies (especially in Oran, Constantine, and Tebessa) and the great interest in Maghrebian prehistory taken by leading figures in France (e.g., marcellin boule, editor of *L'Anthropologie*), the Bordesian analytical revolution penetrated faster in North Africa. The abundance of local sequences, most unusually for Africa, was complemented by several generations of regional syntheses (Vaufrey in 1955, Balout in 1955, Camps in 1974, Hugot in 1979). The downside was a marked deference to the European stages and typological terms.

The remnant Aurignacian question was put to rest by R. Vaufrey, who demolished the land-bridge thesis and showed that the Capsian geometrics and microburins were of Mesolithic (Tardenoisian) age. From the 1930s, under Lionel Balout of the Musée Bardo in Algiers, students such as G. Souville, G. Camps and H. Camps, J. Tixier, and H. Huget received training that stressed the inadequacy of the diagnostic or index artifact. The typological work of R. de Bayle de Hermens (Capsian), H. Camps-Fabrer (bone), and J. Tixier (epipaleolithic) was particularly exacting. Unfortunately, the pace of research in North Africa slowed appreciably as a result of the violence of national independence and the economic and political conditions of the modern Maghrebian states.

Postindependence: Emergence of National Research Goals after 1960

Although the pace of research diminished after independence, there was also a break with traditional North African research in the form of greater internationalization and greater institutional support. Most work continues along the typological direction set by J. Tixier (experimental knapping) and L. Balout (refined local sequences and classification), but some of their younger colleagues (G. Aumassip, A. Gautier, A. Muzzolini, and C. Roubet) have tried to go beyond lithics to a reconstruction of past ways of life. Perhaps these efforts would be more advanced were more North Africans at the forefront of research, but such is not the case despite the opening of serious instruction at the University of Algiers in 1952. Instead, the weight of research is directed toward environmental adaptation or processes, such as the origin of food production, and has shifted east to Libya and more especially to the Egyptian western desert and the prehistoric Nile Valley.

The biggest difference between international efforts in the mahgreb-such as projects run by the Canadian D. Lubell and the German B. Gabriel-and efforts that have a more traditionally typological thrust is a greater appreciation of interassemblage, intersite, and interregional diversity. The Bordesian quantitative standards have been accepted with a Bordes-like resistance to functional studies. In rock art, too, there is an overwhelming tendency by otherwise outstanding observers such as Italian archaeologist Alfred Muzzolini to look for regions of coherent, homogeneous style or design choice-which are thought to be characteristic of bounded, coherent peoples. Change in art style is presumed to be evidence of migration or of population swamping. Still, the institutional support of Mahgrebian research continues, and the Centre Algérien de Recherches Anthropologiques, Préhistoriques et Ethnographiques, and the Laboratoire d 'Anthropologie et Préhistoire et d'Ethnologie of the University of Provence sponsor new research. One clearly sees the integration of older typology and emerging processual concerns in the *Encyclopédie Berbere*, compiled on a continuing basis by G. Camps, and in the journal *Sahara* begun by Muzzolini in 1988.

If the overall effect of independence has been a diminution of research in Congo (formerly Zaire), there has been much new high-quality work in the surrounding central African nations, and the influences of internationalization and greater institutional support are as evident here as they are in North Africa. Although there was not a single archaeologically trained Congolese national at independence, the situation has slowly improved with a steady trickle of students returning from the Free University of Brussels and with the establishment, in 1975, of the Institute of the National Museums of Zaire (IMNZ). The IMNZ is charged with regulating excavations and antiquities generally and has the enormous

ongoing task of stemming the free flow of art and antiquities out of the country.

industrial-scale production. Ethnographers and ethnoarchaeologists have linked studies of ancient iron production to those of the social role of blacksmiths (E. Bernus and N. Echard). Particularly noteworthy is the work on the ancient linkage of social and production concerns by the Senegalese archaeologist H. Bocoum, who is in the vanguard of a new French theoretical paradigm, the *chaines operatoires.*

Research on West African ceramics has also profoundly influenced the direction of French research. On the side of microexamination, there is the experimental physics conducted on Malian lakes region ceramics by the Group Nucleaire d'Orsay (Fontes, Person, Saliege). Concerning interpretation of ethnicity and symbolism of identity, the pioneering work on (Malian) Sarakole pottery by the Swiss A. Gallay (and of various middle Niger groups by E. Huysecom and A. Mayor) has stimulated an interest in ethnoarchaeology in France. T. Togola has begun a study of the technical and social organization of gold production in the famous Bambouk fields of western Mali, and processual studies of settlement evolution and early urbanism have had the most profound impact on the understanding of the early history of West African societies.

Beginning at jenné-jeno (middle Niger) in the late 1970s and continuing up to 1994 with a program of multisite coring (including the present town of Jenné), S. McIntosh and R. McIntosh used controlled stratigraphical excavation, complemented by regional survey, to show that considerable revisions were needed in the historians' conclusion that towns, heterogeneous populations, and long-distance trade were a late (early-second millennium) gift from traders coming across the Sahara. The Jenné-jeno research was just the first glimpse of extensive east-west trade networks, urbanism (often taking a distinctive clustered form), and occupational specialization that developed during the first millennium. The fact that these were indigenous developments was confirmed by subsequent surveys and excavations along the middle Niger by the McIntoshes (at Dia in 1986-1987 and Timbuktu in 1983-1984), by T. Togola at the clustered Akumbu and Boundouboukou sites in the Mema (late 1980s), by the (1982-1987) Malian Institut des Sciences Humaines inventory project (Sanogo, Dembele, Raimbault) in the lakes region immediately upstream of the Niger Bend, and (since 1989) by the Dutch Projet Togue (van der Waals) in the upper inland delta floodplain.

Since 1990, the McIntoshes and their Senegalese collaborator, H. Bocoum, have repeated this successful settlement pattern examination in the middle Senegal Valley in a 460-square-kilometer region flanked by the excavated sites of Cubalel and Sioure and, upstream, at the hinterland of the large site of Sincu Bara. Small early-Iron Age settlements evolved into specialized iron production centers and habitation clusters here as well. However, true urbanism and social complexity appear to have developed genuinely late. Members of the middle Senegal Valley team, I. Thiaw and D. Wolfman, initiated the first application of archaeomagnetic dating to francophone Africa with a dating curve covering the first to the fourteenth centuries a.d.

Conclusion: The Politics of Internationalization

The relationship between France and its ex-colonies continues to be debated, and if anything, the debate became more heated after the end of the cold war. Some people question whether that relationship has retarded democracy in Africa (“Dangerous Liaisons” 1994) and, in a similar vein, whether the close cleaving of francophone African archaeologists to metropolitan paradigms and methods has retarded an appreciation of the richness and originality of the continent's past. Two hotly debated issues are critical to the future of internationalization of francophone African archaeology: the exclusivity of La Francophonie and the traditional French distrust of theory.

The concept of La Francophonie goes beyond the ideal of a geopolitical commonwealth of French-speaking nations. Particularly when applied to Africa, it refers to the sentimental assertion that

France's ties to its ex-colonies are charmed, and quite unlike those of other ex-colonial powers, because of a unique spiritual understanding. Idealized in France, the concept is often vilified in Africa as a justification

Africa, Horn of

The Horn of Africa includes the modern states of Eritrea, Ethiopia, Djibouti, and Somalia. The region consists of temperate highlands surrounded by arid and semiarid lowlands and cut by a rift generating the Danakil Depression. The Horn is inhabited by Cushitic-, Semitic-, Omotic-, and marginally Nilo-Saharan-speaking peoples. The region has the longest cultural record in the world, from the earliest steps in human evolution to the present.

The Horn of Africa is one of the richest regions in Africa with respect to archaeological remains. They cover practically the whole time span from the beginning of the early Stone Age to the nineteenth century, and they reflect the very complex cultural history of the region. Despite this richness, archaeology in the Horn is still in its infancy and in many aspects backward when compared with other African regions. The Horn region is still largely unexplored archaeologically, and what work has been done has focused on only a few specific topics (early prehistory, rock art, megaliths, early historical monuments, medieval monuments), which has resulted in a very fragmentary view of the past of the region (Anfray 1990; Brandt 1986; Clark 1954).

Archaeological research in the Horn has a quite long history, with the earliest records of ancient monuments in northern Ethiopia and Eritrea going back to the early sixteenth century (Anfray 1963; Brandt and Fattovich 1990; Fattovich 1992; Mussi 1974-1975; Michels 1979). In a strictly historical perspective, three main phases (explorative, descriptive, interpretative) can be distinguished in the development of archaeological research in the region.

The explorative phase (ca. 1520-1900) was characterized by the activity of travelers and explorers who focused their attention on the ancient monuments visible in northern Ethiopia and Eritrea, mainly at Aksum, which was the capital of an early Christian kingdom dating to the first millennium a.d. The most eminent ones were F. Alvarez in the sixteenth century; C.J. Poncet in the seventeenth; J. Bruce in the eighteenth; and H. Salt, E. Ruppel, Th. Lefebvre, A. Raffray and G. Simon, and Th. Bent in the nineteenth. These explorers contributed to the popularization, at least in academic circles in Europe, of the existence of an ancient civilization in the region, and they set the foundations for historical archaeology in the Horn.

The descriptive phase (ca. 1900-1950) was characterized by the first semisystematic excavations and reconnaissances conducted by professional archaeologists in different regions of the Horn. G. Revoil was the first traveler to record the occurrence of ancient sites in northern Somalia in the late nineteenth century, and only Salt and Bent suggested some hypotheses about the origins of Ethiopian civilization (Brandt and Fattovich 1990; Fattovich 1992).

In Ethiopia and Eritrea, the most representative of these archaeologists were R. Bourg de Bozas (1906) and henri breuil and Pierre Teilhard de Chardin, (Breuil 1934; Breuil, Teilhard de Chardin, and Wernet

1951), who collected the first Stone Age evidence in southern and eastern Ethiopia and rock-art evidence in eastern Ethiopia; H. Neuville (1928) and F. Azais (Azais and Chambard 1931), who investigated the megalithic monuments (dolmens, tumuli, stelae) in eastern, central, and southern Ethiopia; R. Paribeni (1907), E. Littmann, S. Krencker, and Th. von Lupke (1913), G. Dainelli and O. Marinelli (1912), and S.M. Puglisi (1940), who conducted surveys and excavations in Eritrea and Tigray (northern Ethiopia) and provided relevant knowledge of the ancient Aksumite civilization; A.A. Monti della Corte (1940), G. Bianchi Barriviera (1962, 1963), A. Mordini (1961, Mordini and Matthews 1959), and D. Buxton (1946, 1947, 1971), who systematically explored the medieval rock-hewn churches in northern Ethiopia.

Apart from some hints of legendary origins provided by Arab historians, two sets of factors precipitated the birth of a Saharan archaeology. First, Napoleon's campaign in Egypt, the craze for "Egyptian antiquities," and jean-francois champollion's decipherment of Egyptian hieroglyphics in 1822 that marked the beginning of a prestigious discipline, Egyptology. Second, Algeria was occupied by the French in 1830, just as E. Geoffroy Saint-Hilaire, G. Cuvier, and j. boucher de perthes were laying the foundations of two new disciplines within France, animal paleontology and prehistory. The existence of a proper Saharan rock art was also discovered: the engravings of the Monts des Ksour (Saharan Atlas), first mentioned in 1847 by army officers Jacquot and Koch, and also those of the Mathendous, in Libya, where the German explorer Heinrich Barth identified an engraving known as the "Garamantic Apollo" in 1850. Other nineteenth-century explorers (H. Duveyrier in Algeria, G. Nachtigal in the Tibesti, karl richard lepsius in Nubia, E. von Bary in the Air Mountains) mentioned rock pictures. In 1898 Foureau, with Lamy and a strong escort, headed a remarkable scientific expedition that traveled from Algiers to the Congo. He registered the prehistoric sites he encountered and collected artifacts. The publication of his travels and discoveries marked the end of the

Africa, Sahara

Apart from some hints of legendary origins provided by Arab historians, two sets of factors precipitated the birth of a Saharan archaeology. First, Napoleon's campaign in Egypt, the craze for "Egyptian antiquities," and jean-francois champollion's decipherment of Egyptian hieroglyphics in 1822 that marked the beginning of a prestigious discipline, Egyptology. Second, Algeria was occupied by the French in 1830, just as E. Geoffroy Saint-Hilaire, G. Cuvier, and j. boucher de perthes were laying the foundations of two new disciplines within France, animal paleontology and prehistory. The existence of a proper Saharan rock art was also discovered: the engravings of the Monts des Ksour (Saharan Atlas), first mentioned in 1847 by army officers Jacquot and Koch, and also those of the Mathendous, in Libya, where the German explorer Heinrich Barth identified an engraving known as the "Garamantic Apollo" in 1850. Other nineteenth-century explorers (H. Duveyrier in Algeria, G. Nachtigal in the Tibesti, karl richard lepsius in Nubia, E. von Bary in the Air Mountains) mentioned rock pictures. In 1898 Foureau, with Lamy and a strong escort, headed a remarkable scientific expedition that traveled from Algiers to the Congo. He registered the prehistoric sites he encountered and collected artifacts. The publication of his travels and discoveries marked the end of the

era of the explorers, whether adventurers or scientists. The discipline of Saharan prehistoric archaeology had been founded.

Saharan Archaeological Sites

The First Half of the Twentieth Century: Diffusion, Classification, and Chronology

At the beginning of the twentieth century the French penetrated more deeply into the Hoggar. However, archaeological research in French-speaking Africa concentrated almost wholly on the Maghreb until 1920 to 1930. There, rich historical civilizations and prehistoric cultures were found that looked similar to European ones. They were studied in the same way, with the same words, and with the same goal of organizing the finds into sets of synchronous elements that constituted "stages," analogous with geological and paleontological stages. Then the stages were ordered into chronological sequences. Later on Saharan archaeology was built upon the same fundamental concepts. The first things looked for were the links with Maghreb cultures and the influence, thought to be evident, of pharaonic civilization.

The rock art of the Saharan Atlas was the topic of the first synthesis by G.B. Flamand, *Les Pierres Ecrites* ("Engraved Stones") published after his death in 1921. The classification it proposed is crude: an earlier group in naturalistic style, called "prehistoric," but already recognized as "Neolithic," and a later group in schematic style, called "libyco-berber," with pictures of horses, camels, and inscriptions in the Libyan alphabet. These two groups, which were later named "Precameline" and "Cameline," constituted the fundamental frame of reference for all Saharan classifications.

In 1925 another important work appeared-L. Frobenius and h. obermaier's *Hadschra Maktouba*, which focused on the engravings of the Saharan Atlas. Frobenius was searching Africa for proof of the "Hamitic hypothesis," although neither he nor anybody else ever found it. This theory, developed by C.G. Seligman and others, was in vogue at the time and held that "civilization" had been diffused south of the Sahara (read in the Africa of the Negroes) by either the oriental or northern Hamites, who were pastoral

sites of the Saharan Atlas. He also defended his views on “Egyptian affinities” with rock art, attributed to his NCT where Egypt was regarded as the inspiration and the colonizer.

Libya, an Italian colony since 1912, began to be studied for its prehistory and rock-art sites. A. Desio and P. Graziosi published various sites, mainly rock-art sites, and Graziosi took up that focus again in 1942 in a classical synthesis entitled *L'arte rupestre della Libia* (cave art of Libya). Another classic work of this time was Frobenius's *Ekade Ektab* (1937) on the Mathendous engravings.

The Tassili paintings had been known since 1910, but their importance was not recognized until the 1930s. In 1932 the Tamadjert paintings were discovered, and in 1933 the extraordinary Oued Djerat group. This resulted in several reconnaissance missions to the Djerat, in which the young naturalist, Henri Lhote participated. But World War II halted all projects in central Sahara.

The First Half of the Twentieth Century: The Eastern Sahara Opens

Other Saharan regions had been neglected, and it was not until the 1930s that some reports on the art of Tibesti, Borkou, and Ennedi began to appear. Engravings from Nubian rocks, with their pharaonic boats, were also reported. But between the Nile and the Tibesti stretched 1,000 kilometers of Libyan Desert, the Great Sand Sea-an eternal no-man's-land.

Yet it was not quite absolute desert. The Gorane caravans spoke of a permanent spring in a mountain situated halfway between the Nile and Kufra. In 1923 an Egyptian, Hassan-Bey, crossed from Sollum, on the Mediterranean, to Darfour with a caravan of camels. On his way he recognized the Uweinat granite massif, where there is, in fact, water, and he remarked on its rock art. This was crucial for the development of Saharan research because with this central watering point, the eastern desert was no longer impenetrable. By 1924 Prince Kemal-el-Din reached Uweinat by tractor and described the paintings of the important site of Karkur Talh. During the following decade the rock art of Uweinat as well as that of the neighboring massif, the Gilf Kebir, were studied by many English missions. The Gilf Kebir was supposed to contain the legendary oasis Zerzura, but its location remains a mystery. Barbary sheep still live in the Gilf Kebir.

From 1938 to 1939 the first synthesis on Nubian engravings by Hans A. Winkler was published. His interpretative schemes, based on “autochthonous” and “Eastern Invaders,” considered bold at the time, have become progressively unacceptable. Immediately after World War II two books on central Sudan appeared, and both had great impact: *Early Khartoum* (1949) and *Shaheinab* (1953), both by A.J. Arkell. They were the first reports of true excavations in Sahara-modern, scientific, and multidisciplinary efforts that went beyond mere surface collection. Work on the two Sudanese sites of Khartoum and Shaheinab finally put to rest the Hamitic hypothesis. Indeed, they proved the undoubted antiquity of a Nilotic culture (but not an Egyptian one) and of a “civilization” in black Africa. The discovery of the Sudanese sites had great significance, equivalent to gertrude caton-thompson's proof, twenty years earlier, that the ruins of great zimbabwe were not Phoenician or Sabean but the product of an authentic indigenous African culture.

Arkell's work greatly excited Africanists. Some indulged in lyricism, within the context of the fashionable diffusionist tradition, and changed the details of Hamitic theory to that of a mysterious “Sudanese crucible” where an “African Neolithic” was forged, sending its “civilizing” influence toward the west and across the immense Sahara.

Since 1950: The Central and Western Sahara and the Origin of the Saharan Neolithic

During the immediate postwar period and in the 1950s and 1960s, all the states that occupy the Sahara

gained their political independence in one way or another. In 1956 the Centre Algérien de Recherches Anthropologiques Préhistoriques et Ethnographiques (CRAPE) was founded in Algiers. Travelers' reports and the occasional surface collection of tools (e.g., those of the Missions Berliet Tassili-Tchad in 1959 and 1960) gave way to stratigraphical excavations on

sites of the Saharan Atlas. He also defended his views on “Egyptian affinities” with rock art, attributed to his NCT where Egypt was regarded as the inspiration and the colonizer.

Libya, an Italian colony since 1912, began to be studied for its prehistory and rock-art sites. A. Desio and P. Graziosi published various sites, mainly rock-art sites, and Graziosi took up that focus again in 1942 in a classical synthesis entitled *L'arte rupestre della Libia* (cave art of Libya). Another classic work of this time was Frobenius's *Ekade Ektab* (1937) on the Mathendous engravings.

Some indulged in lyricism, within the context of the fashionable diffusionist tradition, and changed the details of Hamitic theory to that of a mysterious “Sudanese crucible” where an “African Neolithic” was forged, sending its “civilizing” influence toward the west and across the immense Sahara.

Since 1950: The Central and Western Sahara and the Origin of the Saharan Neolithic

During the immediate postwar period and in the 1950s and 1960s, all the states that occupy the Sahara

gained their political independence in one way or another. In 1956 the Centre Algérien de Recherches Anthropologiques Préhistoriques et Ethnographiques (CRAPE) was founded in Algiers. Travelers' reports and the occasional surface collection of tools (e.g., those of the Missions Berliet Tassili-Tchad in 1959 and 1960) gave way to stratigraphical excavations on

Gal Huard tried to group together all rock art into vast pan-Saharan cultures, such as a pre-Neolithic "Culture des Chasseurs" (culture of hunters) and then a Neolithic "Culture des Chasseurs-Pasteurs" (hunters and pastoralists). But these grandiose structures are open to criticism.

Scene with camels (ca. 0 B.C.), In-Itinen (Tassili, Algeria), painting in ochre color. Total length of the scene about 150 centimeters

(Alfred Muzzolini)

Only recently, in a remarkable and copiously documented study by J.-L. Le Quellec (1993), has an effort been made to interpret some thematic classes, using entities borrowed from the history of religions and supposed to be common to all cultures: the categories of the sacred and its symbols.

The Eastern Sahara since 1950

In the late 1960s, several modern excavations just north of Khartoum, at Chador, Saggai, and El Kadada, tried to define more precisely the Mesolithic and the Neolithic described by Arkell. The Neolithic of Shaheinab was found to begin very early, somewhere around 4000 b.c.

Systematic excavations and large-scale surveys were also undertaken, mainly in the Western Desert of Egypt, just north of the border with the Sudan, by the Combined Prehistoric Expedition (Wendorf, Schild, and Close 1984). Several sites, spread from 150 to 500 kilometers from the Nile-notably, Bir Tarfawi and Bir Sahara for the Paleolithic and Nabta Playa and Bir Kiseiba for the Neolithic-have yielded surprising results. Some are of very old occupation, from the Acheulean and then the Mousterian and Aterian, with fauna both from savannah and steppe. A very long hiatus followed, as everywhere else, corresponding to the post-Aterian Hyperarid phase, and a Holocene reoccupation has been noted from around 7800 b.c.

From as early as 7500 to 7000 b.c., there are a few bone fragments of small-sized cattle, ecologically unexpected in a desert biotope and incompatible with other wild fauna recorded at the same site. For these reasons A. Gautier argued that the cattle were domestic, existing a good millennium before the first domestic cattle in the Middle East and three millennia before those from the Neolithic of Merimde in Egypt-a proposition that has aroused controversy. Toward 6000 b.c. ceramics appeared, along with the traces of village structure at

Nabta Playa. However, dozens of living sites of a similar age were discovered between the Nile and the Libyan border, in the Dakhlah oasis, and in the Sudanese Wadi Howar and its surroundings by an important German expedition led by R. Kuper. This picture of a steppe that was relatively inhabited and traveled through during the wet phase of the early and middle Holocene, at least from 6000 to 5000 b.c., will probably prove to be identical to that of the entire Libyan Desert and the plains north of the Tibesti.

Throughout this period of the early Holocene, up to about 4000 b.c., Egypt apparently was a relatively poor province archaeologically because the Neolithic in the Fayum and at Merimde occurred near 4000 b.c., that is, not earlier than at Khartoum. The most important change to the conceptual field of Saharan prehistorians over the last decades is the vision of an Africa with precociously fragmented populations.

The majority of Saharan archaeological studies are concentrated on the periods of the early and middle Holocene. Recent proto-historic periods are, as already pointed out, relatively less studied. It follows that, contrary to what can be noted in sub-Saharan Africa, this prehistoric research, essentially focused on the Neolithic period, is regarded by indigenous people as an intellectual exercise. Although admittedly useful to the understanding of humankind and human evolution, it has no links with their own ethnic or current national identity. Perhaps this is why there are still very few indigenous researchers-far too few to solve such vast problems. Meanwhile, mass tourism has increased, endangering rock art and rock paintings. And because most countries of northern Africa are burdened by war, rebellion, or bandits, they are unable to offer researchers the security needed to conduct their studies.

Africa, South, Historical

Close to the shores of False Bay in the Cape Town suburb of Muizenberg stands what is believed by many people to be the oldest extant nonindigenous dwelling in South Africa. Dated through the Deeds Office, Cape Town, to 1673, the Posthuys (Post House), formed part of a VOC (Verenigde Oostindische Compagnie, Dutch East India Company) outpost. Fittingly, perhaps, it was also the earliest colonial site to be excavated (in the 1970s) by an archaeologist, in this case, Hennie Vos. When offered a post at the Stellenbosch Museum forty kilometers east of Cape Town shortly afterward, Vos naturally concentrated his further efforts in and around that town, doing any archaeological work that came to hand. This included a great deal of rescue archaeology, and Vos has played a major role

the effects of European contact on African tribalism, ethnicity, and identity. The marrying of the two sets of principles promises to yield interesting results.

Africa, South, Prehistory

When the first world prehistories came to be written in the mid-nineteenth century, traces of Stone Age peoples were known from Europe, Egypt, and southernmost Africa. The prehistory of the rest of the globe was then largely terra incognita. The fact that there were stone artifacts recorded from the ends of the African continent should have been reason enough to expect that an important part of the human story was played out on that continent, but it has taken more than a century of observation for that idea to be amply confirmed. Much of the information on the prehistory of southern Africa considered here comes from the Republic of South Africa, but reference is made to the independent states of Lesotho, Swaziland, Namibia, Botswana, Zimbabwe, and Mozambique, countries that share common boundaries with the Republic of South Africa. Proximity means there have been strong links in the development of archaeology in this part of the continent.

South Africa is an elevated subcontinent of plateaus, escarpments, and mountains where surface soil mantles tend to be thin. It lies mainly south of the African woodland savannah and has a significant extratropical area. The vegetation cover is shrub and grassland with thicket and open woodland in the more tropical areas; there are only relict patches of Afro-alpine forest. Archaeological exposures are generally good, and the landscape is littered with traces of the presence of prehistoric peoples as befits a region that has seen changing populations over some 2 million years.

Discovering a Prehistoric Past

It was the remarkable wealth of stone artifacts in South Africa and a Victorian yen for collecting

the effects of European contact on African tribalism, ethnicity, and identity. The marrying of the two sets of principles promises to yield interesting results.

Africa, South, Prehistory

When the first world prehistories came to be written in the mid-nineteenth century, traces of Stone Age peoples were known from Europe, Egypt, and southernmost Africa. The prehistory of the rest of the globe was then largely terra incognita. The fact that there were stone artifacts recorded from the ends of the African continent should have been reason enough to expect that an important part of the human story was played out on that continent, but it has taken more than a century of observation for that idea to be amply confirmed. Much of the information on the prehistory of southern Africa considered here comes from the Republic of South Africa, but reference is made to the independent states of Lesotho, Swaziland, Namibia, Botswana, Zimbabwe, and Mozambique, countries that share common boundaries with the Republic of South Africa. Proximity means there have been strong links in the development of archaeology in this part of the continent.

South Africa is an elevated subcontinent of plateaus, escarpments, and mountains where surface soil mantles tend to be thin. It lies mainly south of the African woodland savannah and has a significant extratropical area. The vegetation cover is shrub and grassland with thicket and open woodland in the more tropical areas; there are only relict patches of Afro-alpine forest. Archaeological exposures are generally good, and the landscape is littered with traces of the presence of prehistoric peoples as befits a region that has seen changing populations over some 2 million years.

Discovering a Prehistoric Past

It was the remarkable wealth of stone artifacts in South Africa and a Victorian yen for collecting

stone artifacts, which were associated with extinct kinds of animals found in Europe. Penning (1886), a geologist of Stow's generation, appreciated that surface finds were not necessarily recent in age. The land surfaces of southern Africa had not been glaciated in the Ice Age, as had happened in Europe, and therefore they were not covered with glacial debris. In a region not affected by glaciation, artifacts occurring on the surface may still be tens and even hundreds of thousands of years old.

Perhaps the clearest statement on how old artifacts in the South African landscape might be came from L. Péringuey, a French-trained entomologist. Péringuey's work took him to the vineyards around Stellenbosch where Acheuean artifacts are regularly plowed out of the ground. Such artifacts were also known to occur in great quantities in the gravels mined for diamonds along the Vaal River and had been found as far afield as Swaziland and Victoria Falls in Zimbabwe. Péringuey recognized that similar kinds of stone artifacts were known from the oldest deposits in France and claimed that the stone artifacts from Stellenbosch were as old as the most ancient in Europe (Péringuey 1900). At the turn of the century it was a revolutionary idea that people may have had as long a history of living in Africa as in Europe.

Péringuey became the director of the South African Museum, and after the turn of the twentieth century, with the growth of museums in South Africa, he and other museum directors were active in promoting archaeological studies. The museums became the storehouses for collections, and the close association between archaeology and museums has continued to the present. One of Péringuey's counterparts, J. Hewitt, a zoologist and director of the Albany Museum in Grahamstown from 1910 to 1954, spent weekends and holidays investigating coastal shell middens and excavated a number of rock shelters. His most important excavations in the 1920s and 1930s were on three farms: Wilton near Alicedale, Howiesons Poort near Grahamstown, and Melkhoutboom, which is inland from Port Elizabeth. These were among the first systematic excavations undertaken in South Africa. Although trained as natural scientists and not as archaeologists, researchers like Hewitt brought a new rigor to the fledgling subject of archaeology.

Beginnings of Professional Studies

The first South African to be trained as an archaeologist was Astley John Hilary Goodwin. Born in Pietermaritzburg in 1900, Goodwin studied archaeology under Miles Burkitt and Alfred Haddon at Cambridge University and returned to South Africa in 1923 (J. Deacon 1990; Schrire, Deacon, Hall, and Lewis-Williams 1986). He gave himself the task of making archaeology a more systematic study. The museum collections had been accumulated by casual rather than systematic collecting, and they represented a body of information that needed to be put in order. In a series of writings in the 1920s, Goodwin developed and publicized his ideas. The culmination was the publication of the *Stone Age Cultures of South Africa,* written in collaboration with Clarence van Riet Lowe (Goodwin and van Riet Lowe 1929). The concept of the book owed much to Goodwin, and van Riet Lowe supplied the information on the archaeology of the interior of the country that he had gathered while working as an engineer engaged in building bridges.

That publication had a lasting influence on the development of archaeology in South Africa. In it, the authors proposed a three-stage division of the Stone Age into the earlier, middle, and later Stone Ages. The earlier Stone Age was characterized by large bifacial (flaked over both faces) artifacts with Acheulean hand-axes being the diagnostic form. The middle Stone Age was characterized by the use of prepared or Levallois-type cores to produce triangular or parallel-sided flakes. The definition of the later Stone Age suggested a technology designed to produce microlithic tools and blades but stressed the association with the San, rock art, and burials. The later Stone Age, therefore, was the link with historical times.

The three Stone Ages proposed were properly technological stages much like christian jürgensen thomsen's three-age system or the three-fold division of the Paleolithic adopted in Europe in the nineteenth century. Goodwin

(1958) in particular took pains to avoid adopting a Euro-biased terminology that would imply far-flung correlations that could not be demonstrated. It is not possible to force South African Paleolithic prehistory into the tripartite European divisions, not the least because there is no equivalent of the Upper Paleolithic represented in sub-Saharan Africa. The later Stone Age of southern Africa is Epipaleolithic, not Upper Paleolithic, in character.

A further legacy of the Goodwin and van Riet Lowe publication is the terms derived from the names of places where type or reference collections were found. The type site name is conventionally used as a label to identify similar artifacts at other sites, the underlying assumption being that differences in artifacts denoted peoples of different cultures, languages, or tribes. It is now known that much of the variability in the stone artifacts had to do with time-successive innovations and that at any one time, similar artifacts were made over much of southern Africa. The archaeological record, for the most part, is too coarse to distinguish social or linguistic groupings. Some labels continue to be used as an archaeological convenience, and considerable effort has been expended in redefining such terms and understanding what implications they carry.

Goodwin and van Riet Lowe had no means of establishing anything other than the relative ages of the stages they recognized from the somewhat meager stratigraphic information at their disposal. At least collections and archaeological sites could be ordered in a gross chronological sense. The later Stone Age was thought to date to the last 2,000 years, with the middle Stone Age extending back perhaps a further 2,000 years. It was not until the advent of radiocarbon dating in the 1950s that more precise estimates of age ranges could be obtained. The radiocarbon revolution when combined with other dating techniques has shown that the guessed ages of these pioneers were out by a factor of at least ten. Thus, 21,000 years is a better estimate for the duration of the later Stone Age than their guess of 2,000 years, while the middle Stone Age may have begun as much as 250,000 years ago.

The two men were the dominant figures in South African archaeology from the 1920s to the 1950s. Goodwin carried out extensive fieldwork in Western Cape Province in the 1930s, notably at the site of Oakhurst (Goodwin 1938) and Cape St. Blaize Cave (Goodwin and Malan 1935) at Mossel Bay. These excavations were aimed at investigating the divisions of the middle and later Stone Ages. After the interruption of World War II, Goodwin devoted himself more to the promotion of archaeology through the founding of the South African Archaeological Society in 1946 and editing the *South African Archaeological Bulletin,* the main publication of the society. This journal published material on the archaeology of different regions in sub-Saharan Africa.

Van Riet Lowe became director of the Archaeological Survey in South Africa and, apart from being the spokesperson for archaeological concerns in the country, he made a major contribution through his studies of the Acheulean gravel deposits of the Vaal River (van Riet Lowe 1952). He died in 1957, a year after his retirement, and Goodwin died in 1959. In two short years, South African archaeology lost its two leading authorities.

Coming of Age

The Archaeological Survey in South Africa was disbanded in 1962, and one of Goodwin's former students who had worked in the survey, B.D. Malan, became secretary of the Historical Monuments Commission, a forerunner of the National Monument Council and the present South African Heritage Resources Agency. Another of Goodwin's students, R.J. Mason, became the founding staff member of a new Department of Archaeology at the University of the Witwatersrand. In 1960, Goodwin's teaching position at the University of Cape Town was filled by R.R. Inskeep, who was initially responsible for training a number of students to fill new posts as they became available.

The economic boom of the 1960s saw archaeology, worldwide, enter a growth phase, and the same was true in South Africa. New posts were created in museums and universities, and from a complement of some 6 professionals

the study of the spread of agriculture, both Khoekhoe pastoralism and the settlement of mixed farming communities; and a field outside the scope of this article, the study of the colonial period, the last 350 years.

Human Origins

It has been established since the 1960s that some sedimentary units in two of the best-known sites, Sterkfontein (Kuman 1994) and Swartkrans (Clark 1993), include undoubted Oldowan and Acheulean artifacts and bone tools. These can be dated by the associated faunas to 2 million years old and are among the oldest dated archaeological occurrences. It has been suggested that the number of burned pieces of bone discovered at Sterkfontein (Brain and Sillen 1988) in deposits that may date to about a million years ago may be early evidence of the antiquity of fire-minding if not of fire-making. After half a century of research, these caverns continue to be a focus of archaeological attention as they continue to provide new evidence of early human behavior.

There are few, if any, acceptable Oldowan-aged sites other than the solution cavern occurrences. However, there is a very strong presence of Acheulean biface makers known throughout the subcontinent, and these would date to between more than 1 million years ago and some 300,000 years ago. They are evidence of the establishment of significant human populations on the subcontinent. As a result of alluvial diamond diggings, the Vaal River terraces and gravels north of Kimberley became known as a prolific source of Acheulean artifacts. Systematic research initiated in the 1930s by van Riet Lowe (Söhnge, Visser, and van Riet Lowe 1937; van Riet Lowe 1952) established Canteen Koppie near Barkly West and Riverview Estates near Windsorton as two of the main sites. Expectations that five or more substages of what Goodwin and van Riet Lowe (1929) defined as the Stellenbosch (Acheulean) culture could be recognized on the principle that bifaces took on more refined forms through time have proved too simplistic (H. J. Deacon 1975). The collections were selected from mining dumps and excavated samples (Beaumont 1999; Mason 1988), and more stratigraphic and dating controls became available only later.

Cornelia in Free State Province and Elandsfontein in Western Cape Province are some of the few Acheulean sites that have provided adequate faunal samples, but in neither case can the fauna be directly associated with the artifacts. A date in the range 400,000-700,000 years ago can be ascribed to these faunas (Klein and Cruz-Uribe 1991), and at Elandsfontein, the Saldanha calvarium, which is morphologically similar to the Kabwe skull from Zambia, was recovered in 1952.

Most Acheulean sites are open stations, and other than the solution cavern occurrences, only three cave sites are known to have been occupied in this time range: Cave of Hearths, Montagu Cave, and Wonderwerk. A human mandible was recovered during 1952 excavations at the Cave of Hearths (Mason 1988) as well as a limited fauna, younger than that from Cornelia. Montagu Cave was reexcavated in 1964 (Keller 1973) and produced large artifact samples of Acheulean and younger age but no fauna. Wonderwerk, a large, deep tunnel-like cave but with some seven meters of deposits of different ages, was again disturbed by guano mining, and it includes important Acheulean horizons (Beaumont 1999). Acheulean sites have proved very difficult to study because of poor preservation of context and associations, which has limited progress in developing hypotheses about the meaning of the Acheulean occurrences.

Since the 1960s, Acheulean studies have emphasized the evidence for activity variation in the relative proportions of large, heavy bifacial tools to small flake tools in separate lake margin occurrences in East Africa. In such situations, the context was assumed to be one of little disturbance. As research has progressed, this assumption has not proved justified, and it is apparent the patterning is more readily

explained by the selective transport of different sizes and masses of artifacts (Isaac 1977). Most South African open-air Acheulean sites are in valleys and on their margins, and although these areas have been geomorphologically active there has not been same degree of winnowing of artifact

modern behavior hypothesis, equates modern behavior with the level of symbolic expression evident some 40,000 years ago with the spread of the Upper Paleolithic into western Europe.

The alternative, earlier modern behavior hypothesis recognizes that behavior is context specific and sees the Upper Palaeolithic as a regional phenomenon not represented in sub-Saharan Africa. It holds that by the beginning of the late Pleistocene (H. J. Deacon 1998), evidence concerning the organization of living space, the arbitrary changes in styles of artifact designs, and the use of colored pigments at middle-Stone Age sites in Africa indicates a capacity for modern symbolic communication. This is part of an ongoing debate that is taking the study of the origins and dispersal of modern humans out of regional contexts and making it global in compass.

Recent Stone Age Ancestors

Southern Africa is one of the few areas of the globe where there are extant communities of hunter-gatherers, the San. Systematic studies of San language and ethnography were initiated in the 1870s by Wilhelm Bleek (Lewis-Williams 2000) and continued after his death by his sister-in-law, Lucy Lloyd (Bleek and Lloyd 1911), and his daughter, Dorothea. After the turn of the century, interest in San ethnography continued, but within South Africa there had been an almost total disruption of traditional San societies. However, San communities continued to exist in Namibia and Botswana (D. F. Bleek 1928), and it was in those countries that there was a revival of research stimulated in the 1950s by the Marshall family (L. Marshall 1976; T.E. Marshall 1959) and later by researchers associated with the University of Harvard and other overseas institutions.

The Bleek and Lloyd historical records and the corpus of more recent ethnographic research continue to provide a rich source of analogies for later-Stone Age studies. Goodwin and van Riet Lowe (1929) appreciated a direct link between the historical San and the later Stone Age but struggled to explain the relationship between the major Wilton and Smithfield cultures they recognized and perceived similarities between the Wilton and the Capsian of North Africa.

Goodwin (1938) had laid the basis for later-Stone Age research through his excavations at Oakhurst, but this work was not followed up with a new phase of excavations until after the 1950s. Holocene Wilton and Smithfield sites could be dated by radiocarbon at the Council for Scientific and Industrial Research facility in Pretoria, which was started by J.C. Vogel. This facility played a large part, not only in ordering Stone Age sites but also in dating the advent of agriculture. Chronologies showed that the cultures Goodwin and van Riet Lowe had assumed to be geographically and culturally distinct entities were better explained in a temporal sequence of innovations and changes in San technology (J. Deacon 1974). Radiocarbon dating has also resolved the age of the youngest middle-Stone Age occurrence to 22,000 years at Strathalan (Opperman and Heydenrych 1990) and the oldest later Stone Age to 21,000 at Boomplaas (H. J. Deacon 1995). The latter age estimate is close to that for the earliest Epipaleolithic industries throughout the continent, which suggests that there was indeed some basis for Goodwin and van Riet Lowe's concern with similar industries found in North Africa.

The continuity between the later Stone Age and the ethnographic present is very impressive with items like ostrich eggshell containers and tortoise-shell bowls still being made as they were 15,000 years ago. This continuity finds no better demonstration than in the use of historical ethnography like the Bleek and Lloyd records to understand the metaphors expressed in the rock art. Although the art has long been trivialized as childlike drawings and engravings to do with hunting magic, myths, and legends, research since the 1960s (Lewis-Williams 1981; Vinnicombe 1976) has highlighted the symbolic significance of depictions like those of the eland and has shown that the art is essentially shamanic and religious. There are more than 10,000 rock-art sites known in South Africa alone, and many more have been recorded

in Namibia, Botswana, Zimbabwe, and Mozambique. Southern African rock art covers the area where San click-language speakers were known or can be suggested

to have been present. An outlier of rock art with similar metaphors occurs in central Tanzania where click languages are also spoken.

Herders and Farmers

Within the last 2,000 years, herding economies have developed in the more arid, western part of the subcontinent and mixed agriculture, in the wetter, eastern half. Historically, herding communities were Khoekhoe speakers, and the largest extant community is the 100,000-strong Nama in Namaqualand and southern Namibia. The identification of sheep remains associated with bag-shaped pottery at Die Kelders in southern Namibia (Schweitzer 1974) showed that it was possible to investigate the history of Khoekhoe settlement through archaeology. A stock post was identified at Boomplaas where age profiles of the animals indicate that stock raising was intensive (H. J. Deacon 1995). A main kraal, or settlement, was identified at Kasteelberg (Smith 1992) in which the remains included not only sheep but cattle that ethnography suggests were ritually slaughtered. Khoekhoen and San interaction was recorded historically, but with the fluid nature of economic and social groupings, it has proved difficult to document them archaeologically.

The Zimbabwe-type settlements attracted early interest not the least because of their association with gold artifacts. However, the first serious archaeological investigation of the ruins of great zimbabwe was undertaken by gertrude caton-thompson (1931), and she was able to show that the settlement was medieval in age based on its porcelain imports. This find was followed by extensive excavations at the Iron Age sites (eleventh to twelfth centuries a.d.) of K2 and Mapungubwe (Fouché 1937) in the Limpopo Valley of the Northern Transvaal in South Africa. Although pioneers like Schofield (1948) continued to study the pottery finds from early farming settlements, such studies only achieved formal recognition after World War. This recognition came through the proposal of the term *Iron Age* (Summers 1951) as distinguished from the Stone Age. With this recognition came the appreciation that the unwritten history of many extant communities in southern Africa was accessible only through archaeology (Mason 1989). Early farming communities contained metalworkers and miners as well as stock farmers; cultivators of millet, sorghum, and other crops; and the manufacturers of regionally and temporally distinctive styles of pottery. Iron technology was a prerequisite for their expansion as it enabled them to bring new fields under cultivation.

The Iron Age of southern Africa is part of the wider phenomenon of the expansion of siNtu, or Bantu, language speakers (Vansina 1995) in equatorial, eastern, and southern Africa. Since D.W. Phillipson's (1977) synthesis, the main debates have been when and by what pathways or “streams” different movements of peoples into southern Africa may have taken place, which underscores the popularity of migration models (Huffman 1989). With large parts of subequatorial Africa underresearched and given that range expansion rather than purposeful migration was involved, the models remain relatively general in their resolution of past events.

The best attested expansion was down the eastern coast, and radiocarbon dating has shown that the distinctive pottery at the site of Silver Leaves in Mapumalanga, dated to a.d. 350, is similar to that which appeared on the Tanzanian coast at Kwale a scant 150 years earlier. Other expansions traced through pottery styles and radiocarbon chronologies appear to have been along a route through Malawi into Zimbabwe and through a western corridor from Angola and Botswana into South Africa. The southernmost limit of the coalescence of these expansions was near modern East London in the Natal province of South Africa, a limit imposed by edaphic and climatic factors.

Radiocarbon dating and the seriation of pottery styles have shown there were a number of expansions and contractions in the agricultural settlement of the subcontinent that are explicable in terms of climatic

forcing and socioeconomic conditions. Largely as a consequence of prosperity brought about through trade with the east coast, progressively more-complex hierarchical societies emerged in the Limpopo Valley (Hall 1987). The best-known sites remain K2 and Mapungubwe, but it is only recently that their significance as precursors to Great Zimbabwe have been appreciated.

PREV NEXT

Great Zimbabwe (a.d. 1250-1450) emerged as the capital of a state (Huffman 1981), an African kingdom similar those that flourished in other parts of sub-Saharan Africa in the last 2,000 years as world trade expanded. Portuguese competition for the Indian Ocean trade routes and internal conflicts fragmented the original Zimbabwe state into several lesser states, which survived into historical times. This fact allows for confidence in linking the Zimbabwe state to Shona language speakers. The histories of the Sotho and Nguni language speakers are less clear, but through tracing traditional decorative motifs in pottery, it can be shown that they were present in southern Africa from the early part of the last millennium (ca. 1000 a.d.). Linking prehistory to the very short period of recorded history remains a goal of researchers.

Perspective

From Victorian antiquarianism, prehistoric archaeological studies have developed in stages. The very visible surface trail of stone artifacts in the landscape encouraged an interest in the peopling of the subcontinent. Beginning in the 1930s, discoveries of the australopithecine remains preserved in solution caverns in dolomites provided a window of opportunity to explore the prehuman ancestry that raymond dart suggested for the Taung child. True human populations making Acheulean artifacts more than 1 million years old are widely represented although progress in the study of these populations has been slow because preservation of remains other than stone is rare and the occurrences are difficult to sample and date. The roots of modern humans now appear to be in the middle Pleistocene in Africa (Howell 1999), which makes the later Acheulean and the Fauresmith of developing interest. The finds of early modern human remains and associated evidence for the emergence of symbolic behavior in beginning late Pleistocene, middle-Stone Age sites like Klasies River have questioned the conventional wisdom that the first evidence of such behavior is in the Upper Paleolithic in Eurasia.

The occurrence of long-sequence cave and rock-shelter sites has made it possible for considerable advances in the study of the middle and later Stone Ages, and a wealth of historical and ethnographic data have aided in these studies. An accessible part of this Stone Age record is the rock art, which, with well in excess of 15,000 sites, is a considerable cultural resource for heritage management. Not only are there surviving San communities, but the descendants of Khoekhoe herders and Iron Age farmers make up the main population of the subcontinent. As archaeology in southern Africa enters the new millennium, it is poised to make a greater contribution to educating communities about their unwritten and largely forgotten past.

Africa, Sudanic Kingdoms

Between a.d. 800 and a.d. 1500, the important kingdoms of Ghana, Kawkaw (Gao), Takrur, and Mali flourished in the Sudanic zone of West Africa between Lake Chad and the Atlantic Ocean. Repeatedly mentioned and described in varying degrees of detail by Arab chroniclers of the period, the capitals and

major entrepôts of these polities have attracted considerable archaeological attention, much of which has been conducted in an historicist mode with archaeology serving mainly to identify the towns and trading posts described in the Arab texts. Archaeological data were sought to embellish or fill out textual accounts; they were rarely used to address questions beyond those already raised by text content or analysis. Because the core areas of the kingdoms lay mainly within the former French West Sudan, the influence of French scholars on the trajectory of research in this century has been considerable. Since the 1970s, however, scholars trained outside the French system, including Dutch, Swiss, Germans, Norwegians, British, and Americans, have increasingly made important contributions.

The Colonial Period (1900-1960s)

For the first half of the twentieth century, archaeological undertakings relevant to the Sahelian kingdoms were pursued by French civil servants and military personnel. There was no professionalization of archaeology analogous to that in England, where scholars of the caliber of mortimer wheeler and gertrude caton-thompson mounted important excavations at sites such as Mohenjo Daro and great zimbabwe. Rather, in French West Sudan, curious administrators and officers who lacked any formal training were offered a variety of opportunities to investigate highly visible archaeological sites. As with the explorers who set out to map the course of the Niger River in the nineteenth century, some of these officials had a gift for systematically describing what they saw along the way but most did not.

Lieutenant Louis Desplagnes had not only a gift for detailed observation and reportage but also a passion for archaeology and ethnology. In his richly detailed *Le plateau central nigérien*

Africa, Sudanic Kingdoms

Between a.d. 800 and a.d. 1500, the important kingdoms of Ghana, Kawkaw (Gao), Takrur, and Mali flourished in the Sudanic zone of West Africa between Lake Chad and the Atlantic Ocean. Repeatedly mentioned and described in varying degrees of detail by Arab chroniclers of the period, the capitals and

major entrepôts of these polities have attracted considerable archaeological attention, much of which has been conducted in an historicist mode with archaeology serving mainly to identify the towns and trading posts described in the Arab texts. Archaeological data were sought to embellish or fill out textual accounts; they were rarely used to address questions beyond those already raised by text content or analysis. Because the core areas of the kingdoms lay mainly within the former French West Sudan, the influence of French scholars on the trajectory of research in this century has been considerable. Since the 1970s, however, scholars trained outside the French system, including Dutch, Swiss, Germans, Norwegians, British, and Americans, have increasingly made important contributions.

The Colonial Period (1900-1960s)

For the first half of the twentieth century, archaeological undertakings relevant to the Sahelian kingdoms were pursued by French civil servants and military personnel. There was no professionalization of archaeology analogous to that in England, where scholars of the caliber of mortimer wheeler and gertrude caton-thompson mounted important excavations at sites such as Mohenjo Daro and great zimbabwe. Rather, in French West Sudan, curious administrators and officers who lacked any formal training were offered a variety of opportunities to investigate highly visible archaeological sites. As with the explorers who set out to map the course of the Niger River in the nineteenth century, some of these officials had a gift for systematically describing what they saw along the way but most did not.

Lieutenant Louis Desplagnes had not only a gift for detailed observation and reportage but also a passion for archaeology and ethnology. In his richly detailed *Le plateau central nigérien*

on the excavations at the two sites, no material was recovered that would permit positive identification of them as the sites of Awdaghost or the capital of Ghana described by early chroniclers. The strong case for these identifications is archaeological rather than epigraphic in nature.

Among the major questions that remain unanswered is the nature of the settlement system at Koumbi Saleh and Tegdaoust. The "city-centric" approach of the Devisse team, which mainly focused on the central area of stone-built ruins, involved little systematic investigation of sites in the hinterland of these two towns. We thus do not know if Koumbi Saleh and Tegdaoust existed essentially as ports of call, supported by trade and local agriculture but largely isolated from other sites of appreciable size, or whether they functioned as part of a well-integrated network of villages and hamlets. Bonnel de Mezières (1923) commented on the dense zone of archaeological material that extended around Koumbi Saleh in a zone thirty-five kilometers in diameter. Because there is no pottery sequence for the region, it is impossible to know which of the sites in this zone were contemporaneous with Koumbi Saleh at various points in its evolution. Thus, we know little of the developing settlement system, which is fundamental to any reconstruction of the nature of the Ghana polity.

The emphasis on the medieval paradigm on North African artifacts and influences has also left us remarkably uninformed as to the Sudanic aspects of the Ghana polity. Al-Bakri's information establishes firmly, however, the very sub-Saharan nature of the kingdom. In his description of the pagan cults of Ghana we readily recognize the forest shrines, fetishes, and sorcery that are widespread in the Mande religion and elsewhere in West Africa.

French archaeological activity in the middle Senegal Valley (MSV), in the area of the early kingdoms of Takrur and Sila mentioned by al-Bakri, was relatively rare during the colonial period and most often took the form of casual surface reconnaissance. The unsystematic collection of a small number of appealing artifacts from surface walking or small-scale sondages was a common method of fieldwork into the 1980s. The animating spirit of these collections, registered with minimal notes or accompanying observations at IFAN in Dakar, was strongly antiquarian.

Internationalization (1970s Onward)

The general site inventory accomplished between 1971 and 1973 under the leadership of Charles Becker (a historian by training) was an important step toward a more systematic approach to archaeology in the MSV (Martin and Becker 1974, 1984). Contemporaneous with the inventory by Martin and Becker were large-scale excavations undertaken by the IFAN physical anthropologist Guy Thilmans and IFAN research associate Annie Ravisé at Sincu Bara. Important not only for highly significant finds of brass and silver artifacts, the excavations also ushered in an era of modern archaeology in the Senegal Valley. The excavation report includes specialized analyses of pollen, sediments, metals and slags, and animal bone, and the spectacular brass and silver artifacts, which suggest that Sincu Bara functioned as an elite site within the Takrur or Sila polity, are thoroughly described. Pottery did not receive equal attention, however, so the establishment of a basic pottery sequence for the region was relegated to a future time. Other important excavations in the MSV were conducted by Bruno Chavane (1985) in the mid-1970s.

With an increasing internationalization of archaeology in the western Sudan after the late 1970s, new paradigms, perspectives, and methodologies were applied to research on the Sudanic kingdoms. Partly as the result of the participation of Americans familiar with research paradigms in mesoamerica and mesopotamia, a diachronic and regional perspective on the origins and development of complex societies was introduced along with methodologies appropriate to those concerns (McIntosh and McIntosh 1984). The fundamental building blocks of this approach are the establishment of detailed

chronological sequences through controlled stratigraphic excavation and a detailed study of domestic pottery assemblages, systematic site survey and surface investigation using

PREV NEXT

may have been integral to the political and commercial activities of the Takrur polity (Robert-Chaleix and Sognane 1983; Robert-Chaleix 1994).

For the other two great polities of the western Sudan, Gao (known to Arab authors as Kawkaw) and Mali, our knowledge remains largely historical. The two archaeological sites known at Gao are the old town (Gao ancien), north of the existing town, and Gao Sané, several kilometers to the east on the opposite side of a channel (which likely flowed perennially in the late first millennium) leading north to the Tilemsi Valley. Numerous brick structures are visible on the surface of both sites, some of which were excavated by Colin Flight of the University of Birmingham to reveal a confusing sequence of building and razing episodes (Insoll 1996 provides a very useful summary). Tim Insoll's archaeological work in 1994 included excavations at both Gao ancien and Gao Sané. Although very limited in scale, his excavations have provided concrete details on the appearance of trans-Saharan trade goods, including ceramics and glass, in the tenth or early eleventh century and insights into the process of Islamization. Gao apparently was a part of trade networks extending to North Africa and Spain.

In the thirteenth century, all the regions discussed above became consolidated within the hegemony of the Empire of Mali, and little archaeological information is available for Mali. The Polish research project at Niani in Guinea (Filopowiak 1979) is noteworthy for its regional perspective, even though claims that the site was the capital of Mali visited by Ibn Battuta in the fourteenth century are problematic. There is, in fact, little compelling evidence from the excavations for occupation deposits dating to this period (McIntosh and McIntosh 1984). Excavations in the Arab Quarter, for example, produced mostly material dated to the seventh to eleventh centuries a.d. and a notable lack of imported goods.

However, from that material we can get a glimpse of Mali society during the period of small villages and petty chiefdoms described by eleventh- and twelfth-century Arab authors in the area called Malal. In this regard, Filopowiak's surface survey of fifty sites (iron-smelting sites, funerary tumuli, small villages) located within a four-square-kilometer area around Niani offers the potential for understanding an evolving settlement system. Of particular interest are small stone tumuli with rock-cut shaft-and-chamber collective graves similar to graves in the southwestern part of modern Mali, which indicate strong first-millennium cultural connections within this whole area that became the political heartland of the Empire of Mali in the thirteenth century. Unfortunately, the systematic study and description of the Niani pottery necessary to establish the chronological relationships of these hinterland sites has not yet been accomplished.

Conclusions

From a colonial, medievalist paradigm concerned mainly with recovering objects, inscriptions, and architecture that testified to outside influences at work in the empires of western Sudan, archaeology has moved since the 1970s to documenting local contexts and components of change. The opening of archaeology in the former French West Sudan to broad international collaboration has resulted in a variety of more regionally based research projects concerned with the establishment of the basic chronological sequences and site inventory data that are the foundation of all sustainable archaeological interpretation. As comparative regional data on settlement systems become available for the first time from different parts of western Sudan, important theoretical issues for archaeology as a whole emerge from the diversity of trajectories leading to the social complexity that may be detected there (McIntosh, S., 1999a, 1999b, 1999c). As a consequence, the empires of western Sudan, which have been largely marginal to mainstream archaeological theorizing about the rise of complexity until now, may in the future play a more prominent role.

Akrotiri-Aetokremnos

Until the excavations by Alan Simmons at Akrotiri-Aetokremnos, there was no evidence of any pre-Neolithic occupation of cyprus. This small, collapsed rock shelter on the south coast of the island contains deposits of stone tools and animal bones representing a relatively short period, approximately 10,000 b.c. A large proportion of the bones are of the pygmy hippopotamus, which became extinct at the end of the Pleistocene period. It is possible that human predation was a factor in this extinction. Although the site has been important in establishing an early date for Mediterranean island colonization, it is still difficult to use this single site as the basis for developing more general models of the processes involved.

Albright, William Foxwell

(1891-1971)

The son of an American Wesleyan missionary couple, Albright spent his childhood in Chile. While working as a high school teacher in South Dakota, he taught himself Hebrew and Akkadian, eventually winning a scholarship to Johns Hopkins University. Albright became one of the most eminent Orientalists of the twentieth century and was known as the father of biblical archaeology. He directed the American School of Oriental Research in Jerusalem from 1920 to 1929, and again between 1933 and 1936. Albright established the modern discipline of biblical archeology, in which ancient Near Eastern archaeological material was used to elucidate scholarly understanding of the Bible. He was to dominate this field from the early 1920s until the 1960s. His protégé, G. Ernest Wright of Harvard University, carried on the Albright tradition by blending the “biblical theology” movement of the 1950s through the 1970s with “biblical archaeology.”

Between the two world wars many of the American excavations in Palestine were at biblical sites and were staffed by Protestant seminarians and clergymen, who were supported by funds raised by churches. These included Albright's own excavations at Tell en-Nasbeh (1926-1935), at Beth-shemesh (1928-1933), and at many smaller sites. Albright also excavated Tell el-Fûl (1922), Bethel (1934), and Tell Beit Mirsim (1926-1932), from which he established a pottery chronology for Western Palestine. Albright was Chairman of the Oriental Seminary at Johns Hopkins, and from 1930 to 1968 he edited the *Bulletin of the American Schools of Oriental Research.* It was in this latter role that he recognized and publicised the great discoveries of the Ugaritic tablets (1929-1930) and the Dead Sea Scrolls (1947 on).

Alesia

Alesia is located at Alise-Saint-Reine in the department of Côte d'Or in France. There were two battles of Alesia. The first, against Julius Caesar, was by a large Gaulish tribal coalition led by Vercingetorix in 52 b.c., and it resulted in the defeat of the latter. The other, which is still taking place today, began in 1850 when scholars began debating the exact location of the famous siege of Alesia, at either Alise on Mount Quxois in Burgundy or Alaise in the department of Franche-Comté, the two most favored sites for this great event. However, tradition also provided the scholars with another site to dispute, the village of Alise-Saint-Reine, which had replaced a Gaulish *oppidum* (fortified town) with a Gallo-Roman town and which, in fact, is the real site of Alesia. In the ninth century a.d., scholars had recorded this link, but it had been forgotten by the Middle Ages. In 1838, a military officer making a relief map of the site of Alise was struck by its coincidental resemblance to Caesar's description of Alesia. Several years later, the people of Franche-Comté, supported by the relief map and the analysis of Caesar's troop movements, debated this claim and proposed Alise as the alternative.

With the encouragement of Napoleon III, soundings were made around Alise between 1861 and 1865, and they revealed the traces of pickax diggings made during a Roman, Gaulish, or German siege. The siege pits corresponded to Caesar's general descriptions, and the many remains of arms and coins dated the battle. Pits were dug alongside the basic *oppidum* and confirmed the existence of a Roman settlement, and a "Gaulish wall" was excavated, but it could have been built after the conquest.

In the years from 1950 to 1990, the corpus of coins, ranging from bronze forgeries of the golden statere of Vercingetorix to coins used during the nineteenth century a.d., was analyzed. Aerial prospecting

revealed many traces of the pits, contours, and camps installed by Caesar around the citadel. Excavations by a Franco-German team made Alise, for the scientific world at least, a special reference site for dating other contemporaneous sites and for the study of Roman army camps. The traces of the pits and camps were validated by excavations in the nineteenth century and Caesar's written descriptions. The pits were laid out on

PREV NEXT

the site exactly as he had described them, and a rigorous study of movable artifacts confirmed their origins and dates. One of the Gaulish walls of the *oppidum* was built before the siege, and the archaeological proof of that fact is incontrovertible.

The hill of Alesia is attached to the chalky Auxis range by only a narrow pass. It resembles a plateau, with a ninety-hectare surface surrounded by steep cliffs, and the impression from the Laumes Plain is much less grand than Caesar's description of it as being as high and great as Sienna's. Rather it is similar to the Puy d'Issolud (Vayrac, Lot), and resembles Uxellodunum, which Caesar put under siege in 51 b.c. The rampart was very little enlarged, because the cliffs discouraged direct attack. However, it is on the plain, as Caesar himself noted elsewhere, that the traces of battle can be best found.

The identification of the site of this battle gave archaeologists a fixed location point for an absolutely certain and essential chronology for the history of weapons, armaments, and coinage. Some of the coins did not have dates, only rare inscriptions of the name of chiefdoms, and only their weights and the alloy compositions enabled them to be classified. The presence of money in Alesia attests to its circulation in 52 b.c., and at this point it is enough to find a monetary series. As Vercingetorix called on the troops from all across Gaul to come to his rescue, Alesia must be considered a reference site for regions that were far away but participated in the uprising.

Caesar's genius was exemplified not only in the conduct of the war's operations, which caused the surrender of the Gaulish coalition, but also in his political exploitation of the situation. In 52 b.c., not only were the so-called conquered cities in revolt but also the great tribes of Bituriges, Arvernes, and all of their allies led by the Heduens. After many months of indecisive fighting, Vercingetorix called for another army to come and help him, but it never reached him; it was unable to penetrate Caesar's defense.

Caesar went into battle at the most decisive moment of the war, and the siege of Uxellodunum the following year was the consequence of this. Contemporaries echo their general's description of this secondary *oppidum* as a key site for a "Gaulish nation," which was of their invention and for their glory. The kings, the emperors, and later the school of the Third Republic changed the rebellion of the Gaulic tribes into the first manifestation of the resistance of a French nation to an enemy. The hexagon shape of france can be justified in two ways: the space was defined by natural frontiers-the Rhine River, the Alps, and the Pyrenees Mountains; in time, it was the coalition of Gaulish peoples around Vercingetorix, who founded a modern French nation at Alesia.

It took more than 100 years of archaeological research to prove that the written record of history was, in part, Caesarian propaganda.

Altamira

Altimira is the name of a cave in Santander Province, northern spain, where Don Marcelino Sanz de Sautuola, a local landowner, discovered Paleolithic paintings and engravings in 1879. The ceiling of the cave is particularly famous as it is decorated with an array of polychrome bison figures. Unfortunately, Sautuola's claims for the art's antiquity were rejected by the archaeological establishment for twenty years as a result of several factors-among them, he was an unknown amateur, no Paleolithic art had previously been found outside France, and the animal figures looked too fresh and sophisticated to be genuinely ancient.

PREV NEXT

Altamira contains a wealth of other paintings and engravings, including “masks” and quadrilateral signs like those of the cave of El Castillo in the same region. The two caves also contain identical multiple-line engravings of deer, both on the walls and on shoulder-blade bone of animal remains found in the cave, and some of these bones have been radiocarbon dated to 13,550 b.c. Altamira's art probably spans a period from about 20,000 to 14,000 years ago. Charcoal from black figures in different parts of the cave has produced direct dates from 16,480 to 14,650 years ago.

Paleolithic cave painting from Altamira

(Ann Ronan Picture Library)

The ceiling is clearly a complex palimpsest of figures from different phases, but scholars from Sanz de Sautuola onward have believed that the polychrome bison were produced in one episode or even by a single artist. However, charcoal in some of the ceiling's bison has yielded radiocarbon results from 14,820 to 13,130 years ago, which, if valid, suggests that the figures may not constitute a single homogeneous composition after all.

American Academy in Rome

The American Academy in Rome is the U.S. center in Rome for scholars, architects, artists, and musicians and incorporates a School of Classical Studies. Originally two separate schools-the American School of Architecture in Rome, founded in 1894 by Charles Follen McKim, and the American School of Classical Studies in Rome, established in 1895 by the archaeological institute of america (AIA)-the American Academy in Rome (AAR) became a single institution in 1912.

The architectural school had taken the French Academy in the grand Villa Medici in Rome as its model, and McKim had envisioned it as a center for architects to study the noble buildings of ancient Rome. Its first home was, however, anything but imperial, consisting of eight rented rooms in the Palazzo Torlonia. The classical school was the second such school the AIA founded, and its model was the American School of Classical Studies in Athens, established in 1882, also in emulation of older European institutions. The Rome classical school, too, began life in rented quarters-in the Villa Aurora on the Pincio Hill.

The two American schools in Rome moved from their separate quarters to a new building on the Janiculum Hill in 1914. This main building, together with the neighboring Villa Aurelia (a 1909 bequest to the architectural school) and several other buildings, is the home of the AAR to this day, and the complex houses a research library, art studios, music rooms, exhibition galleries, and residential and dining facilities. The American Academy in Rome is unique among the many foreign schools in that city because of its status as a privately funded organization and its diverse Rome Prize fellowship program that brings together archaeologists, philologists, historians, art historians, architects, painters, sculptors, and musicians to form a vibrant intellectual and artistic community.

Unlike its sister institution in Greece, the American School of Classical Studies in Rome was unable to

undertake any excavations in Italy for half a century after its foundation. Its members consequently confined their activities to the study of architecture, topography, inscriptions, and classical statuary. Among the noteworthy studies produced during the AAR's early years were Esther Van Deman's on Roman construction techniques and Samuel Ball Platner's on Roman topography.

It was not until after World War II that a more receptive attitude in Italy toward foreign excavation permitted members of the AAR to begin major fieldwork. In 1948, under the direction of

Frank E. Brown, a U.S. team began to uncover the remains of the Republican colony of Cosa on the coast northwest of Rome, focusing on the temples of the Capitolium, the civic buildings of the Forum, and some private houses. Publications of the excavations have appeared in several volumes of the *Memoirs of the American Academy in Rome.* The academy donated the site and its museum to Italy in 1981. In Rome itself, the AAR has excavated in the Regia and the Atrium Vestae in the Forum Romanum and, most recently, on the slope of the Palatine Hill.

American Antiquity

American Antiquity is the quarterly journal of the Society for American Archaeology (SAA), and it includes articles on the archaeology of North and South America and archaeological method and theory worldwide. The SAA was founded in 1934 to promote communication within the professional archaeological community and between professional and avocational archaeologists through various means, including a journal. In 1937, Carl E. Guthe proposed the name *American Antiquity* for the journal, following the lead of the English journal *Antiquity*.

All members in the society receive *American Antiquity,* and funding for its publication comes primarily from dues paid to the society. Prior to 1958, authors paid for some or all of the cost of illustrations. Until 1993, a single nominee for editor was selected for a four-year term (shortened to three years in 1978) by the society's nominating committee and was "elected" by the membership. Now, as a result of a change in the bylaws, the editor is selected by the SAA executive board and is no longer a voting member of that governing body.

The early editors managed the journal from their institutional office with editorial assistance from spouses, students, and assistant editors representing different geographical areas or archaeological specialties. As the workload increased, associate editors were added for different sections of the journal. In 1989, a full-time managing editor took over many of the production tasks.

Review of articles submitted was in the hands of the editor and the assistant editors until 1969 when peer review of each submission by two people was instituted. The number of reviewers for each manuscript was increased to four in 1989. Prior to peer review, the acceptance rate of article submissions was 65-90 percent, and at times editors were desperate for copy. After peer review began, a change that coincided with a period of tremendous growth in the society, the acceptance rate fell below 50 percent.

The general character of the journal's contents has remained fairly uniform even though the organization

has changed. The principal purpose of the journal from the beginning was to present research articles, and these make up the majority of each issue. Although issue contents are usually determined by what is submitted, occasional special issues are designed with a particular geographic or topical focus. The twenty-fifth and fiftieth anniversaries of the SAA were occasions for special issues of historical interest.

In the early issues, a correspondence section was included to provide a forum for brief comments by amateurs, but as it worked out, professional archaeologists dominated that section along with the others. A facts and comments section was added in 1938. The notes and news section continued the annual archaeological fieldwork summary compiled by the National Research Council's Committee on State Archaeological Surveys and published in *American Anthropologist* until 1932. That section, which became current research in 1962, provided up-to-date

summaries of archaeological research in the Americas and for a brief period (1973- 1976), the Old World. The section was dropped in 1994 because of space constraints.

The book review section, always important for membership participation and reader interest, includes books from all areas of the world. An important section published annually is the report of the society's business meeting, including committee reports. Until 1974, this section also included titles of papers given at the annual meeting.

As membership in the SAA has always been dominated by citizens of the United States, articles in *American Antiquity* have had a strong focus on America north of Mexico, even though there have been occasional complaints from the membership about the number of Mesoamerican articles. Steps to internationalize the journal include publication of a few articles in Spanish in the 1940s, inclusion of translated Russian articles in the early 1960s, institution of an annual review of Old World archaeology in 1978 (discontinued in 1990), and publication of Spanish abstracts for articles beginning in 1989. In the late 1980s, the demand for a journal specifically devoted to Middle and South America was strong enough that the society created *Latin American Antiquity*, which is available to SAA members at an additional charge. This journal began publication in 1990, and since then, *American Antiquity* has focused more on articles on archaeology in the United States and Canada and on archaeological method and theory. As foreign membership and subscription increased in the 1970s, particularly in Europe, *American Antiquity* became the medium by which the state of American archaeology is judged.

The contents of *American Antiquity* provide a fairly good measure of the interests and theoretical orientations of professional archaeologists in the United States, but the journal does not reflect the work of Americanists in other countries nearly as well. In one study of the journal's contents for the first fifty years, articles on excavation, material culture, and culture process were found to account for 60 percent or more of the articles until the last half of the 1960s. Since that time, the number of articles devoted to these three areas has declined, and articles on floral and faunal remains and analytical methods have increased to give a more balanced coverage of archaeological topics.

In another study that looks at the trends in articles emphasizing data, method, or theory for the first forty years of the journal, articles emphasizing data consistently made up 60 percent or more of the total published until the term of the last editor in the sample, Edwin N. Wilmsen, when the proportion dropped to one-third. Interestingly, this dramatic shift also occurred at the time when peer review was introduced. Articles on method consistently represented around 20 percent of the articles until the 1960s when they began to increase, reaching 50 percent by the early 1970s. Articles on theory were always 10 percent or less except during the terms of the earliest and latest editors, when they reached 15 percent.

Archival materials relating to *American Antiquity* are housed in the National Anthropological Archives of the National Museum of Natural History of the Smithsonian Institution. Materials over ten years old are available to researchers except for confidential files, such as referee comments, which are restricted for fifty years.

Andrew L. Christenson

American Journal of Archaeology

The *American Journal of Archaeology* is the official journal of the archaeological institute of america (AIA). In January 1885, fewer than six years after the formation of that institute, Arthur Lincoln Frothingham, Jr., published the first issue of the *American Journal of Archaeology for the Study of the Monuments of Antiquity and of the Middle Ages.* The new journal was to be “the official organ of

the Archaeological Institute of America," and its stated goal was "to further the interests for which the Institute was founded."

Twelve years later, the young periodical, now simply called the *American Journal of Archaeology (AJA),* marked the inauguration of its second series by placing the institute's seal on its title page and adopting as its subtitle, "the Journal of the Archaeological Institute of America." The rationale for the second series was to bring

"greater unity and uniformity" to the institute's diverse publications. Henceforth, *AJA* would be the sole venue for the publication of articles on the fieldwork and research conducted by the AIA's new American schools of classical studies established in 1882 in Athens and in 1895 in Rome. Although *AJA* no longer has a monopoly on AIA research (the American School in Athens, for example, has published its own journal, *Hesperia,* since 1932), more than a century later the second series continues to appear in quarterly fascicles. *AJA* remains the AIA's official journal and publishes each April the abstracts of the papers presented at the institute's annual meeting in December; the citations of the AIA's awards for scholarship, teaching, and service; and the texts of important resolutions of the AIA's governing council.

Although the original mission of *AJA* was to "treat all branches of Archaeology and Art-Oriental, Classical, Early Christian, Mediaeval, and American," the archaeology of the AIA's own continent never gained a strong foothold in the journal, and scholars of medieval art preferred to publish their research in art history publications rather than archaeological journals. From the beginning, *AJA,* like the AIA itself, reflected its founders' preoccupation with the classical world, especially Greece. The defined scope of *AJA* today is "the art and archaeology of ancient Europe and the Mediterranean world, including the Near East and Egypt, from prehistoric to late antique times." In recent years, although retaining its focus on Greece and Rome, *AJA* has published articles on all periods of Old World art and archaeology as well as newsletters on fieldwork in Cyprus, Iraq, Israel, Jordan, Sardinia, Syria, and Turkey. Other regular features have been a series of critical reviews of Aegean prehistory, book reviews, obituaries, and the proceedings of the AIA's annual meetings.

In conformity with an AIA 1973 resolution opposing the illicit international trade in antiquities and the despoliation of archaeological sites, *AJA*'s editorial policy precludes "the announcement or initial scholarly presentation of any object in a private or public collection acquired after 30 December 1973, unless the object was part of a previously existing collection or has been legally exported from the country of origin."

American School of Classical Studies at Athens

The American School of Classical Studies at Athens, the largest foreign research center in Greece, is dedicated to the study of Greek archaeology, history, and culture. Founded in 1882 by the archaeological institute of america (AIA), the American School of Classical Studies at Athens (ASCSA)

was conceived as a place where U.S. scholars could study classical Greek monuments at first hand. In establishing a research center in Greece, the AIA was following the lead of France, whose school in Athens had opened in 1846, and of Germany, which had inaugurated the Athenian branch of the Deutsches Archäologisches Institut in 1874. But unlike its European counterparts, the ASCSA, like the AIA itself, was (and still is) a privately funded organization dependent on college and university support as well as the generosity of individuals and foundations.

The ASCSA began in rented quarters near the Arch of Hadrian, but two years later the Greek government donated land for a permanent home on the south slope of Mt. Lykabettos adjacent to the plot previously given to the British School of Archaeology. The Americans moved into their newly constructed Main

Building in 1888, which was enlarged in 1913-1916, 1958-1959, and 1992. Construction of a residential/dining facility, Loring Hall, took place in 1930.

In 1922, Joannes Gennadius, a prominent Greek diplomat, offered to donate his extensive personal library on the history and culture of Greece to the ASCSA if the school would build a separate building to house it and make the collection available to researchers of any nationality. A gift from the Carnegie Foundation made possible construction of the Gennadeion, a neoclassical marble structure, which opened in 1926. It houses not only rare books but also Edward Lear landscapes of Greece and archival material on the archaeologist Heinrich Schliemann.

Immediately after its foundation, the ASCSA launched a program of excavation and publication-even before the school began construction of its permanent headquarters. The first major ASCSA site was the Argive Heraion, excavated between 1892 and 1895. The school's two largest continuing excavations are at Corinth and in the Athenian Agora, but members of the school have explored Greek sites that span a very wide range, both chronologically and geographically, including Franchthi Cave, Lerna, Olynthos, Messenia, Nemea, Samothrace, Keos, and Kommos.

Work began in Corinth in 1896, and the excavation of a major ancient Greek city lent prestige to the fourteen-year-old U.S. institution. The French and Germans had earlier secured permits to excavate at Delphi (the Americans had also wanted a permit to excavate there but had failed to obtain one) and Olympia, respectively. Excavation in the historic Plaka district of Athens to uncover the classical Agora started in 1931. Reconstruction of the Stoa of Attalos to serve as the excavation headquarters; a museum was begun in 1953 and completed in 1956.

The ASCSA initially published reports of its fieldwork in the *American Journal of Archaeology,* but the opening of the Agora excavations prompted the school to create its own journal, *Hesperia,* in 1932. The ASCSA also publishes a multivolume series for each of its major excavations, monographs on diverse topics, site guides, and a series of inexpensive *Picture Books* for the general public. The school offers a formal curriculum as well as research fellowships for graduate students during the academic year and a summer program for both students and teachers. It is the official liaison between more than 150 affiliated North American colleges and universities and the Greek Ministry of Culture, which grants all fieldwork permits.

American Schools of Oriental Research

The American Schools of Oriental Research (ASOR) is the principal North American research organization for the study of the ancient Near East. Founded in 1900 under the aegis of the Archaeological Institute of America (AIA), the Society of Biblical Literature, and the American Oriental Society, the ASOR is a consortium of approximately 140 North American colleges, universities, museums, seminaries, and libraries. Its administrative offices are currently on the campus of Boston University and are housed in the same building as the AIA's national headquarters.

Like its AIA siblings, the American School of Classical Studies in Athens and the American Academy in Rome, ASOR is a privately funded rather than a government-funded institution. ASOR has three permanent research centers abroad: the W.F. Albright Institute of Archaeological

PREV NEXT

Research (AIAR) in Jerusalem; the American Center of Oriental Research (ACOR) in Amman, Jordan; and the Cyprus American Archaeological Research Institute (CAARI) in Nicosia. These centers sponsor scores of field projects in the Middle East.

ASOR publishes the *Bulletin of the American Schools of Oriental Research* (the first issue appeared in 1919), the *Journal of Cuneiform Studies* (begun in 1947), *Biblical Archaeologist* (a popular journal launched in 1938), and several monograph series. ASOR celebrated its centennial on 15 April 2000 with a conference at the Smithsonian Institution in Washington, D.C., entitled "Footsteps in the Dust: A Century of ASOR Discoveries in the Ancient Near East."

ASOR established its first overseas research center in 1900 in Jerusalem. The AIAR's present home, just north of the old walled city, opened in 1925. Originally called the American School of Oriental Research, the AIAR assumed its present name in 1970 in honor of william foxwell albright, a pioneer in the scientific excavation of sites in Palestine and a longtime director of the school. The building, which was enlarged in 1930 and renovated in 1985, houses a research library, laboratories, and residential and dining facilities for fellows and visitors. The AIAR sponsors seminars, workshops, and lectures and currently coordinates the excavation, surveying, and publication of approximately twenty archaeological sites, chief among them Ashkelon, Caesarea, Sepphoris, and Tel Miqne-Ekron.

ASOR's Jordanian center was born in 1968 after the Six-Day War in June 1967 between Israel and the Arab world brought an end to AIAR work in the Hashemite Kingdom. The Jordanian government regarded the new branch of ASOR, originally called the American Research Center in Amman, as an exiled operation of the Jerusalem school. Reflecting the new political reality of the Middle East, in 1970 the Amman Committee of ASOR became a separate corporate entity and assumed its present name (the Jerusalem school took on its new name at the same time). ACOR is now the largest research institute in Amman and is the liaison between the Jordanian Department of Antiquities and North American excavators and researchers. ACOR's present headquarters, constructed in 1984-1986, are in a five-story structure located near the University of Jordan and the British and German archaeological institutes. The building houses a research library, offices, workrooms, a lecture hall, a conservation laboratory, and residential and dining facilities. ACOR currently coordinates about thirty excavations, surveys, or publication projects covering several millennia of the history of Jordan. Among the most notable sites are 'Ain Ghazal, Petra, Aqaba/Ayla, and the Citadel of Amman.

The newest of ASOR's research centers, CAARI, founded in 1978, is the only foreign organization in Cyprus dedicated to archaeological study, and it opens its doors to visitors from all over the world. CAARI's headquarters, a remodeled two-story residence built in the 1930s, is in central Nicosia near the Cyprus Museum. Like the AIA institutions in Jerusalem and Amman, CAARI houses a research library, laboratory, workrooms, and residential quarters; sponsors lectures and symposia; and offers research fellowships. As the liaison between the Cypriot Department of Antiquities and North American scholars, CAARI facilitates numerous American field and research projects on the island from prehistory through the classical, Byzantine, Venetian, and Ottoman periods.

Andersson, Johan Gunnar (1874-1960)

The first major archaeological fieldwork in china was carried out by Western scientists attached to the Geological Survey of China established in Beijing in 1916. J.G. Andersson was a

PREV NEXT

fossil hunter and explorer who spent long periods in China, where he became fascinated with stories of "dragon bones," which were highly valued by the Chinese for their magical and pharmaceutical uses. In 1921, the search for fossils led Andersson to Zhoukoudian Cave, in Hebei province near Beijing, which was a giant fissure in a limestone cliff filled with fossil animal bones. Excavation revealed a major Chinese Paleolithic site, containing human skeletal material in the same levels as crude stone tools, animal bones, and traces of thick hearths. Zhoukoudian was excavated under the direction of Canadian anatomist Davidson Black. The first skull cap of *Homo erectus*, known initially as Peking Man or Sinanthropus, was excavated by Chinese archaeologist pei wenzhong in 1929. The site has yielded the only large population of *Homo erectus*, with fragments of more than forty individuals of the species worldwide. Most of the bones were lost during World War II.

Antiquity

In 1925, o.g.s. crawford, then age thirty-nine, had the idea of a new archaeological publication to serve the very lively and active group, the then-young generation of archaeologists working in England. Existing journals smoldered on, but they neither flamed nor gave light. Unusually, Crawford did not seek a publisher, for he wanted a completely free hand to say and to publish whatever he liked. Instead, he set up *Antiquity* as his own enterprise with money borrowed from a friend.

Sending a prospectus to 20,000 names and addresses, he soon had over 600 subscribers, and the venture was launched as a quarterly journal in 1927. Reports on the Glozel affair, the faking of Neolithic writing in eastern France, helped energize the new venture, and in 1928, the journal published the first scholarly report of leonard woolley's excavation of the royal tombs at ur in mesopotamia.

In rereading the early articles published in *Antiquity*, the journal's distinctive character is evident. In each number, Crawford wrote a lively editorial with snippets of news, comment, and reports of passing events and curiosities with an archaeological aspect; as he said, "Try living on a desert island with a book of verse and no loaf of bread-or *Antiquity* without a jug of wine!" (Crawford 1955, 177). His own interests in aerial photography are evident, and the field reports start from the focal area in the classic landscapes of southern Britain, especially its chalk land. Crawford's broader interests are also revealed in the coverage of Africa; there is, for example, pioneering work in the field that would now be called "ethnoarchaeology." Great names of the next generation, like christopher hawkes and stuart piggott, are conspicuous. Names from the Americas are largely absent.

The first number of the tenth volume, for March 1936, shows the pattern in its 128 pages: editorial, six long reports ("The Coming of Iron," "Pit and Pit-dwellings in Southeast Europe," "Roman Barrows," "Easter Island," "Anglo-Saxon Vine-Scroll Ornament," and "Cyclopean Walls at Tarragona"), ten short reports and a pair of air photographs, book notes, and twenty-two book reviews. Of one book, Crawford commented, "We are surprised that the Oxford University Press should sponsor such a shocking piece of work as this." The diversity is important, and the range of subjects in each of the year's other three numbers is equally diverse.

Crawford edited *Antiquity* largely on his own, and when he died in 1957 it was found that no provision had been made for a successor. glyn daniel was persuaded to take it on, in tandem with his wife, Ruth

Daniel, as production editor, and he published his first issue early in 1958. In order to safeguard the future of the journal, £5,000 was gathered from well-wishers to buy the publication, and a nonprofit organization, Antiquity Trust, was created to own it in perpetuity.

Like Crawford, Daniel had a good eye for news and the telling of anecdotes, and his Cambridge, television, and book-editing contacts made for a continuing broad vision. The makeup of a typical Daniel issue, the first number of the

fortieth volume, for March 1976, is as follows: editorial, six long reports ("Prehistoric Archaeology in Thailand," "The Origins of Writing in the Near East," "The Destruction of the Palace of Knossos," "Ugarit," "The Ezero Mound in Bulgaria," and "The Vix Mound"), eleven short reports including an air-photographic report, and twelve book reviews.

During the long Daniel era, which lasted until 1986, it became harder for *Antiquity* to maintain its established role. The "general readers," people with a broad interest in archaeology among many other things, seemed to be disappearing (if they had ever existed), and the publication could no longer be part journal, part popular magazine. About half of the circulation of *Antiquity* went to libraries, mostly in universities, and the balance to individuals who were often in some way in the business of archaeology. The world of archaeology continued to expand in every way, but *Antiquity* did not. Production costs reduced it to three thinner issues a year instead of four, so it began to have too few pages to cover that larger world with any fullness.

I was appointed editor in 1987 in succession to the Daniels, again in partnership with the editor's spouse, Anne Chippindale. *Antiquity* was switched to the then-new printing technology of desk-top production. In 1988, it was again published quarterly with a total of about 1,000 pages a year. The content has remained the same-a personal editorial, research reports of varied length, and a strong review section-and so has the commitment to lively and novel work, to rapid publication, and to good presentation. Various devices have been created with its review editors, first Timothy Taylor and then Cyprian Broodbank, to cover new publications well in the review section, it being quite impossible to keep up with *all* that is new.

Archaeology is becoming more specialized and more subdivided, as other sciences have before it. Nearly all the general journals of science have disappeared, leaving only *Nature* and *Science*-the two heavyweights-and I think the same will be true in archaeology. *Antiquity* has been able to cover a broad field of archaeology only by becoming larger. As I envisaged it, inside each larger number of *Antiquity* there is a smaller number, different for each single reader, of those contributions that are of telling interest. [Editorial note: Christopher Chippindale was editor of *Antiquity* until the end of 1997.]

Anyang

Anyang is one of the most significant sites of the Shang dynasty in china (approximately thirteenth century b.c.). Excavated by archaeologist li chi between 1928 and 1937, Anyang comprises a royal cemetery of massive shaft graves and a diversity of major public buildings, residences, and workshops. Anyang has been a major source of information about Shang material culture and burial practices, and the scale of the remains has been thought to demonstrate that the site was the capital of late Shang China.

Tim Murray

Arabian Peninsula

The Arabian peninsula is an area in which archaeological research has always been conditioned by a host of political, economic, religious, and social factors over which individual researchers have had little

or no influence. The relative isolation of the region until recently has meant that the constraints affecting archaeology have remained obscure to all but those actually engaged in fieldwork there. Indeed, Arabia is, generally speaking, obscure in most people's imaginations-a land of harsh climatic conditions, ultraconservative religious movements, and oil; a land without the obvious heritage of Persia, mesopotamia, or Egypt; a land in which little of archaeological interest or value is thought to exist. The experience of the last few decades in particular has proved these assumptions wrong, but few people are aware of the reasons why it took so long for this change in awareness to occur.

Histories of Arabian exploration abound. The pre-twentieth-century exploration of the peninsula

fortieth volume, for March 1976, is as follows: editorial, six long reports ("Prehistoric Archaeology in Thailand," "The Origins of Writing in the Near East," "The Destruction of the Palace of Knossos," "Ugarit," "The Ezero Mound in Bulgaria," and "The Vix Mound"), eleven short reports including an air-photographic report, and twelve book reviews.

During the long Daniel era, which lasted until 1986, it became harder for *Antiquity* to maintain its established role. The "general readers," people with a broad interest in archaeology among many other things, seemed to be disappearing (if they had ever existed), and the publication could no longer be part journal, part popular magazine. About half of the circulation of *Antiquity* went to libraries, mostly in universities, and the balance to individuals who were often in some way in the business of archaeology. Archaeology is becoming more specialized and more subdivided, as other sciences have before it. Nearly all the general journals of science have disappeared, leaving only *Nature* and *Science*-the two heavyweights-and I think the same will be true in archaeology. *Antiquity* has been able to cover a broad field of archaeology only by becoming larger. As I envisaged it, inside each larger number of *Antiquity* there is a smaller number, different for each single reader, of those contributions that are of telling interest. [Editorial note: Christopher Chippindale was editor of *Antiquity* until the end of 1997.]

Anyang

Anyang is one of the most significant sites of the Shang dynasty in china (approximately thirteenth century b.c.). Excavated by archaeologist li chi between 1928 and 1937, Anyang comprises a royal cemetery of massive shaft graves and a diversity of major public buildings, residences, and workshops. Anyang has been a major source of information about Shang material culture and burial practices, and the scale of the remains has been thought to demonstrate that the site was the capital of late Shang China.

Tim Murray

Arabian Peninsula

The Arabian peninsula is an area in which archaeological research has always been conditioned by a host of political, economic, religious, and social factors over which individual researchers have had little

or no influence. The relative isolation of the region until recently has meant that the constraints affecting archaeology have remained obscure to all but those actually engaged in fieldwork there. Indeed, Arabia is, generally speaking, obscure in most people's imaginations-a land of harsh climatic conditions, ultraconservative religious movements, and oil; a land without the obvious heritage of Persia, mesopotamia, or Egypt; a land in which little of archaeological interest or value is thought to exist. The experience of the last few decades in particular has proved these assumptions wrong, but few people are aware of the reasons why it took so long for this change in awareness to occur.

Histories of Arabian exploration abound. The pre-twentieth-century exploration of the peninsula

is well summarized by F. Hommel (1903) and david g. hogarth (1904), but for the first half of the twentieth century, A. Grohmann (1963) is the only comprehensive survey yet published. Quite obviously, there is a difference between exploration and archaeology. The heroic accounts of the often dangerous expeditions to Yemen led by Joseph Halévy in 1869, Eduard Glaser in 1884-1894, and Count Landberg in 1898; of the journeys to Madain Salih, al-'Ula, and Tayma in the Hejaz (northwestern Arabia) undertaken by Charles Doughty in 1876-1878, Julius Euting in 1884, Charles Huber in 1884, and the Dominican fathers A.J. Jaussen and R. Savignac from 1907 to 1910; and of the unparalleled survey of central Arabia conducted by G. and J. Ryckmans, Captain P. Lippens, and H. St. J.B. Philby in 1951 do not, properly speaking, belong to the history of Arabian archaeology. These investigations were primarily epigraphic ones, for the early "penetration of Arabia," to use Hogarth's phrase, was largely the work of scholars of Semitic languages seeking to throw new light on the Bible.

Nineteenth-century scholars, many of whom were products of the German comparative philological method, looked to the newly discovered inscriptions of southern and northwestern Arabia for answers to Old Testament riddles. As Hommel wrote in 1903: "The queen of Sheba proved Solomon with hard questions, all of which in his wisdom he answered her. Now we who study the Old Testament, reversing the process, go to the wonderland of that queen with a multitude of inquiries, to many of which it has already given us a satisfactory reply. For the fact that we now have such comparatively clear views on all these points is due chiefly to the results of epigraphical researches in Arabia during the nineteenth century" (751).

When Hommel and Hogarth praised the intrepidness of the likes of Halévy and Glaser, they did so with good reason. More than one would-be explorer of Yemen lost his life in the attempt, and political conditions throughout most of the Arabian peninsula during the nineteenth century, with the possible exceptions of Bahrain and Oman, were indeed anarchic by any standard. Ottoman influence was only slight in Yemen and al-Hasa, today's eastern province of Saudi Arabia; inner Arabia was lawless and outside the sphere of the great powers; and diplomatic representation was nonexistent in all but a few ports of call in the Arabian Gulf. Thus, in contrast to Mesopotamia, iran, turkey, Syria, and Egypt, where more-stable political conditions permitted the undertaking of archaeological excavations by British, French, and eventually American and German missions in the late nineteenth and early twentieth centuries, the Arabian peninsula was virtually untouched until after World War II. With this general background in mind, let us turn now to a closer examination of the individual subregions of the Arabian peninsula, since the history of archaeological research in each has followed a unique trajectory.

Yemen

Despite the fact that the first southern Arabian inscriptions were copied as early as 1810 by the German schoolteacher Ulrich Jasper Seetzen, Yemen's archaeological heritage has only been slowly revealed since that time. Tribal conflict in Yemen has long been endemic, which had precluded field research on anything but a very restricted scale.

Excavations at al-Huqqa in 1928 by C. Rathjens and H. von Wissmann were the first ever conducted in Yemen, and helped by the British political presence in Aden, gertrude caton-thompson and R.A.B. Hamilton worked in the Hadhramaut in 1937-1938. World War II interrupted the fieldwork, and there was little activity until 1951-1952, when the American explorer and later oil baron, Wendell Phillips, launched his American Foundation for the Study of Man (AFSM) expeditions to Timna (capital of the kingdom of Qataban), Hajar Bin Humaid (a major stratified prehistoric site), Marib (capital of the kingdom of Sheba), and Khor Rori (a southern Arabian colony founded on the coast of Dhofar in what is now Oman. The work at Marib ended abruptly when relations broke down between the team's epigrapher, Father A. Jamme, and the local governor and the Americans were forced to flee Yemen

after a series of incidents involving harassment, intimidation at

gunpoint, and temporary confinement by the military.

Although sporadic discoveries were reported in the decades following 1952, it was not until 1974 that a French mission, working at Shabwa, capital of the kingdom of Hadhramaut, resumed regular excavations, which have continued, off and on, to this day. By the late 1970s, a research station of the German Archaeological Institute (deutsches archäologisches institut) had been established in Sanaa, the capital of Yemen, and in the early 1980s, an important Italian expedition began working on Bronze Age remains in the country. At about the same time the AFSM resumed work in the Wadi al-Jubah under the direction of J. Sauer. Several years later, a Soviet team, working in what was then the communist People's Democratic Republic of Yemen, established a mission with excavations both at Qana on the coast and Raybun in the Hadhramaut.

At the time of writing, tribal conflicts had once again curtailed work by Italian, French, and German scholars in the northern part of Yemen where the political authority of the central government is weak. The 1990 political unification of the two Yemens also brought tensions to the surface between authorities who had formerly been responsible for antiquities in each state, which exacerbated an already difficult situation.

Bahrain, Kuwait, Qatar, and the United Arab Emirates

A primitive attempt to excavate several burial mounds on Bahrain in 1879 by Captain E.L. Durand was the first archaeological excavation of any kind on the Arabian peninsula. Durand was followed by a series of amateurs, including Mr. and Mrs. T. Bent (1889), A. Jouannin (1903), Captain F.B. Prideaux (1906), Major C.K. Daly (1921-1926), and E.J.H. Mackay (1925). In the early 1950s, T.G. Bibby, an employee in Bahrain of the Iraq Petroleum Company, developed an interest in the mystery of the more than 100,000 burial mounds that dot the northern portion of the main island. Bibby contacted his old friend, the Danish prehistorian P.V. Glob. Bibby, who had worked with Glob in Norway and had himself married a Dane, proposed that a Danish team come to work on Bahrain. At the same time, R.H. Dyson of the University of Pennsylvania made a similar proposal to the emir of Bahrain, who consulted his British adviser, Sir Charles Belgrave, as to how best to proceed. Belgrave chose to toss a coin, and the Danes won.

That was the beginning of what grew into the largest foreign expedition ever mounted by Denmark. Glob put separate teams to work in the 1950s and 1960s not only at the great mound of Qalat al-Bahrain but on Bronze Age and Hellenistic settlements on Failaka (Kuwait), prehistoric sites in Qatar, and third-millennium graves and habitation sites (Umm an-Nar, Hili, Qattarah) in what were then the Trucial States (now the United Arab Emirates). An entire generation of Danish archaeologists participated in the Gulf expeditions, including H.H. Andersen, K. Frifelt, K. Jeppesen, H. Kapel, P. Kjærum, and P. Mortensen. Frifelt subsequently went on to conduct her own fieldwork at Bat in Oman while several of the others are or have been involved in the publication of the massive amount of material generated by the dozens of excavations and surveys conducted by the expedition. Publication of these results has been a major problem, however, partly because most of the people involved went on to assume posts dealing with Danish prehistory that gave them neither the time nor the institutional context in which to adequately digest and analyze the results of the fieldwork.

Since the end of the Danish expedition in 1965, much excavation has been conducted by French scholars such as M. Kervran and P. Lombard, and during the 1990s, a British expedition at Saar has been uncovering a large settlement of the early second millennium. Bahrain is also exceptional for the high level of involvement on the part of local nationals. The Department of Antiquities has conducted salvage excavations at literally thousands of graves threatened by development during the fifteen years

before 2000.

Unable to continue her work in Iran after the 1966 excavations at Bampur, the British archaeologist B. de Cardi began survey work in Ras al-Khaimah, the northernmost of what was then the Trucial States, in 1968. This was followed in

1973 by the visit of a team of Iraqi archaeologists on a goodwill mission to the newly created United Arab Emirates (UAE). The Iraqis conducted soundings at a host of important sites, including Tell Abraq, ed-Dur, Mleiha, Julfar, and al-Qusais. Excavation activity remained sporadic, however, until the mid-1980s when teams from Belgium, Great Britain, Denmark, France, Germany, Japan, and Switzerland began to focus their efforts on a wide range of prehistoric and early historic sites. More recently, Australian and Spanish teams have also begun work in the UAE.

The reasons behind this flurry of activity, which continues to this day, are varied. Many of the scholars involved had formerly worked in Iran or Iraq, areas no longer accessible for political reasons. The comparative ease of working in the UAE, the high level of support given to foreign teams by local governments, the relatively unbureaucratic nature of the enterprise when compared to conditions in many other countries in western Asia, and the inherent interest of the archaeological problems being investigated have all contributed to a burgeoning of archaeological research in southeastern Arabia.

Archaeology in Kuwait, initially dominated by the Danish expedition, was later pursued by the American T.H. Carter and, from 1983 to 1988, by a French mission led by J.-F. Salles. Interrupted by the Gulf War, French excavations have now resumed on several of the smaller offshore islands.

Archaeology in Oman, on the other hand, has had quite a different history. Following the expulsion of Wendell Phillips's team from Yemen, the AFSM turned its sights on Oman where R. Cleveland initiated excavations at Sohar in 1958. Prior to that time, the region had been only sporadically explored during the mid-nineteenth and early twentieth centuries. It was not until Sultan Qaboos deposed his father Sultan Taimur in 1970 that the country moved from a state of medieval isolation to one of comparative wealth as its oil resources were exploited.

The creation of a Ministry of Heritage and Culture was an early, enlightened move on the part of the new ruler, as was the appointment of the late Andrew Williamson from Oxford, an expert in the archaeology and economic history of medieval Iran, as the ministry's archaeological adviser. Williamson invited archaeologists from Harvard University to undertake the first systematic surveys and test excavations in Oman, and other scholars, including B. de Cardi and M. Tosi, soon initiated new projects.

In spite of the death of Williamson in 1975, when the Land Rover he was in (with a military escort) hit a landmine in Dhofar (where the communist-backed guerrillas supporting the separation of Dhofar Province from the Sultanate of Oman had only recently been suppressed), archaeological exploration by foreign teams flourished in the 1970s and early 1980s, not least because of the care and support provided by the Italian archaeologist P. Costa, who succeeded Williamson as archaeological adviser. A major focus of work by a team led by G. Weisgerber from the German mining museum in Bochum has been the investigation of copper metallurgy in the Oman mountains and the identification of Oman with the copper supply area known in Mesopotamian cuneiform sources as *Magan.* Italian surveys and excavations by M. Tosi and P. Biagi have focused on maritime adaptation in coastal Oman.

Saudi Arabia

Territorially speaking, the Kingdom of Saudi Arabia occupies the largest portion of the Arabian peninsula, but paradoxically, archaeological exploration there has lagged far behind what has been achieved in most of the other countries on the peninsula. The earliest explorations in the Hejaz brought to light important epigraphic finds, many of which are to be found today in the louvre in Paris (since most of the early explorers were French) and Istanbul (because the Hejaz was, nominally at least, part of the Ottoman Empire). However, the fanaticism and xenophobia of the population, most of whom belonged to the Wahhabi sect of Islamic fundamentalists, meant that exploration was very limited throughout the

early twentieth century, and individuals who were able to travel freely throughout Saudi Arabia, such as H. St. J.B. Philby, a close friend of the founder of the kingdom, Abdul Aziz Ibn Saud, were rare. A major influx of American oilmen and their families began in the 1930s,

however, and over the years many employees of Arabian American Oil Company (ARAMCO) made important surface finds that were communicated to scholars in Europe and America.

It was not until 1968 though that the first archaeological excavations were sanctioned in the kingdom. In that one year, T.G. Bibby was granted permission to work at Thaj, a large Hellenistic city in northeastern Arabia; P.J. Parr led a survey team to the Hejaz; and G. van Beek undertook a survey and soundings at Najran near the Saudi-Yemeni border. A Society of History and Archaeology was established in the history department at the University of Riyadh (now King Saud University) in 1969 (the present Department of Archaeology and Museology dates only to 1978), and in 1972, A.R. Al-Ansary, a specialist in pre-Islamic Arabian epigraphy and a student of the Leeds Semitist B.S.J. Isserlin, initiated excavations at the late pre-Islamic site of Qaryat al-Fau in the interior of Saudi Arabia where generations of Saudi nationals have gained field experience in Arabian archaeology.

A. H. Masry, a Saudi national who earned his Ph.D. under robert mccormick adams and robert j. braidwood at the University of Chicago, returned to Riyadh in 1973 as director of antiquities, and three years later, he launched an ambitious program of survey and test excavation around the country. Known as the Comprehensive Survey of the Kingdom of Saudi Arabia, the project aimed at surveying the country, making surface collections, identifying sites of particular importance for future investigation and protection, and laying the groundwork for a network of provincial museums. The comprehensive survey continued until the mid-1980s and was followed by select excavations at sites such as Thaj and Tayma. Many Saudi nationals who had gained their initial training in Riyadh with Al-Ansary and later field experience in the Department of Antiquities and Museums were sent abroad during this period to do postgraduate study in the United States and Great Britain. The drop in oil revenues during the late 1980s, the ensuing budget deficit in Saudi Arabia, and the departure of Masry to a nonarchaeological post in London led to stagnation in archaeological research in Saudi Arabia.

Retrospect and Prospect

The fact that, for political reasons, little fieldwork was possible in the Arabian peninsula during the nineteenth and early twentieth centuries has meant that, relative to the surrounding regions, much less was known of this area until recently. Since the 1950s, however, there has been a steady stream of foreign teams working in all of the countries of the peninsula. Obviously, the rate of progress depends very much on foreign and local funding sources and political stability. Tribal wars in Yemen and the 1990 Gulf War are examples of political events that have halted or severely curtailed archaeological research on the Arabian peninsula.

The institutional framework of the archaeology being carried out by foreign teams varies greatly. Many expeditions owe their existence to the interests of one scholar who builds up a team of colleagues and brings funding from his or her nation's public and private funding agencies. The French work in the Gulf states has been more of a coordinated effort on the part of the National Center of Scientific Research (CNRS), and Yemen is the only country on the peninsula with permanent, foreign research “schools” (French, German, and American). It is apparent that in the case of such schools, archaeological research is viewed as part and parcel of an overarching policy of cultural exchange between the country sponsoring the foreign teams and the host nation. In such a situation, archaeology, benefiting from government funding, is used as an arm of foreign (cultural) policy. The presence of a team from a given foreign country in a particular Arab state is viewed as beneficial by the foreign power, as its presence helps to spread goodwill, heighten awareness of that country, contribute to local heritage interests, and ultimately, sell the products of that country in a foreign market.

With the exception of the extraordinary efforts made by the Bahraini Department of Antiquities to

excavate graves threatened by the construction of new urban areas, it cannot be said that the large number of foreign missions working on the Arabian peninsula has been matched by a corresponding number of local ones. National museums exist in all countries of

the peninsula, but degrees of awareness of archaeology, heritage, and history vary greatly from country to country. Journals for the dissemination of archaeological research exist in Oman *(Journal of Oman Studies)* and Saudi Arabia *(Atlal),* and in varying degrees, antiquities laws have been passed and departments of antiquities have been set up and empowered to protect local sites and monuments. Finding bright and competent nationals to pursue careers in archaeology has been difficult, however, for in many of the countries of the peninsula the monetary rewards to be won in business by a bright student so far surpass what one can expect to earn and achieve as a civil servant that few of the best and brightest have been attracted to a career in archaeology.

The neocolonial aspect of foreign teams exploiting the past of a host country is only part of the truth, however, for in many cases the attitude taken toward archaeologists is the same as that taken toward petroleum engineers or any other foreign technical specialist. If non-Arabs from the West have the particular expertise needed to investigate the past that is lacking locally, then there is no harm in letting such work be done by them. Moreover, in all of the countries of the peninsula there is a certain population of nonlocal Arab archaeologists working on a contract basis for the universities and antiquities departments, which often includes scholars with advanced degrees from universities in the West. Just as American or British engineers seek lucrative employment in the tax-free Gulf states, so, too, do archaeologists from the Sudan, Egypt, India, Pakistan, Iraq, Jordan, Lebanon, and Syria for whom the language and culture of the Arabian states is no barrier to the pursuit of their profession. In some rare cases, such as Oman, however, programs to nationalize the workforce have tended to push foreign “experts” out of certain jobs, including archaeological advisory ones, which has affected Arab and Asian archaeologists as well as Western ones.

Arambourg, Camille (1888-1969)

Born in Paris, Camille Arambourg graduated as an agricultural engineer and became interested in paleontology when he discovered fossil fish while working at improving the water supply of his parents' vineyard in Algeria. He fought in the Dardanelles and in Macedonia during World War I, and afterward his interest in fossils led him to undertake further studies in geology.

In 1920, Arambourg became professor of geology at l'Institut Agricole d'Alger where he worked for the next ten years. During that time he also studied in Paris under marcellin boule at the Muséum National

d'Histoire Naturelle. In 1932-1933, he led an expedition to the Omo Valley in Ethiopia where he collected Pleistocene vertebrate fossils and made a detailed study of the geology of the region. In 1938, he succeeded Boule at the museum and moved to Paris.

After World War II, Arambourg returned to work in North Africa. In 1947-1948, he excavated at Saint Arnaud (now Ain Hanech) in northern Algeria, and along with other fossils located in this early Pleistocene site, Arambourg found worked, spheroid stone tools, the first to be found in North Africa. In 1954-1955, he excavated at Ternifine near Mascara in northwestern Algeria, and there he found fragments of three hominid mandibles, a parietal bone in association with Acheulean bifaces, Clactonian-like stone tools, and a rich variety of extinct mammalian bones. Based on this evidence, Arambourg argued that the Acheulean stone toolmakers had been “pithecanthropoid” hominids, a theory that was reinforced by a similar discovery at a Moroccan site in 1955. Arambourg

also argued that these North African remains were similar to the bones found at the site of Choukoutien (now Zhoukoudian) in China, and, indeed, these mandibles, and those from Zhoukoudianzhen are now recognized as belonging to *Homo erectus*.

Arambourg also excavated the cave of Tamar Hat in Algeria. The only Ibero-maurusian sequence excavated to bedrock, it has been dated at ca. 20,600 b.p. The cave was used as a camp for hunting Barbary sheep, and its three meters of deposit indicated that it had been used and reused by people for nearly 5,000 years.

Arambourg was seventy when he retired from the museum, but he remained actively involved in research until his death. Between 1967 and 1969, he led the French team of the International Palaeontological Research Expedition to the Omo Valley in Ethiopia, and during the first field season, Arambourg and his colleague Yves Coppens found an Australopithecine mandible. The Omo research expedition was a complex paleoanthropological project, and its results became a keystone in understanding the chronology of African prehistory.

Arambourg's monograph on North African vertebrate paleontology was published posthumously in two parts in 1970 and 1979. He was president of the Societé Geologique de France and the Societé Prehistorique Francaise, he received the Gaudry Prize in 1959, and he was elected to the Academie des Sciences in 1961.

Archaeological Heritage Management

The concepts of antiquities, monuments, and heritage are relatively recent innovations. An awareness of the special qualities of structures and artifacts produced by earlier peoples and generations developed slowly and sporadically over a long period in various parts of the world. The deliberate collection of artifacts from earlier periods was observed in china during the Han dynasty in the first century b.c. (Schnapp 1993), and there were conscious efforts by Roman emperors, notably Hadrian (a.d. 117-138), to protect and conserve notable structures from past epochs, such as dynastic Egypt and classical greece. It is arguable, however, whether such activities can be interpreted as conscious attempts at heritage management. In both cases, collectors may well have been motivated by a mixture of religious, philosophical, political, and aesthetic objectives.

The systematic study of relics from the past and deliberate actions designed to ensure their conservation may be deemed (in Europe at least) to have begun with the Renaissance and the reintroduction of the values of classical antiquity. Rome was where the values encapsulated in the remains of its imperial past were first identified and where conscious efforts were made to conserve them starting in the latter part of the fifteenth century. The artist Raphael (Raffaello Sanzio, 1483-1520) was instructed by Pope Leo X in 1515 to carry out a survey of the monuments of the city of Rome (Jokilehto 1999, 32 ff.) and was given the resounding title of “prefect of marbles and stones.” In a report produced four years later, Raphael set out in meticulous detail the requirements of such a survey, which was carried out by other papal functionaries. From this time onward, the buildings of imperial Rome and the marble statuary and facings that decorated them no longer served solely as a quarry for bedecking palaces and churches (or, worse, as a source of materials for lime kilns).

Meanwhile, in northern Europe, a second movement was developing that was to lay the foundations of modern heritage management. The systematic study and recording of antiquities, both portable and monumental, diffused northward through the work of French antiquaries such as Nicolas-Claude Fabri de Peiresc (1580-1637). As such work moved into lands that had been little, if at all, influenced by Roman culture, the quest for information shifted to the landscape-in particular, the many field monuments such as earthworks and stone settings-that were still to be found in profusion at that time. Attention was also directed toward early buildings such as castles, monasteries, and churches whose origins owed nothing to classical models. In England, John Leland (1506?- 1552) was appointed to the post of king's antiquary by Henry VIII in 1533, and his peregrinations

around the country produced a paradigm for future investigations. Of those who followed Leland, the most influential was william camden (1551-1623), and his monumental work *Britannia,* published in1586, was the first general guide to the antiquities of a single country. Its subjects ranged from prehistoric stone circles (notably Stonehenge) to Roman ruins (such as the forts of "the Saxon shore") to Saxon work preserved in later churches.

In Great Britain, Camden's work was continued by diligent field antiquarians such as Robert Plot (1640-1696) and edward lhwyd (1660- 1708) in Wales and john aubrey (1626-1697) and william stukeley (1687-1765) in England. Elsewhere in northern Europe similar studies were being carried out by peripatetic scholars. In Denmark, ole worm, or Olaus Wormius (1588-1654), published several works on the antiquities of that country in which he sought to establish direct links between monuments and history. He was influential in the composition of a royal decree that was sent in 1626 to all Danish clergy requesting them to report on all the historical remains in their parishes. johan bure, or Johannes Bureus (1568-1652), spent much of his long life touring his native land of Sweden studying antiquities, in particular, runic inscriptions. Bure became the first holder of the post of royal antiquary. It was in Sweden that the first university chair of antiquities was created, at the University of Uppsala in 1662.

Elsewhere in Europe, similar studies were being undertaken by scholars who adopted the title of "antiquary." In France, the major figure was the Benedictine priest bernard de montfaucon (1655-1741), whose initial paleographic and philological studies led him to the study of antiquities and culminated in his seminal book, *L'antiquité expliquée et représentée en figures* (1719). His work inspired other French antiquaries to begin the systematic survey of the historic landscape. In the last volume of his *Recueil d'antiquités égyptiennes, étrusques, grecques, et gauloises* (1767), another major figure, Anne Claude Philippe de Turbières de Grimoard de Pestels de Lévis, comte de caylus, published detailed surveys of many prehistoric and Gallo-Roman field monuments in France.

In the eighteenth century, there were attempts by European scholars to analyze and classify the whole of nature and human life. The work of the encyclopedists and of Carolus Linnaeus (Carl von Linné, 1707-1778) had a profound influence on antiquarian studies, and the most significant impact was probably that exercised on christian jürgensen thomsen (1788-1865). When he was appointed the first curator of the Danish National Museum 1816, he was called upon to prepare some rational form of presentation for the many thousands of ancient artifacts in that heterogeneous "cabinet of curiosities," and to do so, he derived the three-age system (Stone, Bronze, and Iron Ages), which laid the foundations for modern prehistoric studies.

The Development of Legislation

In 1666, four years after Olof Verelius became the first professor of antiquities at Sweden's Uppsala University, he was appointed royal antiquary. The first result of this appointment was the promulgation of a royal proclamation that declared all field monuments in the Swedish kingdom (which at that time included Finland) were the property of the crown, which undertook to protect and preserve them. The decree also imposed strict controls over all forms of intervention on such monuments. Three years later, a second royal proclamation extended this protection and control to all "portable" antiquities, which similarly became crown property. There are two interesting features in this pioneer legislation. First, while the ownership of monuments and artefacts was vested in the crown, their protection and preservation was in the name of the Swedish people, as part of their heritage. Second, antiquities were deemed to be protected even before they were discovered; thus, protection was accorded to them from the moment of their discovery.

It was another seventy years before another European state introduced similar heritage protection

legislation. The discovery of the buried cities of herculaneum and pompeii led Charles IV, the Bourbon king of Naples, to assert in 1738 royal ownership of all buried materials and sites in his kingdom. This relatively simple

colonies, based on what became known as “the Westminster model constitution,” and British legislation in India served as the basis for the formulation of improved protection of the cultural heritage of that newly independent country.

Over the second half of the twentieth century, there was progressive extension and improvement of heritage legislation. Every year was marked by new or amended laws being passed by national legislatures in at least one country in the world. In addition, work began within the framework of the League of Nations in the interwar years that led to the drafting and adoption in the 1970s of international conventions, under the aegis of the United Nations Educational, Scientific, and Cultural Organization (UNESCO), designed to protect and preserve the cultural heritage. Similar conventions have also been prepared at the regional level, notably by the Council of Europe.

Managers

Legislation is effective only if provision is made for its implementation and for the enforcement of penalties when it is transgressed. The earliest recorded appointments of what today would be known as “heritage managers” were made by Renaissance popes, as in the case of Raphael. There was a continuous policy of restoration and conservation of ancient monuments in Rome, supervised by different commissions and executed by distinguished artists and architects such as Antonio Canova (1757-1822). Similar provisions applied in other cities and states of pre-unification Italy, such as Naples.

A number of European countries followed the same pattern in the late-eighteenth and early-nineteenth centuries. In most cases, this began with the appointment of a voluntary commission of experts drawn from the academies and universities and employing architects and conservators on specific contracts. However, these bodies found themselves requiring the services of full-time professional officials as interest in and concern for antiquities grew. The role of architects in the development of heritage management was an important one. In Germany, Karl-Friedrich Schinkel (1781-1841) played a crucial role in the preservation of monuments in the territories of the kingdom of Prussia. He proposed the establishment of a formal organization for this work, but it was not until two years after his death that the first conservator of artistic monuments was appointed. France had anticipated such an appointment, the post of inspector-general of historical monuments in France being created by Louis-Philippe shortly after his accession in 1830. The first such inspector was Ludovic Vitet (1802- 1873), and he was succeeded in 1834 by Prosper Mérimée (1803-1870), better known as the author of *Carmen* but notable for his intervention to save the Roman and medieval defenses of Carcassonne in southern France.

German conservators such as Schinkel and, in particular, the Bavarian Leo von Klenze (1784-1864) provided professional advice to the new Greek state after 1830. The first general conservator was Kiriakos Pittakis (1798- 1863), and he was assisted by Danish and German architects. In Russia, an Imperial Archaeological Commission was set up in 1859, and soon afterward the country's first full-time inspector was appointed.

The Scandinavian tradition began with the appointment of Verelius as royal antiquary in 1666. The monuments service grew steadily, and from the nineteenth century onward, it made extensive use of the talents of the leisured, educated middle class (clergymen, teachers, retired army officers) for the surveying and recording activities that spread over the entire country. Denmark did not follow suit until the first decade of the nineteenth century, but work there developed very rapidly, not only in the evolution of museology but also in systematic field survey. jens jacob worsaae (1821-1885), who had worked with Thomsen (whom he succeeded in 1865) at the National Museum, was appointed inspector-general of antiquities in Denmark by the king in 1847, and he traveled over the entire country in the years that followed recording monuments of all kinds. He built up a professional staff from 1865

onward, and in 1873 began the systematic survey of all the field monuments in Denmark, with voluntary assistance. This work was to continue for some fifty years, and the field reports,

urban renewal, pipeline projects, open-cast mineral working, deep plowing, illegal excavations, drainage of wetlands, military training, and uncontrolled tree growth. This was the period, beginning in the late 1950s, of "rescue archaeology," with its dramatic overtones.

The conventional professional services were overwhelmed by the tasks that confronted them, and different strategies emerged. In some cases, the professional bodies were considerably enlarged, as in Japan and Sweden, so as to be able to undertake the work demanded of them from their own resources. In others, more modest enlargement was accompanied by the extensive use of archaeological contractors (universities, museums, private professional groups), as in the United Kingdom and Germany and, more recently, in Italy and Sweden. It is noteworthy that systems of this kind are becoming increasingly common, not only for rescue excavations but also for inventory and physical conservation. In the United States, where there has never been a centralized monuments service, this work has been undertaken almost entirely by private agencies following the passage of the 1974 Archaeological and Historic Preservation Act, which required funds to be allocated for archaeological mitigation in all projects on federally owned land or projects financed by the federal government.

Solutions to the problems of archaeological heritage management vary according to the constitutional structures of different countries. In federal states, such as Australia, canada, and Germany, responsibility for heritage management is largely devolved down to the state or province level. In a sense, the same is also the case in the United Kingdom, where there are separate services for England, Scotland, Wales, and Northern Ireland. In certain countries with centralized governments, such as the People's Republic of China, Italy, and spain, there is a central supervisory body responsible for overall policymaking and the disbursement of central government funds, but executive control rests with provincial administrations or, in the case of Italy, regional superintendents. Finally, there are those countries, which make up the majority, in which heritage management is the responsibility of a centralized agency. However, a movement toward decentralization is becoming increasingly apparent, and in the United Kingdom, the management of protected monuments is now being transferred to local authorities; currently, there are proposals to introduce a similar system in Mexico.

Archaeological Institute of America

The Archaeological Institute of America (AIA) is the oldest and largest archaeological organization in North America. Founded in 1879 in Boston, Massachusetts, by Charles Eliot Norton and eleven other Bostonians, the AIA quickly formed additional chapters in New York, Baltimore, and Philadelphia and, by the end of the century, in the Midwest as well. A chapter opened in Los Angeles, California, in 1903. Today, the AIA has more than 100 local societies throughout the United States and Canada and more than 11,000 members on several continents. In 1994, the Archaeological Institute of

America/Institut Archéologique d'Amérique was incorporated in Canada as an independent affiliate of the AIA in the United States.

The original goal of the nineteenth-century organization was to support archaeological excavation and publication both at home and abroad, but Old World archaeology, especially classical archaeology, has always played a dominant role in the AIA. Although the institute founded a School of American Archaeology in 1907 (today the School of American Research in Santa Fe, New Mexico), the first archaeological schools the AIA created-and still its principal affiliated organizations-were the american school of classical studies at athens, founded in 1882, and the American School of Classical Studies in Rome, established in 1895, now a division of the American Academy in Rome. The AIA is also the "parent" of the american schools of oriental research, founded in 1900, which oversees three archaeological schools in Jerusalem; Amman, jordan; and Nicosia, cyprus.

The AIA's first excavations took place between 1881 and 1883 at Assos in northwestern turkey, with the cosponsorship of the recently established Boston Museum of Fine Arts. (In one of the last agreements of its kind, the Turkish government granted the Boston museum permission to export one-third of the excavated finds to help build its collections of classical art.) After the AIA opened research schools abroad, almost all subsequent U.S. excavations in the Mediterranean and Mideast have been conducted under the auspices of AIA's affiliates or individual universities rather than the institute itself.

Consistent with its founders' belief in the importance of publication as well as exploration, the AIA inaugurated the *american journal of archaeology (AJA)* in 1885. A magazine aimed at a much larger popular audience, *Art and Archaeology,* appeared in 1914 but ceased publication two decades later. In 1948, the AIA launched a successor magazine, *Archaeology,* which currently appears bimonthly and has a circulation exceeding 200,000. Unlike *AJA,* which is a journal of Old World archaeology, *Archaeology* is global in scope. Between 1948 and 1973, the AIA also published a series of monographs in cooperation with the College Art Association, and in the 1990s, the institute initiated a new publication series consisting of both monographs and colloquium proceedings. The AIA also oversees the publication of the American volumes of the *Corpus Vasorum Antiquorum.*

Other than its status as a privately funded nonprofit organization, one of the distinctive features of the AIA that separates it from many other national archaeological societies is that it counts thousands of laypeople among its members. Central to its public outreach effort is its national lecture program, begun formally in 1896 although the institute had sponsored a lecture series by Rodolfo Lanciani a decade earlier. Currently, the AIA sends three lecturers annually to each of its local societies. The institute also holds an annual meeting at different cities throughout the United States and Canada at which scholars present the results of their fieldwork or research projects.

Archaeometry

Although the term *archaeometry* is of fairly recent origin, it is now used to cover an important field of archaeological research, one that has its own journals, major symposium sessions, and research centers. The term *archaeometry* was coined by the British archaeologist christopher hawkes to name the bulletin of the Research Laboratory for Archaeology and the History of

PREV NEXT

Art at Oxford University, which began publication in 1958. Yet archaeometry is now more than just the name of a journal; it is a field of study. Indeed, the discipline of archaeometry was practiced for many years before it was actually named. In a historical review on scientific measurement in archaeology, Stuart Fleming (1982), of the Museum Applied Center for Archaeology at the University of Pennsylvania, places the origin of archaeometry in the late 1920s when an astronomer, andrew ellicot douglass, from the University of Arizona pioneered the dating technique of dendrochronology.

Although the journal was not initially explicit about what archaeometry was, its articles were restricted to the hard sciences, i.e., they were based in physics and chemistry. To understand the history of archaeometry is to understand the major developments within the hard sciences in answering archaeological questions. Archaeological geology, for instance, has a long history. In the early nineteenth century, charles lyell's *Principles of Geology* gave time depth to the world, which early European archaeologists used to incorporate their models of human antiquity and theories of evolution. Geology thus gave the means for associating flint tools with fossil mammals and the relative dating of the ice ages.

Occasional examples of the application of chemistry and physics in answering questions about the past can be found throughout the nineteenth and early twentieth centuries, yet the true development of archaeometry can be traced to later in the twentieth century and is intertwined with two developments. The first concerns archaeologists' seeking answers to specific problems that were a product of the theoretical developments within the discipline. The second is tied to advances in science and technology. Two approaches are presented here: the use of characterization studies in identifying trade and exchange and the use of dating techniques in determining time depth. The post- World War II developments in nuclear science have been crucial in both instances.

Characterization Studies

Advances in science and technology have made the sourcing and characterization of many archaeological materials that provide evidence for the physical identification of their movement easily available. These advances have gone hand in hand with a shift in archaeological theory in which archaeologists began to see the usefulness of using trade and exchange in modeling the distribution of materials over space and in explaining changes in societies over time.

The identification of traded archaeological material is not a recent phenomenon. Perhaps the most famous early study was by Anna Shepard, who in the 1930s and 1940s postulated the exchange of pottery over wide areas of the U.S. Southwest by analyzing mineral inclusions in thin sections to pinpoint the origins of such minerals (Shepard 1965). Chemical techniques to identify the elemental composition of archaeological materials as a means of characterization are also not new. Neutron activation analysis was applied to coins from the Louvre in 1952, and in 1957, oriental ceramics were analyzed using the nondestructive methods of X-ray fluorescence spectrometry (XRF) and X-ray diffraction (XRD) analysis (Young and Whitmore 1957). Access to these techniques, however, was restricted and costly.

A major advance in the chemical analysis of archaeological material came from the initiative of Robert Oppenheimer. On 8 March 1956, he assembled a group of archaeologists and chemists at the Institute of Advanced Studies, Princeton, to discuss the possibility of applying methods of nuclear research to the study of archaeology (Sayre and Dodson 1957). As a result of this meeting, work was undertaken at two laboratories, the Brookhaven National Laboratory in the United States and the Research Laboratory for Archaeology and the History of Art in Oxford, England. Techniques deployed included neutron activation analysis (NAA) and spectrographic methods.

Those studies were reasonably successful in being able to separate pottery wares from Asia Minor,

greece, and italy or different factories of Samian ware, and the studies laid the foundations for chemical analyses in the next three decades, in which thousands of analyses using varying techniques were carried out on many types of objects including pottery, stone (obsidian,

marble, chert, volcanic rocks), amber, and metals, including coins. Apart from NAA, XRF, XRD, and spectrographic methods, techniques currently in use include proton-induced X-ray emission and proton-induced gamma ray emission (PIXE-PIGME), inductively coupled plasma emission spectrometry (ICP), lead isotope analysis, and electron microscopy. Major changes in the instrumentation of these techniques have meant that more elements can be analyzed with higher precision. The choice of technique depends on the availability to the archaeologist and the cost.

A variety of archaeometric techniques could be used to characterize these wine cups and containers from a newly discovered storeroom.

(Gamma)

The need for characterization studies is the result of a reorientation in the ways archaeologists have perceived how trade and exchange have operated in the past. The realization that migrationist/invasion models could not adequately explain the distribution of material across the landscape, or changes in societies over time, led archaeologists to look at other mechanisms. By studying trade and exchange, the intention was to reconstruct the economies and organizations of past societies and their changes over time. Access to and control over prestige goods through trade and exchange were seen as the prime movers for change leading to ranked societies.

Dating Techniques

Colin Renfrew (1982, 94) pointed out that dating is the most fundamental archaeometric technique available to archaeologists. Two of the most important techniques that revolutionized archaeology are dendrochronology and radiocarbon dating. Today, many techniques are used in dating, including luminescence, fission track, potassium argon, fluorine and nitrogen dating, obsidian hydration dating, and amino racemisation analysis on bone. When these techniques were developed, archaeologists were ready to apply them.

Dendrochronology

Dendrochronology was pioneered in the beginning of the twentieth century by the astronomer A.E. Douglass. The Laboratory of Tree-ring Research at the University of Arizona was set up shortly afterward, and a few more laboratories added forty years later. Toward the

When these techniques were developed, archaeologists were ready to apply them.

Dendrochronology

Dendrochronology was pioneered in the beginning of the twentieth century by the astronomer A.E. Douglass. The Laboratory of Tree-ring Research at the University of Arizona was set up shortly afterward, and a few more laboratories added forty years later. Toward the

beginning of the twenty-first century, there were over 100 tree ring programs (Dean 1997, 33). The technique entails the use of tree growth rings for dating and studying climatic variations in the past. Although Douglass had been researching tree growth rings since the beginning of the twentieth century, it was in the 1920s that he applied the technique to archaeology by constructing a chronology for Pueblo ruins of the U.S. Southwest. A tree adds a ring (xylem growth) each year, so by counting the number of rings one can obtain an estimate of age. The thickness of the ring is dependent on climatic variations: wet years produce thick rings; dry years, thin rings. Ring patterns from different species of trees are compared and cross-dated with known age samples to form a baseline with which to compare older samples, thus building up a sequence of tree ring growth back into the past.

The Radiocarbon Revolution

One of the most important archaeometric techniques is radiocarbon dating, one of a number of techniques that use radioactive decay. It was pioneered by willard libby, then of the University of Chicago, in the late 1940s and is based on the premise that all living organisms have an uptake of radiocarbon (carbon-14) that ceases when they die. As carbon-14 is unstable, it decays at a half-life of what Libby thought was 5,568 years. By measuring the amount of radioactive carbon of organic matter in an archaeological sample (charcoal, bone, or shell) of known age and comparing it to the radiocarbon in living matter, Libby was able to estimate the time lapse since the organism died.

Radiocarbon dating has undergone many changes since its advent, in particular with regard to refinement in the calculation of the half-life, the development of a calibration curve to give calendar years, and in the techniques for measuring the amount of carbon-14 in a sample. Accelerator mass spectrometry (AMS), for instance, is a relatively new method that determines the amount of carbon-14 in a sample by measuring the atoms directly. Although more expensive than the conventional C-14 dating, this method can utilize much smaller samples.

The importance of radiocarbon dating for both chemistry and archaeology cannot be overestimated. Libby was awarded the Nobel Prize for Chemistry in 1960, and laboratories were set up at the University of Pennsylvania in 1951 and in various centers in Europe soon after the one at Chicago. For the first time, chronologies could be established for areas where conventional dating techniques were difficult to apply. The human time depth of areas such as Australia, Southeast Asia, and the Pacific was recognized for the first time, and a “revolution” occurred in dating Europe's prehistory, which had been previously based on cross-dating to objects of known age. For a full discussion on the radiocarbon revolution on European and U.S. archaeology see Renfrew (1976) and G. Marlowe (1999), respectively.

Luminescence Dating

Although first suggested in the mid-1950s and there was an application to archaeological pottery in the 1960s, it has only been since 1970 that thermoluminescence dating (TL) has been applied routinely in archaeology with levels of precision of plus or minus10 percent. Major developments occurred after dedicated laboratories were set up, such as that by Michael Aitken at Oxford University during the 1960s, and a book on the technique and its application to archaeology was published in 1979 (Fleming 1979).

The advantage of TL is that it dates the artifact itself. TL has been used to date archaeological materials that have mineral grains, such as quartz and feldspar, and have been exposed to heating: pottery, flint, burned stone, earth ovens, etc. TL is based on the assumption that energy from long-term exposure to ionizing radiation is built up or trapped over time in the lattice of crystals. When heated above 500 degrees centigrade, this stored energy is released in the form of emitted light called thermoluminescence,

and the TL clock reset back to zero. The measurement of TL emitted can indicate the time elapsed since the last firing.

Major advances have occurred since the development of the technique, including the use of optical dating (OD). Rather than dating minerals

beginning of the twenty-first century, there were over 100 tree ring programs (Dean 1997, 33). The technique entails the use of tree growth rings for dating and studying climatic variations in the past. Although Douglass had been researching tree growth rings since the beginning of the twentieth century, it was in the 1920s that he applied the technique to archaeology by constructing a chronology for Pueblo ruins of the U.S. Southwest. The advantage of TL is that it dates the artifact itself. TL has been used to date archaeological materials that have mineral grains, such as quartz and feldspar, and have been exposed to heating: pottery, flint, burned stone, earth ovens, etc. TL is based on the assumption that energy from long-term exposure to ionizing radiation is built up or trapped over time in the lattice of crystals. When heated above 500 degrees centigrade, this stored energy is released in the form of emitted light called thermoluminescence,

and the TL clock reset back to zero. The measurement of TL emitted can indicate the time elapsed since the last firing.

Major advances have occurred since the development of the technique, including the use of optical dating (OD). Rather than dating minerals

that have been exposed to heat, OD measures exposure to light, that is, the stored energy released by an exposure to a beam of light, for instance, blue/green light or infrared radiation (see Aitken 1997, 183). Optically stimulated luminescence (OSL) is defined by Aitken as "commonly used as an umbrella term that includes both types of stimulation as well as use of other wavelengths" (Aitken 1997, 183).

The discovery of the 5,000-year-old frozen "ice man" in 1991 afforded a unique opportunity for the application of biological techniques to an archaeological find.

(Gamma)

Optical dating, like thermoluminescence, allows the dating of sediments. The dating of sediment became possible in the 1980s, with the dating of unburned sediment extending the chronology of Australia (Roberts, Jones, and Smith 1990).

Future Directions in Archaeometry

Advances in science have given archaeologists unique insights into the social and economic development of societies through identifying trade and exchange, and they have given chronological depth to the discipline. These advances have been supported by the development of institutional laboratories. The collaboration between archaeology and physics was to bear fruit in the 1950s with the establishment of the Oxford Research Laboratory for Archaeology and Art, which arose out of the collaboration between an archaeologist (Christopher Hawkes, professor of European archaeology) and a physicist (Lord Charwell, professor of physics). Other early laboratories include the Applied Science Center for Archaeology at the university of pennsylvania museum of archaeology and the british museum. These laboratories set the standards for interlaboratory comparisons, and meeting places were arranged to ensure open dialogue among the practitioners. Subsequently, a series of conferences arose, including the International Symposium on Archaeometry, which is held every two years (the thirty-second symposium was held in 2000).

Since 1980, there has been a proliferation of journals, societies, and news groups covering the many different types of applications of science to archaeology. Since the success of the journal *Archaeometry*, other journals have been started, including *Journal of Archaeological Sciences,*

Argentina

The Early Nineteenth Century

The quest for knowledge of our past is one of the most universal human preoccupations, but it is not necessarily the first priority of a nation, state, or people. For this reason, in Argentina (as in many other countries) it is difficult to pinpoint the particular moment in time when archaeological inquiry began. Travelers, pioneers, and colonizers left important references and data about this huge South American country beginning in the early sixteenth century when the Spanish first arrived on its shores, looking for a maritime passage between the Atlantic and Pacific Oceans. After Argentina gained its independence from Spain in 1816, many of its intellectuals began to be influenced by the great European naturalists of the nineteenth century, not only through their books but also through their visits to the country.

Under this naturalist boom the Argentine government established the Museo Nacional in 1864, which was the foundation of archaeological research there. The museum comprised an archaeological section where researchers such as Burmeister, F.P. Moreno, F. Ameghino, J.B. Ambrosetti, E. Boman, Outes, Casanova, and Gallardo began Argentine archaeology. They were influenced by Charles Darwin, Alexander von Humboldt, and William Wallace and also by the Argentine historical movement known as

the Generación de 1880. Scholars such as F. Ameghino, F.P. Moreno, and R. Lista explored Argentina and collected different kinds of scientific information, including archaeological evidence.

The results of this research were initially circulated within a small academic milieu-among the staff at the Museo Nacional and the Sociedad Científica Argentina, for example. It was not until the creation of the Museo de Ciencias Naturales at the Universidad de La Plata (ULP) in 1880 and the Museo Etnográfico at the Universidad de Buenos Aires (UBA) in 1904 that archaeology was inserted into the curriculum of some history courses.

This first Argentine archaeology was characterized by a historical perspective and the meticulous description of collected artifacts. Important museum collections were established as a result of different expeditions, and most of the archaeological materials were gathered from exploratory excavations or exposed surfaces. The interpretations of the collections were based on linguistics, ethnography, and ethnohistory, focusing

Travelers, pioneers, and colonizers left important references and data about this huge South American country beginning in the early sixteenth century when the Spanish first arrived on its shores, looking for a maritime passage between the Atlantic and Pacific Oceans. After Argentina gained its independence from Spain in 1816, many of its intellectuals began to be influenced by the great European naturalists of the nineteenth century, not only through their books but also through their visits to the country.

Under this naturalist boom the Argentine government established the Museo Nacional in 1864, which was the foundation of archaeological research there. The museum comprised an archaeological section where researchers such as Burmeister, F.P. Moreno, F. Ameghino, J.B. Ambrosetti, E. Boman, Outes, Casanova, and Gallardo began Argentine archaeology. They were influenced by Charles Darwin, Alexander von Humboldt, and William Wallace and also by the Argentine historical movement known as

the Generación de 1880. Scholars such as F. Ameghino, F.P. Moreno, and R. Lista explored Argentina and collected different kinds of scientific information, including archaeological evidence.

The results of this research were initially circulated within a small academic milieu-among the staff at the Museo Nacional and the Sociedad Científica Argentina, for example. It was not until the creation of the Museo de Ciencias Naturales at the Universidad de La Plata (ULP) in 1880 and the Museo Etnográfico at the Universidad de Buenos Aires (UBA) in 1904 that archaeology was inserted into the curriculum of some history courses.

This first Argentine archaeology was characterized by a historical perspective and the meticulous description of collected artifacts. Important museum collections were established as a result of different expeditions, and most of the archaeological materials were gathered from exploratory excavations or exposed surfaces. The interpretations of the collections were based on linguistics, ethnography, and ethnohistory, focusing

on the relationship between the known native populations and the recovered archaeological artifacts. Archaeology was regarded as part of the natural sciences, but two different influences affected it: the first and most common was the naturalist influence, as expressed in the works of Moreno and Burmeister (which in turn influenced Lista, Roth, and Pico), and the second was the evolutionary influence, as seen in the work of the Ameghino brothers and Ambrosetti. Between these two perspectives were the works of people such as S. Lafone Quevedo, Zeballos, Rusconi, Montes, and Vignati. Patagonia, the Argentine northwest, and the Pampas were the regions most explored during the nineteenth century, primarily by researchers who lived in Buenos Aires and La Plata. There were few local researchers in other cities, with the exception of A. Quiroga in Catamarca.

The last thirty years of the nineteenth century were important for the development of Argentine archaeology because they established the regionalization of future work. During these years travelers, naturalists, and explorers were able to conduct research because leaders of the Generación de 1880 were establishing and maintaining territories and boundaries to support their political and economic interests. In Patagonia, for instance, Argentina disputed the frontier with chile, which necessitated constant territorial reconnaissance; inhabited by hunter-gatherers, Patagonia was regarded as a land of savagery. In the northwest region, the Argentine government was trying to establish certain industries, including the sugar industry, and it needed the cooperation of local workers; the social structures of the northwest, given the Inca influence and the significant and large Creole population there, were easy to incorporate into the Argentine economy. (The difference between these two regions-a very real one from both anthropological and archaeological points of view-became the basis of the stereotype that has been perpetuated over time.) The Pampas-the land of gauchos and *estancias* (large rural holdings)-was far away from frontier problems and Creole populations, and it, too, was easily incorporated into the Argentine economy. These three regions would be the subjects of major archaeological investigations in the twentieth century.

The First Half of the Twentieth Century

The first decades of the twentieth century were significant because of the number of foreign researchers at work in Argentina's northwest region, among them R. Lehmann Nitsche, Boman, and E. Nordenskölld. The Museo de La Plata held the most important archaeological collections, including one from F.P. Moreno. In 1911 the Instituto Geográfico Argentino, which had supplied more funds for archaeological projects than any other institution, disappeared, and the Sociedad Científica Argentina began to support archaeological investigations. The University of Buenos Aires and the University of La Plata also started to fund archaeological research and expeditions, the most important of which were those of UBA's Museo Etnográfico and ULP's Museo de Ciencias Naturales specifically in the northwest region. In addition, significant private support for archaeology came from individuals, such as B. Muñiz Barreto. During these years Argentina began to participate in and be recognized by the rest of the scientific world, and it hosted two international congresses of Americanists, one in 1910 at Buenos Aires and the other in 1932 at La Plata. At both congresses significant discussions were devoted to the archaeology of Patagonia and the northwest.

Even as archaeological investigations of the Pampas comparatively decreased, more archaeological expeditions headed to the northwest region than to any other area of Argentina in the first decades of the twentieth century-including those by Ambrosetti (see photo, page 108), Weiser, Lehmann Nitsche, max uhle, and Gerling. Meanwhile, the first chronological frameworks for Argentine archaeology began to appear: for the northwest by Ulhe, Boman, and Ambrosetti; for Patagonia by junius bird; and for the Pampas by the Ameghino brothers. Archaeology was still only taught in single courses at the Universities of Buenos Aires and La Plata, and the naturalist influence on archaeology slowly waned, with historical

and ethnohistorical explanations becoming more popular. In the 1930s Imbelloni was the first archaeologist to

use the methods of the Vienna school. In 1936 the Sociedad Argentina de Antropología was created, with only ten members; Outes served as its first president. This society arranged a number of important scientific meetings-the Semana de Antropología-for the discussion of anthropology and archaeology.

(Photo by Noel Montoya)

During the economic depression of the 1930s, and throughout World War II, archaeology and prehistory courses were given at other universities such as Rosario, Cuyo, Tucumán, and Córdoba, resulting in a significant increase in the number of researchers and research projects. In addition, archaeological investigations of whole new areas were launched-in the Mesopotamia regions by Serrano and de Aparicio and in Cuyo by Canals Frau and Semper. However, most of the fieldwork was still done in the northwest; the least was done in the Pampas and Patagonia.

The Second Half of the Twentieth Century

During the post-World War II period Argentine archaeology flourished. This was the consequence of the work of Wendell C. Bennett and A.R. González in the northwest and the arrival in Buenos Aires of O. Menghin. After 1955, with the advent of radiocarbon dating, more-regional explanations of archaeological variation were discussed. Between 1950 and 1960 both the University of Buenos Aires and the University of La Plata began to teach anthropology and to specialize in archaeology, definitively incorporating both in an Argentine university degree. Other universities followed their example over the next decades.

The work of González and Menghin characterized Argentine archaeology after the 1960s. González, working in the northwest, and Menghin, working first in the Pampas and later in Patagonia, resolved the theoretical framework for each region, and their studies were followed up by other archaeologists, such as Cigliano, Bórmida, Schobinger, and Lafon. However, they also represented two opposing traditions and schools of thought: González the North American culture-history school and Menghin the Vienna school. Both of them established general regional chronologies that would be used for the next forty years.

The Argentine national government became

with the need to build middle-range theory and in the amount of work related to formation processes (taphonomy), faunal analysis, and regional studies.

The rebirth of democracy at a national level has led to the return of the exiled archaeologists who emigrated in 1976, the creation of new careers in archaeology at other universities, and more opportunities for research. The Argentine National Congress of Archaeology now meets regularly and more frequently than in the past-every two to three years-and a number of important regional meetings address specific topics. Northwest regional studies have begun to flourish once again, and the Pampas has been definitively incorporated into archaeological discussions, as have the Sierras Centrales, Cuyo, and the Mesopotamian regions. New research areas in Patagonia have also been incorporated. Unfortunately, however, some parts of Argentina, such as the Chaco, remain almost archaeologically unknown today.

After the 1980s it became common for Argentine archaeologists to pursue postdoctoral work overseas-especially in the United States and the United Kingdom-and Argentine archaeologists now routinely attend international congresses and meetings, not only submitting papers but also organizing symposiums. In addition, a number of Argentine students have taken postgraduate courses in North American and European universities since 1995.

Argentine Archaeology Today

As a normal consequence of the maturing of Argentine archaeology, there are few debates today pitting the northwest against Patagonia or processual against more traditional archaeology. Theoretically and methodologically speaking, Argentine archaeology now comprises a variety of perspectives: the evolutionist approach (Lanata, Borrero); social theory in all its different aspects (Nielsen, Acuto, Lazarri, Zarankin); postprocessual archaeology (Haber); historical archaeology (Senatore, Bárcena); urban archaeology (Weissel); underwater archaeology (Elkin); and heritage and conservation (Endere and Curtoni). There is also an increase in contract archaeology. The chronological frameworks of the northwest from the 1960s are being rebuilt and extended not only by members of younger generations of archaeologists, such as Ratto and Muscio, but also by older and more established members of the field, such as Pérez Gollán and Tarragó. Finally, the Asociación de Arqueológos Profesionales de la República Argentina (AAPRA) was founded in 1998, and J. Rodriguez was elected as its first president.

Ashmolean Museum

Opening on 24 May 1683, the Ashmolean Museum in Oxford, England, was originally based on the private collection of Elias Ashmole (1617-1692), which was presented to the University of Oxford. At the core of Ashmole's gift was a collection originally assembled by John Tradescant the elder (died 1638) and his son John Tradescant (1608-1662).

The first curator of the Asmolean Museum was Robert Plot, an antiquary of distinction. Unusually, from the start the Ashmolean was open to the public and had clear research and teaching (as well as display) functions. The fortunes of the museum waxed and waned over the next 150 years with the natural history side of the collections assuming greater importance than the human antiquities.

However, from the mid-nineteenth century onward, the character of the Ashmolean Museum changed to the form we know today, comprising

with the need to build middle-range theory and in the amount of work related to formation processes (taphonomy), faunal analysis, and regional studies.

The fortunes of the museum waxed and waned over the next 150 years with the natural history side of the collections assuming greater importance than the human antiquities.

However, from the mid-nineteenth century onward, the character of the Ashmolean Museum changed to the form we know today, comprising

significant collections of antiquities derived from archaeological excavation and collection. Many famous collections have been presented to the Ashmolean, an example being sir richard colt hoare's donation of "the Douglas collection" of Anglo-Saxon antiquities in 1827. The museum has also benefited from the activities of its keepers, the most famous of whom was sir arthur evans. Under Evans, the Ashmolean once again rationalized its exhibits, expanded, and moved into new premises in Beaumont Street in Oxford. These changes have ensured that the Ashmolean remains one of the most significant archaeological museums in the world, and the research of its staff allows it to remain at the cutting edge of world archaeology.

Atwater, Caleb (1778-1867)

An early American antiquary and amateur archaeologist who was born in North Adams, Massachussets. Atwater received a B.A. from Williams College and became a Presbyterian minister; he later studied and practiced law in New York City. After moving his legal practice to Circleville, Ohio, in 1815 to practice law, he used his spare time to study and record local earthworks and antiquities. The American Antiquarian Society (established in 1812) published his *Descriptions of the Antiquities Discovered in the State of Ohio and Other Western States* (1820) in the first volume of their transactions.

The earth mounds discovered west of the Appalachian Mountains contained artifacts made of pottery, shell, and native copper, and they challenged the widespread belief that native American Indians were too primitive and inferior to create such "sophisticated" artifacts and complex structures. Indeed at that time the bulk of observers could not accept that the ancestors of native American Indians were capable of such building feats, and their origins of the earth mounds became the focus of an ongoing debate. Some antiquarians and members of the public argued that they were built by Vikings or other Europeans, or by the ancestors of Mexicans

who later moved south. Other scholars proposed that indigenous Americans had destroyed the civilization that built the mounds, and used this as part of a justification to in turn destroy them. Atwater had his own theory about their origin, arguing that the mounds had been constructed by Hindus who had migrated from India, via Ohio, to Mexico. Notwithstanding these now discredited hypotheses, Atwater's study contained valuable descriptions of the earthmounds, which were later destroyed.

Atwater became an active local politician, and in 1829 he was appointed by President Jackson to help negotiate a treaty with the Winnebago and other Indians at Prairie du Chien in what is now Wisconsin. In 1833 he published an account of this process and his travels, which included his earlier study on antiquities in *The Writings of Caleb Atwater.* In 1838 he published *A History of the State of Ohio, Natural and Civil,* one of the earliest histories of the state.

Aubrey, John (1626-1697)

John Aubrey was born and grew up near Malmesbury, Wiltshire, England, where Neolithic remains cover the countryside. The son of local gentry, Aubrey was a close friend of the philosopher Thomas Hobbes and attended Trinity College, Oxford, where he indulged his passion for learning and his insatiable curiosity for all things old.

John Aubrey

(Ann Ronan Picture Library)

The formative influence on Aubrey's early career was william dugdale's *Antiquities of Warwickshire* (1656), which inspired him to begin a similar survey of Wiltshire. Most of the material he collected for his “Wiltshire Antiquities” could be classified as local history and his compilations were for the most part fairly conventional and in the tradition of Dugdale.

The unconventional material in his collections related to ancient stone monuments and earthworks, to which he was powerfully attracted. His familiarity with Wiltshire had made him aware of the large number of standing stones, tumuli, and barrows scattered across the country, and his imagination was stirred by his attempts to guess the origin and purpose of these monuments. Stonehenge had always fascinated him, but he himself discovered the even larger Neolithic monumental complex at avebury in 1649, when he was out hunting. The nucleus of Avebury was largely known as an ancient site, but Aubrey was the first to recognize the full extent of the monument and to appreciate that it was not a camp but some kind of ceremonial site, the scheme of which had been obscured by the growth of the village on the spot. He identified the circle of megaliths for the first time as a man-made construction and he returned many times to map the complex and reflect on its significance. He traced the bank and fosse, proving that it was not part of a defensive system. He identified the first section of the great avenue and suspected it had a ceremonial function. He was able to reconstruct a secondary circle of stones within the greater circle. He also tried to locate the complex within the landscape, by noting the old approach roads and the relationship of Avebury to Silbury Hill and to neighboring barrows.

As his interest in the explication of ancient monuments grew he abandoned “Wiltshire Antiquities” and began a new manuscript devoted

Australia, Historical

Formal British settlement of Australia did not begin until 1788, with the establishment of the convict colony at Sydney, but there is a much longer history of European exploration, which began with the Dutch in the seventeenth century. Along the north coast of Australia there was also an extensive trading system with fishermen from Southeast Asia that dates to at least the eighteenth century (McKnight 1976). European settlement began in earnest in the nineteenth century, and the archaeological record of colonization has been shaped by the influences of global economies and industrial technologies, which were by then well established. Since the 1970s terrestrial and maritime archaeologists have begun to investigate this material record, and vital and dynamic fields of research have emerged. The archaeology of the postcontact period is typically called "historical archaeology," although "contact archaeology" and "Aboriginal historical archaeology" are also used to describe the archaeology of the Aboriginal people during the same period.

The origins of historical archaeology in Australia date to the 1960s and the first excavations of European settler sites. At the Australian National University in Canberra, Jim Allen (Allen 1969) undertook Ph.D. research on Port Essington, in the Northern Territory, while Campbell McKnight (1976) studied the Macassan trepang industry (sea slug harvesting) that flourished in the same region, also for a Ph.D. At the University of Sydney, Judy Birmingham (1976) carried out excavations at James King's pottery at Irrawang, New South Wales, and at the Tasmanian Aboriginal settlement of Wybalenna on Flinders Island. At the University of New England, Graham Connah began the study of the pastoral establishment of Winterbourne (Connah, Rowland, et al. 1978). In Melbourne, Bill Culican from the University of Melbourne excavated the Fossil Beach cement works on the Mornington peninsula (Culican and Taylor 1972). During the same decade, sport divers in Western Australia discovered the wreck sites of Dutch East India Company ships, among them the *Batavia* and the *Vergulde Draeck* (Green 1973, 1989), and maritime archaeology in Australia began.

Ian Jack (1985, 153-156) attributes the emergence of historical archaeology at this time to two developments. One was an increasing interest in what he terms *local history* within university history departments and the attendant interest in its surviving physical remains. The second development came from within departments teaching classical and Near Eastern archaeology where a need was identified for a less costly means of training students in excavation methods than the traditional practice of taking them to sites overseas. Thus, one of the important forces shaping historical archaeology in Australia was, from the outset, its institutional home in departments of prehistory, classical, and Near Eastern archaeology.

As those departments were themselves closely modeled on British university systems, anthropology was not as great an influence in Australian historical archaeology as it was in the United States. In addition to those with a training in archaeology, other early practitioners came from a variety of backgrounds, including history, geography, architectural history, and engineering. All of these scholarly traditions influenced the field, and the wide-ranging and multidisciplinary nature of historical archaeology in Australia was thus established from the beginning. In 1971, the Australian (now Australasian) Society for Historical Archaeology (ASHA) was formed, and it was followed in 1982 by the Australian Institute of Maritime Archaeology (AIMA).

The field grew rapidly during the 1970s, led by scholars at the University of Sydney and the University of New England and as a result of the emergence of cultural heritage management. By 1983 and the publication of the first issue of ASHA's journal *Australian Journal of Historical Archaeology* (later *Australasian Historical Archaeology*), Jane Wesson (Wesson 1983, 1984) was able to compile a bibliography of more than 450 entries. Many of these studies were necessarily descriptive, as

researchers attempted to define the nature of material record of Australia's settler society.

Other scholars, however, were already seeking to understand local sites within wider historical and archaeological contexts. Allen (1973)

Australia, Prehistoric

The practice of archaeology in Australia has always been conditioned by two major factors: by ideas that European Australians have had about the nature and history of Aboriginal society and by the fact that European Australians have maintained a close and abiding interest in the history of European civilization. For the greater part of the last 200 years, archaeology in Australia has generally meant

archaeology done by Australians in the Mediterranean and the Middle East, as part of a more general inquiry into the history of civilization and (more particularly) the archaeology of the Bible. This area remains a significant focus for archaeological activity by Australians, with courses in ancient history, art history, classics, and Near Eastern studies being offered at many Australian universities and with considerable funds being provided by the Australian government to support field research in italy, greece, cyprus, Egypt, turkey, jordan, and Syria.

Since the 1960s, however, there has been a tremendous growth of interest in the archaeology of Aboriginal Australia and in the historical archaeology of European settlement. During this period university departments teaching Australian archaeology have been established, legislation protecting the archaeological heritage of black and white Australians has been passed by state and federal departments, major government agencies (such as the Australian Heritage Commission) have been established to administer such legislation, thousands of sites have been located, recorded, and excavated, and Australian archaeology has acquired international prominence. By far the majority of Australian archaeologists work in this field, and it has now become clear that their discoveries have revolutionized white people's understanding of Aboriginal society in Australia. The implications of that improved understanding (particularly a growing acceptance of the value of Aboriginal Australia and of the need to restore self-determination to the traditional owners of the continent) have become powerful elements in contemporary Australian politics and society.

In this entry these two branches of Australian archaeology are discussed separately because,

notwithstanding the fact that they are frequently taught at the same universities (with students taking courses in both areas), there has been remarkably little professional contact between the two fields until recent times. This is partly explained by the real differences in technique and approach that exist between them, but these differences are just as great in the archaeology of Africa, Southeast Asia, and the Pacific, where many Australians also work. A more complete explanation would encompass an understanding of the cultural and institutional contexts of the two fields and of their very different histories.

Australian Prehistoric Archaeological Sites

The Archaeology of European Civilization

Australians of European ancestry have long been interested in the history of European civilization. Although formal courses in the art and archaeology of the Mediterranean did not begin at the University of Sydney until 1946, the Nicholson Museum (the core collection of which was given to the university in 1860) became

a focus for students of Classical antiquity before that time. In 1948 the Department of Archaeology was established, and the professor Dale Trendall (Australia's most eminent classical scholar) was joined by J.R.B. Stewart (who would become a professor) to expand offerings in the archaeology of Cyprus and the Middle East. Since then the teaching of classical and Middle Eastern archaeology has flourished, especially at the University of Sydney but also at the Universities of Melbourne, La Trobe, Macquarie, Monash, New England, Queensland, and Tasmania and at the Australian National University (ANU). Field research has been undertaken in Greece at Zagora on the island of Andros, at Torone in the Chalkidiki, and at Koukos near Sykia. Australian teams have also worked at Pompeii and I Fani in Italy, at Teleilat Ghassul and Pella in Jordan, and in Egypt, Cyprus, Turkey, the Persian Gulf, and Syria. Universities and the great state galleries and museums have not been the only sources of funding and inspiration for research into the archaeology of the Middle East. Indeed, one private foundation, the Australian Institute of Archaeology in Melbourne (founded in 1946 with a focus on using archaeology to prove the literal truth of the Bible) has made significant financial contributions to research and the education of the general public. The vigor of this field of archaeology is reflected in the recent founding of the journal *Mediterranean Archaeology* as a vehicle for the publication of research undertaken in Australia and elsewhere. Perhaps most significant was the foundation of the Australian Archaeological Institute at Athens. Begun in 1981 by Alexander Cambitoglou, then professor of Classical archaeology at Sydney University, the institute has developed into a significant force for the promotion of classical scholarship and has branches in all the states of Australia.

The Archaeology of Australia

Although the archaeology of Australia has only recently been taught in Australian universities, an interest in the archaeology of the region began with the European conquest of the continent in 1788. Detailed studies of Aboriginal life and customs were undertaken for a wide variety of purposes, but questions of origin and antiquity were always prominent. Where had the Aborigines come from? How long had they been in Australia? Were the inhabitants of Tasmania and the Aborigines of the mainland really the same people? What lessons could Europeans learn from the Aborigines?

It was soon recognized that the conquest of Australia would have disastrous consequences for the traditional landowners, as dispossession was frequently followed by death due to social dislocation, disease, and frontier violence. These factors underscored the conventional wisdom about “strong” races overcoming the “weak” and led to the widespread acceptance of the inevitability that traditional Aboriginal society would die out. This popular understanding gave further impetus to those hoping to record examples of the most savage (and hence most primitive) of all the human races, before all evidence of the “childhood of humanity” disappeared from view. Thus, from the first, an understanding of the antiquity of Aboriginal Australia and the need to document traditional societies under great stress became part of the same process. Archaeology, ethnography, and anthropology have had an enduring relationship in Australia ever since.

The sense that Australian Aborigines were a “people without history” stemmed from the fact that for the greater part of the nineteenth century European observers could not imagine a people more primitive than contemporary Aborigines. This meant either that Aboriginal society had remained fixed and unchanged since the initial colonization of Australia or that it had experienced periods of growth and stasis and degeneration over the centuries. In either case the contemporary inhabitants (particularly the Tasmanians) were believed to be the best examples of what Europeans had looked and behaved like long ago. Thus an important early stimulus to archaeological inquires was the sense that Europeans were documenting their own history in their studies of Australia. Yet there were always inconsistencies in this approach, especially when it was recognized that the real social and cultural differences between

Aboriginal societies at contact were magnified by differences in

numbers of archaeologists, the expanding range of working environments (from universities and museums to private consultancies, government agencies, and Aboriginal organizations), the vast increase in government and private funds being applied to archaeological investigations, and the increasing importance attached by Australians to the archaeology of their country. Beginning with the appointment of john mulvaney to the History Department at Melbourne University in 1953 and greatly strengthened by appointments made to the Anthropology and Prehistory Departments at Sydney and ANU shortly afterward, the archaeology of Aboriginal Australia has become a very significant element in Australian culture. Since 1970, thousands of sites have been recorded and excavated, and our understanding of the human history of the continent has been transformed. Sites such as Lake Mungo have been placed on the World Heritage register, and the presence of significant cultural remains in Kakadu National Park and southwest Tasmania contributed to their World Heritage listings as well. Australians now understand that the Aboriginal history of their country exceeds 40,000 years and is marked by great cultural change and variety. Australian archaeology is taught in every mainland state and territory today, and it plugs into an increasingly complex infrastructure of government agencies created to administer heritage legislation and promote an understanding of Aboriginal Australia (such as the Australian Institute of Aboriginal and Torres Straits Islander Studies, founded in 1961). During this period Aboriginal people have reasserted their rights and interests in the investigation and management of their heritage. As a result Australian archaeologists of the modern era are more aware that they are investigating not the relics of a dead or dying society but the history of a living one. The implications of this fundamental change of focus have been very significant indeed.

Oceania, Asia, and the Archaeology of Contact

During this same period Australian archaeologists also paid increasing attention to the islands adjacent to the tropical coastlines. Although a great deal of the focus has been on Papua New Guinea and Melanesia, Australians have worked (and continue to work) in Timor, Indonesia, and Southeast Asia. Research initiatives, such as the Lapita Homeland Project organized by Jim Allen, first professor of archaeology at La Trobe University in Melbourne, were based on a perception that understanding the history of oceanic exploration and settlement required the assembly of an international team of researchers. Much the same thinking has supported a more consistent push by Australian-based researchers into China and south Asia.

Although there has long been a strong focus on establishing the antiquity of human occupation in Australia, the 1990s also witnessed a rapid expansion in contact archaeology, a branch of the general discipline that deals with the archaeology of Aboriginal Australia during the phase of initial contact by Europeans, Macassans, and, in some cases, Chinese. It is widely recognized that contact archaeology's subject matter can be more general than this-for example, it might cover longer periods of interaction between Aboriginal people and others at places such as mission stations as well as pastoral and industrial enterprises. Again the question of what constitutes contact is quite vexed because it is now understood that items of European material culture were entering Aboriginal societies well in advance of actual European exploration or settlement. This type of “wave effect” certainly applies to disease, for Aboriginal populations (particularly in the southeast of the continent) were already seriously jeopardized by the introduction of exotic viral and bacterial infections.

Interest in contact archaeology is increasing among archaeologists, but it has long been a significant inquiry for Aboriginal people. Although some see it as the archaeology of the “end” of traditional Aboriginal society and the beginning of European Australia, others are beginning to realize that contact studies might allow us to examine the archaeology of present-day Aboriginal Australia-particularly of Aboriginal communities that have been established since the middle of the nineteenth century. It is

frequently difficult to identify Aboriginal people in

the absence of identifiably Aboriginal material culture (such as stone tools), but archaeologists are developing approaches that integrate oral histories, archaeological investigation, and documentary evidence (such as maps, company records, private diaries, and the records of government departments) to overcome this "invisibility" factor.

The benefits of this new approach have been seen in our enhanced understanding of how Aboriginality has changed and developed in institutional environments such as the Lake Condah Mission (Victoria) and Wybalenna (Flinders Island). Contact sites associated with less-structured contexts, such as Macassan trepanging (sea slug harvesting) sites (northern Territory) or stock camps such as Burghley (Tasmania), are also being investigated.

Past, Present, and Future?

Understandings of the nature and significance of the human history of Australia have long had great influence beyond the shores of the island continent. In the nineteenth century (and well into the twentieth century), reports of the customs, technologies, and societies of indigenous Australians played a vital role in the development of anthropology and archaeology. Indigenous Australia was considered to be one of the great laboratories of "primitive" human beings. With the great expansion of archaeological research beginning in the 1960s, Australians came to understand the scale and richness of the history of Australia before the European invasion in the late eighteenth century. These developments also attracted the attention of archaeologists (particularly in the United States and the United Kingdom) who were keen to conduct ethno-archaeological studies among contemporary indigenous Australians. The primary purpose of these studies was to pursue inquiries about prehistoric society, technology, and human ecology on the world scale. These studies attracted considerable interest among local archaeologists, but by far the bulk of their attention was (and still is) firmly focused on establishing the antiquity of human beings on the continent and documenting the changing relationships between people and environment. The benefits deriving from this foundational work are undeniable, but they have led to a sense of theoretical stagnation within a discipline concentrated on absolute dating technologies as well as a decline in the impact of archaeology on Australian society. Thus, although the archaeology of Australia continues to pose great methodological and theoretical challenges to the field, the struggle to broaden the focus of research beyond a concentration on antiquity and human ecology is perhaps the greatest challenge of all.

Austria

General Structure

Archaeology in Austria is carried out within two academic disciplines: classical archaeology and pre- and proto-history. The investigation of the Stone, Bronze, and Iron Ages is the domain of prehistory; the archaeology of the provinces of Raetia, Noricum, and Pannonia, in part coeval with the area of modern Austria is the domain of classical archaeology. Prehistorians study all of the areas north of the Danube, i.e., those that lay beyond the limits of the Roman Empire, in the Roman imperial period, migration period, and early Middle Ages. Generally speaking, medieval and historical archaeological research in Austria today is conducted more by prehistorians and less often by classical archaeologists. An exception to this rule is provided by the archaeological investigation of churches and urban centers, which is mainly conducted by classical archaeologists. The study of the epigraphic finds, so important for Roman provincial history, is the domain of ancient history, and ancient coins found in the country are the province of numismatists. In Austria, provincial Roman archaeology is not an independent discipline.

The Prescientific Period

One of the first scholars interested in antiquities in Austria was Thomas Ebendorfer von Haselbach (1387-1464), who founded the discipline of history at the University of Vienna. Other scholars in the humanist tradition linked to the court of Emperor Maximilian I included Konrad Celtis and Johannes Cuspinian; later there were Carolus Clusius and Wolfgang Lazius, the latter the first scholar to publish on the Roman monuments of Vienna and to inspire a corpus of ancient coins. The first collections began at this time, and the imperial collection in Vienna and the antiquarian collection in Ambras Castle in the Tirol should be noted. The most important find of this period is the Jüngling of Magdalensberg ("youth" or "young man of Magdalensberg"), which was discovered in state of Carinthia (German, Kärnten) in 1502.

During the Baroque era, the research of Johann Dominikus Prunner in Zollfeld (Carinthia) and the excavations of Maximilian III in Carnuntum took place. In the eighteenth century, the Münz- und Antikenkabinett (Cabinet of Coin and Antiquities) was established; today, they are departments of the Kunthistorischen Museum Wien (Viennese Museum of Art). Johann Josef Hilarius Eckhel, who took over the directorship of this collection in 1774, was also appointed to the chair of Altertümer und historischen Hilfsmittel (Antiquities and Historical Sources) at the University of Vienna.

Beginning in the middle of the eighteenth century, the collection of archaeological finds intensified-for example, Franz Steinkogler of Hallstatt collected Roman objects that have remained in the Mathematischen Turm (Mathematical Tower) of the Kremsmünster Monastery. In the early ninteenth century, reports of finds began to increase, and regional museums were founded, beginning with the Joanneum in Graz (1811), followed by the Ferdinandeum in Innsbruck (1823) and the Oberösterreichische Landesmuseum (Upper Austrian Regional Museum, 1833).

Among the scientific organizations founded in this period, the Geschichtsverein für Kärnten (Kärnten Historical Society), established in 1843, is particularly important. Not only does it publish one of the oldest and most important regional scholarly journals, *Carinthia,* but it also undertook the earliest excavations at Magdalensberg. In 1840, Johann Gabriel Seidl, an employee of the Münz- und Antikenkabinett, began to compile a collection of all notices of

Davidson, "Archaeologists and Aborigines" (1992), *Australian Journal of Anthropology* 2: 247-258; and J. Flood "'Tread Softly for You Tread on My Bones': The Development of Cultural Resource Management in Australia," (1989), in H. Cleere, ed., *Archaeological Heritage Management in the Modern World* (London: Unwin Hyman), 79-101.

The standard work on Australian prehistoric archaeology is D.J. Mulvaney and J. Kamminga, *The Prehistory of Australia,* 3d ed. (St. Leonards, NSW: Allen and Unwin, 1999). Beginning in the middle of the eighteenth century, the collection of archaeological finds intensified-for example, Franz Steinkogler of Hallstatt collected Roman objects that have remained in the Mathematischen Turm (Mathematical Tower) of the Kremsmünster Monastery. In the early ninteenth century, reports of finds began to increase, and regional museums were founded, beginning with the Joanneum in Graz (1811), followed by the Ferdinandeum in Innsbruck (1823) and the Oberösterreichische Landesmuseum (Upper Austrian Regional Museum, 1833).

Among the scientific organizations founded in this period, the Geschichtsverein für Kärnten (Kärnten Historical Society), established in 1843, is particularly important. Not only does it publish one of the oldest and most important regional scholarly journals, *Carinthia,* but it also undertook the earliest excavations at Magdalensberg. In 1840, Johann Gabriel Seidl, an employee of the Münz- und Antikenkabinett, began to compile a collection of all notices of

finds and their publications. In this way, *Carinthia* came to be the most important scientific journal for Austrian archaeology.

Provincial Roman Archaeology

Most of the scholarly institutions concerned with classical archaeology were founded during the second half of the nineteenth century. In 1869, Alexander Conze was appointed to the newly established Lehrkanzel für Klassische Archäologie (Chair of Classical Archaeology) at the University of Vienna, and together with Otto Hirschfeld (holder of the Lehrkanzel für römische Geschichte, Altertumskunde, und Epigraphik [Chair of Roman History, Archaeology, and Epigraphy]) he founded the Archäologisch-epigraphische Seminar (Archaeological-Epigraphic Institute) in 1876. Conze was followed in the Chair of Classical Archaeology by Otto Benndorf, Emil Reisch, Camillo Praschniker, Otto Walter, Fritz Eichler, Hedwig Kenner, and Jürgen Borchhardt.

Other institutions founded in Vienna included the Archäologisch-philologische Gesellschaft (Archaeological-Philological Society) at the University of Vienna. Established in 1889, today it is known as Eranos Vindobonensis, as well as the Kommission zur Erforschung des römischen Limes (Commission for the Study of the Roman Limes). Limes are the boundaries of Roman defense and influence. Established by the Academy of Sciences in 1889 as a result of a proposal from Friedrich von Kenner, the commission publishes the series *Der römische Limes in Österreich (RLÖ)* [The Roman Limes in Austria]. At the instigation of Otto Benndorf, the Österreichische Archäologische Institut (Austrian Archaeological Institute) was founded in 1898. Benndorf's successors as director included Robert von Schneider, Emil Reisch, Camillo Praschniker, Rudolf Egger, Josef Keil, Otto Walter, Fritz Eichler, Hermann Vetters, and Gerhard Langmann. The institute not only organizes numerous excavations, it also publishes excavation reports on Roman provincial sites in the supplements of its *Jahreshefte* [Yearbooks].

The Institute für Klassische Archäologie (Institute of Classical Archaeology) of the University of Graz was founded in 1895 (the first professor in 1890 was Wilhelm Gurlitt, followed by Rudolf Heberdey, Arnold Schober, Erna Diez, and Hanns-Thuri Lorenz), and the Institute für Klassische Archäologie of the University of Innsbruck was begun in 1899 (professors since World War II were Alfons Wotschitzky, Bernhard Neuss, and Elisabeth Walde). Both of these institutes concentrated on the art history aspects of classical archaeology in the Roman provinces. Studies of funerary monuments and bronzes were particularly stressed. More recently, settlement studies and research on Roman villas have been carried out. Provincial Roman archaeology has been represented at the University of Salzburg since the 1970s in the Institut für Alte Geschichte (Institute of Ancient History) where Norbert Heger, Kurt Genser, and Erwin M. Ruprechtsberger have been active in the field.

In addition to the national institutions already named, regional ones have carried out the bulk of the fieldwork in the field of provincial Roman archaeology in Austria. It is impossible to name all of the regional and city museums, associations, institutes, and their members who have been involved in this work (for more information see Niegl 1980). Most of the significant cities of Austria Romana, including Carnuntum, Vindobona, Solva, Teurnia, Virunum, Aguntum, Lauriacum, Lentia, Iuvavum, Veldidena, and Brigantium, have been investigated, though only rarely have architectural remains been preserved. Exceptions include the Archäologische Park Carnuntum (Carnuntum Archaeological Park), adjacent to the Museum Carnuntinum (established 1904) as well as the site displays created by Gernot Piccottini at Magdalensberg and by Wilhelm Alzinger at Aguntum.

Of the many archaeologists involved in such work, some of the outstanding ones who were active in the early twentieth century were Maximilian Groller von Mildensee, Friedrich von Kenner, Wilhelm

Kubitschek, Rudolf Egger, Erich Swoboda, Arnold Schober, Rudolf Noll, and Hedwig Kenner. The focus of their work was, in addition to art history problems, early Christian monuments and the Roman *limes.* In his book on the provincial capital Carnuntum (reprinted three times), Erich Swoboda, professor of ancient history at the University of Graz,

PREV NEXT

combined the results of archaeological fieldwork with provincial Roman history. Treatments of grave and votive inscriptions were undertaken by ancient historians beginning with Otto Hirschfeld and Eugen Bormann who worked on *Corpus inscriptionum latinarum* III with Theodor Mommsen. Today, this tradition is carried on by Ekkehard Weber and Manfred Hainzmann. The numerous publications of Fritz Lochner-Hüttenbach are also noteworthy.

Supraregional, monographic studies of small finds are rare. Ceramic research was initiated by August Schörgendorfer and Éva Bónis (Hungary), and *terra sigillata* (red ware pottery) studies were begun by Paul Karnitsch (Austria). Lamps were first systematically studied by Franz Miltner (Austria); *fibulae* (broaches) by Ilona Kovrig (Hungary) and Jochen Garbsch (Germany); bronzes by Robert Fleischer (Austria); bronze vessels by Aladar Radnóti (Hungary); and bricks by Alfred Neumann (Austria). These subjects are researched today by numerous archaeologists working in various parts of Austria. The bibliography in the journal *Pro Austria Romana* gives a good overview of this material. The *Kärntner Museumsschriften* [Kärnten Museum Series] and *Der römische Limes in Österreich* [The Roman *limes* in Austria] are two important series in which individual categories of finds are treated in monograph-length studies.

Research Foci since 1960

The establishment in 1966 by the Austrian Academy of Sciences of the Kommission für das Corpus der Skulpturen der Römischen Welt (CSIR, Commission for the Corpus of Sculpture in the Roman World) is an initiative in which many archaeologists, both from the regional museums and from the Federal Monuments Authority (Bundesdenkmalamt), participate. In 1969, a second chair in Klassische Archäologie mit besonderer Berücksichtigung der Feldarchäologie (Classical Archaeology with Particular Attention to Field Archaeology) was established. First occupied by Vetters, it has also been led by Fritz Krinzinger. Since 1978, the Numismatische Kommission der Österreichischen Akademie der Wissenschaften (Numismatic Commission of the Austrian Academy of Sciences), under the direction of the late Robert Göbl, has published *Die Fundmünzen der römischen Zeit in Österreich* [Numismatic Finds of the Roman Period in Austria]. Thus, for the systematic cataloging of individual categories of material, the various commissions established by the Austrian Academy of Sciences since the 1960s have been of enormous value, particularly since old groups of finds have been restudied in their entirety and published in a new, improved format.

Today, archaeological research in Carinthia is particularly noteworthy, e.g., Piccottini's investigations of traces of early Roman settlement at Magdalensberg and Franz Glaser's work on early Christian churches at Hemmaberg and a late antique bishopric in Teurnia. Such research projects, carried out systematically over a number of years with the results regularly published, are a hallmark of Austrian archaeology.

Another area of research focus is the Roman *limes.* In recent decades Herma Stiglitz and Hannsjörg Ubl have undertaken numerous excavations, although final publications for most of their sites have yet to appear. As a result it is difficult to get an overview of the excavations of Carnuntum, the most important Roman city in Austria, particularly as excavations have been carried out at numerous locales and only rarely published in a coordinated way. Around Carnuntum the damage done by illicit excavators working with metal detectors is clear, as are the problems created by so much uncoordinated fieldwork. Thus, one must conclude that the fragmentation of the research efforts of a relatively small number of investigators among such a large group of institutions and publications is an unfortunate characteristic of provincial Roman archaeology in Austria. The journal *Pro Austria Romana,* founded by Rudolf Noll in 1951, and the annual Österreichische Archäologentage (Austrian Archaeologists Meetings), which began in 1983, have been helpful in facilitating the exchange of up-to-date information. The most important major congress in recent years was the 14. Internationale Limeskongreß (Fourteenth

International Limes Congress) held in Carnuntum in 1986 (proceedings published in *RLÖ* in 1990).

Prehistory

Prehistoric research in Austria began slightly later than classical archaeology. The foundations of prehistoric inquiry were laid down by Moritz Hoernes around 1860, albeit not in an academic context. In 1870, the Anthropologische Gesellschaft in Wien (Anthropological Society of Vienna) was founded under the leadership of Ferdinand Freiherr von Andrian-Werburg, and the subjects of prehistory, ethnography, ethnolology, and physical anthropology all found a common home there. A prehistoric collection was displayed in the Anthropologisch-ethnographischen Abteilung (Department of Anthropology and Ethnography) of the Naturhistorischen Hofmuseum (Imperial Museum of Natural History), founded in 1889. In 1878, the Prähistorische Commission (Prehistoric Commission) of the Kaiser was founded by the Akademie der Wissenschaften (Imperial Academy of Sciences), under the chairmanship Ferdinand von Hochstetter.

In 1889, Hoernes described Eduard Freiherr von Sacken and Ferdinand von Hochstetter as the two prongs of prehistoric research in Austria, and the division between theoreticians (Sacken) and practitioners (Hochstetter), so typical of Austrian prehistory, was already apparent. Hoernes received the first lectureship in prehistoric archaeology at the University of Vienna in 1893; in 1899, he was appointed to an extraordinary position, albeit in geography; and in 1911, he was given an established chair. Thus, the prehistoric research institutions, which remain important to this day, were all established in Vienna in the second half of the nineteenth century.

Hoernes's study of classical archaeology, his work in the Natural History Museum, and his association with the Anthropological Society laid the foundation for the three research interests that are prominent in his major publications: prehistory as an historical discipline (*Die Urgeschichte des Menschen nach dem heutigen Stand der Wissenschaft* [Prehistory of Mankind in the Light of Current Research], 1892); prehistoric archaeology in the sense of an art history of the remote past (*Urgeschichte der bildenden Kunst in Europa* [Prehistory of the Fine Arts in Europe], 1898); and prehistory as an anthropological discipline with links to physical anthropology and ethnology (*Natur und Urgeschichte des Menschen* [Nature and Prehistory of Mankind], 1909). Hoernes was, first and foremost, a compiler, but in his later years he was also a teacher.

Following Hoernes, Oswald Menghin thought of prehistoric archaeology as a branch of universal history. His close connection with the Viennese school of ethnology, which was deeply influenced by the culture area *(Kulturkreis)* theories of Father Wilhelm Schmidt, influenced Menghin's view of history, which is made clear in his major work *Die Welgeschichte der Steinzeit* [World History of the Stone Age]. The geographical breadth of Menghin's lectures attracted many foreign students as well, and this breadth, which extended well beyond the confines of Austria, is clearly reflected in the Wiener Prähistorische Gesellschaft (Viennese Prehistory Society, which emerged in 1914 from the Anthropological Society and returned to it after 1945) and its journal, *Wiener Prähistorische Zeitschrift* [Viennese Journal of Prehistory].

In 1945, after World War II, Richard Pittioni became the new professor at the University of Vienna. In his *Urgeschichte des österreichischen Raumes* [Prehistory of the Austrian Region], Pittioni elaborated a systematic view of Austrian prehistory, the roots of which were first published in 1937. This work was last revised in 1980. Methodological questions were of particular interest for both Menghin and Pittioni. In this regard, the position of prehistory within a family tree of the sciences was of particular interest, as was its relationship to related disciplines and to complementary natural sciences. In addition, Pittioni was responsible for a sophisticated terminology. On the other hand, his use of parallels between prehistoric find complexes and sociological entities seems too mechanical now, and his overall presentation of prehistory seems too schematic.

J. Ramsauer's excavations in the cemetery at Hallstatt between 1846 and 1863 mark the beginning of scientific excavations in Austria, and Ferdinand von Hochstetter's work was also significant. At the request of the Academy of Sciences, Hochstetter introduced lake-dwelling research

For the late Bronze Age (Urnfeld period), the cemetery studies of Clemens Eibner and the long-term settlement excavations of F. Felgenhauer and Herwig Friesinger are particularly noteworthy.

Four-thousand-year-old body discovered in an Austrian glacier

(Gamma)

Research into the early Iron Age (Hallstatt period) has concentrated on the eponymous site of Hallstatt. New excavations begun there by Karl Kromer in the 1960s were taken over by Fritz Eckart Barth and continue to this day. The excavations of the prehistoric salt mines of Hallstatt are not only unique in Austria but constitute an important research focus of mining archaeology in a broader European context. Two research projects are of particular importance for the late Iron Age (la tène period): the excavations of Dürrnberg bei Hallein in Salzburg and Magdalensberg in Kärnten. *Die Kelten in Österreich* [The Celts in Austria] by Gerhard Dobesch, professor at the Institute of Ancient History in Vienna, brings together all of the ancient sources for this period and forms the foundation for the historical interpretation of the relevant archaeological remains.

In general, it can be said that settlement archaeology has been most prominent since the 1960s, whether studies of specific settlement areas (e.g., Stillfried), valley systems (e.g., the Kamp, Inn, and Danube Valleys), or larger regions (e.g., the Bischofshofen area). Thematic investigations, such as the mining study of the Grauwacken area and the establishment by Franz Hampl of an open-air museum in Asparn on the Zaya River in the 1960s (opened in 1970), are also important. Similarly, the development of modern archaeological techniques, particularly aerial photography, has been significant. The large-scale investigations of the numerous prehistoric cemeteries and settlements of the Traisental (lower Austria) have opened up entirely new perspectives. For the first time, large cemeteries have been excavated and salvaged, and beginning in 1981, Neugebauer has been in charge of some ongoing, year-round salvage excavations.

Proto-history

In 1940, Eduard Beninger became the first Austrian to write a doctoral thesis dealing with

proto-history, and he was followed by Herbert Mitscha-Märheim, Herwig Friesinger, and Falk Daim. Proto-history was still not recognized as a separate discipline as late as 1952, as is shown by the fact that Mitscha-Märheim's *venia legendi* (right-to-lecture qualification) from the University of Vienna included the awkward title "non-Roman archaeology of the first millennium in Central Europe." In 1949, a Conseil du Haute Moyen-Age (Council of the High Middle Ages) was formed in Linz, and members included, among others, Wilhelm Albert R. von Jenny, Rudolf Egger, Erich Zollner, and Mitscha-Märheim.

Thanks to the systematic study of Germanic, Avar, and Slavic finds by Friesinger and students of Mitscha-Märheim (who succeeded to the chair formerly held by Pittioni in 1978), the state of proto-history publications is relatively good. Peter Stadler's studies on the seriation of Avar cemeteries have broken new ground, methodologically speaking, in terms of both chronology and spatial analysis. A series edited by Daim entitled *Studien zur Archäologie der Awaren* [Studies in the Archaeology of the Avars] publishes work by many colleagues in countries east of Austria. Close cooperation with the Institut für österreichische Geschichtsforschung (Institute of Austrian Historiography) has been particularly stimulating and has led to important discussions of ethnogenesis as well as to academic conferences in neighboring countries, including the regular symposia on *Ausgewählten Problemen der Frühgeschichte* [Selected Problems of Protohistory].

One of the first articles on medieval ceramics was by Beninger (Beninger 1958), and for this reason he can be considered a pioneer in the field of medieval archaeology. Later scholars active in this area included Hertha Ladenbauer-Orel, for city and church excavations; F. Felgenhauer, who founded an archive for medieval archaeology; and Pittioni, who in 1976 proposed the creation of a Kommission für Mittelalter-Archäologie (Commission for Medieval Archaeology) within the Prehistoric Commission of the Austrian Academy of Sciences. In 1989, Sabine Felgenhauer completed a doctorate in medieval archaeology, and in 1992, Daim was appointed to an extraordinary professorship in proto-history and medieval archaeology at the Institute of Pre- and Protohistory of the University of Vienna.

The roots of the archaeology of the modern era go back to the terms *Industriearchäologie* ("industrial archaeology") and *Gasthausarchäologie* ("inn" or "hotel archaeology") introduced by Pittioni in 1968 and 1969, respectively. Thereafter, rescue excavations took place in advance of major building projects in, for example, Salzburg and Vienna. In 1989, Spindler's activities in this regard were recognized institutionally with the establishment of an Abteilung für Mittelalterarchäologie und Neuzeitliche Archäologie (Department of Medieval and Modern Archaeology) in the Institute of Pre- and Protohistory. Methodologically speaking, "modern" archaeology remains closely linked to medieval archaeology. Industrial archaeological investigations have been particularly important along the Steirisch rail line, and practitioners in this field have recently investigated battlefields and remains of World War II. The significance of such sites was discussed at a symposium convened in 1990, but most participants were sceptical of their worth.

Protection of Monuments

With respect to archaeological excavation and the protection of sites and finds, the highest civic authority in Austria is the Bundesdenkmalamt, which succeeded the Zentralkommission zur Erforschung und Erhaltung der kunst- und historischen Denkmale (Imperial Central Commission for the Investigation and Preservation of Historical and Artistic Monuments). The role of the Department of Sites is to make determinations regarding the protection of endangered sites and monuments as well as to organize and carry out salvage excavations in Austria. However, because of a general policy of not using consultants, the personnel of the department are often overworked. Other duties, consistent with those of monuments authorities elsewhere, include the maintenance of a country-wide registry of all archaeological sites as

well as assistance with conservation and restoration projects. Normally regional archaeologists (e.g.,

Fritz Moosleitner in Salzburg, Diether Kramer in Steiermark, and Karl Kaus in Burgenland) collaborate with the Bundesdenkmalamt on salvage excavations, but the ultimate responsibility for these excavations rests with the Department of Sites within the Bundesdenkmalamt.

Education

Today, there are two institutes of pre- and proto-history and four institutes of classical archaeology in Austria. Pre- and proto-history are taught at the Universities of Vienna and Innsbruck, and classical archaeology is offered at the Universities of Vienna, Salzburg, Graz, and Innsbruck. In addition, archaeology is taught in the Institute of Ancient History at the University of Salzburg. Roughly half of the lecturers are not employed by the universities but teach in addition to their regular work in museums or the Bundesdenkmalamt.

Archaeology in Austria Today

The fragmentation of archaeology into different academic disciplines has led to the frequent absence of fruitful, positive discussion. Moreover, it has made it much more difficult to gain a synthetic view of the country's past. To date, interdisciplinary research institutes with particular thematic concentrations have not been established, and the fact that most projects, financed by grants, are funded only over the short term hardly helps matters. Even sensational new finds, such as the Bronze Age Ice Man discovered in 1991, fail to improve the situation.

Compared to similar institutions in other countries the Austrian Bundesdenkmalamt functions poorly. The general regard in which archaeology is held in Austria is low, and the legal foundations of the relevant legislation concerning sites and monuments are often divorced from reality. Fulfilling the requirements of the existing laws is almost impossible, and the cooperation between regional and federal offices required by the archaeological research increases the difficulties of compliance.

Moreover, a publicly available register of all protected sites and monuments, and clear signs in the landscape to point them out to visitors, are lacking, so the public is scarcely aware that certain sites are, in fact, protected. The Österreichisches Nationalkomitee zur Koordination und Beratung im Bereich der archäologischen Forschung Österreichs (Austrian National Committee for Coordination and Advice on Archaeological Research in Austria), an advisory council, has as its main task a long overdue review and reorganization of the structures in place. Coordination of all federal, regional, and local offices; amateur investigators; and folk museums and a definition of their jurisdictions and responsibilities, along with the identification of opportunities for cooperation in the protection of monuments and the prosecution of research, would be highly desirable.

Avebury

Located in southern England, the site of Avebury comprises a large enclosure that features extensive earthworks and arrangements of standing stones of the late Neolithic age. First brought to prominence by the patient recording work of william stukeley in the eighteenth century, the site has been much damaged, and many of the standing stones have been buried or broken up. Stukeley's map is therefore invaluable, and its accuracy has been confirmed by excavation and nondisturbing remote sensing techniques such as aerial photography. Avebury and the slightly later site of Stonehenge have often been compared as they both stand at the center of large landscapes featuring earthworks and other associated sites. Located in the Avebury landscape are the West Kennet Long Barrow, Windmill Hill (both earlier than the monument

itself), and Silbury Hill (roughly contemporaneous with Avebury).

Avebury, Lord (Sir John Lubbock)

(1834-1913)

Best known to archaeologists as the author of *Prehistoric Times* (which went through seven editions from 1865 to 1913), Sir John Lubbock was also prodigiously talented in other areas. Born into a titled family (his father was a baronet), Lubbock went to Eton and then entered the family banking business. However, in common with many people of his social standing in England, Lubbock spent his time away from banking engaged in a wide range of scientific pursuits. In this respect he was following in the footsteps of his father, who was an amateur astronomer and a friend of Charles Darwin. Lubbock's views on natural history (and eventually on human evolution) were strongly influenced by Darwin. Equally, Lubbock's position as an influential Victorian scientist (he held offices in the Royal Society, the British Association for the Advancement of Science, the Geological Society of London, and the Linnaean Society, among others) was of great value to Darwin when the time came to promote public acceptance of his account of the evolution of life on earth.

Lord Avebury, from an 1884 print

(Ann Ronan Picture Library)

Notwithstanding his activities as a banker, member of Parliament, vice-chancellor of the University of London, and keen student of insects and wildflowers, Lubbock's enduring fame results from his central role in the foundation of prehistoric archaeology in Great Britain. Through the publication of *Prehistoric Times* and a later work, *The Origins of Civilization* (1870), Lubbock set much of the agenda for the emerging science of prehistoric archaeology. His keen

interest in the antiquity of human beings, his classification of the Stone Age into Paleolithic (old Stone Age) and Neolithic (new Stone Age), and his firm belief that the purpose of archaeology (and anthropology) was to demonstrate the essential unity of human beings did much to establish the public face of prehistoric archaeology as a legitimate scientific pursuit. This work bore fruit in 1882 when, as a member of Parliament for the University of London, Lubbock's long years of advocacy paid off with the passage of the first Ancient Monuments Protection Act, a measure designed to preserve the physical remains of the prehistory of Britain.

After the passage of this Act, Lubbock's fascination with prehistoric archaeology had to compete more directly with his other research in natural history, but he continued to serve as a senior member of the core anthropological and archaeological societies in Britain and to carry on a voluminous correspondence with scholars from all over the world. Lubbock's advocacy of the three-age system was instrumental in its acceptance in England, but subsequent research indicates that his translation of Swedish archaeologist sven nilsson's *The Primitive Inhabitants of Scandinavia* (1868) stressed an evolutionary message that was somewhat at odds with the original text. There is no modern biography of Lubbock.

Aztecs

"Aztecs" is the name popularly used today to label the people of central mexico that Hernán Cortés conquered in 1521. Actually, "the Aztecs" never used the term to describe themselves; rather, they were Nahuatl-speaking peoples divided into about twenty different ethnic groups. The most famous of these groups, and the preeminent one when the Spaniards arrived in Mexico, were the Mexica, whose capital was tenochtitlán.

B

Babylonian Civilization

Although sharing roots with other Mesopotamian civilizations, such as the Sumerian and the Assyrian, the Babylonian civilization derived from the city of Babylon, a major city in southern mesopotamia (now Iraq). Much of what we know about the history of the Babylonian civilization comes from the analysis of cuneiform texts that have been preserved among the ruins of palaces, temples, and administrative buildings. Monuments and other items of material culture have been used to give further texture to information derived from the excavation of cities and from surveys of the landscape of the region.

Fragment from an early Babylonian royal stela

(Ann Ronan Picture Library)

The empire of Hammurabi (1792-1750 b.c.) marks the emergence of Babylon as the major cultural and political center of the region as a result of warfare and later economic reorganization. The empire barely survived Hammurabi's reign, however. The decline of the old Babylonian kingdom after Hammurabi was most likely the result of a complex interplay of political and environmental factors, the latter directly related to the changing behavior of the Euphrates River as a source of water for irrigation. After Babylon was attacked by the Hittites in 1595 b.c., the political picture becomes hazy until the mid-fifteenth century b.c. when the Kassites seized control of Babylon. Although

The empire of Hammurabi (1792-1750 b.c.) marks the emergence of Babylon as the major cultural and political center of the region as a result of warfare and later economic reorganization. The empire barely survived Hammurabi's reign, however. The decline of the old Babylonian kingdom after Hammurabi was most likely the result of a complex interplay of political and environmental factors, the latter directly related to the changing behavior of the Euphrates River as a source of water for irrigation. After Babylon was attacked by the Hittites in 1595 b.c., the political picture becomes hazy until the mid-fifteenth century b.c. when the Kassites seized control of Babylon. Although

there is ample evidence for political upheavals both before and after the Kassite period, it is also clear that the language and other cultural institutions that lay at the heart of the Babylonian civilization continued to prosper. The political instability of Babylon was further increased by the growing power of the Assyrian empire, and on more than one occasion the city was occupied by Assyrian kings or their nominees.

That situation persisted until the end of the seventh century b.c., when the Babylonians (in league with the Medes) turned the tables on the Assyrians and destroyed them. This change of fortunes ushered in the neo-Babylonian empire under Nebuchadnezzar II (604-562 b.c.), which included a major restoration and expansion of Babylon, the most famous features of which were the Ishtar Gate and the Hanging Gardens.

However the neo-Babylonian empire was as short-lived as Babylon, and the territory fell victim to the Persians under Cyrus II (559-530 b.c.). The gods and religious customs and the language of Babylon lay at the heart of its civilization, but in the long term, loss of political independence meant that its distinctive form lost out after an eventful 1,200-year history.

Ban Chiang

Jointly excavated by the University of Pennsylvania and the Thai Department of Fine Arts in the 1970s, Ban Chiang, a major site in northeastern Thailand, essentially set the framework of a regional chronology. Although the dating of the site (via radiometric means) remains somewhat controversial, there is little doubt that the long sequence of occupation (from about 3600 b.c. to a.d. 500) makes it an ideal place to explore the cultural history of the region.

The value of Ban Chiang is further enhanced by the richness of the site, which boasts evidence of early rice cultivation (once thought to predate that in China but now believed to postdate it), early bronze technology, and a diversity of ceramic, metal, and shell objects. Aside from the long cultural sequence (which spans technological developments from the Stone Age through the Bronze Age to the Iron Age), one of the reasons for the richness and diversity of the cultural remains found at Ban Chiang is that there is evidence of ordinary habitations as well as graves.

In the field of numismatics, Banerji wrote a large number of papers, which were mostly

published in the Calcutta Asiatic Society journals and proceedings. He edited a large number of inscriptions for *Epigraphia Indica* (see vols. 15, 16, 18, 19), and the range of his edited inscriptions was chronologically and geographically wide. His mastery of the primary sources of ancient India led him to a study of its political history, and one of his books on the subject is *The Age of the Imperial Guptas* (1933). He wrote extensively in his mother tongue, Bengali, even writing a large number of historical novels with themes selected from ancient India.

Banpo

Excavated between 1954 and 1957, the Neolithic village of Banpo is a short drive from Xi'an, the capital of Shaanxi Province in central china. Banpo has great significance in the history of Chinese archaeology for several reasons. First, the well-preserved remains of houses, ditches, and burials and the large number of artifacts that were found during excavation make this a type site for the Yangshao phase of the early Chinese Neolithic period (about 5000 b.c. to 4000 b.c.).

Second, the site was interpreted as providing clear evidence of the existence of a matrilineal society during the Neolithic period, an interpretation that accorded very well with the analysis of precapitalist societies put forward by Friedrich Engels (ca. 1884) in his *Origins of the Family, Private Property, and the State* and subsequent Marxist ideological interpretations encouraged by the Chinese Communist Party. Third, the site was transformed into a major museum based around a building that completely enclosed a large portion of it, including different types of houses and burials. This major museum, which recently had a tourist village constructed adjacent to it, continues to play a significant role in informing the Chinese people about life in Neolithic China.

Bay Springs Mill, Mississippi

In 1836, one George Gresham built a water-powered sawmill and gristmill on Mackeys Creek in northeastern Mississippi, and in 1852, the Bay Springs Union Factory was built at the same location to spin cotton and wool raised locally. Unlike most textile mills of the period, the Bay Springs Mill spun yarn that local families knitted into socks and wove into cloth for themselves and for sale. The development of power looms in New England had largely made this kind of symbiosis impractical by 1820, but at Bay Springs this relic of the early years of industrialization continued operating until 1885 when the mill burned.

In 1979, a team of researchers led by William H. Adams investigated the mill and surrounding community, including a general store, a Masonic lodge, a barracks, nine farmhouses, six millworkers' houses, and two other mill buildings. Much of the original equipment remained on the site, and Steven D. Smith, Timothy B. Riordan, and Albert F. Bartovics analyzed the archaeological remains. The historical

geographer Howard Adkins researched the documentary history of this community, and the folklorists David F. Barton and Stephen Poyser interviewed over sixty people-their recordings are in the Library of Congress, the Mississippi Department of Archives and History, and the Indiana University Folklore Archives. The community approach used at silcott, washington, and waverly plantation was used at Bay Springs as well to provide a broader historical context for the material recovered. The study of commodity flows by Riordan and Adams provides a model for quantifying material culture within the context of the national market.

W. H. Adams

Beazley, Sir John Davidson

(1885-1970)

Beazley was born in Glasgow, the son of a member of the Arts and Crafts movement, so it is perhaps not surprising that he was to be fascinated by craftsmen and artists for most of his life. He attended Balliol and Christ Church Colleges at Oxford, where he later became Lincoln

published in the Calcutta Asiatic Society journals and proceedings. He edited a large number of inscriptions for *Epigraphia Indica* (see vols. 15, 16, 18, 19), and the range of his edited inscriptions was chronologically and geographically wide. His mastery of the primary sources of ancient India led him to a study of its political history, and one of his books on the subject is *The Age of the Imperial Guptas* (1933). He wrote extensively in his mother tongue, Bengali, even writing a large number of historical novels with themes selected from ancient India.

Beazley, Sir John Davidson

(1885-1970)

Beazley was born in Glasgow, the son of a member of the Arts and Crafts movement, so it is perhaps not surprising that he was to be fascinated by craftsmen and artists for most of his life. He attended Balliol and Christ Church Colleges at Oxford, where he later became Lincoln

professor of archaeology. Beazley was a fine classical scholar and an excellent teacher, but his major interests were Greek art and Attic vase-painting. Vase-painting, because of its quality and the fact it had survived when all other forms of painting in ancient greece did not, made it particularly important to the history of art. Beazley's work on vase painting was to revolutionize the disciplines of art history and archaeology.

By the early twentieth century the collections of Greek pottery formed by sir william hamilton and other aristocratic antiquarians during the early nineteenth century had found their way into museums across Europe. German scholars such as Hartwig, Hauser, and Furtwangler had noted that some pots carried short inscriptions, including what appeared to be “signatures” or short texts giving the name of an artist, followed by a verb, as in “made or painted by,” which allowed a typology based on signed works to be created. German scholars applied this typology only to those pots that were signed and were diagnostic of a particular style or technique.

Beazley broadened this method to include the whole corpus of Attic pottery. By identifying the unconscious details of individual artists-such as painted features and elements-he was able to add unsigned pieces to the rest of the corpus of signed ones-and so tens of thousands of Attic red-figure and black-figure pottery could be grouped as the works of individual artists. Beazley's method has been described as identifying the “hands” of the painters and potters of Athens, and these additional identifications supplemented the names of craftsmen that appeared on the pottery. Thus he was able to transform the hitherto chaotic study of vase-painting into an organized field of study, similar to other documented schools of painting. He went on to successfully apply his method to Etruscan, Corinthian, Eastern Greek, and South Italian pottery.

Beidha

Excavated by English archaeologist Diana Kirkbride between 1958 and 1967, Beidha is a significant Natufian and prepottery Neolithic site in southern jordan. Excavation revealed changes in domestic architecture and provided evidence of the early cultivation of barley and emmer wheat (prior to the development of a domesticated morphology for these plants). Beidha also exhibited evidence of long-distance trade in obsidian, the origins of which are at Anatolia in central turkey.

Belgium

The state of Belgium was founded in 1830. Within its small territory (30,513 square kilometers), it comprises two major language groups, which has been an important factor in the country's recent political history. Since 1980, Belgium has been a federal state divided into three regions, each with substantial autonomy. The Flemish region, which occupies the northern part of the country, consists of sandy lowlands bordering the North Sea and part of the central Belgian loam belt covering a range of

low foothills. The linguistic border between the Flemish- and French-speaking populations runs across these hills from east to west. Brussels is a separate bilingual region.

To the south, there are Cretaceous limestone formations dissected by the Sambre and Meuse Rivers. From there, the land rises to the Ardennes uplands with a maximum altitude of just below 700 meters above sea level. Belgium was the first country on the European continent to go through a process of industrialization early in the nineteenth century, and this industrialization entailed major infrastructural and mining activities. The country's geographical features, political developments, and economic prosperity have all been influential in the development of archaeology in Belgium.

The leading role of Belgian naturalists and geologists in the establishment of prehistory during the later nineteenth century is well known. Earlier, however, historians had been

professor of archaeology. Beazley was a fine classical scholar and an excellent teacher, but his major interests were Greek art and Attic vase-painting. Belize

Belize, until 1973 the Crown Colony of British Honduras, is the only part of the Americas within the British Empire in which an ancient civilization flourished. Located on the eastern side of the Yucatán Peninsula bordering mexico and guatemala, it occupies part of the area in which the preclassic, classic, and postclassic Maya culture thrived from the first millennium b.c. until the Spanish conquest in the sixteenth century a.d., a span of over 2,500 years. The presence of Maya ruins, the absence of other archaeological remains, and the British colonial history of Belize, which set it apart politically and culturally from its hispanophone neighbors, all governed a distinctive progress of archaeological investigation in the nineteenth and twentieth centuries.

The history of Maya archaeology generally can be divided into five successive periods (Hammond 1983b). During the first two of these-*the era of the Spanish travelers* (1524- 1759) and *the era of the Spanish explorers* (1759- 1840)-Belize remained little settled and archaeologically unnoted. Two Americans, john lloyd stephens and frederick catherwood, passed through Belize in October 1839 on their first expedition to visit maya sites in Central America and Yucatán, but their visit did not encourage archaeological interest in this small nation. Nor was interest sparked when Patrick Walker, the colony's secretary, led an expedition from Belize hoping to forestall Stephens at the ruins of palenque on the far side of the Maya lowlands.

During the succeeding *period of the major scholars* (1840-1924), little attention was paid to archaeology in Belize until the end of the nineteenth century, although Belize City was the port of entry for traffic into the Peten, Guatemala's northern rain forest department where many of the most noted Maya cities stand. Even the publication in London of Alfred Maudslay's great *Biologia Centrali-Americana: Archaeology* (1889- 1902), which showed in detail how impressive the sites of tikal, Palenque, Quirigua, Copan, and chichén itzá were, apparently had no impact on British Honduras, although the sites of Lubaantun and Xunantunich were known and reported in the local press toward the end of the century.

Bell, Gertrude Margaret Lowthian

(1868-1926)

Born in County Durham, the daughter of Sir Thomas Hugh Bell, a local industrialist, Gertrude Bell was among the first female students at Oxford at Lady Margaret Hall. She graduated in 1888 at the age of twenty with first class honors in modern history, the first woman to attain this level at the university.

Gertrude Bell

(Hulton Getty)

Bell began her long relationship with the countries of the Near East when she first visited her diplomat uncle and aunt, Sir Frank and Lady Lascelles, in Tehran, Iran. She learned Persian and later published a verse translation of Persian poetry. However it was in 1899, when Bell spent some time in Jerusalem learning Arabic and visiting Petra and Palmyra, that she really became interested in desert travel and archaeology. Bell's love of alpine mountaineering occupied her for the next five years, as she explored the Engelhorner mountains and ascended the Matterhorn from the Italian side.

In 1905 Bell traveled from Jerusalem, through Syria and Cilicia, to Konya in central Turkey. She became a self-taught and competent field archaeologist and in 1907, with Sir W.M. Ramsay, explored the Hittite and Byzantine site of Bin-Bir-Kilisse. In 1909 she traveled down the Euphrates from Aleppo and returned by way of Baghdad and Mosul in Iraq. She explored Ukhaidir, a huge Abbasid Palace, in 1911. All of these travels resulted in popular publications. Bell then set out to explore central Arabia, where only one other European woman had been. Starting from Damascus she traveled to Hail but was not allowed to travel any further and was kept as an honored prisoner until she had no alternative but to go back to Baghdad.

PREV NEXT

In 1914 with the outbreak of war Bell joined the Red Cross and worked in Boulogne, France. In 1915 she was sent back to London to reorganize Red Cross headquarters. In the same year when the Arabs rebelled against Turkish rule Bell was drafted into the War Office's Arab Intelligence Bureau and moved to Cairo. Her task was to collect and summarize information about the Bedouin tribes and sheikhs of northern Arabia whose rebellion against Turkey was supported by the British. She was later attached to the military intelligence staff of the Mesopotamian Expeditionary Force and became political officer and Oriental secretary to Sir Percy Cox. Her special knowledge of Arab politics, her prewar friendships with Arab leaders, and her linguistic abilities were valuable to successful liaisons between the British and the rebelling desert tribes. Bell moved to Baghdad in 1917, after its capture, and she continued to act as an adviser in a civil capacity, as chief political officer, completing an administrative review of mesopotamia in 1920. She and Sir Percy Cox, then high commissioner in Mesopotamia, strongly supported the election of Saud Emir Feisal and the creation of a new Arab government in Iraq.

While she continued to work as political secretary, Bell was made Iraq's Director of Antiquities, responsible for all archaeological excavations and for establishing an antiquities service and a national museum at Baghdad. The museum was inaugurated in 1923 and moved into its new building in 1926. Bell was looking for a permanent director of antiquities so that she could return to England after her ten years of service in Iraq, when she died in Baghdad. She was buried in the English cemetery in Baghdad and in 1927, at the suggestion of King Feisal, a wing of the Baghdad Museum was named for her.

Belzoni, Giovanni Battista

(1778-1823)

When Napoleon invaded Egypt he took with him dozens of scholars and scientists to explore and record its ancient monuments. The twenty-four volume *Description d'Egypt* published in 1809 introduced Europe to ancient Egyptian civilization, provoking enormous interest both popular and museological, which led to the development of a lucrative market for Egyptian antiquities. Napoleon's army and his agent Drovetti had already plundered many antiquities when the British consul-general in Cairo, the former portrait painter Henry Salt, hired Giovanni Belzoni to ensure Britain's share. The Italian Belzoni had been a strong man in a circus before he began to collect antiquities on Salt's behalf, and his collecting techniques reflected this background. There was nothing scientific or careful about his removal of artifacts. Indeed it was his strength and his abilities to use levers and pulleys that enabled Belzoni to transport the monumental granite head of Rameses II from Thebes, and Rameses III's sarcophagus from the Valley of the Kings, back to England. In October 1817 Belzoni discovered the tomb of Seti I, the most richly decorated of all Egyptian royal tombs in the Valley of the Kings. Because it could not be transported as a whole Belzoni spent a great deal of time and effort recording the details of the wall paintings of the tomb for posterity.

Belzoni returned to England in 1819 and was taken up by London society. In 1821 he opened the Egyptian Hall in the british museum. He died in Benin in West Africa in 1823 on an expedition to find the source of the River Niger.

Bernal Garcia, Ignacio

(1910-1992)

Born in Paris, France, the son of a wealthy landowning Mexican family, Ignacio Bernal Garcia first studied law before transferring to study anthropology at the National Institute of Anthropology and the National Autonomous University of Mexico (UNAM), from which he received a Ph.D. and an LL.D. in 1949.

Bernal is best known for his work at the great sites of monte albán, Dainzu, and others in the southern highland Mexican state of Oaxaca and for excavations and restorations at teotihuacán. He was professor of archaeology at both UNAM from 1948 and at Mexico City College from 1950 to 1962. He was director of anthropology at the University of the Americas from 1948 to 1959 and the National School of Anthropology and History from 1950 to 1955 and director of the National Museum of Anthropology from 1962 to 1968. He also worked for the United Nations Educational, Scientific, and Cultural Organization (UNESCO) during the 1950s in the areas of international and prehistoric monument protection and education.

Bersu, Gerhard (1889-1964)

A German archaeologist and Director of the Romisch-Germanischen Kommission in Frankfurt, a key German archaeological institution, Bersu was removed by the Nazis in 1935 for refusing to adhere to National Socialist ideology. He emigrated to Britain, where he introduced Continental methods of excavation to English archaeologists. These included the open area excavation of settlement sites, which comprised the stripping of large areas to reveal the plans of buildings and other structures and the spatial and chronological relations between them.

These methods were used in the now-classic excavations at the Iron Age farm of Little Woodbury in Wiltshire from 1938 to 1939. Little Woodbury was an oval ditched enclosure in which potholes were found. Occupied from 400 to 200 b.c., it contained one large round house, a small circular structure, four post granaries, and storage pits.

During the Second World War, Bersu excavated Iron Age houses on the Isle of Man during his internment there as a German citizen. From 1947 to 1950 he was professor of archaeology at the Royal Irish Academy, Dublin. In 1950 he returned to Frankfurt.

Beyer, Henry Otley (1883-1966)

In the history of Philippine archaeology the name Henry Otley Beyer is prominent. A pioneer in Philippine anthropological research, Beyer was one of the first scholars to explore the beginnings of Philippine society and culture. By organizing the enormous amount of archaeological data he collected during his years of active work in the philippines, he launched the search for explanations regarding the peopling of the archipelago and the cultural relationships that existed between Filipinos and their Southeast Asian neighbors.

Beyer was born into a pioneering German-American family in Edgewood, Iowa, on July 13, 1883. Even as a young boy he was noted to have the interests of a naturalist, and he enjoyed spending time by himself in the woods near the farm where he grew up.

Majoring in chemistry and geology, Beyer graduated from the University of Denver in 1904. During archaeological fieldwork in the summer he probed the remains of the Indians of the Southwest. This apparently was his first exposure to archaeology and he also worked on the collection of artifacts from the ruins. In 1910 he went to Harvard on a scholarship, completing a one-year graduate program in anthropology.

Beyer was first introduced to the Philippine culture when he visited the 1904 Louisiana Purchase Centennial Exposition in Saint Louis, Missouri. The exposition included an exhibit on Philippine ethnic groups that featured complete

Bernal Garcia, Ignacio

(1910-1992)

Born in Paris, France, the son of a wealthy landowning Mexican family, Ignacio Bernal Garcia first studied law before transferring to study anthropology at the National Institute of Anthropology and the National Autonomous University of Mexico (UNAM), from which he received a Ph.D. and an LL.D. in 1949.

Bernal is best known for his work at the great sites of monte albán, Dainzu, and others in the southern highland Mexican state of Oaxaca and for excavations and restorations at teotihuacán. He was professor of archaeology at both UNAM from 1948 and at Mexico City College from 1950 to 1962. He was director of anthropology at the University of the Americas from 1948 to 1959 and the National School of Anthropology and History from 1950 to 1955 and director of the National Museum of Anthropology from 1962 to 1968. He also worked for the United Nations Educational, Scientific, and Cultural Organization (UNESCO) during the 1950s in the areas of international and prehistoric monument protection and education.

Bersu, Gerhard (1889-1964)

A German archaeologist and Director of the Romisch-Germanischen Kommission in Frankfurt, a key German archaeological institution, Bersu was removed by the Nazis in 1935 for refusing to adhere to National Socialist ideology. He emigrated to Britain, where he introduced Continental methods of excavation to English archaeologists. These included the open area excavation of settlement sites, which comprised the stripping of large areas to reveal the plans of buildings and other structures and the spatial and chronological relations between them.

These methods were used in the now-classic excavations at the Iron Age farm of Little Woodbury in Wiltshire from 1938 to 1939. Little Woodbury was an oval ditched enclosure in which potholes were found. Occupied from 400 to 200 b.c., it contained one large round house, a small circular structure, four post granaries, and storage pits.

During the Second World War, Bersu excavated Iron Age houses on the Isle of Man during his internment there as a German citizen. From 1947 to 1950 he was professor of archaeology at the Royal Irish Academy, Dublin. In 1950 he returned to Frankfurt.

Bibracte

Bibracte is located at Mont Beuvray in the commune of Saint-Leger-sous-Beuvray in the French department of Saône-et-Loire. The *oppidium* (fortified town) of Bibracte, the city of Greater Gaul that witnessed the return of Julius Caesar on many occasions, was the capital of the tribe known as Heduens, who lived west of what is now the region of Burgundy. The Heduens were allies of the Romans and defected to Caesar at the beginning of the revolt of 52 b.c. It was in Bibracte that Vercingetorix pleaded his case for a union of tribes against Caesar, it was in Bibracte that Caesar compiled most of his book on Greater Gaul during the winter of 52-51 b.c., and it was close to this city that the Helvetians had fought their battles in 58 b.c. at the beginning of the rebellion.

By the fifteenth century a.d., it was traditional to locate Bibracte on Mont Beuvray, but scholars of the eighteenth century, anxious to claim greatest antiquity for the town of Autun, refuted that location. However in 1851, a young wine merchant, Jean-Gabriel Bulliot, began to reexamine all of the evidence through with a survey of the area and its archaeological evidence. It took him fifteen years, and the moral and financial encouragement of Emperor Napoleon III, to justify his thesis to his scholarly adversaries-Bibracte was on Mont Beuvray. The archaeological research was pieced together between 1867 and 1895, the year his nephew archaeologist joseph déchelette, the celebrated author of the *Manuel d'archéologie,* took over the project and continued his uncle's work until 1907. The research on Bibracte played a large role in the development of archaeological methods in France and in what became known as Iron Age studies: “the Beuvraisian” was for a long time the name given to the last phase of the late la tène period, 140-30 b.c.

Mont Beuvray, which stands out from the southern Morvan Mountains, is more than 800 meters in altitude and comprises three hills whose rounded slopes are joined by gentle plateau. Covered by fir tree forests, it was still partly cultivated and partly planted with beech and chestnut trees as late as the 1950s. The substrata, disturbed by numerous tectonic movements, is essentially composed of rhyolites. Bulliot located a rampart five kilometers long that ran in part along the upper reaches of the slopes and delimited a surface area of approximately 135 hectares. Recent research has identified a second line of defense, even older, that encircled an area of 200 hectares.

Bulliot noted the first rampart in 1867, but it was not until 1868, after the publication of research concerning the fort of Murcens, located in Cras in the department of Lot, by E. Castagne that Bulliot began to establish links between his structure of beams and rocks and “the Gaulish wall” written about by Caesar during the siege of Bourges (Avaricum) in 52 b.c. (*Bello gallico* 7.23). The extent of this wall, with its beams fixed into each other by long iron pieces, and the development of monumental

gateways marked the impetus to establish, for the first time in the Celtic world, an urban area or town, not just a hill fort, that was distinct from the surrounding country.

Bulliot insisted that the original occupations of this built-up area would have included parts of the town that were devoted to artisans working in iron, bronze, and enameling. There would have been a residential quarter grouping the houses of the rich together, which would have been constructed from local materials but would have used Roman plans and building techniques. Part of the plateau would have been

Bibracte

Bibracte is located at Mont Beuvray in the commune of Saint-Leger-sous-Beuvray in the French department of Saône-et-Loire. The *oppidium* (fortified town) of Bibracte, the city of Greater Gaul that witnessed the return of Julius Caesar on many occasions, was the capital of the tribe known as Heduens, who lived west of what is now the region of Burgundy. The Heduens were allies of the Romans and defected to Caesar at the beginning of the revolt of 52 b.c. It was in Bibracte that Vercingetorix pleaded his case for a union of tribes against Caesar, it was in Bibracte that Caesar compiled most of his book on Greater Gaul during the winter of 52-51 b.c., and it was close to this city that the Helvetians had fought their battles in 58 b.c. at the beginning of the rebellion.

By the fifteenth century a.d., it was traditional to locate Bibracte on Mont Beuvray, but scholars of the eighteenth century, anxious to claim greatest antiquity for the town of Autun, refuted that location. However in 1851, a young wine merchant, Jean-Gabriel Bulliot, began to reexamine all of the evidence through with a survey of the area and its archaeological evidence. It took him fifteen years, and the moral and financial encouragement of Emperor Napoleon III, to justify his thesis to his scholarly adversaries-Bibracte was on Mont Beuvray. The archaeological research was pieced together between 1867 and 1895, the year his nephew archaeologist joseph déchelette, the celebrated author of the *Manuel d'archéologie,* took over the project and continued his uncle's work until 1907. The research on Bibracte played a large role in the development of archaeological methods in France and in what became known as Iron Age studies: “the Beuvraisian” was for a long time the name given to the last phase of the late la tène period, 140-30 b.c.

Mont Beuvray, which stands out from the southern Morvan Mountains, is more than 800 meters in altitude and comprises three hills whose rounded slopes are joined by gentle plateau. Covered by fir tree forests, it was still partly cultivated and partly planted with beech and chestnut trees as late as the 1950s. The substrata, disturbed by numerous tectonic movements, is essentially composed of rhyolites. Bulliot located a rampart five kilometers long that ran in part along the upper reaches of the slopes and delimited a surface area of approximately 135 hectares. Recent research has identified a second line of defense, even older, that encircled an area of 200 hectares.

Bulliot noted the first rampart in 1867, but it was not until 1868, after the publication of research concerning the fort of Murcens, located in Cras in the department of Lot, by E. Castagne that Bulliot began to establish links between his structure of beams and rocks and “the Gaulish wall” written about by Caesar during the siege of Bourges (Avaricum) in 52 b.c. (*Bello gallico* 7.23). The extent of this wall, with its beams fixed into each other by long iron pieces, and the development of monumental

gateways marked the impetus to establish, for the first time in the Celtic world, an urban area or town, not just a hill fort, that was distinct from the surrounding country.

Bulliot insisted that the original occupations of this built-up area would have included parts of the town that were devoted to artisans working in iron, bronze, and enameling. There would have been a residential quarter grouping the houses of the rich together, which would have been constructed from local materials but would have used Roman plans and building techniques. Part of the plateau would have been

taken up by a market and sanctuaries. If this urban plan is taken at face value today, then the idea of living conditions, which reflect the workings of a real town, from the end of the second century b.c. become characteristic of the late La Tène period, and subsequently the reply to F. Braudel's question, “Was there really a type of Gaulish town before the Roman conquest?” would be yes.

The archaeological remains were reexamined in 1984, supported by a research center that was welcomed by university teams from all over Europe because the site of Mont Beuvray had remained an important point of reference for all Celtic specialists. The large numbers and variety of artifacts attracted numismatists, epigraphers, and ceramologists, and the stratigraphy, as an open-area site, was the source of much useful archaeological research. The first results focused on what had developed essentially between the second and the first centuries b.c., between the La Tène C (II) and the Roman stratigraphic horizons, wedged before the camps of the German limes (fortified frontier). Neither the buildings, nor the phases of construction, nor the events of the years 58-52 b.c. could be read at the site, but dendrochronology provided some sort of precision in dating, with the identifiable phases in combination with all the variables covering a period of about twenty years.

The remains of the Porte du Rebout revealed at least four principal phases of construction between 90 and 10 b.c. The first phase of this gate was more than twenty meters in size, gigantic in comparison to similar gates found at more modern Celtic *oppida.* The gate's northern access consisted of a passage forty meters in depth. During subsequent phases, its size was reduced, and the Gaulish wall was replaced by wooden foundations and earthen embankments. The fortification, with its role as much monumental as defensive, would have necessitated thousands of hours of work, dozens of tons of iron, and thousands of cubic meters of wood.

Bulliot had already assigned a significance and luxury to the houses of the rich residential quarter, which rivaled the houses of pompeii. One of the houses covered 3,000 square meters, and its atrium and peristyle were Roman in style. The remains revealed five successive building stages and floors, all built during the first century b.c., and the original wooden construction was little by little transformed into a stone mansion.

Trade and the craft industry evolved more quickly than architecture. Artisan production soon became mass production, for example, in the fabrication of fibulae (metal pieces); materials, shapes, and molds were modified to ensure greater productivity. We can follow the evolution of the supply of wine, from different parts of italy and spain, thanks to the innumerable amphorae at the site.

It is this process of acculturation that is being followed today at Bibracte. The sanctuary, the lanes, and the tombs will all reveal, in a very short time, how they were transformed from an *oppidum,* a concept that was perhaps completely new in the second century b.c., into a veritable Roman town. It was the generosity of the Emperor Augustus, when he allowed the creation of the town of Autun-Augustodum to be built from the remains of Bibracte in about 15 b.c., that ruined the site and eventually led to this archaeological project of the late twentieth century.

Binford, Lewis R.

(1929-)

One of the most influential archaeologists of the twentieth century, Lewis R. Binford was born in Norfolk, Virginia. After high school he attended Virginia Polytechnic Institute (1948-1952), and

following a stint with the U.S. Army in Korea he gained a B.A. in anthropology from the University of North Carolina (1957). Moving to the University of Michigan, Binford received his M.A. in 1958 and his Ph.D. in 1964. Although Binford was at this stage primarily a student of North American prehistoric archaeology, his interest in world prehistory and general archaeological method and theory was already apparent.

Between 1961 and 1965, Binford taught in the Department of Anthropology at the University of Chicago, a period in which he took the first steps toward defining an original position on the relationships between archaeology and anthropology. During these years, Binford's focus on the nature of the archaeological record, on ethnoarchaeology, on the use (and abuse) of inference and analogy in archaeology, and on understanding variability in lithic assemblages made him the center of changes sweeping the practice of archaeology in North America. Although these changes would be later thought of as “the new archaeology,” or processual archaeology, and attract a large following, it is clear that Binford was following a research agenda of research of a breadth and significance that was not widely understood.

In 1966, he left Chicago for the Department of Anthropology at the University of California, Santa Barbara, and soon after moved to the Department of Anthropology at the University of California, Los Angeles. It was during this period that Binford's fame as the progenitor of the “new” archaeology first gained widespread attention, especially in 1968 with the publication of *New Perspectives in Archaeology,* a book of essays by the most significant of the new archaeologists, which he edited with his wife, Sally Binford. In 1968, Binford moved to the Department of Anthropology, University of New Mexico, staying there until he became the distinguished professor of anthropology at Southern Methodist University in Dallas, Texas, in 1991.

After 1968, Binford continued to develop his ideas about the nature of the archaeological record and the role of the archaeologist as anthropologist. He has published numerous books and articles, given conference addresses, seminar presentations, and been an invited speaker at many of the major archaeological departments around the globe. Although his focus has tended to be on the prehistoric record, Binford has undertaken significant ethnoarchaeological field research in Alaska and observed similar studies in Australia. He has also pursued fundamental research into site formation processes and taphonomy as well as continuing his interests in assemblage variability and the origins of humanity. A noted speaker and fierce debater, Binford has collected volumes of his essays, which are made more interesting still by frequent asides and vignettes of his personal history. Binford remains a strong opponent of those who seek to move archaeology away from a concern with science.

For an archaeologist of his undoubted influence and significance, Binford has been granted few honors by the members of his profession. He received an honorary doctorate from the University of Southampton in the 1980s, and in 2000, the University of Leiden in the Netherlands conferred a doctorate on him.

Bird, Junius Bouton

(1907-1982)

Born in Rye, New York, Bird became an accomplished sailor and outdoorsman at an early age and sailed to the Arctic several times, where he undertook his first research in Greenland and Labrador. A pioneer of radiocarbon dating methods and the study and conservation of textiles, Bird worked as an archaeologist at the American Museum of Natural History in New York City for fifty years.

Between 1936 and 1937 Bird excavated Fell's Cave and other sites in Chilean Patagonia, where he found human artifacts in association with extinct fauna, establishing the antiquity of the Paleo-Indian occupation of South America. In 1941 Bird excavated a long prehistoric sequence in the Atacama region in northern

PREV NEXT

chile. From 1946 to 1947 he worked in peru, as part of the virú valley survey, where he excavated the mound at Huaca Prieta. Data from this excavation not only proved the existence of pre-ceramic cultures on the Peruvian coast, but also established textiles as the major form of expression of ancient Andean culture. Bird continued to work at smaller sites in South America, but in his final years he worked in panama.

Bird received the Viking Fund Medal and the Order of the Sun of Peru. He was president of the Society of American Archaeology and chairman of the Anthropology Section of the New York Academy of Sciences. He received an honorary doctorate from Wesleyan University in 1958.

Biskupin

The site of Biskupin is located in Bydgoszcz Province in northwestern poland. It is an early-Iron Age fortified settlement belonging to the late Lusatian culture and dates to approximately 750-550 b.c. Biskupin is the country's best known archaeological site both within Poland and outside of it.

Biskupin

(Klaudyna Kucharska/Archivum Fotograficzne Meseum Archeologicznego)

The settlement at Biskupin was situated on an island, defended by timber breakwaters, and fortified by ramparts of timber compartments filled with earth and stones. The earth embankments were usually built on a foundation of beams and secured by vertical piles. The gateways to the settlement were an important part of fortifications, and the main feature of each was an approach that was lined on both sides by massive palisade walls and was probably covered on the top.

The settlement inside was constructed according to a plan, with a regular network of streets and communication tracks. The main arterial road was the street leading around the ramparts, and there were eleven parallel streets perpendicular to the arterial road. There was a small square near each of the gateways. The settlement consisted of 104-106 rectangular timber

houses laid out on a regular street system, and they may have housed up to 1,000 people. Each house interior was divided into two parts with the entrance fulfilling economic functions. Two phases of occupation have been distinguished, and 75 percent of the site has been excavated thus far.

Plan of Biskupin

The fortified settlement of Biskupin was found in 1933 and excavation began in 1934. Fieldwork was directed by józef kostrzewski and Zdzislaw Rajewski with the participation of Wojciech Kocka, Tadeusz Wieczorowski, Feliks Wydra, and Jozef Szubert. Excavations were carried out in the years 1934-1939, and when they resumed in 1946 after World War II, they continued until the 1960s. Various specialists from complementary disciplines participated: soil and geological studies (Feliks Terlikowski, Jozef Czekalski, Karol Paulo), palynological analyses (Adam Paszewski, Julian Witold Rafalski), archaeozoological studies (Edward Lubicz-Niezabitowski), botanical and dendrological studies (Bronislaw Jaron, Tadeusz Dominik), ethnographic research of the Biskupin architecture (Stanislaw Poniatowski), and others.

Photographic documentation of the site was very important. Wojciech Kocka developed the technique of taking pictures from a small balloon, and there were very successful attempts to produce color photographs as early as 1939. Research at Biskupin marked enormous progress in Polish archaeological studies. It was truly comprehensive, owing to the fruitful cooperation with specialists from other disciplines. This cooperation was characterized by real partnership, and it led to the development of new methods of excavation. The large scale of the research was also significant. After World War II, Biskupin was the place where practical courses on excavation methods for students of archaeology, history, and the history of art were organized. As a result, the great majority of students of that time gained their archaeological experiences in Biskupin.

Biskupin is now a well-known archaeological open-air museum. It was, and still is, an important center for experimental archaeology, especially in building, tillage, food preparation, stone and flint work, antler and bone work, wood and wool work, clay processing, and the obtaining of tar.

Blegen, Carl William (1887-1971)

Born in Minneapolis, Minnesota, Blegen excavated at Korakou, Prosymna, and Pylos in greece, but he is best known for his extensive excavations at Troy. Blegen was professor of classical archaeology at the University of Cincinnati, Ohio (1927-1957). As secretary of the american school of classical studies at athens, Blegen, along with Alan Wace, director of the British School in Athens, devised a chronology for mainland Greece for the Early, Middle, and Late Helladic periods through the pottery sequence from their excavation of the

prehistoric site of Korakou in Corinthia (1915- 1916). Blegen and Wace were convinced that although Minoan in origin Mycenean civilization was not the result of the conquest of mainland Greece, as argued by sir arthur evans, but was a combination of Minoan civilization with another civilization on the mainland.

To elucidate the relationship between Mycenean and Minoan civilization Wace began excavating Mycenae in 1921 (and finished, after many interruptions, in 1955) while Blegen investigated Troy, which he regarded as a key Aegean and Anatolian site. Between 1932 and 1938 Blegen tested sections of the mound that had not been touched by heinrich schliemann and wilhelm dorpfeld, finding that the previously identified nine cities of Troy only represented two or more phases in the Bronze Age out of a total of forty-six phases. He attributed Homer's Troy to the major period VIIa (ca. 1250 b.c.) because there was strong evidence that the city was destroyed by war.

In 1939 Blegen returned to mainland Greece to find the Mycenean capital of Messinia, which Homer had said belonged to "King Nester of Pylos." He excavated the hilltop of Espano Englianos and found a Mycenean palace, the excavation of which was not completed until 1966. The palace of Pylos was much better preserved and more carefully excavated than those at Mycenae or Tiryns, even if it was not as large. While its layout and decoration were similar to those of Minoan palaces, it was more fundamentally like Greek Mycenean palaces. In this architectural analysis Blegen had accurately defined the extent of Minoan influence on Mycenean Greece. Of equal importance were hundreds of clay tablets inscribed with early European script and dating from ca.1250 b.c. discovered by Blegen at Pylos. Blegen's account of the history of Pylos received important confirmation when michael ventris deciphered Linear B in 1951.

Bogazköy

Bogazköy is the site of the ancient city of Hattusha, the capital of the Hittites. Located in north-central Anatolia (turkey), Bogazköy was first discovered in 1834 by French archaeologist Charles Felix Marie Texier, who also recorded bas relief carvings of humans and animals and some unusual hieroglyphs. The site was further described on several occasions during the late-nineteenth century, but it was not until 1906 when Hugo Winckler (an Assyriologist) began to excavate that a great archive of cuneiform tablets was uncovered. Some of these were in Hittite, but a sufficiently large number were in Akkadian, an ancient language that had already been deciphered. Excavation by German teams at Bogazköy has continued and has revealed much about Hittite history.

Tim Murray

Bolivia

Colonial Period (1530-1824)

After the discovery of the New World, the Spanish colonial system was established in a large part of the Americas, including what is now Bolivia. During this period, early Spanish chroniclers started to describe the customs, traditions, and monuments of native cultures.

An extensive array of documents was produced, such as the early chronicles and descriptions by both Spaniards and Creoles, legal and litigant documents, and administrative censuses for taxes. Such efforts

have had a variety of purposes: they provide the information needed to “adapt” the native socioeconomic institutions into the colonial system; to “civilize” and christianize the Indians; to claim ancient rights pertaining to land, wealth, and status in favor of native elites; or to denounce the abuses of Indians on the part of theSpanish authorities and *encomenderos*. Because of the varied nature of such documents, each provides a different perspective on the impact that the colonial system had on native Bolivian populations. These documents are also of great anthropological value for understanding complex cultural variability in the Andes and for an accurate combination of the archaeological and ethnohistorical disciplines in the reconstruction of the prehistoric Bolivian past.

prehistoric site of Korakou in Corinthia (1915- 1916). Blegen and Wace were convinced that although Minoan in origin Mycenean civilization was not the result of the conquest of mainland Greece, as argued by sir arthur evans, but was a combination of Minoan civilization with another civilization on the mainland.

To elucidate the relationship between Mycenean and Minoan civilization Wace began excavating Mycenae in 1921 (and finished, after many interruptions, in 1955) while Blegen investigated Troy, which he regarded as a key Aegean and Anatolian site. Between 1932 and 1938 Blegen tested sections of the mound that had not been touched by heinrich schliemann and wilhelm dorpfeld, finding that the previously identified nine cities of Troy only represented two or more phases in the Bronze Age out of a total of forty-six phases. He attributed Homer's Troy to the major period VIIa (ca. 1250 b.c.) because there was strong evidence that the city was destroyed by war.

In 1939 Blegen returned to mainland Greece to find the Mycenean capital of Messinia, which Homer had said belonged to "King Nester of Pylos." He excavated the hilltop of Espano Englianos and found a Mycenean palace, the excavation of which was not completed until 1966. The palace of Pylos was much better preserved and more carefully excavated than those at Mycenae or Tiryns, even if it was not as large. While its layout and decoration were similar to those of Minoan palaces, it was more fundamentally like Greek Mycenean palaces. In this architectural analysis Blegen had accurately defined the extent of Minoan influence on Mycenean Greece. Of equal importance were hundreds of clay tablets inscribed with early European script and dating from ca.1250 b.c. discovered by Blegen at Pylos. Blegen's account of the history of Pylos received important confirmation when michael ventris deciphered Linear B in 1951.

Bogazköy

Bogazköy is the site of the ancient city of Hattusha, the capital of the Hittites. Located in north-central Anatolia (turkey), Bogazköy was first discovered in 1834 by French archaeologist Charles Felix Marie Texier, who also recorded bas relief carvings of humans and animals and some unusual hieroglyphs. The site was further described on several occasions during the late-nineteenth century, but it was not until 1906 when Hugo Winckler (an Assyriologist) began to excavate that a great archive of cuneiform tablets was uncovered. Some of these were in Hittite, but a sufficiently large number were in Akkadian, an ancient language that had already been deciphered. Excavation by German teams at Bogazköy has continued and has revealed much about Hittite history.

The Republican Period (1825-1890)

The consolidation of Bolivia as a state brought with it a series of changes in the way native antiquities were perceived. Still with a colonialist approach, a new interest emerged in ancient cultures and native groups. During the first part of this period, foreign scholars visited Bolivia with a renewed interest in ethnography, ancient monuments, natural sciences, zoology, and botany. Their focus was mostly descriptive, and the value of their documents lies in the extensive descriptive information provided. The most important scholars visiting Bolivia at this time included Alcides D'Orbigny (1839), a French naturalist whose main goal in the 1830s was to compile information about the diversity of the

human races in South America; Johan J. Tschudi (1851), a German naturalist who described the early native monuments around 1838-1842; and Francis de Castelnau (1851), who argued that Tiwanaku was an influential predecessor of the Inca empire. Ephraim George Squier (1870), a U.S. diplomat appointed to Lima, peru, in the 1860s, stands out for his detailed description and mapping of Tiwanaku and other important archaeological sites (Albarracín-Jordan 1999; Ponce Sanginés 1995).

Bolivian Archaeological Sites

On the local level, the consolidation of Bolivia as a nation state was coupled with the need of emerging Creole elites to develop their own sense of identity, one that was different from that of colonial Spain but still divorced from the oppressed Indian populations. Additionally, the increasing visits of foreign explorers involved with diplomatic affairs renewed the interest of the Bolivian government in its ancient monuments. For example, the Bolivian president José Ballivian ordered nonsystematic excavations in Tiwanaku with only the goal of collecting archaeological pieces for the local museum in the city of La Paz (Ponce Sanginés 1995). The perception that archaeology was simply part of art history, involved with the recollection and collection of aesthetic artifacts, was part of a broader tendency in the first stages of archaeology before its consolidation as a science. During this period, and even later, most of the archaeological work in Bolivia was restricted to the collection of artifacts and description of archaeological monuments.

The Beginnings of Archaeology (1890-1952)

During the last decade of the nineteenth century and the first half of the twentieth, the beginnings of Bolivian archaeology emerged with a more scientific approach. These first efforts were by foreign researchers visiting Bolivia, most of them part of research programs promoted by international museums. The goal of these scholars was, not just scientific inquiry, but in some cases, to acquire archaeological collections for exhibition in foreign museums. This practice of acquiring collections of artifacts from developing countries for display in the home country's museums was part of the colonial approach to archaeology and typical of those times. On a national level, this was the period of intensive exploitation and export of tin and the advent of liberalism and modernism into the Bolivian political arena.

Adolph Bandelier, an archaeologist working in the American Museum of Natural History in New York City, visited different places in Peru and Bolivia during 1892-1897. From Bolivia, Bandelier (1910) provided important descriptions, maps, and collected indigenous myths of origin from the Island of the Sun, the Island of the Moon, and Tiwanaku (the mythical centers of origin of the Inca empire). He also collected archaeological objects that were later transported to the American Museum of Natural History.

Erland Nordenskiöld, a Swedish scholar, also conducted several scientific expeditions with an archaeological and ethnographical focus in different areas of Bolivian territory during 1901-1914. His work was conducted not only in the Bolivian highlands, but he was also one of the first to provide firsthand information about the intermediate valleys and Amazonian tropics. He described the variety of ethnic groups inhabiting those areas, and he also carried out excavations at several habitation mounds in the lowlands (Trinidad), at sites located in the valleys of Cochabamba (Mizque, Caballero, Saipina), and in Santa Cruz. He provided the first relative chronologies and detailed artifact inventories, and he identified previously unknown archaeological cultures. His extensive work was published in 1953.

The work of Arthur Posnansky (1904-1940) also stands out. As a naval engineer from Vienna who was impressed by the ruins of Tiwanaku, Posnansky (1945) produced detailed maps of the monuments and structures in Tiwanaku. He also speculated that this ancient culture was the cradle of American humans

and that Tiwanaku was on the shores of an ancient lake.

In 1903, a multidisciplinary French expedition directed by Georges de Crèqui-Montfort made the first excavations in Tiwanaku. Several areas of Tiwanaku were excavated such as the pyramid of Akapana, the semi-sunken temple of

late intermediate period and Inca remains (Rydén 1952, 1957). During 1958, a German, Heinz Walter, conducted excavations in the regions of Mizque-Lakatambo (Cochabamba) and Icla-Chullpamoko (Chuquisaca) to investigate the chronology and stylistic distribution of local ceramic styles (Walter 1968).

In 1955, the American archaeologist alfred kidder from the Museum of Pennsylvania visited Bolivia and studied the ruins of Chiripa, the cultural predecessor of Tiwanaku during the formative period. He excavated the ceremonial mound of Chiripa, along with Gregorio Cordero, a Bolivian archaeologist working at the National Museum of Tiwanaku (Kidder 1956). Unfortunately, little information about these excavations was published. Between 1974 and 1975, David Browman also focused his efforts on the excavation of Chiripa, providing a new interpretation of the origins and formation of Tiwanaku as the capital of a multiethnic confederation and highlighting the role of llama caravans in the economic and political integration of the Bolivian highlands and valleys (Browman 1981).

There was almost an absence of Bolivian archaeologists excavating or generating theoretical interpretations during this period. Among the few and most important ones were Maks Portugal Zamora and Gregorio Cordero Miranda, both of whom were involved in the direction of the National Museum of Tiwanaku. Portugal Zamora (1957) excavated different archaeological sites such as Chiripa and others in the highlands while Cordero Miranda (1955, 1978) focused his research in Tiwanaku and excavating different areas, including the Pumapunku pyramid. However, most of their investigations were neither documented nor published, which is a loss for Bolivian archaeology.

Another significant feature of this period is the near absence of Bolivians participating in international archaeological projects. When Bolivians did participate, their role was secondary. There are three main reasons for this situation: first, Bolivian archaeology was not as yet institutionalized; second, Bolivian researchers did not have a clear vision about the role of archaeology as a scientific discipline; and third, the economic support of archaeology by the Bolivian state was minimal.

Institutionalization and the Rise of National Archaeology

The nationalist revolution in 1952 had a great impact on the way Bolivian archaeology was organized and structured at the government level. One of the goals of the new revolutionary government was to reinforce the image of a unified nationhood by creating a sense of national identity. In this process, the construction of a glorious past became an important element, and archaeology gained the support of the emerging elites. In 1958, the Center of Archaeological Investigations in Tiwanaku (CIAT) was created under the direction of the Ministry of Education, and its main goal was to conduct extensive research and archaeological excavations in Tiwanaku.

The creation of CIAT constituted the first systematic effort of the Bolivian state toward the institutionalization of archaeological research. Starting in 1957, under the direction of Carlos Ponce Sanginés and the sponsorship of the Bolivian government, different areas of Tiwanaku such as Kalasasaya and Akapana were extensively excavated, preserved, and restored, constituting what is today one of the most important sites of Bolivian patrimony. As a result of these excavations, Ponce formulated an evolutionary sequence for Tiwanaku, based on radiocarbon dating, as follows: (1) Hamlet Tiwanaku, b.c. 1590-a.d. 43; (2) Urban Tiwanaku, a.d. 43-667; and (3) Imperial Tiwanaku, a.d. 667-1050. It is clear that Tiwanaku was not just a ceremonial center, as previously suggested (Bennett 1934), but an extensive urban center and the capital of an expansive empire (Ponce Sanginés 1981). Ponce's ideas and interpretation remain pivotal for the understanding of the Tiwanaku polity, and they were spread widely through a series of publications.

In 1975, the National Institute of Archaeology (INAR) was established as the main government

organization in charge of executing, organizing, sponsoring, and regulating archaeological research in all of Bolivia. Ponce Sanginés, its main promoter and first director, organized a series archaeological projects in

of archaeological projects and have promoted the protection of the prehistoric cultural heritage in those regions. Added to these efforts, the creation of the Department of Anthropology and Archaeology at the University of San Andrés in La Paz in 1984 provided a firm base for the education of a new generation of Bolivian archaeologists.

Current Archaeological Research

Since the 1980s, new multinational and multidisciplinary projects have been conducted in Bolivia. The Wilajawira archaeological project, under the direction of Alan Kolata and Oswaldo Rivera Sundt, has revealed the importance of raised fields in the Tiwanaku agricultural economy, the centralized structure of the Tiwanaku state (with a quadripartite hierarchical system), and the nature of urbanism in the Tiwanaku core (Kolata 1989, 1993).

The International Seminar of Archaeological Excavations in Tiwanaku, a part of the Wilajawira project directed by Kolata and Ponce Sanginés, developed a number of specifically oriented research areas such as paleoethnobotany and diet analysis (Lennstrom, Hastorf, and Wright 1991), settlement pattern studies (Albarracín-Jordán 1990; Mathews 1992), household and domestic archaeology (Bermann 1994; Janusek 1994), craft specialization (Rivera Casanovas 1994), public architecture (Couture 1992; Manzanilla and Woodard 1992; Rivera Sundt 1989; Sampeck 1991), physical anthropology and demography (Blom 1999), paleozoology (Webster 1993), and ceramic analysis (Alconini 1995; Sutherland 1991). Undoubtedly, the Wilajawira archaeological project constituted the largest multinational effort, produced a great body of information about Tiwanaku, and set the foundation for a multidisciplinary approach to Bolivian archaeology.

Other multinational and multidisciplinary projects have been conducted in the highlands. Since 1992, Christine Hastorf, head of the Taraco archaeological project, has been conducting an extensive investigation of the site of Chiripa, a pre-Tiwanaku polity that arose during the formative period near the shores of Lake Titicaca. The most important contributions of this project were the excavation and exposure of the ceremonial core of Chiripa, comprising a series of terraced platforms, specialized architecture, and burial and domestic areas around a semi-sunken temple. The project has also refined the chronological sequence of the site, conducted regional studies, and paleobotanical analysis (Hastorf et al. 1996). Another large-scale project was the Iwawe archaeological project, which was directed by William H. Isbell and Juan Albarracín-Jordán between 1995 and 1998 in the Iwawe region near Lake Titicaca. This work clarified our understanding of the formative period and the origins of Tiwanaku before it became a state (Isbell 1993). Charles Stanish and others have conducted extensive excavations and settlement studies at the Island of the Sun, Lake Titicaca (Stanish et al. 1996).

Small-scale projects, with Bolivian participation, have also been conducted in the Bolivian highlands. These include the Yaya-Mama archaeological project, coordinated by Karen Mohr Chavez, Sergio Chavez, and Eduardo Pareja in the region of Copacabana and adjacent areas since 1993, which seeks to understand the role played by religion in the unification of the various polities around the lake before the emergence of Tiwanaku. A new approach to archaeology has been implemented by Sergio Chavez in his promotion of the participation of local indigenous Aymara communities in different stages of archaeological research, part of a strategy to make them active participants in the reconstruction and reappropriation of their own cultural past.

Other regions of Bolivia were also subjected to similar multinational and multidisciplinary projects in the decade 1990-2000. Albert Meyers (1997), from the University of Bonn, and a German-Bolivian team have extensively excavated, conserved, and restored different areas of Samaipata, an Inca complex with one of the largest carved rocks in South America located at the margins of the sub-Andean piedmont

before the rise of the Amazonian savannas. Other small-scale binational projects have been conducted in these tropical areas. In Beni, Clark Erickson, along with Bolivian and American archaeologists, has documented the landscape,

Bonampak'

A classic Maya site in Chiapas in southern mexico, Bonampak' is most famous for the well-preserved murals adorning the interior walls of its principal temple. For decades the temple had been a place of worship by the Lacandon Maya, who today inhabit the region, but the murals became known to the outside world only in 1946.

Bonampak' was the capital city of one of the many small kingdoms that formed the map of the Maya world during the Maya classic period (a.d. 250-900). It alternated between peaceful and bellicose relations with its neighbors, and like many other kingdoms during the classic period was at times dominant and at other times subservient in the hierarchy of kingdoms in the complex political geography of the times. The most famous king of Bonampak' was Yajaw-Chan-Muwa:n, who was responsible for most of the carved monuments that survive at the site. Yajaw-Chan-Muwa:n, who was related by marriage to the royal family of Yaxchilan that lived in a neighboring kingdom, became king of Bonampak' in a.d. 776, toward the end of the capital's history. In one of his carved stelae (Bonampak' Stela 2), he portrays himself about to let blood from his genitals, flanked by his wife (a princess of Yaxchilan) and his mother.

Yajaw-Chan-Muwa:n also built and decorated Structure 1 of Bonampak', which contains the famous

murals. These murals are among the best preserved in Mesoamerica and give a fascinating glimpse into classic Maya ritual, warfare, and courtly life. The murals cover the surfaces of all three rooms of the temple. The first room portrays an elaborate procession at the Bonampak' court, in which the key event is the public presentation of the young son of Yajaw-Chan-Muwa:n as the heir apparent to the throne of the kingdom. In the second room is the depiction of a pitched battle in which Yajaw-Chan-Muwa:n and his allies are victorious. Over the doorway of this room, the captives-destined for sacrifice-are displayed before Yajaw-Chan-Muwa:n. The murals in the third room show the victory dance of the triumphant Bonampak' lords while a captive is being sacrificed and members of the court are engaged in letting their own blood.

A view from the back, toward the entrance, Temple of Murals, Bonampak'

(Ann Ronan Picture Library)

These wonderful murals were intended to be a lasting record of the ceremonies surrounding the designation of Yajaw-Chan-Muwa:n's son as heir to the throne. The irony is that the young boy portrayed in the murals almost certainly never became king, for, apparently, the site was abandoned before he ever came of age, and

there are indications that the murals were never quite completed.

Maya Civilization

Bordes, François

(1919-1981)

One of the most influential Paleolithic archaeologists of the twentieth century, François Bordes was most famous for his standard Mousterian stone tool typology. He created the typology during the 1950s and refined it over the next decades until it gained enormous influence in the classification of Mousterian materials in Europe and southwestern Asia.

Bordes's great area of influence was in the heartland of French Paleolithic archaeology, southwestern france, including the Périgord region, and is best expressed by his classic excavation of the sites of Combe Grenal and Pech de l'Azé. Bordes's great advance on previous classifications was in his use of statistical analysis for very large assemblages, which allows the archaeologist to plot changing distribution of artifact types between sites and over time. Bordes also argued that his system allowed the archaeologist to identify the existence of distinct tribes during the Mousterian period in southwestern France, his logic being that distinct toolmaking traditions were the expression of distinct tribal ethnicities. This argument was strongly contested by American archaeologist lewis binford (among others), who contended that the variability that Bordes had identified was more likely the product of the different functions the tools were used to perform, different raw materials, different stages in a total production process for tools (reduction sequence), or different

time periods. Notwithstanding these arguments, many archaeologists would readily accept the assertion that Paleolithic archaeology was transformed by Bordes's vision. In his spare time, Bordes wrote science-fiction stories and cultivated an interest in cartooning.

Botta, Paul Emile

(1802-1870)

The son of distinguished Italian historian Carlo Botta, Paul Emile Botta was physician to Pasha Mohammed Ali of Egypt. In 1833 Botta was appointed French consul in Alexandria and in 1840 he was transferred to Mosul in northern Iraq with instructions to find and excavate the biblical city of nineveh.

Botta began excavating at Quyunjik, which was believed to be Nineveh, in 1842 but found little to interest him in his initial excavations. There appeared to be more of archaeological interest at nearby Khorsabad, and in 1843 Botta moved his excavations to this site, where he unearthed the palace of Sargon II (721-705 b.c.). With the support of the French government, and with 300 workmen, Botta dug Khorsabad for two years, acquiring magnificent bas-reliefs, artifacts such as four-meter-high winged bulls with human heads, and many cuneiform tablets, which were displayed at the louvre in Paris in 1846. Botta's discoveries caused huge interest in Paris-equivalent to the excitement engendered by Napoleon's Egyptian expedition.

Botta and artist Eugene Flandin published the *Monument du Nineve,* a four-volume record and illustration of the site, between 1846 and 1850. The Paris revolution of 1848 put an end to French work in Mesopotamia, and in 1851 Botta was dismissed in political disgrace. He was transferred to minor diplomatic posts in Jerusalem, Tripoli, and Syria. He died in Lebanon in 1870.

Boucher de Perthes, Jacques

(1788-1868)

A French customs official, an amateur antiquary, and a provincial man of letters, Boucher de Perthes has been sometimes described as the founder of the discipline of prehistory because of his discovery of ancient bifacially flaked stone tools in the gravels of the Somme River in northern France, tools that he attributed to “antediluvian” (pre-flood) human beings.

As president of a regional learned society he began his career in prehistory at the age of 49, assisting his

friend Dr. Casimir Picard, who was compiling an archaeological survey of the Somme Valley. He continued this work after Picard died. In 1837 during an excavation underneath the town walls of Abbeville, Boucher de Perthes found stone tools in the same stratigraphic levels as animal remains and pottery. While these artifacts became part of the Natural History Museum's collection, they were not recognized by the scientific establishment as being made by humans, and were classified as geological and paleontological-of natural rather than human scientific interest.

Boucher de Perthes also excavated at Menchcourt-les-Abbeville, a site formerly dug by Georges Cuvier, which was full of fossil elephant and rhino bones. Here he found not only stone tools but also polished pebble stone axes. Boucher de Perthes believed that if the tools and the bones were found in the same undisturbed stratigraphic unit then they were likely to be of the same age. In 1842 he retrieved a bifaced stone tool from these units and he continued to find and collect stone tools from numerous local railway cuttings, canal building sites, and quarries. Boucher de Perthes begun to write up his discoveries in what was to become the first part of *Antiquités celtiques et antédiluviennes,* in which he argued for the great age of the stone tools he had discovered. In this highly idiosyncratic work Boucher de Perthes advocated the need for methodological conventions of description and analysis that he felt would distinguish a science of archaeology, while at the same time arguing that his stone tools had been made by Celts who lived before the biblical flood. While he was not without supporters, the French scientific establishment,

time periods. Notwithstanding these arguments, many archaeologists would readily accept the assertion that Paleolithic archaeology was transformed by Bordes's vision. In his spare time, Bordes wrote science-fiction stories and cultivated an interest in cartooning.

Boucher de Perthes, Jacques

(1788-1868)

A French customs official, an amateur antiquary, and a provincial man of letters, Boucher de Perthes has been sometimes described as the founder of the discipline of prehistory because of his discovery of ancient bifacially flaked stone tools in the gravels of the Somme River in northern France, tools that he attributed to “antediluvian” (pre-flood) human beings.

As president of a regional learned society he began his career in prehistory at the age of 49, assisting his

friend Dr. Casimir Picard, who was compiling an archaeological survey of the Somme Valley. He continued this work after Picard died. In 1837 during an excavation underneath the town walls of Abbeville, Boucher de Perthes found stone tools in the same stratigraphic levels as animal remains and pottery. While these artifacts became part of the Natural History Museum's collection, they were not recognized by the scientific establishment as being made by humans, and were classified as geological and paleontological-of natural rather than human scientific interest.

Boucher de Perthes also excavated at Menchcourt-les-Abbeville, a site formerly dug by Georges Cuvier, which was full of fossil elephant and rhino bones. Here he found not only stone tools but also polished pebble stone axes. Boucher de Perthes believed that if the tools and the bones were found in the same undisturbed stratigraphic unit then they were likely to be of the same age. In 1842 he retrieved a bifaced stone tool from these units and he continued to find and collect stone tools from numerous local railway cuttings, canal building sites, and quarries. Boucher de Perthes begun to write up his discoveries in what was to become the first part of *Antiquités celtiques et antédiluviennes,* in which he argued for the great age of the stone tools he had discovered. In this highly idiosyncratic work Boucher de Perthes advocated the need for methodological conventions of description and analysis that he felt would distinguish a science of archaeology, while at the same time arguing that his stone tools had been made by Celts who lived before the biblical flood. While he was not without supporters, the French scientific establishment,

through the Academie des Sciences, flatly rejected his claims in 1846.

Jacques Boucher de Perthes

(Science Photo Library)

Ten years later Boucher de Perthes experienced a kind of rehabilitation. In 1858 the Geological Society of London, largely prompted by the great hugh falconer, visited Abbeville to examine his evidence and to compare it with material found in England. In 1859 the Royal Society of London upheld that "flint implements were the product of the conception and work of man," and that they were associated with numerous extinct animals. In 1859 Albert Gaudry, the French Natural History Museum's paleontologist, defended Boucher de Perthes's findings to the Academie des Sciences, and this time that learned establishment recognized the antiquity of mankind and the evidence for it. Charles Darwin's *Origin of Species* was published that same year.

Boule, Marcellin

(1861-1942)

Marcellin Boule was born on 1 January 1861 at Motsalvy, in the French province of Cantal and was introduced to the natural sciences in his youth by the local pharmacist, Jean-Baptiste Rames, who was also an amateur geologist. Boule studied first in Toulouse and took degrees in natural science and geology. While there, he met the prehistorians and cave art specialists emile cartailhac and Louis Lartet, and they introduced him to paleoanthropology and prehistory. In 1886, he won a scholarship to Paris to study, and there his chief mentors were Ferdinand Fouque, a geologist at the College de France who introduced him to petrography, and Albert Gaudry, a paleontologist at the Muséum National d'Histoire Naturelle. In 1892, Boule became Gaudry's assistant at the museum and succeeded him as professor of paleontology in 1903, a position he held to his retirement in 1936.

Boule received the Chevalier de la Légion d'Honneur for his reorganization of the museum's paleontology gallery, which was opened in 1898. He was one of the founders and editor (1893-1930) of the distinguished journal *L'Anthropologie*. Boule was the unrivaled leader of French paleontology in the first third of the twentieth century, receiving the Huxley Medal from the Royal Institute of Anthropology of Great Britain and Ireland and the Wollaston Medal from the Geological Society of London. He taught and inspired many French paleontologists.

Two major works stand out from his prolific output. The first is the study of the La Chapelle-aux-Saints skeleton, in which Boule was able to explain his ideas on paleontology by proposing an original identification and reconstruction of Neanderthal man. He insisted that Neanderthals could not be ancestral to modern man, that they were a genuine fossil with no descendants. He was to use the same argument later about *Homo erectus,* the pithecanthopines discovered in Indonesia and China. He believed that there was a yet-to-be-found hominoid ancestor from which modern humans had

descended.

The second major work is his popular book *Les hommes fossiles, eléments de paléontologie humaine* (1921), which summarized his thinking

about human ancestry for the general public. Albert I, prince of Monaco, was so impressed by this book that he founded the Institut de Paléontologie Humaine in Paris in 1914. The first organization for specialized research in the field, Boule was the Institute's first director when it opened in 1920.

Boule believed that the function of paleoanthropology was to revitalize prehistory by giving it the status of a "historical science," one that was indispensable to the study of the earliest humans. In the context of late-nineteenth-century prehistory, Boule's contribution was innovative. Using Quaternary geology, paleontology, and archaeology, Boule provided an alternative method to the study of prehistory. His method replaced the predominant one elucidated by gabriel de mortillet, one that was based exclusively on the classification of artifacts manufactured by humans. Boule argued that stone tools could only be used as chronological data if they were a proven part of geology and paleontology.

Boxgrove

In West Sussex (United Kingdom), 12 kilometers inland from the current shoreline of the English Channel, lies the parish of Boxgrove, where Middle Pleistocene sediments have been exposed in quarries along the southern margin of the hills of the South Downs. From the beginning of the twentieth century onward, similar deposits in the region were reported to yield archaeological finds. Research by the British Geological Survey in the 1970s demonstrated the occurrence of archaeological materials within the deposits at Boxgrove, and a survey and trial excavation undertaken by Mark Roberts in 1983 established the presence of a rich archaeological horizon. Funding by English Heritage enabled further research in 1984, and in 1985 the Boxgrove Lower Palaeolithic Project was set up by the Institute of Archaeology, part of University College London.

Excavations carried out until 1996 under the direction of Mark Roberts and Simon Parfitt have revealed extensive lithic scatters comprising large amounts of debitage (debris made by stone tools), numerous hand-axes, and some cores and flake tools. Moreover, the site complex has yielded one of the most diverse vertebrate faunas from a Lower Paleolithic context in Europe. The assemblages have been dated on the basis of mammalian biostratigraphy to the last temperate stage of the Cromerian Complex, tentatively correlated with Oxygen Isotope Stage 13 (524,000-478,000). Although later dates have been proposed on the basis of other data, such as the calcareous nannofossils, Boxgrove occupies a prime position in the ongoing debate about the earliest occupation of northern Europe. A robust hominid tibia found at Boxgrove in 1993 has been assigned to *Homo* spp., with possible further reference to *Homo* cf. *heidelbergensis* on temporal and geographic grounds.

Geologic study suggests that the archaeological remains were deposited within a markedly changing environment. Under decreasing marine influence the area developed from a beach setting, through a lagoonal setting in which artifacts were left on intertidal mudflats, and into a more terrestrial setting that later became inundated with freshwater. The excellent preservation of artifacts in the lagoonal silts and their exposure over relatively large areas have earned Boxgrove the description of "a Middle Pleistocene

pincevent," as have the detailed excavation and documentation procedures applied.

The assemblages recovered at Boxgrove are interpreted in terms of the procurement and processing of animal and lithic resources by hominids. Large mammal bone fragments with cut marks and percussion damage suggest meat and marrow exploitation. Use-wear on a small number of hand-axes is interpreted to stem from contact with meat and hide. All the lithic artifacts are made of locally available flint, and refitting data suggest that lithics in varying stages of reduction were transported. Other finds include an antler hammer with splinters of flint embedded in the striking surface and a horse scapula with damage suggested to be the result of a projectile impact.

PREV NEXT

The excellent preservation and documentation of archaeological data from Boxgrove have fueled expectations that assemblage studies will yield new insights into hominid behavior. Different data sets have been compiled to suggest that the hominids who left their artifacts at Boxgrove hunted large game, cooperated with each other, planned ahead, and used spoken language. Although these characteristics would not be unbecoming to those thought to be among the earliest colonizers of northern Europe, they remain contested. As research continues, the data from Boxgrove may prove particularly informative for the potential of and the limits to archaeological interpretation.

Braidwood, Robert John (1907-)

Robert Braidwood, born in Detroit, Michigan, in 1907, first studied to be an architect but returned to university in 1930 to study art history and anthropology because of the adverse effects of the Great Depression on the building industry. He traveled to Iraq in 1930-1931 to participate in the excavation of Seleucia, and this trip marked the beginning of his long interest in and significant contributions to Near Eastern archaeology. Braidwood worked briefly in Illinois and New Mexico, but all the rest of his fieldwork was under the aegis of the University of Chicago's oriental institute: Syria, 1933-1938; Iraq, 1947-

1948, 1950-1951, and 1954-1955; iran, 1959- 1960; and turkey, 1963 until the mid-1990s.

Seleucia, south of Baghdad. Robert Braidwood participated in an ongoing excavation here, which eventually uncovered four levels of occupation.

(© Arthur Thevenant/CORBIS)

During the 1930s, Braidwood participated in Amuq expeditions in Syria directed by henri frankfort, who became professor of Near Eastern archaeology at the Oriental Institute and was the head of Braidwood's dissertation committee. In 1945, Braidwood became the first specialist in prehistory to hold a full-time position at the institute (as well as a joint appointment in the University of Chicago's Department of Anthropology). He held both positions until 1978 when he became emeritus professor of Old World prehistory at the institute and emeritus professor of anthropology.

Braidwood's name is most closely associated with a major transition in the human past-the origins of food production in the Near East-and with the site of jarmo in northern Iraq, for many years the oldest village of farmers and herders known anywhere in the world. Braidwood's contribution, in the 1950s and 1960s, to the archaeology of agricultural origins and to archaeology more generally was primarily methodological, conceiving and implementing interdisciplinary staffs at the fieldwork level. He initiated a highly productive research trajectory that has claimed the attention of several generations of archaeologists and natural scientists. The interdisciplinary investigations he pioneered in Iraq and Iran became models for elucidating agricultural transitions and have also been acknowledged as the best means to delineate regional culture-historical sequences.

Members of Braidwood's project teams also intitiated two other important firsts in Near Eastern field archaeology: systematic ethnographic observations for archaeological purposes and the recovery of pollen from deeply stratified wet contexts. Much of what Braidwood pioneered is now central to archaeological research design, and he was a powerful force in world archaeology for at least three decades.

Brazil

Periods in the History of Archaeology

The history of archaeology in Brazil has been divided into phases following different criteria. Most authors consider that archaeology should have its own disciplinary history, untied to the overall political history of the country. André Prous (1992) identified five periods and Alfredo Mendonça de Souza (1991) followed the same disciplinary history approach but proposed only four periods.

The history of archaeology in Brazil should not, however, be considered independent from Brazilian history. Because the development of archaeology's practice, theory, and methodology depends directly on the sociopolitical conditions in a given country, it is possible to relate the social practice of archaeology and political changes. As with any intellectual endeavor, archaeological activities are the result of social conditions and relations prevailing in different periods. Thus, we can say that archaeology in Brazil went through seven phases: the colonial period (1500-1822); the Brazilian Empire (1822-1889); the early republic (1889-1920s); an intermediate period (1920s-1940s); the inception of university research (1950-1964); the military period and the constitution of an archaeological establishment (1964-1985); and democracy and a pluralist archaeology (1985 onward).

The Colonial Period (1500-1822)

There are few references in colonial sources to archaeological sites, though Fernão Cardim (1925) referred to shellmounds, known in Brazil by their Tupi name *sambaquis,* and Feliciano Coelho's soldiers, as early as 1598, mentioned rock inscriptions (Prous 1992, 5). However, travelers and writers such as Yves d'Euvreux (1985), Gabriel Soares (1944), G. Carvajal (1942), Father Anchieta (1988), André Thevet (1944), and Hans Staden (1930) described native inhabitants and their culture, furnishing a good deal of data on Indian material culture. Thanks to these sources, it is possible to study native settlements while taking into full account the historical evidence relating to the following areas: the East Amazon basin area (Porro 1992; Taylor 1992; Erikson 1992;

1948, 1950-1951, and 1954-1955; iran, 1959- 1960; and turkey, 1963 until the mid-1990s.

The history of archaeology in Brazil should not, however, be considered independent from Brazilian history. Because the development of archaeology's practice, theory, and methodology depends directly on the sociopolitical conditions in a given country, it is possible to relate the social practice of archaeology and political changes. As with any intellectual endeavor, archaeological activities are the result of social conditions and relations prevailing in different periods. Thus, we can say that archaeology in Brazil went through seven phases: the colonial period (1500-1822); the Brazilian Empire (1822-1889); the early republic (1889-1920s); an intermediate period (1920s-1940s); the inception of university research (1950-1964); the military period and the constitution of an archaeological establishment (1964-1985); and democracy and a pluralist archaeology (1985 onward).

The Colonial Period (1500-1822)

There are few references in colonial sources to archaeological sites, though Fernão Cardim (1925) referred to shellmounds, known in Brazil by their Tupi name *sambaquis,* and Feliciano Coelho's soldiers, as early as 1598, mentioned rock inscriptions (Prous 1992, 5). However, travelers and writers such as Yves d'Euvreux (1985), Gabriel Soares (1944), G. Carvajal (1942), Father Anchieta (1988), André Thevet (1944), and Hans Staden (1930) described native inhabitants and their culture, furnishing a good deal of data on Indian material culture. Thanks to these sources, it is possible to study native settlements while taking into full account the historical evidence relating to the following areas: the East Amazon basin area (Porro 1992; Taylor 1992; Erikson 1992;

Wright 1992); the North Amazon region (Farage and Santilli 1992; Menéndez 1992; Amoroso 1992); the South Amazon area (Perrone-Moisés 1992; Franchetto 1992; Lopes da Silva 1992); the northeast (Paraíso 1992; Dantas, Sampaio, and Carvalho 1992); the southwest (S. Carvalho 1992); the south (Monteiro 1992; Kern 1982); and the entire country (Fausto 1992). Evidence provided by these documents include written descriptions as well as drawings and paintings that are very useful in the analysis of material remains; Hans Staden's drawings are perhaps the best example of this kind of early evidence. But the use of all this early evidence necessitates an awareness of the bias of the early authors. U. Fleischmann and M.R. Assunção (1991) studied the documents, emphasizing that the authors were not describing but interpreting native customs according to both their own ideologies and their own interests. This means that colonial sources, iconography, and written documents alike, although very useful, must be interpreted within their social context. They are overwhelmingly biased against Native Americans, Africans, and even poor Europeans, and thus they must be studied carefully by archaeologists.

The Brazilian Empire (1822-1889)

Peter Wilhelm Lund, born in Copenhagen in 1801, is considered to be the first scholar to describe Brazilian prehistory. He went to Brazil as early as 1825, staying for three years and returning in 1833. Lund established a paleontological laboratory in the village of Lagoa Santa, in Minas Gerais Province, where he found human and animal fossils. The Brazilian emperor Peter II, under the influence of classical German education, went in person to Lagoa Santa to visit the Danish scholar. Between 1834 and 1844 Lund surveyed some 800 caves and found fossils thousands of years old. He collected a great deal of material and studied a variety of extinct fauna. At Sumidouro Lake he found human bones associated with extinct animals. Paleontologists who followed Georges Cuvier, such as his pupil Lund, believed there had been a universal biblical deluge and that the association of human remains with extinct animals meant that men had lived in the New World before the deluge. Although Lund was not sure that Cuvier's universal deluge theory was useful for the Americas, he was a Christian, and he did not choose to challenge current ideas, preferring instead to isolate himself and avoid controversial attitudes. Lund was a leading pioneer in his field, and his position illustrated the tensions arising from undertaking scientific archaeological work in Brazil. Dogma and supposedly established truths, when challenged by evidence, tended to prevail and force people to comply.

At the same time, the National Museum, thanks to Charles Wiener (1876), pioneered the studies of lithic material, and the Canadian Charles Friedrich Hartt (1871, 1872, 1874, 1876, 1885) explored the Amazon basin, a region also studied by D.S. Ferreira Penna (1876) and J. Barbosa Rodrigues (1876, 1892). Karl Rath (1871) studied shellmounds, and the German scholar Fritz Mueller was employed by the National Museum as natural and human material collector. The activities of all these researchers were an outgrowth of the enlightened character of the Brazilian royal court. During the second half of the nineteenth century, thanks to Emperor Peter II and his European outlook, there was official sponsorship of fields such as paleontology and ethnology. Ladislau Neto (1876, 1885a, 1885b), as director of the National Museum, was perhaps the first Brazilian to explicitly study and write about archaeology as such. Neto sought out Native Americans and was very much in touch with international academic standards. His exchange of letters with the French scholar Ernst Renan is a prime example of the good communications existing between these early Brazilian and European scientists. It is clear that, from its inception, archaeology in Brazil was linked to both foreign influence and state patronage.

The Early Republic (1889-1920s)

Archaeology during the early republican period continued to be dominated by people attached to museums. With the growing importance of the State of São Paulo within the federation of Brazilian states

and as a result of its economic

Wright 1992); the North Amazon region (Farage and Santilli 1992; Menéndez 1992; Amoroso 1992); the South Amazon area (Perrone-Moisés 1992; Franchetto 1992; Lopes da Silva 1992); the northeast (Paraíso 1992; Dantas, Sampaio, and Carvalho 1992); the southwest (S. Carvalho 1992); the south (Monteiro 1992; Kern 1982); and the entire country (Fausto 1992). Evidence provided by these documents include written descriptions as well as drawings and paintings that are very useful in the analysis of material remains; Hans Staden's drawings are perhaps the best example of this kind of early evidence. But the use of all this early evidence necessitates an awareness of the bias of the early authors. U. Fleischmann and M.R. Assunção (1991) studied the documents, emphasizing that the authors were not describing but interpreting native customs according to both their own ideologies and their own interests. This means that colonial sources, iconography, and written documents alike, although very useful, must be interpreted within their social context. They are overwhelmingly biased against Native Americans, Africans, and even poor Europeans, and thus they must be studied carefully by archaeologists.

The Brazilian Empire (1822-1889)

Peter Wilhelm Lund, born in Copenhagen in 1801, is considered to be the first scholar to describe Brazilian prehistory. He went to Brazil as early as 1825, staying for three years and returning in 1833. Lund established a paleontological laboratory in the village of Lagoa Santa, in Minas Gerais Province, where he found human and animal fossils. The Brazilian emperor Peter II, under the influence of classical German education, went in person to Lagoa Santa to visit the Danish scholar. Between 1834 and 1844 Lund surveyed some 800 caves and found fossils thousands of years old. He collected a great deal of material and studied a variety of extinct fauna. At Sumidouro Lake he found human bones associated with extinct animals. Paleontologists who followed Georges Cuvier, such as his pupil Lund, believed there had been a universal biblical deluge and that the association of human remains with extinct animals meant that men had lived in the New World before the deluge. Although Lund was not sure that Cuvier's universal deluge theory was useful for the Americas, he was a Christian, and he did not choose to challenge current ideas, preferring instead to isolate himself and avoid controversial attitudes. Lund was a leading pioneer in his field, and his position illustrated the tensions arising from undertaking scientific archaeological work in Brazil. Dogma and supposedly established truths, when challenged by evidence, tended to prevail and force people to comply.

At the same time, the National Museum, thanks to Charles Wiener (1876), pioneered the studies of lithic material, and the Canadian Charles Friedrich Hartt (1871, 1872, 1874, 1876, 1885) explored the Amazon basin, a region also studied by D.S. Ferreira Penna (1876) and J. Barbosa Rodrigues (1876, 1892). Karl Rath (1871) studied shellmounds, and the German scholar Fritz Mueller was employed by the National Museum as natural and human material collector. The activities of all these researchers were an outgrowth of the enlightened character of the Brazilian royal court. During the second half of the nineteenth century, thanks to Emperor Peter II and his European outlook, there was official sponsorship of fields such as paleontology and ethnology. Ladislau Neto (1876, 1885a, 1885b), as director of the National Museum, was perhaps the first Brazilian to explicitly study and write about archaeology as such. Neto sought out Native Americans and was very much in touch with international academic standards. His exchange of letters with the French scholar Ernst Renan is a prime example of the good communications existing between these early Brazilian and European scientists. It is clear that, from its inception, archaeology in Brazil was linked to both foreign influence and state patronage.

The Early Republic (1889-1920s)

Archaeology during the early republican period continued to be dominated by people attached to museums. With the growing importance of the State of São Paulo within the federation of Brazilian states

and as a result of its economic

hegemony, there was cultural shift in the country from the court in Rio de Janeiro to the new Paulista elite. This shift explains the role the Paulista Museum played in the field from the beginning of the twentieth century. To be sure, there were people studying elsewhere, such as the Swiss Emílio Goeldi (1897-1898, 1900), who explored the Amazon basin from his post at the Museu do Pará (now known as the Museu Paraense Emílio Goeldi), or Alberto Loefgren (1893, 1903), who studied shellmounds from São Paulo and Rio de Janeiro, as did Ricardo Krone (1902, 1909, 1910, 1914, 1918). However, long-standing archaeological activities were in São Paulo. The German scholar Hermann von Ihering (1895, 1902, 1904, 1907, 1911) became director of the Paulista Museum in 1895 and was in charge until 1916, when he was dismissed for political reasons (Losano 1992, 99). Although Ihering was a racist and even defended the extermination of native Indians in Brazil, and although he opposed the idea that shellmounds were evidence of prehistoric human settlements, he should be considered as the first conservative ideologist of Brazilian archaeology. It is interesting to note that he was, at the same time, out of touch with modern research in Europe and a political reactionary. The conservative establishment born in the 1960s would inherit this outlook.

Teodoro Sampaio (1916, 1918, 1922) was perhaps the best example of this generation of pioneer scholars, none of them professional archaeologists. His general paper entitled “Brazilian Archaeology” (1922) and believed wholeheartedly that rock scratches should be interpreted as hieroglyphic writing.

The Formative Period (1920-1949)

Important changes occurred in Brazil during this period, particularly in terms of political, social, and cultural upheavals. Rebellions, revolutions, and dictatorship went hand in hand with cultural transformation. Modernism and later fascist and communist ideas fostered discussions on democracy in intellectual circles. From that point on intellectuals would address the peoples' interests, and even as the masses were the subject of intellectual discourse, they were also its ultimate audience. The establishment of the first university in Brazil in the early 1930s, São Paulo State University (USP), was a direct result of this new situation. As a side effect archaeologists began to take the public into account and tried for the first time to carry out taxonomic scientific analysis.

This period thus witnessed two new developments in archaeology: the study of artifact collections and the publication of manuals. Anibal Mattos continued the tradition of earlier periods but produced scholarly manuals, especially on material from the State of Minas Gerais. Mattos's *Brazilian Prehistory Handbook* (1938) is still worth reading, particularly his introductory assessment of the disputes between different practitioners. Angyone Costa (1935, 1936, 1984) produced the first overall introductions to Brazilian archaeology and prehistory. Frederico Barata (1944, 1950, 1952) wrote the first introduction to prehistoric art in Brazil. The Argentinean Antônio Serrano (1937, 1938, 1940,1946) studied Brazilian collections of artifacts and thus established a new field in Brazilian archaeology. This whole period before the introduction of archaeology into the Brazilian academic world (that is, prior to the 1950s) is usually dismissed by students of the history of Brazilian archaeology. But the significance of the publication of the first manuals and the inception of collection studies should not be underestimated, considering that archaeology in Brazil continues to lag behind that of other Latin American countries in both these areas. Consequently, this formative period should be reinterpreted as an important landmark. If there is a lack of handbooks and collection studies later on, notably after 1964, the reasons should be sought not in the period from the 1920s to the 1950s but rather in the military clampdown on the academic world in the 1960s and 1970s.

The Inception of University Research (1950-1964)

After World War II Brazil enjoyed its longest democratic period. The participation of Brazilian soldiers

in the Allied fight against fascism in Europe (1942-1945) established the basis for the overthrow of the Brazilian dictatorship

PREV NEXT

hegemony, there was cultural shift in the country from the court in Rio de Janeiro to the new Paulista elite. This shift explains the role the Paulista Museum played in the field from the beginning of the twentieth century. To be sure, there were people studying elsewhere, such as the Swiss Emílio Goeldi (1897-1898, 1900), who explored the Amazon basin from his post at the Museu do Pará (now known as the Museu Paraense Emílio Goeldi), or Alberto Loefgren (1893, 1903), who studied shellmounds from São Paulo and Rio de Janeiro, as did Ricardo Krone (1902, 1909, 1910, 1914, 1918). The Inception of University Research (1950-1964)

After World War II Brazil enjoyed its longest democratic period. The participation of Brazilian soldiers

in the Allied fight against fascism in Europe (1942-1945) established the basis for the overthrow of the Brazilian dictatorship

PREV NEXT

(which held power from 1937 to 1945). Democracy meant the introduction of broader concerns with intellectual discourse and the spread of the university and other learning institutions throughout the country. Furthermore, industrialization, especially in south Brazil, made relatively large funds available for cultural activities.

It was in this context that academic or scholarly archaeology was created by the leading Brazilian humanist Paulo Duarte. Thanks to his friendship with Paul Rivet, director of the Musée de l'Homme in Paris, and complementing his own struggle for human rights in Brazil, Duarte created the Prehistory Commission at USP in 1952. An outstanding Brazilian intellectual, he was able to change long-standing features of Brazilian archaeology-its tendency to be parochial, racist, and out of touch, in the tradition of Ihering and others. Duarte was not a museum director pretending to be a scholar, as was the case of directors before and after him. Rather, he was an intellectual and human rights activist who struggled to introduce ethical principles into the very act of creating archaeology as an academic discipline. Duarte also worked politically to craft legislation to protect Brazilian heritage, and thanks to his efforts, the Brazilian Parliament enacted a federal bill (approved as Bill 3924 in 1961) protecting prehistoric assets (Duarte 1958). He studied shellmounds (1952, 1955, 1968, 1969) and encouraged French archaeologists Joseph Emperaire and Annette Laming-Emperaire (1975).

The Military Period and the Constitution of an Archaeological Establishment (1964-1985)

On April 1, 1964, there was a military coup in Brazil, and the armed forces held power until March 15, 1985. Twenty years of authoritarian rule meant that all kinds of human rights abuses were committed. From 1964 until 1968 political repression involved the suppression of formal liberties. After 1968 the military introduced more violent practices, such as expulsion, detention without trial, torture, and murder. Within academia, suppression meant censorship first and expulsion later. The very slow process of relaxing this repression began in the late 1970s and continued until 1985.

In archaeological terms, the main contributors to the discipline during this period were two Americans, Clifford Evans and Betty Meggers (1947, 1954). Although they had excavated at the mouth of the Amazon River as early as 1949 and had produced papers before 1964, it was only after the military coup of April 1964 that Evans and Meggers were able to set up a network that would result in the development of an archaeological establishment.

Duarte's scholarly archaeology project was mildly opposed by people in power at first, so between 1964 to 1969 he was deprived of funding (the most subtle but effective weapon). Cuts in university budgets in general affected, first and foremost, the human and social sciences, and in the case of archaeology budgetary restrictions were a very powerful way of hindering development. This passive strategy changed as the military begun to use force to rule the country and subdue intellectual opposition in general. The new and violent approach of the authorities was evidenced by the official support of death squads in the late 1960s, introducing Brazilians to the disgusting concept of “missing people” (i.e., people who were arrested and executed secretly because of their political beliefs). Intellectual life underwent radical changes. In the words of Octávio Ianni (1978):

For those who controlled state power from the 1964 coup, there was and there is, in 1978, a need to control, to marginalize, to curb or to suppress dissident voices. The cultural policy in Brazil in the period 1964-1978 divides intellectuals in three categories. There is an encouraged or protected intellectual production; it is the official one. For people in power, this is the only sound production. Then, there is the tolerated overlooked production. Finally, there is the forbidden, censored one.

The archaeological establishment created by the military followed the official line, using Ianni's terms, and

Brazilian archaeology was once again in the hands of museum directors and other bureaucratic officials. Perhaps the best (or worst) example involved Paulo Duarte.

The scholarly study of historical sites in Brazil has been particularly seminal in the two areas of African material culture and Jesuit missions. Carlos Magno Guimarães has been studying Maroon (fugitive slave) settlements in Minas Gerais for more than a decade, and he has examined written documents and archaeological material. Other scholarly archaeological research on runaway slaves started in 1992 at the Palmares *quilombo,* the largest maroon settlement, which blossomed during almost all of the seventeenth century (Funari 1991a; Orser 1992a). The study of African material culture is important both scientifically and socially, as these scholarly enterprises can address the problem of the struggle for freedom by ordinary people. The archaeological study of the Jesuit missions in the south of Brazil has been going on for years and is now the best example of what scholarly historical archaeology has achieved in Brazil. Arno Alvarez Kern (1982, 1984, 1985, 1987, 1988, 1989, 1991a, 1991b) has been directing fieldwork at different Jesuit mission towns. He established a field school for students and has trained many undergraduate and graduate pupils, typically using written documents and material culture. In addition, papers and books on the mission sites have been regularly published, which is unusual and worthy of particular praise.

In Brazilian archaeology in general during this period, no handbook was produced, and the overwhelming majority of papers were excavation or survey reports, often in the form of master's theses or Ph.D. dissertations. These works usually dealt with a single site or even a single fieldwork season, as the titles of two dissertations-"Archaeological Excavations at Corondo Site, 1978 Season" (E. Carvalho 1984) and "Rescue Archaeology at Tucurui Region" (Costa 1983).

Current Trends (1985 Onward)

"I know enough history to realize that great crises move slowly, and such poor little chaps as ourselves can only take pride in our resignation." Marc Bloch's words (in Fink 1991, 54) describe the feelings of Brazilian intellectuals who survived the long ordeal of military rule. By the late 1970s Brazilian humanities scholars and social scientists were able to reintroduce free and uncensored discussion to academia, and as a result Brazilian scholarship in history, anthropology, and sociology became both scientifically structured inside the country and more widely recognized abroad through different interpretive schools and trends. This has been a much tougher task for archaeology for many reasons, not least of all because the archaeological establishment, impervious to change, continued to control funds for fieldwork. Walter A. Neves (1988, 205) emphasized that "no law, no political determination, no governmental aims or potential competence can stand up to the academic corporativism." Even foreign researchers such as Anna Roosevelt (1991, 106-107) had problems publishing evidence and interpretations contradicting established truths. Others, among them Denis Vialou and Vilhena Vialou, were the targets of different attacks by local patrons, despite the fact that they authored many papers on Brazilian prehistory that were published abroad.

Brazilians continue to be victims of human rights abuses, massacres by security forces (Margolis 1992), and death squad activities. However, the restoration of civilian rule in 1985 has meant that freedom of expression, if nothing else, is once again viable. It has become possible to develop some unconventional approaches, and the publication of an issue of *Les dossiers d'archéologie* on Brazil (March 1992) bears witness to the renewed blooming of Brazilian archaeology. The first interpretive handbook on archaeology written by a Brazilian came out in the late 1980s (Funari 1988). In addition, Prous (1992) has published a 605-page description of archaeological activities in Brazil, and summarizing papers have also been published (e.g., Prous 1987).

The History of Archaeological Theory in Brazil

Brazilian archaeology's theoretical trends have depended directly on the overall, changing political

background. The early historical and humanist approach of the years between 1950 and 1964, under direct European influence (cf. the case of the other social sciences, as described in Pereira de Queiroz [1989]), was overturned by

Breuil, Abbé Henri

(1877-1961)

Born in Mortain in the Department of Manche in france, Henri Breuil trained as a priest and was ordained in 1900. His interest in paleontology began during his priestly education, but his career as a prehistorian took off later under the influence of the archaeologists emile cartailhac, Louis Capitan, and denis peyrony. Between 1901 and 1905, Breuil helped Capitan and Peyrony investigate several major prehistoric sites and caves in the Dordogne region of France, such as Les Combarelles and Font-de-Gaume, and he accompanied Cartailhac on his cave explorations, including the one to altamira in spain.

In 1905, on the basis of his experience and his resulting publications, Breuil became a professor at the Catholic University of Fribourg, and in 1910 he went to Paris to become professor of prehistoric ethnography at the Institut de Paléontologie Humaine. From 1929 until 1947, Breuil was the first professor of prehistory at the Collège de France.

Breuil reclassified the artifact sequences and chronology of the Paleolithic period, and his scheme of successive cultural periods still forms, with some revisions, the current framework for the interpretation of European prehistory. Breuil not only added several new Paleolithic stages-the Clactonian, Levalloisian, and Tayacian-but also refined the Chellean period into the Acheulean, which then progressed and was transformed into the Mousterian. He also revised the chronology of the upper Paleolithic period, arguing for the significant impact of Aurignacian cultures on Mousterian traditions and establishing that the Aurignacian preceded the Solutrean; he also divided the Magdalenean into six phases based on changes in tool types.

Breuil's explorations of cave art continued as well. In 1906, he and Cartailhac explored the cave of Niaux in the Ariège, and much later, he was the first to enter the cave of lascaux after its discovery by schoolboys in 1940. He was recognized as the international expert on Paleolithic cave art, and with each new discovery, he became the arbiter of authenticity. He visited, recorded, and reproduced cave art and cave decorations, not just in western Europe, but in Africa, the Sahara, Abyssinia, Asia Minor, and china . Breuil saw in this art not only the fruit of artistic spontaneity but also a communal religious and magical expression testifying to collective interests linked to the way of life of the great hunters of prehistory. Breuil was the first prehistorian to explore and decipher this art, and he also established the

chronological and methodological bases for its study.

Breuil worked briefly in China at Zhoukoudian in the early 1930s and after World War II in southwestern Africa and Rhodesia (now Zimbabwe). He received many awards and honors, including being elected to the Institut de France in 1938 and receiving the Huxley Medal from the Royal Anthropological Institute in 1941.

Britain, Prehistoric Archaeology

Scholars writing about the prehistoric archaeology of Britain have played a central role in the development of archaeology in the Anglo-Saxon world. Given this fact, it is remarkable that no substantial, book-length history of British archaeology has yet been written. This observation is even more striking when we consider that archaeologists such as glyn daniel (1943, 1964, 1967, 1971, 1975, 1976, 1981) and stuart piggott, not to mention vere gordon childe, j. g. d. clark, and david clarke, have made such significant contributions to the historiography of archaeology generally.

Of course, there are studies of specific episodes or periods in the history of archaeology in Britain. Graham Parry (1995), Piggott (1975, 1976, 1978, 1981, 1985), and Michael Hunter (1975) have written illuminatingly about the history of antiquarianism, particularly about the work of william stukeley, william camden, john aubrey, and others. Barry Marsden (1984) has produced an often amusing (and richly detailed) account of the activities of antiquaries and archaeologists during the nineteenth century. Analyses of the role of archaeologists such as lord avebury (Sir John Lubbock) and augustus pitt rivers in the passage of heritage-preservation legislation in the nineteenth century (Chapman 1989a; Chippindale 1983; Murray 1990) have appeared alongside detailed discussions of the discovery of high human antiquity (Grayson 1983; Murray 1997; Van Riper 1996). In addition, more specific discussions of changing perceptions of sites such as Stonehenge (Chippindale 1985), the historiographic significance of sites such as the Glastonbury Lake Village (Coles, Goodall, and Minnitt 1992) and Little Woodbury (excavated by gerhard bersu) (Evans 1989), or the history of British Paleolithic archaeology (Davis and Charles 1999; Roberts 1999; Roe 1981a; Spencer 1990) have provided much-needed context to broader considerations. And notable archaeologists have been encouraged to indulge in autobiography (see, for example, Daniel and Chippindale 1989), complementing a growing list of biographies and biographical essays (particularly those of Gordon Childe, Pitt Rivers, sir flinders petrie, gertrude bell, and T.E. Lawrence, as well as the entries in both volumes of *The Great Archaeologists,* ed. Tim Murray, 1999).

At a larger scale historians of science such as P. Levine (1986) have explored the professionalization of British archaeology within the context of British history. And some general histories of archaeology, including those written by G.E. Daniel (1975) and B.G. Trigger (1987), in the course of reconstructing the origins and growth of archaeology and the archaeological perspective, have provided an outline of the history of prehistoric archaeology in Britain. These overviews have to some extent been matched by the introductory chapters to surveys of British prehistoric archaeology, such as those by T. Darvill (1987, 13-27), J. Hunter and I. Ralston (1999), I. Longworth and J. Cherry (1986), C. Renfrew (1972), and D. Roe (1981b).

Notwithstanding the importance of these general overviews, however, our understanding of the context of archaeology and archaeological knowledge in British society is still quite rudimentary. A great deal of fundamental research into all aspects of that history remains to be done. In recent years some attention has been given to the need to study the histories of county and metropolitan archaeological societies (particularly those founded in the nineteenth century), and considerable encouragement has been given to efforts to explore the lives of the less famous British archaeologists (especially women-see, for example,

M. Diaz-Andreu and M.L.S. Sorensen 1998). But there is still a very long way to go.

This state of affairs is all the more curious when we consider the major role played by British archaeology (and archaeologists) in the development of archaeological theory in the last

usefully by the enigmatic James Douglas (1753- 1819), whose *Nenia Britannica* (1793) was a thorough and at times brilliant discussion of the burial customs of "ancient Britons."

Generations of systematic (and frequently unsystematic) fieldwork had, by the end of the eighteenth century, created a crisis in British antiquarian circles. Although a great deal of material culture had been excavated, swelling the collections of antiquaries and providing the foundations for the collections of new museums, its usefulness for writing history was severely curtailed by what seemed to be insuperable problems with establishing chronology. Many of the more careful observers (especially those with field experience in either excavation or survey) well understood that everything could not be the same age and that there was variation within and between sites and artifact types, but things basically came to a grinding halt at that point. Naturally, this did not stop antiquaries from continuing their researches. Indeed, in many ways the problem became even more acute through the systematic work of richard colt hoare, william cunnington, and others; in *Ancient Wiltshire* (1810-1821), for instance, Colt Hoare took pains to limit his interpretations to the physical data he had at hand-interpretations that were consequently confined to admitting his inability to write the history of prehistoric Wiltshire.

It is well known that the solution to Colt Hoare's problems-the three-age system-had already been worked out in Scandinavia by c. j. thomsen and jens jacob worsaae. Although Thomsen's great work was not translated into English until 1848 (as the *Guide to Northern Archaeology*) and Worsaae's was not issued in English until 1849 (as *The Primeval Antiquities of Denmark*), some British antiquaries were *au fait* with the system before then. Nonetheless, the three-age system received a mixed welcome in Britain and from institutions such as the British Museum. Thomas Wright, who regarded himself as one of the leading British antiquaries, would have none of it, but Sir John Lubbock enthusiastically embraced it as a major step forward. Throughout the rest of the period (and continuing for the remainder of the nineteenth century) differences of opinion about the value of the three-age system (or perhaps more spectacularly the discovery of high human antiquity) were aired in a wide variety of scientific and antiquarian associations. The case study that follows focuses on the British Archaeological Association (BAA) and the Royal Archaeological Institute (RAI), but the same kinds of issues were the meat and drink of debate and dispute in similar associations in Britain (and, of course, elsewhere in Europe).

Certainly, excavation continued right across Britain, but the goals of such work became increasingly diverse as the problems with chronology, so apparent in the efforts of Colt Hoare and his predecessors, were gradually resolved by adjusting the three-age system to more closely fit regional realities in British prehistoric archaeology. One example of this growing diversity was the work of John Thurnam (1810-1873), whose primary interest was in the skeletal remains found in barrows and tumuli. Thurnam (later in partnership with J.B. Davis [1801-1881]) sought to use these remains to write the racial history of Britain, a goal that he and Davis believed they had achieved with the publication of *Crania Britannica* (1856- 1865). Others, such as Thomas Bateman (1787- 1835), Charles Roach Smith (1807-1890), and the indefatigable Canon William Greenwell (1820-1918), continued to dig barrows at a fast pace and with rather broader interests in mind. Greenwell's *British Barrows* (1877) represented the high tide of antiquarian activity in a world where the kind of prehistoric archaeology undertaken had clear cultural and political implications. It is testimony to the three-age system that the resolution of chronological problems, however imperfect it was, could release such passion and creativity among those writing the prehistory of Britain.

Case Study: Institutions and Disciplinary Identity in the Mid-Nineteenth Century

This analysis of the early years of the British Archaeological Association and the Royal Archaeological Institute should be read in conjunction with the entry, "Royal Archaeological Institute," by Martin Millett in this encyclopedia. Here, the reasons for their foundation with regard to

PREV NEXT

out against hybridity of the races, an article of faith in the polygenist camp. Finally, he contended, civilization was for given races only. The data of archaeology, to Davis's mind at least, formed an important basis from which to mount an argument against the reality of monogenism, despite the arguments of James Cowles Prichard and others: “It is scarcely necessary to allude to the most extraordinary doctrine that the discovery of stone weapons and implements in every quarter of the globe, is a valid evidence that the very same race, a nation of workers in stone, has been spread over all these vastly separated countries. Such incredible hypothesis is by no means necessary to account for this fact” (Davis 1856, 324).

Instead of the monogenist hypothesis, Davis offered the fact that, within very broad bounds, humans have similar physical structures and bodily needs. Yet notwithstanding these similarities, the use of stone occurred during different periods and to different extents. On this basis Davis considered the term *stone-period* or *stone-age* to be incorrect (an objection frequently voiced by Rhind and others but not necessarily for the same reasons). Davis's conclusion was that archaeology had to become ethnology and contribute to the debates that were conducted under its aegis. The first step toward a useful contribution was for archaeologists to do more ethnology, particularly within the British Isles, where racial differences were thought to be marked.

Narrative: 1860-1900

During the forty years between the acceptance of high human antiquity (in 1859) and the end of the nineteenth century, British prehistoric archaeology became widely accepted as a science. By that most delicate of measures-the passage of legislation to protect ancient monuments, which limited the private rights of individuals and established government agencies to bring that legislation into effect (see Murray 1990)-the science of prehistoric archaeology had gained popular and scholarly recognition as an important Victorian scientific and cultural endeavor. As mentioned, serious debate had taken place before this period about the nature of prehistoric archaeology, and the issues raised by Davis and others mentioned in the case study continued to plague practitioners until the 1870s. It is important to note that the fights between the proponents of ethnology, anthropology, archaic anthropology, and prehistoric archaeology (which were just some of the many diverse positions taken up by people with an interest in the prehistory of Britain) were primarily waged at the level of institutions and societies. Although relationships between the British Archaeological Association and the Royal Archaeological Institute were far from cordial, they had nothing of the viciousness that characterized the exchanges between the Ethnological and Anthropological Societies of London and between the members of the British Association for the Advancement of Science (see Stocking 1971).

Despite the significance of the application of the three-age system to British prehistoric archaeology after Thomsen's and Worsaae's works were translated, it was the discovery of high human antiquity that seized the imagination of the scientific world. D.K. Grayson (1983) and A. Bowdoin Van Riper (1996) have discussed this history in considerable detail, and much has also been written about the role played by Sir John Lubbock (and his *Prehistoric Times* [1865]) and E.B. Tylor (and his *Researches into the Early History of Man* [1865] and *Primitive Culture* [1870]) in the creation of what Trigger called “evolutionary archaeology.” But the dominance of evolutionary theory in British prehistoric archaeology was always tempered by the needs of history-particularly the racial history of the British Isles. Attempts to square British history with the three-age system would be made by generations of barrow diggers such as Canon Greenwell, John Thurnam, Charles Roach Smith, and Thomas Bateman (who was among the first to apply the principles of the system in Britain in his *Vestiges of the Antiquities of Derbyshire* [1848]).Yet there was never universal approbation of that concept or of the idea that the British past could unproblematically serve Lubbock's or Tylor's universal models of human history. Certainly, the

canny observer Daniel Wilson well understood the difference and forswore the more serious of Lubbock's overgeneralizations. But again, although much of the period after 1860 was devoted to an elaboration of the

three-age system and its subdivisions (both in Britain and in France), such elaborations inevitably led to an appreciation of difference and variety, as well as change, in both prehistoric Britain and its Continental neighbors.

This recognition of variety (and of the reality of history) became all the more obvious as truly systematic attempts to describe the artifacts of British prehistory increasingly came to the fore, an outcome that also rested on the gradual improvement in excavation strategy and techniques that had been fostered at Brixham Cave but greatly enhanced by the work of Pitt Rivers, especially at Cranborne Chase (1887). Building on the traditions of Fausett, Roach Smith, and others, Sir John Evans, in two remarkable books (*Ancient Stone Implements: Weapons and Ornaments of Great Britain* [1872] and *Ancient Bronze Implements* [1881]), developed the typology of such artifacts to the level at which the patterns of chronology and distribution raised significant historical questions. Although British prehistory was devoid of an absolute chronology for all but the later phases of the Iron Age, sufficient information existed for Boyd Dawkins and other workers to set the British Paleolithic within a Continental sequence (a task also completed by gabriel de mortillet in France) and for oscar montelius's European chronology to be applied to Britain. The essence of that chronology and of those sequences was that British prehistory was a kind of afterthought to the great forces of moving populations and changing climates that characterized Europe. But there were always bits that failed to fit, as arthur evans was able to demonstrate in his celebrated analysis of the cemetery at Aylesford in Kent (1890). The task of comprehending the prehistory of Britain as a problem in itself was to occupy archaeologists for the next half century, as the dual inheritances of evolutionary universalist archaeology and the historicism of the three-age system played themselves out in what was later proven to be an illusory temporal environment. The absence of absolute chronology and the essentially circular interpretive logic that flowed from the relative chronologies of Montelius and de Mortillet would heighten the concentration on simple historicist explanations for cultural change at the very time when prehistoric archaeology (certainly as espoused by Gordon Childe) required more.

Evans was, of course, quite right about the significance of the evidence from Aylesford. What British prehistoric archaeologists urgently needed to do was to write history, to make the classifications of Montelius and others relate in real historical terms to the patterns being noted in the field. But prehistoric archaeology (as a part of anthropology) was far from alone in this concern with history and historicism. Although from the 1880s onward perceptions of human diversity made a forceful return to the ranks of anthropological theory, this diversity was clearly to be located in ethnic and cultural, rather than purely physical, differences. The explanations for diversity and similarity would increasingly be sought in cultural-historical factors, instead of the doctrine of independent inventions and the psychic unity of humankind. Real historical forces acting on real (different) groups of people, past and present, could explain the peculiar differences between human beings far more convincingly than generalized uniformitarian forces. Anthropology and prehistoric archaeology, previously focused on providing evidence of the evolution of human beings and their societies and cultures, now became more firmly linked to a less encompassing task-writing the ethnic histories of European nations.

Narrative: 1901-1960

Often described in histories of British archaeology as the phase of culture-history in which archaeologists further honed their excavation skills and used their abilities in artifact analysis and the creation of typologies to create histories of British prehistoric "cultures," the first sixty years of the twentieth century saw both continuity and change. There was continuity in the sense that the typological studies and Continental prehistories of Montelius, de Mortillet, and others provided an essential starting point. And there was change also in the sense that serious debate about the relationships between archaeological

and anthropological knowledge tended

of the Mesolithic that were being developed by J.G.D. Clark.

Clearly, Childe and Clark had widely differing views about politics, but in emphasizing these differences, scholars have tended to gloss over more significant similarities in theories and goals. Beginning with *The Mesolithic Age in Britain* (1932) and culminating in his highly influential work at the site of Star Carr (published in 1954) and in *Prehistoric Europe: The Economic Basis* (1952), Clark elaborated an archaeology that required its practitioners to extend their competence to contextual factors. He reminded British prehistorians of the basic disciplinary commitment to understanding *how* prehistoric societies actually functioned, rather than just contenting themselves with charting the distributions of artifact types and culture areas. In this focus on the need to understand society, he was closer to Childe than many others of his time.

Childe's and Clark's advocacy of the principles of social archaeology would bear fruit in coming decades. There is little doubt that the crowning theoretical achievement of British prehistoric archaeology during the first sixty years of the twentieth century (despite most practitioners' lack of interest in this field) was a broadening and deepening of the relationships between history, archaeology, and anthropology. For the majority of archaeologists who focused on issues of typology and chronology, the world was about to change, and social archaeology was to provide a new reason for being.

Narrative: 1961 to the Present

Renfrew (1972) has rightly observed that the cracks in the interpretive consensus of culture-history and typology (brought about by the economic prehistory of J.G.D. Clark) were greatly enlarged by the application of radiocarbon dating to British prehistory. Radiocarbon dates first became available in the late 1950s, and it was soon clear that there were serious disparities between the dates arrived at through conventional typological study (previously the mainstay of British prehistoric archaeology, no matter the period) and those being produced by radiometric means. The first significant impact was on the Neolithic period-famously at the site of Durrington Walls, where the radiocarbon dates were much older than those established by the excavator stuart piggott (then the doyen of British Neolithic studies) on the basis of typological analysis. From this point on no part of British prehistory was immune, although it is fair to say that the major impacts were felt by archaeologists working in the Neolithic, Bronze, and Iron Ages. Renfrew (1972) neatly summarized this history as not just being about dates but as fostering a fundamental shift in the direction of European prehistory as well. For example, new dates from Wessex and other places made it clear that cultural elements such as megalithic tombs (once thought to have been diffused from the south of the European landmass) could now be argued to have had a local origin.

It has become clear that no-one is seriously arguing for strong and significant Aegean influence upon the early bronze age of Britain, whether or not there may have been some contacts between the two regions. No-one today would *explain* the developments of the British early bronze age in these terms…. The Wessex-Mycenae link is no longer regarded, as it was by Evans and Childe, as a lynch-pin for British chronology, nor are the accompanying diffusionist arguments accepted any longer (Renfrew 1974, 33).

Archaeologists had to find new models of British prehistory to account for what now seemed better understood by exploring the internal dynamics of prehistoric societies and seeking explanations for change that emphasized cultural processes, in addition to diffusion through invasion and migration. But there was a significant sense of continuity here as well, as previous work on environmental reconstruction and prehistoric human ecology played an important part in J.G.D. Clark's demolition of the invasion hypothesis in 1966. It is always risky to point to specific dates as watersheds, but Renfrew's assessment of the importance of radiometric dating in the development of British prehistoric archaeology after 1966 was very close to the mark.

Although Clark had essentially “created” world prehistory in 1961 by applying radiometric-dating technologies on a global scale, the

in fostering discussion and debate in an increasingly diverse discipline.

Conclusion

One goal of this all too brief discussion of the history of British prehistoric archaeology was to determine whether the great diversity of the discipline's past and its contemporary practice could be effectively synthesized through the identification of overarching themes and issues. This synthesis (and others, such as Renfrew 1974) has been only partially successful, primarily because there is still so much that we do not know about the specifics of that history. Certainly, in those areas in which detailed research has been carried out, a complex and frequently counterintuitive history has been revealed. Given the fact that British prehistoric archaeologists have long had considerable impact on practices outside of Britain (particularly in the Anglo-Saxon world), a deeper understanding of the discipline's social and cultural history is important for archaeologists across the globe.

British Museum

Founded by act of the British Parliament in 1753, the British Museum is widely regarded as having one of the greatest collection of antiquities anywhere in the world. As is true for many great museums, such as the ashmolean in Oxford and the louvre in Paris, the British Museum was founded on the private collections of individuals, in this case Sir Hans Sloane and Sir Robert Bruce Cotton. In its early years, the British Museum was favored by monarchy. In 1757, King George II presented the Royal Library to the museum, and the library of George III was transferred there in 1828.

Notwithstanding the very great importance of the British Museum as a library, the fortunes of its collections of antiquities are of perhaps greater importance. These were also supplemented by royal patronage. For example, George III presented the Rosetta Stone after its capture from the French in Egypt (1799). Parliament has also been a benefactor, especially in the celebrated case of the Parthenon marbles purchased from lord elgin in 1816.

The British Museum has since acquired antiquities from all parts of the world, but it is especially strong in British antiquities and those derived from Egypt, western Asia, Greece, and Rome. Major pieces such as the material from nimrud, nineveh, and Khorsabad (building on the collections and excavations of sir austen henry layard), the magnificent artifacts excavated by sir leonard woolley at ur, and elements of the mausoleum of Halicarnassus and the Temple of Artemis at ephesus were acquired through the efforts of private collectors. The egypt exploration society was also a major source of Egyptian antiquities from the late-nineteenth century until the beginning of the World War II.

Notwithstanding the mechanics of assembling such great collections, the British Museum has also played a major role in pure archaeological research. Throughout the twentieth century, research by British Museum staff members has added considerably to our knowledge of archaeology on the global scale.

Brixham Cave

Located on the Devonshire coast of England, Brixham Cave was discovered in 1858. The story of its excavation and the role the discoveries made there played in the history of archaeology is an enduring one. Owing to the great skills and energy of early archaeologists hugh falconer and william pengelly, it was possible to raise funds and the support of some of the most eminent British scientists of the day (such as charles lyell, Richard Owen, and joseph prestwich) to undertake a systematic excavation of the cave. Falconer understood clearly that maintaining tight stratigraphic control was crucial to securing plausible evidence of the coexistence of ancient human beings and extinct animals, and such control was achieved thanks to innovations in excavation techniques made by Pengelly and Prestwich.

The site was excavated between 1858 and 1859, and a body of evidence was produced that, although initially convincing only Falconer and Pengelly (along with a few others), when viewed along with the evidence from French archaeologist jacques boucher de perthes's excavations in the Somme Valley became the first widely accepted evidence of an even greater human antiquity.

British Museum

Founded by act of the British Parliament in 1753, the British Museum is widely regarded as having one of the greatest collection of antiquities anywhere in the world. As is true for many great museums, such as the ashmolean in Oxford and the louvre in Paris, the British Museum was founded on the private collections of individuals, in this case Sir Hans Sloane and Sir Robert Bruce Cotton. In its early years, the British Museum was favored by monarchy. In 1757, King George II presented the Royal Library to the museum, and the library of George III was transferred there in 1828.

Notwithstanding the very great importance of the British Museum as a library, the fortunes of its collections of antiquities are of perhaps greater importance. These were also supplemented by royal patronage. For example, George III presented the Rosetta Stone after its capture from the French in Egypt (1799). Parliament has also been a benefactor, especially in the celebrated case of the Parthenon marbles purchased from lord elgin in 1816.

The British Museum has since acquired antiquities from all parts of the world, but it is especially strong in British antiquities and those derived from Egypt, western Asia, Greece, and Rome. Major pieces such as the material from nimrud, nineveh, and Khorsabad (building on the collections and excavations of sir austen henry layard), the magnificent artifacts excavated by sir leonard woolley at ur, and elements of the mausoleum of Halicarnassus and the Temple of Artemis at ephesus were acquired through the efforts of private collectors. The egypt exploration society was also a major source of Egyptian antiquities from the late-nineteenth century until the beginning of the World War II.

Notwithstanding the mechanics of assembling such great collections, the British Museum has also played a major role in pure archaeological research. Throughout the twentieth century, research by British Museum staff members has added considerably to our knowledge of archaeology on the global scale.

Brixham Cave

Located on the Devonshire coast of England, Brixham Cave was discovered in 1858. The story of its excavation and the role the discoveries made there played in the history of archaeology is an enduring one. Owing to the great skills and energy of early archaeologists hugh falconer and william pengelly, it was possible to raise funds and the support of some of the most eminent British scientists of the day (such as charles lyell, Richard Owen, and joseph prestwich) to undertake a systematic excavation of the cave. Falconer understood clearly that maintaining tight stratigraphic control was crucial to securing plausible evidence of the coexistence of ancient human beings and extinct animals, and such control was achieved thanks to innovations in excavation techniques made by Pengelly and Prestwich.

The site was excavated between 1858 and 1859, and a body of evidence was produced that, although initially convincing only Falconer and Pengelly (along with a few others), when viewed along with the evidence from French archaeologist jacques boucher de perthes's excavations in the Somme Valley became the first widely accepted evidence of an even greater human antiquity.

Brodar, Srecko (1893-1987)

A pioneer of Paleolithic archaeology in slovenia, Srecko Brodar first studied natural sciences in Vienna. He graduated from the University of Zagreb in 1920, and received his Ph.D. from Ljubljana University in 1939. In 1946 he became a professor at Ljubljana University, director of the Institute of Archaeology at the Slovenian Academy of Arts and Sciences, and member

of the International Quaternary Association and the international union of prehistoric and protohistoric sciences (UISPP).

Brodar was the first trained Paleolithic archaeologist in Slovenia. He began his archaeological career in 1928 with the excavation of the Upper Paleolithic cave site of potočka zijalka in the Karavanke mountains in northern Slovenia. The results of his research on this site greatly influenced the interpretation of the process of Wurm glaciation in alpine areas. Prior to the outbreak of World War II, Brodar discovered five new Paleolithic sites in Slovenia and demonstrated the connection between the Paleolithic cultures of the eastern alpine region with Paleolithic settlements on the Slovenian Pannonian Plain and in northwestern Italy.

After the war, Brodar's research focused on the Karst area of southwestern Slovenia, especially on the multiperiod Paleolithic and prehistoric site of Betalov Spodmol near Postojna. Brodar also discovered the first Mesolithic settlements in Slovenia, such as the Spehovka cave. He substantially contributed to the development of Paleolithic studies in the other republics of the former Yugoslavia, especially in Serbia and Bosnia and Herzegovina.

Brześć Kujawski

The site of Brześć Kujawski, located in the Polish province of Wloclawek, comprises a group of settlements and inhumation cemeteries located in the black-earth region of Kuiavia in central poland. The site belongs either to the Brześć Kujawski group of the Lengyel culture, according to Konrad Jazdzewski s classification (Jazdzewski 1938, 6), or to the late Band Pottery culture, according to the cl assification of Lech Czerniak (Czerniak 1994, 66). The best known site, site 4, is a large settlement site with fifty-one trapezoidal long houses from a few phases of occupation along with outbuildings, objects, and human graves. On the basis of this material, the Brześć Kujawski group of the Lengyel culture was distinguished.

From 700 pits, 1,800 postholes, fifty-five human graves, and twenty hearths were excavated. Trapezoidal houses, up to forty meters in length and not smaller than thirteen meters, were also located. The long axis of the houses was oriented north and south with a slight northwest tilt. The interior of these houses was divided into three parts. The external pillars, which were construction elements of the walls, were situated in ditches. The walls were constructed from both whole tree trunks and logs split lengthways. The split logs were set upright in the trench, alternating with the flat side facing outward so that the interior and exterior walls were smooth. The houses were associated with a variety of features found in the immediate area. Adult burials have been found in storage pits near the long houses, and other burials have been found in graves and pits in the settlement. Some of the graves are typical inhumation graves mainly containing dress ornaments and copper grave goods. The settlement and the graves are contemporary, but the majority of the graves date from the late phase of the settlement.

The settlement is situated on the bank of a lake. During the occupation of the site, which lasted more than 200 years, the houses were destroyed and rebuilt many times, and some estimates suggest that

houses were rebuilt eleven times. The many phases of occupation are indicated by overlapping house plans. The causes of the frequent rebuilding are thought to be the result of a rotational system or as a consequence of natural destruction, such as fire. The settlement usually consisted of forty-nine long houses, and household cluster was the archaeological manifestation of a fundamental socioeconomic unit of the Brześć Kujawski group. The settlement is related to a set of smaller camps in the neighborhood.

The settlement of Brześć Kujawski was excavated before World War II. The initiators of the excavation were Konrad Jazdzewski and Stanislaw Madajski, who carried out large-scale excavations

of settlements of cultures of southern origin in the Brześć Kujawski region from 1934 to 1939. The excavations in Brześć Kujawski were carried out later by Maria Chmielewski and Waldemar Chmielewski in the 1950s and by Ryszard Grygiel and Peter I. Bogucki in the 1970s and 1980s.

Plan of Brześć Kujawski

Arkadiusz Marciniak

Buckland, William

(1784-1856)

English geologist, Anglican priest, and professor of mineralogy at Oxford University, William Buckland believed that universal catastrophes had wiped out species and that God had created new ones to take their place. Buckland studied the chronology and stratigraphy of caves, and along with the French geologist Georges Cuvier explored the association between fossil humans and the remains of extinct animals. Evidence of the increasing complexity of plant and animal life in successive geological strata was viewed by Buckland as the result of separate and individual acts of creation and not as a developmental sequence. He believed that God and not the natural world was responsible for evolution.

In 1823 Buckland published his *Reliquiae diluvianae,* listing all the then-known finds of fossil human and faunal remains. He concluded that human bones were not as old as the animal bones with which they were found because they were intrusions, the result of geological processes, faults, or tectonic movements. For over twenty years his views dominated the scientific establishment, until those of geologist charles lyell, and the antiquaries and archaeologists who had burgeoning evidence of human antiquity, superseded them.

Bulgaria

For objective historical reasons, the beginning of Bulgarian archaeology has been traced back no earlier than the last decades of the nineteenth century. During the sixteenth to the nineteenth centuries, many European travelers who passed through the Ottoman Empire described various antiquities in Bulgarian lands. Thus, in 1868, the French scholar A. Dumont traveled in southern Bulgaria, then under Ottoman rule, and later published his reports (Dumont 1892). However, it would be some years after Bulgaria was emancipated in 1878 before the pioneers of Bulgarian archaeology started excavating sites and studying diverse ancient and mediaeval artifacts. The pioneers were usually Bulgarian enthusiasts whose experience in archaeology was acquired in the course of their work; therefore, it was the Czech scholars C. Jireček, V. Dobrusky, and H. and K. Škorpil who initiated real archaeology in Bulgaria and published the first archaeological studies (Dobrusky 1896, 1897; Jireček 1877, 1881; H. Škorpil 1894; H. Škorpil and K. Škorpil 1896).

von Bunsen, Christian Karl Josias

(1791-1860)

Educated at various German universities in modern, ancient, and original languages; theology; and law, Bunsen joined his mentor Barthold Niebuhr in Rome during the early nineteenth century where Niebuhr was Prussian minister to the Vatican. Bunsen succeeded to this post in 1824 and, with his English wife, made their residence the center of a German cultural milieu in Rome.

Bunsen was also interested in archaeology and art, and during his years in Rome his residence also became a meeting place for artists, archaeologists, and scholars from every country. The sculptor Thorwaldsen, the philosopher Chateaubriand, jean-françois champollion, and Leopardi were visitors. Archaeologists such as F.G. Welcker, professor at Bonn and one of the most renowned philologists of the time, Heinrich Panofka, and Eduard Gerhard congregated around Bunsen.

Gerhard was to become the lifetime administrator of the Instituto di Corrispondenza Archeologica (which later became the deutsches archäologisches institut). The institute was Bunsen's initiative, conceived as an international organization, whose main task was to improve the knowledge of antiquities among archaeologists and art historians. There was so much being discovered about the past at this time that the institute was responsible for producing a formidable range of regular publications on notable archaeological discoveries. Scholars, collectors, and archaeologists contributed to its publications in the areas of method (academic philology); aesthetics, in the style of johann joachim winckelmann; and the discoveries of the Grand Tour. These publications created a kind of living encyclopedia of archaeology covering all categories and specialties, such as museum catalogues, topographic description, epigraphy, ceramic studies, and iconography.

Bunsen left Rome in 1838. He was Prussian minister to Switzerland until 1841 and then he was minister to England, the most important diplomatic post at the time. He worked hard to improve international relations between Prussia and England, which were strained by the Schleswig-Holstein issue. He also tried to bring Prussia into the alliance against Russia during the Crimean War, and as a result of this he was recalled to Prussia in 1854.

At the court Bure began to decipher Nordic

runes, a script used on the monuments, memorial stones, and artifacts throughout northern Europe, and he was one of the first to collect and systematically analyze these ancient inscriptions. He established a runic alphabet and transcription rules, he proposed a dating system, and he began a collection of Swedish inscriptions. From 1599 Bure and two assistants went on topographic and archaeological surveys, carefully recording and illustrating monuments and ancient examples of runic epigraphy. Bure transformed the antiquarian tour into a systematic study, completing the first professional archaeological survey. He is regarded as one of the founders of landscape archaeology.

Bure's travels and collections were strongly supported by the king of Sweden and in 1630 Gustav Adolphus published a statute protecting Swedish antiquities. Sweden was the first state in the world to not only endow an archaeological service but also to legislate to protect its heritage. As important, for the first time here was evidence and proof of a past that was neither Roman nor Greek and that was recognized as being worthy of protection and study in its own right.

Cambodia

The spectacular ruin of Angkor Wat is an enduring icon of Cambodian archaeology and a powerful symbol of national identity. Europeans "discovered" this ruin in the mid-nineteenth century and ultimately attributed it to the ancestors of ethnic Khmers who live in Cambodia today. Cambodia was part of an area historically known as Indochina, a colonial entity controlled by the French from the mid-nineteenth to mid-twentieth centuries. Since French colonial archaeologists who worked in Cambodia also worked in other areas of Indochina, understanding the history of Cambodian archaeology requires some knowledge of the history of archaeology throughout Indochina, including work in the neighboring countries of Vietnam and Laos.

Indochinese archaeology began in earnest during the mid-nineteenth century and reached its apex in the first half of the twentieth century. During this time archaeology was a distinctly colonialist endeavor that was embedded in a broader *mission civilisatrice* (civilizing mission). Archaeology, epigraphy, and art history were undertaken by a host of colonial officials and administrators who believed that research on the cultures and history of this new French colony served as one means of gaining-and maintaining-colonial control over the region.

Since 1850 Cambodian archaeology has been characterized by two parallel archaeological traditions: one rooted in the humanities and the other in the natural sciences. The historical tradition focuses on the ancient civilizations of the region and combines architectural, art-historical, and epigraphic approaches with archaeological methods to study developments since the beginning of the Roman Empire (ca. 500 b.c.-a.d. 1432). The prehistoric tradition, drawing extensively from a geological background, studies the period before about 500 b.c. and has focused most of its attention on Holocene developments that culminated in the Bronze Age.

The Indochinese peninsula, which would ultimately become Vietnam, Cambodia, and Laos, attracted French commercial and missionary interests by the mid-nineteenth century. Despite great resistance by the Vietnamese, the French raised its flags in the southern and northern capitals (Saigon and Hanoi, respectively) by 1873. Cambodia, under a weak sovereign, acceded to the French in 1864, and the feuding kingdoms of Laos were unified between 1885 and 1899. Through military power and fueled by commercial interest, French Indochina was born.

The Impact of Nineteenth-Century Expeditions on European Knowledge of Cambodia's Past

Several important expeditions were undertaken through the new French Indochina during the mid- and late nineteenth centuries to chart its territory, document the resources of the region, and seek potential trade routes to link the colony with markets in southern China. From 1858 to 1861 the French explorer and naturalist Henri Mouhot undertook three natural history expeditions that covered regions of Thailand, Laos, and Cambodia. Mouhot described the customs of the peoples he met during these travels, and in his January 1860 visit to northwestern Cambodia, he encountered the crumbling ruins of Angkor Wat. Mouhot died of a fever near Luang Prabang, Laos, in 1861. Two years later his

Mouhot described the customs of the peoples he met during these travels, and in his January 1860 visit to northwestern Cambodia, he encountered the crumbling ruins of Angkor Wat. Mouhot died of a fever near Luang Prabang, Laos, in 1861. Two years later his

of Mouhot, de Lagrée, and Pavie that images of a glorious and vanished Cambodian past were lodged in the minds of Europeans, whose countries were then colonizing most of Southeast Asia.

Cambodian Archaeology through-Nineteenth-Century Research

Investigations also began at archaeological sites throughout the colony during this period. The earliest of these endeavors were carried out by army and naval officers, administrators, and missionaries who lacked formal training in archaeology. They concentrated their efforts in Vietnam (particularly in the north) and in northwestern Cambodia and studied art history, epigraphy, and archaeology. Most work focused on the period that began with the Roman Empire and ended in the European Middle Ages; in Indochina this period is characterized by monumental Khmer and Cham architecture. From 1879 to 1885 Etienne Aymonier undertook his exhaustive study of archaeological sites and Khmer inscriptions throughout Cambodia. Visits to the Cambodian site of Samrong Sen, together with archaeological work conducted there by several notables (e.g., Noulet, Fuchs, Moura, emile cartailhac), yielded bronze weapons and tools and established the notion of an Indochinese Bronze Age. In 1886 Gustave Dumoutier and Paul Bert arrived in Hanoi and launched the first systematic archaeological and historical research in Vietnam.

The end of the nineteenth century witnessed a turning point in colonial research on Indochina's archaeological past. This shift was marked by Gen. Paul Doumer's establishment, on December 15, 1898, of a permanent archaeological mission in Indochina. This institution was to be under the control of the Académie des Inscriptions et Belles-Lettres, and its mission was to coordinate all historical, epigraphical, art-historical, and archaeological research in the region. The governor-general then created the Geological Service of Indochina in 1899, headed by Henri Mansuy and M. Lantenois. Most prehistoric archaeological research during the colonial period was done through this institution. In 1901 Louis Finot was appointed the first director of the permanent archaeological mission, which was then renamed the École Française d' Extrême Orient (EFEO).

Louis Finot earned degrees in law and literature before he began his research on Sanskrit and assumed the directorship of EFEO, the institution that would become the premier organization to focus on Indochina's cultural heritage for the rest of the colonial period. Interestingly, few of the early and important EFEO archaeologists had technical training in the field: Lunet de Lajonquière was a military officer, Henri Mansuy had no formal college degree, Louis Bezacier and Henri Parmentier were architects, and Louis Malleret went to Indochina as a language teacher. The field of Southeast Asian studies was so underdeveloped in Europe at the time that even those with professional training (such as Victor Goloubew, whose background lay in art history) had little familiarity with the region before their arrival.

EFEO's explicit goal was to conserve and restore the ruined Khmer and Cham monuments of Indochina; safeguarding monuments that would otherwise be destroyed involved not only their study but also their restoration or conservation. In 1907 France signed a treaty with Siam (Thailand) that assured the return of three western provinces of Cambodia containing Angkor and its associated monuments. In 1908 EFEO launched its systematic program to conserve and restore the monuments of Khmer (and, to a far lesser extent, Cham). EFEO founding directors Louis Finot and Alfred Foucher also established the Service Archéologique as one arm of the institution.

Understanding the history of archaeological research in Cambodia requires a dual focus on developments in both prehistoric and historical archaeology. Colonial archaeological research in these two realms began in earnest in the second decade of the twentieth century and continued vigorously until the outbreak of World War II. The effective end of EFEO archaeological service occurred in 1945, and

the French withdrawal from Vietnam in 1954 resulted in the transfer of authority from France to the newly independent countries of Cambodia, Vietnam, and Laos. In Cambodia the period before World War II was the

golden age of archaeology; field research ceased altogether by the early 1970s. Archaeological work in Laos also faltered after this time. Vietnam, however, quickly established institutes of archaeology in the north (in Ha Noi) and in the south (in Ho Chi Minh City) and pursued a vigorous program of archaeological research, with a strengthened focus on prehistoric archaeology.

Prehistoric Archaeology in Indochina: 1901-1970

Intellectual influences on prehistoric archaeology derived from the natural sciences, with a strong emphasis on geology and paleontology. The earliest prehistoric archaeological research was undertaken in the late nineteenth century at sites such as Samrong Sen. It was only with the establishment of the Geological Service of Indochina that technical experts (Henri Mansuy, Madeleine Colani, Etienne Patte, Max de Pirey, J. Fromaget, Edmond Saurin) began to grapple with the region's prehistory. The first and most important of these scholars was Mansuy, who helped establish the Geological Service in 1899. His archaeological work at Samrong Sen and Long Prao comprised a small part of his impressive corpus of field research on Pleistocene and Holocene sites in Cambodia, Upper Laos, and northern Vietnam.

In the next three decades prehistoric archaeologists visited and excavated sites throughout Indochina whose occupational period ran from the Paleolithic (Pleistocene) to the Iron Age. The early to middle Holocene was one of the first periods to receive systematic archaeological attention. In the 1920s Madeleine Colani's reconnaissance of caves and rock shelters in northern Vietnam identified a Mesolithic-like tool tradition of early-Holocene age. Named after Hoa Binh Province (in Vietnam) where these sites were originally found, Hoabinhian sites were found in Upper Laos and northern Vietnam. From 1966 to 1968 Roland and Cecile Mourer excavated the Hoabinhian of Laang Spean in northwestern Cambodia in what represents the most systematic prehistoric archaeological work in Cambodia yet published. Vietnamese research on the Hoabinhian since 1960 is too voluminous to report here.

Work by Henri Mansuy in the caves of northern Vietnam, particularly in the mountain range of Bac Son, recovered stone tools and human remains from a late-Hoabinhian/early-Neolithic cultural manifestation that is now called the Bacsonian tradition. The general paucity of “Neolithic” research in Cambodia remains problematic. Bernard-Philippe Groslier's excavations in 1959 at four monuments in the Angkor region uncovered “Neolithic” adzes but did not investigate this time period. During the 1950s and 1960s both Louis Malleret and Groslier worked in eastern Cambodia (in Kompong Cham Province) at circular earthwork sites; work in the 1990s at these sites has produced dates that begin-but do not terminate-in the Neolithic period (i.e., ca. 4000 b.p.).

The next breakthrough in Indochina's prehistoric archaeology focused first on the Iron Age and then on the Bronze Age. In 1909 M. Vinet published the first report of earthenware jar burials in the region of Sa Huynh. Fifteen years later Henri Parmentier published results of archaeological work that included illustrations of jar burials containing cremations, beads, and iron tools recovered from the site of Sa Huynh (in Quang Ngai Province, central Vietnam). In 1934, using results of excavations in the region, Madeleine Colani proposed the term *Sa Huynh culture* for one manifestation of Indochina's Iron Age.

Ancient bronze drums from Southeast Asia were the subject of comparative study by Franz Heger in 1902. In 1924 tax collector L. Pajot reported bronze artifacts that a fisherman found in a riverbank along the Ma River in northern Vietnam. Subsequent EFEO excavations recovered several graves, remains of pile houses, and bronze artifacts, which Victor Goloubew published in 1929. Olov Janse's excavations at Dong Son from 1934 to 1939 recovered bronze drums in stratigraphic context. In 1935 Madeleine Colani reported the recovery of molds for casting bronze tools as part of the megalith culture from Upper Laos, now known as the Plain of Jars.

In Cambodia systematic excavations of Bronze Age sites were restricted to Mansuy's work (published in 1902 and 1921) at Samrong Sen and to

Paul Lévy's work in the late 1930s at three sites in the Mlu Prei region (in Kompong Thom Province). Most bronze objects ascribed to Samrong Sen lack provenance, but Mansuy's work recovered stone adzes, bronze objects, and human remains. Lévy's excavations at Mlu Prei recovered earthenware pottery, bronze tools, and at least one sandstone mold used to cast bronze axes and sickles.

Work by J. Fromaget and Edmond Saurin established the existence of a Paleolithic tradition in the caves and rock shelters of Upper Laos in 1934. Excavations there recovered a middle-Pleistocene animal assemblage and fragments of human bone. That work, together with Saurin's subsequent work on Pleistocene gravel terraces in northeastern Cambodia and Russian archaeologist Pavel Boriskovsky's in northern Vietnam, argued for a Paleolithic “pebble tool” culture in Indochina. The evidence for a Cambodian Paleolithic, offered by Saurin in the mid-1960s, is particularly equivocal, but most archaeologists now believe that humans occupied Indochina during the Pleistocene.

The foregoing summary of prehistoric archaeology in Indochina highlights some of the major developments from 1901 to 1970. A huge number of prehistoric archaeological sites were discovered and excavated during this time. Colonial archaeology made significant contributions, and Vietnamese archaeologists have made great strides in our understanding of Indochina's prehistory. To explain key developments in the prehistoric sequence, colonial archaeologists working throughout Southeast Asia at the time offered a variety of diffusion and migration models, rather than independent invention. It is perhaps intriguing that the adoption of radiocarbon-dating techniques in Indochinese archaeology coincided with the emergence of indigenous archaeologists and the appearance of alternative models that emphasized local development rather than importation from beyond the region.

Historical Archaeology in Indochina: 1901-1970

It might well be said that the history of colonial archaeology in Indochina is the history of Angkorian archaeology. The EFEO's mission was the documentation and protection of archaeological sites, and several scholars made significant contributions to our knowledge of Cham archaeology, notably Henri Parmentier, J.-Y. Claeys, and Louis Bezacier. Nonetheless, Angkor occupied the heart and soul of EFEO, and much of that organization's research focused on the Angkorian and pre-Angkorian periods. The abundance of EFEO research cannot be summarized here; sections that follow use selected examples of archaeological work to illustrate general trends.

The collection of monuments that is often glossed as “Angkor” is found immediately north of the Tonle Sap Lake in northwestern Cambodia. The primary goal of work at Angkor was the conservation of the monuments, and the Conservation d'Angkor was created in 1908 after Siam returned Cambodia's three western provinces. In Phnom Penh, Georges Groslier established the Musée Albert Sarraut in 1920, under the patronage of King Sisowat and (French) Résident Supérior Baudoin. Renamed the National Museum of Cambodia, the institution serves as the repository for Khmer sculptures, inscriptions, and other Cambodian antiquities. The Archaeological Park of Angkor was established in 1926. Henri Marchal and Maurice Glaize, two of Angkor's conservators between 1916 and 1953, introduced the method called “anastylosis” from Dutch conservators in Java. EFEO conservation involved more than engineering and consolidation: it also involved epigraphic research to assign ages to the monuments, compiling archaeological maps (using ground and aerial techniques) to study the construction sequence in different areas, and archaeological work in connection with restoration.

Archaeological research was also undertaken through EFEO activities that involved the location, mapping, and dating of monuments. One aspect of the organization's early mission-documentation-involved a general reconnaissance of archaeological sites to supplement earlier reconnaissance by Etienne Aymonier. Lunet de Lajonquière undertook an archaeological survey from

1900 to 1908 that identified the geographic limits of the Khmer Empire. At its peak the empire extended west into central and

at Oc Eo. From 1952 to 1953 Groslier directed archaeological excavations at the Royal Palace that uncovered a cemetery of cremated remains. In the 1950s both Malleret and Groslier investigated prehistoric circular earthwork sites in eastern Cambodia.

After achieving independence in the 1950s, the three countries of Indochina pursued archaeological work to varying degrees. In Vietnam archaeology served nationalistic interests, and efforts were concentrated on finding the roots of Vietnamese civilization. After 1954 the states of North and South Vietnam established the institutes of archaeology in Hanoi and Ho Chi Minh City, respectively. Archaeological work continued unabated in Vietnam throughout the Vietnam War, although research slowed in both Cambodia and Laos during this time. Conservation activities at Angkor went on, as did the historical and epigraphical research that laid the foundations for archaeological interpretations of the monuments.

Cambodian Archaeology since 1970

A bleak period in Cambodian archaeology began in 1970 with the onset of civil war in the country. All archaeological research activities ceased, and the next five years were plagued by political instability that ultimately forced the closure of the Conservation d'Angkor in 1972, the end of its work in 1973, and the departure of its staff. The Khmer Rouge used Angkor to recall former glory and spared the ruins from the destruction that they wrought on Buddhist temples throughout the country. Angkor was completely abandoned until the end of the Pol Pot regime in 1978, and forces of nature undid much of the clearing work that the EFEO had undertaken to protect the monuments from destruction.

Most of Cambodia's trained archaeologists and technical experts perished between 1975 and 1978 as a result of the Khmer Rouge plan to eliminate the educated elements of society. With the entry of Vietnamese soldiers in 1979 as part of Vietnam's occupation of Cambodia, Angkor's antiquities were pillaged, and Angkorian artifacts (sculpture, architectural elements, other artifacts) flooded the international antiquities market. Only one international team, from India, dared return to Angkor Wat soon after 1979, when fighting between the Vietnamese and the Khmer Rouge continued in the region.

With the Vietnamese withdrawal and the process of reconstruction after 1989, Cambodian

and possibly prehistoric sites in the region and to document the growth of urban settlement there. Several studies have challenged Groslier's hydraulic city model by analyzing the nature and availability of arable and irrigable land with respect to the giant reservoirs (*baray*) that Bernard-Philippe Groslier believed were used to channel water to fields.

A number of important conservation and restoration projects have begun or resumed at Angkor since 1989. Foremost among the countries sponsoring such efforts is Japan; its United Nations Educational, Scientific, and Cultural Organization (UNESCO) Japanese Trust Fund (Japanese Government Team for Safeguarding Angkor, orJSA) is supporting work at Angkor Wat and Angkor Thom. In addition, Sophia University is conducting research at Banteay Kdei, and EFEO has resumed its work in Angkor Thom after a twenty-year hiatus. Other ongoing projects around Angkor include those sponsored by Hungary, Indonesia, Italy, and the United States (World Monuments Fund). The governmental organization Autorité pour la Protection du Site et l'Aménagement de la Région d'Angkor (APSARA) was created in 1995 to assume responsibility for managing the Angkor area.

Angkor Wat-and Cambodia's archaeological sites in general-are sources of pride, and Cambodians support efforts to study and protect their ancient heritage. Perhaps the most distinctive features of the archaeological work pursued in Cambodia since 1989, be it research or conservation, are its collaborative nature and its commitment to training future generations of Khmer archaeologists. From the late nineteenth century to the mid-twentieth century, colonial-period archaeologists made impressive contributions to our understanding of Indochina's archaeological past. With classroom, field, and professional training programs now in place, the history of Cambodian archaeology in the next century promises to include many contributions by indigenous archaeologists who are studying their own archaeological heritage.

Camden, William

(1551-1623)

Born in London the son of a painter, William Camden attended St. Paul's School, where he received an excellent classical training, and then proceeded to Oxford. In 1575, he became a master at Westminster School in London, where he taught for the rest of his life.

Camden was the founder of antiquarian studies in England through his immensely influential book *Britannia,* which was first published in 1586, and he brought a wide range of skills to the elucidation of the remote past of his country. Well read in Greek and Roman literature, he was familiar with all the references to Britain made by the ancient historians, geographers, and poets. He was an eminent topographer and had a pronounced interest in coins and inscriptions. He was expert in genealogies and the history

PREV NEXT

of significant families and knowledgeable about the office and ceremonies of state. He became the historian of his own age, writing an important account of the reigns of Elizabeth I and James I, so that by the end of his own life he was not only the master of British antiquity but also the interpreter of the modern political scene.

William Camden

(Hulton Getty)

Britannia broke with the mythologies of British history by taking advantage of the existence of a wide range of well-edited classical texts, the product of a century of humanist scholarship. Camden was persuaded that the people who occupied Britain at the time of the Roman invasions were closely related to the Gauls, whom he was able to identify as a Celtic people. He also examined the origins of the Picts and the Scots. To solve problems of origins and relationships, Camden employed etymology. Already proficient in Greek and Latin, he learned Welsh and studied Anglo-Saxon. He was also particularly attentive to the coinage of the Britons in the first century a.d. But it was the relating of history to landscape that was the permanent achievement of *Britiannia.* The body of the book took the form of a "perambulation" through the counties of Britain, with Camden offering a many-layered account of each particular region. Camden made a number of field trips to examine monuments and to gather information-he saw more of Britain at first hand than any previous observer.

Six editions of *Britannia* were published between 1586 and 1607, an English translation appeared in 1610 and 1637, and another Latin edition was published in Frankfurt in 1590. The appearance of *Britannia* in 1586 might well have prompted the formation of the society of antiquaries of london, which began to meet in that year. It certainly encouraged the growth of antiquarian studies in provincial centers by stimulating local curiosity about the regional past.

Camden enjoyed the friendship of a wide circle of European humanist scholars, such as Scaliger, Ortelius, Lipsius, Hondius, Casaubon, Peiresc, Hotman, and de Thou. Largely through his contacts, English antiquaries of the Jacobean age were linked to their European counterparts.

Canada

The border between Canada and the United States slices arbitrarily across North America, and European colonization began north of the border almost as early as to the south. Yet, for climatic and geological reasons, European settlement progressed more slowly in Canada, and the bulk of the country's population remained concentrated near the border. The surface area of Canada is larger than that of the United States, but Canada is only about one-tenth as populous. Because of this and related political factors, archaeology has developed in Canada more slowly and somewhat differently than it has in the United States.

Antiquarian Beginnings

It is recorded that Indian stone tools were dug up in the course of construction work in southern quebec at various times during the seventeenth century. In 1700, workmen unearthed some magnificent ground slate projectile points at Bécancour. These finds, now known to date from the Archaic period (3000-2000 b.c.), were preserved at the Ursuline convent in nearby Trois-Rivières and constitute Canada's oldest archaeological collection.

In the first half of the nineteenth century, farmers and other interested British colonists in southern Ontario and the Maritimes began to assemble private collections of Indian artifacts. Relic hunters also pillaged Indian burial sites to recover such materials. Only brief accounts of these activities were recorded in local newspapers and British journals.

The most sustained archaeological work of this period was initiated by two Jesuit priests soon after members of that order returned to Quebec in 1842. Father Jean-Pierre Chazelle identified the stone ruins of two seventeenth-century Jesuit missions in southern Ontario, and following in his footsteps, first Father Felix Martin and then Professor Joseph-Charles Tache of the University of Laval explored the Huron Indian sites around these missions. Apart from this work, there was little concern with archaeology in French-speaking Quebec. Unlike English Canadian farmers, French Canadian ones were uninterested in the artifacts they unearthed in the course of their farming operations.

After 1853, two leading Canadian scholars studied and wrote about archaeology. daniel wilson, a Scottish archaeologist who eventually became president of the University of Toronto, and John William Dawson, a Nova Scotian geologist who was principal of McGill University in Montreal. Both did archaeological work in Canada in the 1850s and early 1860s, and Wilson asserted that his ambition was to become “a Canadian antiquary.” Yet both men's interests soon became more broadly anthropological. Despite their many anthropological publications that incorporated archaeological data, neither of these eminent scholars made a tangible contribution to the development of archaeology in Canada.

Throughout the nineteenth century, Canadians remained largely preoccupied with practical matters, and it was expected that gifted individuals would apply their talents to public life. Pursuits such as archaeology were not viewed as suitable full-time occupations for men of ability. Academics were few in number and so deeply involved in political and religious controversies that they had little time for archaeology.

Even so, in the second half of the nineteenth century, natural history, literary, and historical societies were founded, or became more active, in Montreal, Toronto, Halifax, and St. John, New Brunswick. These societies played a major role in drawing their members' attention to archaeological developments in Europe and the United States, and their journals made possible the publication of archaeological research. In 1863, members of the Nova Scotian Institute of Natural Science were inspired to excavate local shell mounds by the Swiss archaeologist Adolf Morlot's report of Danish shell-mound investigations published in the widely distributed *Annual Report of the Smithsonian Institution* for 1860. In 1884, the Natural History Society of New Brunswick published George Matthew's account of a stratified shell midden at Bocabec, New Brunswick; the best excavation carried out by a Canadian in the nineteenth century. Although numerous studies of the archaeology of the Maritime Provinces were published locally in the late nineteenth century, no specifically archaeological positions were established in universities or museums in that part of Canada. In Quebec, only a small number of archaeological studies were published, mainly by English-speaking residents of Montreal. A few brief notes on archaeological finds appeared in *Le Naturaliste Canadien* in the 1880s.

Developments of more lasting importance for Canadian archaeology centered on the Canadian Institute (later the Royal Canadian Institute) founded in Toronto in 1849 by provincial land surveyors and other professionals wishing to promote the advancement of the natural sciences and the arts. In 1852, the institute issued a circular drafted by Sandford Fleming, civil engineer and future inventor of standard time, urging the reporting of Indian sites that

PREV NEXT

American opinions about the Mound Builders. Farther west, archaeological material was collected in the 1890s by geologists and surveyors from eastern Canada, many of them working for the Geological Survey of Canada. At this time, resident amateur archaeologists also began to study the Indian burials, middens, and the rock art of British Columbia.

Canadian archaeologists generally viewed Indians in the same way U.S. evolutionary anthropologists did: as peoples whose cultures were very primitive and therefore prehistorically must have been similar to what they were like at the time of European discovery. As a result, these archaeologists saw no need to try to work out elaborate chronologies. In Canada, the successful government efforts, after the Indians ceased to be useful allies against the United States, to move them as quietly as possible onto reserves or to more remote parts of the country meant that Indians did not loom large in the experience or imagination of most Euro-Canadians. In the United States, as prolonged and violent confrontations with aboriginal peoples came to an end, Indians were appropriated by their conquerors as romantic symbols of republican freedom, a theme that had little appeal for Canadians. As a result of these developments, there was far less pressure on governments in Canada than there was in the United States to devote public funds to prehistoric archaeological research.

The little interest that Canadians had in prehistoric archaeology waned in the early twentieth century. It was virtually extinct in the Maritimes by 1919, partly as a consequence of the economic decline of that region, and there was also diminishing interest in Manitoba, British Columbia, and Ontario as the broader concern to study Canada's past that had arisen following confederation in 1867 subsided. No provincial government provided the means for training archaeologists or employment for them. Even the position of provincial archaeologist in Ontario lapsed after Boyle's mediocre successor died in 1933.

In 1897, the Jesup North Pacific Expedition of the American Museum of Natural History began archaeological work in coastal British Columbia. This was the first of many foreign (mainly U.S. and Scandinavian) expeditions that carried out archaeological research in Canada, and in particular, they added to an understanding of Arctic prehistory. Although some of these expeditions provided Canadian archaeologists with opportunities to do fieldwork, others contributed nothing to the institutional development of Canadian archaeology and even retarded it by removing artifacts from Canada. Although such incursions into southern Canada had largely ceased the end of the century foreign expeditions continue to be authorized in northern Canada.

The Belated Development of Prehistoric Archaeology

A new phase in Canadian archaeology began in 1910 when the Geological Survey of Canada established an Anthropology Division. For many years, scientists attached to the survey had been collecting archaeological and ethnological material in western Canada, and pressure from a small number of Canadian amateur anthropologists and from the British Association for the Advancement of Science finally resulted in the allocation of government funds to this unit. Its first director was Edward Sapir, a young U.S. linguistic anthropologist who had studied with Franz Boas at Columbia University in New York City. Within two years, Sapir had hired Harlan Smith, a middle-aged U.S. archaeologist who had worked for the Jesup Expedition in British Columbia, and William Wintemberg, an amateur archaeologist from Ontario who had assisted Boyle. Working together in Ontario and Nova Scotia, Smith taught Wintemberg how to excavate and write site reports, with an emphasis on the functional interpretation of artifacts. Thereafter, despite frail health, Wintemberg carried out surveys and excavations in Newfoundland (not yet part of Canada), New Brunswick, and on the prairies while Smith continued to concentrate on British Columbia.

Wintemberg's most important research was done in southern Ontario, where he worked out a rough

chronology of Iroquoian cultural development. Yet, so great was his isolation from mainstream U.S. archaeology, it was only

in the Old Crow region of the Yukon and in other studies, no satisfactory resolution of this problem has been achieved.

As chronologies for more recent periods were better understood, archaeologists began to seek a more detailed understanding of the factors that accounted for change over time. In some fields, such as the study of Iroquoian prehistory, where Canadian archaeologists initiated extensive site surveys and began to excavate entire habitation sites, both the scale and the quality of archaeological research came to surpass what was being done in adjacent parts of the United States.

A survey carried out by Roy Carlson in 1973 indicated that the most widely shared interest of archaeologists working in Canada was the study of cultural history, and an analysis of the *Canadian Journal of Archaeology* reveals that 67 percent of the articles published in that journal between 1988 and 1992 dealt with culture history while about 40 percent exhibited an interest in ecology. The preoccupation with recovering primary data and building cultural chronologies tended to insulate Canadian archaeology from the impact that processual archaeology had in the United States during the 1960s. Most U.S. archaeologists who found employment in Canada and Canadians who had studied in the United States had received their training prior to the rise of processual archaeology, and some were inclined to be hostile or indifferent to the new movement; others embraced it.

In general, however, the demands of archaeological research in Canada and the agenda set by the National Museum tended to dilute the impact of the movement. Many Canadian archaeologists became genuinely interested in the ecological approaches advocated by processual archaeology, but most of them rejected its antihistoricism, extreme positivism, and privileging of a deductive methodology. This espousal of an eclectic, middle-of-the-road approach appears to have been more than a result of the late development of archaeological research in Canada or of the proverbial Canadian penchant for compromise. Theorists such as Gordon Lowther, Alison Wylie, Marsha Hanen, Jane Kelley, and Bruce Trigger have formulated philosophical underpinnings for such an approach that involve a blend of relativism and empiricism, which appears to be increasingly marketable abroad as postmodern trends impact on archaeology everywhere.

A major challenge confronting archaeologists working in Canada today is to establish effective working relations with indigenous peoples, who are increasingly determined to control their cultural heritage and securing the legal right to do so. Many native people object on religious grounds to the excavation of burial sites and places where their ancestors lived. Others see archaeology as enhancing an understanding of aboriginal history and culture. The Canadian Archaeological Association is seeking to develop cooperative agreements and principles of conduct to govern relations between archaeologists and the indigenous peoples. On the whole, such discussions have been productive, although it is clear that archaeology is going to have to change to address issues of major concern to aboriginal people. These issues generally relate to the recent past and favor a combination of archaeology, ethnology, and oral history that recent generations of ecologically inclined archaeologists have tended to ignore. A more contentious legal issue is whether public ownership of the archaeological record is vested in the government or belongs to native peoples.

Historical Archaeology

Historical archaeology, which is concerned primarily with sites relating to European settlement in Canada, began in the 1890s when Chazelle relocated the two Jesuit mission sites in southern Ontario. For a long time there was little more than an interest in identifying the locations of buildings and major events associated with the early colonization of eastern Canada. In 1919, the federal government created the Historic Sites and Monuments Board, which commemorated but did not have the power to

protect such sites. The first scientific excavation of a historical site was carried out between 1941 and l943 by Kenneth Kidd of the Royal Ontario Museum at the larger and earlier of the Jesuit mission sites that Chazelle had identified. The excavation of this site was completed between

1947 and 1951 by Wilfrid Jury, after which Sainte-Marie Among the Hurons was reconstructed as a tourist attraction by the Ontario government. Kidd's monograph on that site was a milestone in the early development of historical archaeology in North America.

Historical archaeology tended to interest the Canadian public more than prehistoric archaeology, and governments viewed the reconstruction of historical sites as a way to encourage tourism, especially in poorer areas of the country. In 1961, the federal government established the Canadian Historic Sites Service (now the Archaeology Division of the Canadian Parks Service) with John Rick as senior archaeologist. This service was intended to encourage the excavation of historic sites as well as their reconstruction for historical and recreational purposes. Among the numerous projects that provided cultural images for Euro-Canadians were the excavation and rebuilding of the French fortress of Louisbourg in Nova Scotia and the Viking settlement at L'Anse aux Meadows in Newfoundland. Between 1962 and 1966, six research positions were added to the service and large amounts of contract funding were made available by the federal government. In more recent years, there has also been growing interest in industrial archaeology, which is supported by conservation groups.

For a long time, the Historic Sites Service and the Archaeological Survey of Canada tended to divide the work according to whether sites dated from the historical or prehistoric periods. Because of the specialized skills required to carry out historical archaeology, many of the original archaeologists attached to the Historic Sites Service were recruited from abroad. They had little interest in prehistoric archaeology and initially had few connections with the existing archaeological community. After the merger with Parks Canada, a growing number of Historic Sites Service archaeologists were knowledgeable about prehistoric as well as historical archaeology. The archaeology departments at Calgary and Simon Fraser Universities were generally more willing to train historical archaeologists than were anthropology departments, which remained focused on prehistoric archaeology, but Canada still does not have a major center for educating historical archaeologists. Individuals who were trained in prehistoric archaeology but have done major work on historical sites include the late Walter Kenyon of the Royal Ontario Museum and James Tuck at Memorial University of Newfoundland. The Canadian Parks Service issues its own publications dealing with historical archaeology, and relatively few articles on this subject appear in the *Canadian Journal of Archaeology*.

Heritage Management

The oldest heritage legislation in Canada is the British Columbia Historic Objects Preservation Act of 1925, which was designed primarily to prohibit the removal of rock carvings and other aboriginal artifacts from that province. Between 1954 and 1980, expanding provincial government bureaucracies, following the examples of other countries, passed heritage acts to provide legal protection for cultural resources and allocated funds to conserve and manage them. The powers granted to regulatory bodies included requiring assessments of archaeological potential in advance of land use, licensing archaeological activities, and the obligatory reporting of the findings of archaeological research. The implementation of the legislation varied according to the strength of the provincial legislation, the will of the provincial governments to enforce it, and the highly variable resources of the different provinces.

Federal antiquities legislation, though not integrated in a single body of law applying to all contexts, is incorporated within several acts, the principal ones being the Canada Environmental Assessment Act and the Canadian Cultural Property Export and Import Act. The drafting of comprehensive legislation has been impeded by interdepartmental jurisdictional disputes and by the refusal of some aboriginal peoples to acknowledge government ownership of archaeological remains.

The growth of archaeological resource management provided two new categories of employment for

archaeologists. A significant number of civil service posts were created within government departments to deal with a mixture

of administrative and salvage activities. Much of the fieldwork and report writing associated with resource management now is done through contracting, which has led archaeologists to establish private consulting firms for this purpose. Since the early 1980s, as employment in universities, museums, and governments has become hard to find, these firms have provided most of the jobs available to young archaeologists. At present, cultural resource archaeologists generally are better funded and are carrying out more excavations in Canada than are university and museum archaeologists.

Archaeology Abroad

Early in the twentieth century, a few Canadians began to do archaeological work abroad. The most famous was the Peking-based physician Davidson Black, who in 1927 identified *Sinanthropus pekinensis* (Peking Man) and was involved in the excavations at Zhoukoudien until his death in 1934. The Canadian School of Prehistoric Research, a privately funded institution founded in 1925 by the geologist Henry Ami, carried out Paleolithic excavations in France into the 1930s. Amice Calverley, who began to work for the egypt exploration society in 1927, copied the reliefs of the Temple of Seti I at Abydos and published them between 1933 and 1959.

The person who had the greatest impact on Canadian archaeology done abroad was Charles Currelley, who excavated in Egypt for the Egypt Exploration Fund from 1902 to 1907, originally as an assistant to w. m. f. petrie, before becoming the first director of the Royal Ontario Museum of Archaeology when it was established in Toronto in 1912. This museum, which absorbed the old Ontario Provincial Museum, was to become a major center for archaeological research both within Ontario and outside Canada. Homer Thompson, who held appointments at both the University of Toronto and the Royal Ontario Museum beginning in 1933, was a key member of the american school of classical studies' project to excavate and restore the Agora in Athens. A.D. Tushingham, who moved from Queen's University to the Royal Ontario Museum in 1955, remains active in biblical archaeology.

Since 1945, archaeologists employed at the Royal Ontario Museum have excavated in iran, Iraq, greece, Egypt, the Sudan, belize, and other countries. Some of the excavations have been carried out in collaboration with other institutions, and Royal Ontario Museum archaeologists have participated in research organized by other groups. Often work has continued at the same site or in the same region for many years. This research, together with studies of the vast Chinese collections assembled during Currelley's directorship, has made the Royal Ontario Museum Canada's most important center for archaeology abroad. It has also played an important role in encouraging the development of classical, Near Eastern, and Egyptian archaeology at the University of Toronto.

Since 1960, a substantial number of archaeologists who do research abroad have found employment across Canada in university departments of anthropology, archaeology, classics, history, Near Eastern studies, art history, and religion. By the mid-1970s, these archaeologists outnumbered university-based archaeologists studying Canada by more than two to one. In 1961, the federal government supplied funding for a Canadian expedition, led by Philip Smith, that carried out prehistoric research as part of the UNESCO Campaign to Save the Monuments of nubia. Since then, research abroad has been greatly facilitated by federal government funds supplied through the Canada Council and the Social Sciences and Humanities Research Council of Canada. This peer-reviewed funding, which takes the form of major grants extending over a number of years, is available for projects both inside and outside Canada and has supported archaeological research in many parts of the world.

Important archaeological projects have been carried out by classical archaeologists from the University of Toronto, the University of Alberta, McMaster University, McGill University, the University of British Columbia, and the University of Laval. Egyptian archaeology has been vigorously pursued by

archaeologists from the University of Toronto, while the University of Calgary has become a center for African archaeology. Possibly the most publicized Canadian

work done abroad is Donald Redford's excavations in Egypt at Karnak East in connection with the Akhenaton Temple Project. The Canadian Archaeological Institute at Athens and the Canadian Academic Centre in Italy were both established in 1978, and the Canadian Institute in Egypt was founded two years later. All three institutes facilitate archaeological research in these countries under the aegis of the Canadian Mediterranean Institute. At present, the future of this institute, and of all Canadian archaeology done abroad, is seriously threatened by continuing cutbacks in federal funding.

Despite shared methodological interests, there are few professional contacts between Canadian archaeologists excavating inside Canada and those working abroad, except at the Royal Ontario Museum or in university archaeology or anthropology departments. There is also little interaction among archaeologists studying different parts of the world. The Canadian Society for Archaeology Abroad, founded in 1969 to represent the interests of these archaeologists, has ceased to exist. Archaeologists researching abroad who do maintain contacts with archaeologists working inside Canada frequently share an anthropological interest in ecological studies and in reconstructing social life while those with a more humanistic orientation tend to avoid such contacts. This situation reinforces a division between anthropological and humanistic archaeologists, who in Canada, as in the United States, remain psychologically as well as disciplinarily isolated from one another. One bridge between these two groups is the multifaceted, Toronto-centered Dakhla Oasis Project, which has brought together both sorts of archaeologists to study the culture history of that region of Egypt from prehistoric times to the Christian period.

Conclusion

In Canada, archaeology does not constitute a single discipline or even a shared approach to studying the past. Prehistoric archaeology, as it relates both to North America and to the rest of the world, is generally located in the anthropology or archaeology departments of universities. The two Canadian archaeology departments were founded by anthropological archaeologists, and the departments share an anthropological orientation. Historical archaeology is generally taught in archaeology departments; yet, despite its importance as a practice, its institutionalization in Canadian universities remains weak. The archaeology of the literate civilizations of the Mediterranean world and the Near East is more likely to be studied in departments of classics and Near Eastern studies.

In museums, the situation is quite different. Most of them employ only archaeologists who study the history and prehistory of Canada. The one important exception is the Royal Ontario Museum, which has a large staff representing in its various departments and cross-appointments with the University of Toronto all the branches of archaeology. This is the only archaeological unit in Canada in which both the anthropological and the humanistic traditions of archaeology are substantially represented. There is no society or journal in Canada that embraces the work of all archaeologists. Proposals for formal cooperation between Canadian anthropological and humanistic archaeologists have elicited no positive response.

The relations between prehistoric archaeology and anthropology are looser in Canada than in the United States. There is no over-all anthropological association, as the Canadian Anthropology Society is a grouping of social anthropologists. Archaeologists working in anthropology departments have long complained that the numerical domination of these departments by social anthropologists has kept the number of prehistoric archaeologists employed in universities low. It has also hindered the hiring of archaeologists who specialize in technical analysis, which in turn has lowered the quality of archaeological training in such departments. Even so, most prehistoric archaeologists remain unwilling to abandon their ties with anthropology, and even those who work in archaeology departments see their main interests and orientation as being anthropological. Yet a growing number of archaeologists who

have found employment in cultural resource archaeology, and therefore tend to be interested exclusively in Canadian archaeology,

Caribbean

In 1963, French West Indian archaeologists initiated a series of biennial meetings called the International Congress for the Study of Pre-Columbian Cultures of the Lesser Antilles (Map 1). Over the next decades, so many specialists in the prehistory of the rest of the West Indies, Venezuela, and the Guianas began to attend these meetings that the name was changed to the Congress for Caribbean Archaeology.

The term *Caribbean* is not used in this context to the refer to the entire Caribbean basin but to a culture area that existed in the eastern half of the basin during pre-Columbian times (Willey 1971, 360-393). The western half of the basin formed a separate intermediate area, called that because it lay between the centers of civilization in mexico and peru (Map 2). Few intermediate-area specialists come to the Caribbean congresses; they have little incentive to participate because the problems they study differ from those in the eastern half of the basin.

During prehistoric times, the two areas constituted separate interaction spheres (Caldwell 1966, 338), kept apart because the people living there were unable to travel back and forth across the Caribbean Sea. The inhabitants of the two spheres developed differently because they were unable to exchange artifacts, customs, and beliefs. Christopher Columbus's introduction of European ships, capable of traveling on the high seas, remedied this difficulty and made possible a single circum-Caribbean sphere, with its own set of problems.

This article focuses on the Caribbean sphere and its problems, but it is not entirely limited to pre-Columbian times. It also covers the disappearance of the native peoples as they came into contact with European, African, and Asian immigrants. It thus includes the indigenous side of the so-called Columbian exchange of cultural, linguistic, and biological traits that took place in the circum-Caribbean sphere (Crosby 1972).

Research within these limits has progressed through a sequence of four stages, during which the participants expanded to increasingly high levels of abstraction, each made possible by the results achieved on the previous levels. The initial stage may be called that of artifactual research because it was marked by the discovery, collection, and interpretation of structures and manufactures. In the second stage, chronological research, Caribbeanists began to organize their finds into systems of areas, periods, and ages. In the ensuing stage of culture-historical research, they used those systems to differentiate human populations or peoples, each with its own distinctive culture, and to investigate the peoples' ancestries, that is, their cultural heritages. In the final stage of sociocultural research, they focused on the societies into which the population groups organized themselves and studied the ways in which these social groups used and modified both their cultural and their natural heritages (Rouse 1986, Fig. 30).

Artifactual Research

Archaeology began in the Caribbean area, as elsewhere, with the discovery, description, and identification of buildings, tools, and other artifacts-and with their removal to private homes and public museums. At first, these items of material culture were collected individually; later, they were excavated in the form of assemblages from the sites where they had been deposited.

So far as is known, the first European settlers did not undertake archaeological research. It was not until 1740 that an explorer named Nicolas Hortsmann reported the discovery of petroglyphs (rock carvings) in the present country of Guyana (Osgood 1946, 21). In 1749, Father Juan de Talamanco, a Spanish historian and archaeologist, made a pioneer study of four carved stone figures of Taino Indian deities *(zemis)* that had been sent to him from the northern part of the Dominican Republic, and in 1775, Pedro del Prado, a Cuban, wrote about a stool *(dujo)* of the Tainos that had been found in the eastern part of

his country (Ortiz 1935, 71-72).

The first known exhibition of artifacts took place in Puerto Rico in 1854. It featured the collection of Jorge Latimer, a local merchant, that was eventually acquired by the Museum of Natural History of the smithsonian institution, Washington, D.C. (Coll y Toste 1907, 30- 31). In 1867, the government of British Guiana (now Guyana) established a museum to house items obtained from the local Indians and their sites. This museum, which bears the name of Walter Roth, a longtime director, includes natural as well as cultural objects. Its holdings in the former field are dominant, as is the collection in the Smithsonian's Museum of Natural History (Osgood 1946, 40-41).

Few intermediate-area specialists come to the Caribbean congresses; they have little incentive to participate because the problems they study differ from those in the eastern half of the basin.

During prehistoric times, the two areas constituted separate interaction spheres (Caldwell 1966, 338), kept apart because the people living there were unable to travel back and forth across the Caribbean Sea. The inhabitants of the two spheres developed differently because they were unable to exchange artifacts, customs, and beliefs. Christopher Columbus's introduction of European ships, capable of traveling on the high seas, remedied this difficulty and made possible a single circum-Caribbean sphere, with its own set of problems.

This article focuses on the Caribbean sphere and its problems, but it is not entirely limited to pre-Columbian times. It also covers the disappearance of the native peoples as they came into contact with European, African, and Asian immigrants. It thus includes the indigenous side of the so-called Columbian exchange of cultural, linguistic, and biological traits that took place in the circum-Caribbean sphere (Crosby 1972).

Research within these limits has progressed through a sequence of four stages, during which the participants expanded to increasingly high levels of abstraction, each made possible by the results achieved on the previous levels. The initial stage may be called that of artifactual research because it was marked by the discovery, collection, and interpretation of structures and manufactures. In the second stage, chronological research, Caribbeanists began to organize their finds into systems of areas, periods, and ages. In the ensuing stage of culture-historical research, they used those systems to differentiate human populations or peoples, each with its own distinctive culture, and to investigate the peoples' ancestries, that is, their cultural heritages. In the final stage of sociocultural research, they focused on the societies into which the population groups organized themselves and studied the ways in which these social groups used and modified both their cultural and their natural heritages (Rouse 1986, Fig. 30).

Artifactual Research

Archaeology began in the Caribbean area, as elsewhere, with the discovery, description, and identification of buildings, tools, and other artifacts-and with their removal to private homes and public museums. At first, these items of material culture were collected individually; later, they were excavated in the form of assemblages from the sites where they had been deposited.

So far as is known, the first European settlers did not undertake archaeological research. It was not until 1740 that an explorer named Nicolas Hortsmann reported the discovery of petroglyphs (rock carvings) in the present country of Guyana (Osgood 1946, 21). In 1749, Father Juan de Talamanco, a Spanish historian and archaeologist, made a pioneer study of four carved stone figures of Taino Indian deities *(zemis)* that had been sent to him from the northern part of the Dominican Republic, and in 1775, Pedro del Prado, a Cuban, wrote about a stool *(dujo)* of the Tainos that had been found in the eastern part of

his country (Ortiz 1935, 71-72).

The first known exhibition of artifacts took place in Puerto Rico in 1854. It featured the collection of Jorge Latimer, a local merchant, that was eventually acquired by the Museum of Natural History of the smithsonian institution, Washington, D.C. (Coll y Toste 1907, 30- 31). In 1867, the government of British Guiana (now Guyana) established a museum to house items obtained from the local Indians and their sites. This museum, which bears the name of Walter Roth, a longtime director, includes natural as well as cultural objects. Its holdings in the former field are dominant, as is the collection in the Smithsonian's Museum of Natural History (Osgood 1946, 40-41).

Chronological Research

By the 1920s, professional archaeologists had accumulated enough assemblages to use as the basis for setting up sequences of local periods, and by the 1930s, they had formed sufficient sequences to begin synthesizing them into regional charts or chronologies. As in other parts of the world (see, e.g., Willey and Phillips 1958), they placed the local periods whose assemblages were most alike at the same heights in the charts on the assumption that the inhabitants who were able to mutually influence each other would have produced the most similar assemblages. They checked their results by hypothesizing the existence of horizons, that is, local complexes of cultural traits presumed to have been contemporaneous, and by determining whether these "time markers" actually did have a horizontal distribution on their charts. If they did not, the charts and hypotheses were reconciled in an effort to produce the most accurate and most practicable systems of local periods within which to organize the assemblages.

Gudmund Hatt, a professor at the University of Copenhagen, pioneered the new approach. In 1924, he undertook excavations in the formerly Danish part of the Virgin Islands, which the United States had just purchased from his country. He classified his finds into three successive groups and named each group after sites from which he had obtained typical assemblages: (1) Krum Bay, (2) Coral Bay-Longford, and (3) Magens Bay-Salt River. He placed (1) at the beginning of his sequence because it lacked ceramics and put (2) before (3) because, wherever the two occurred in the same site, the assemblages belonging to (2) underlay those in (3). He also noted that (2) was characterized by white-on-red-painted pottery, which had not previously been found in the Greater Antilles, whereas the modeled-incised pottery of (3) resembled that of the Taino Indians, who occupied the Greater Antilles in Columbus's time (Hatt 1924; Birgit F. Morse, personal communication).

In 1935, Cornelius Osgood, professor and curator of anthropology at Yale University, established a Caribbean anthropological program with the intention of tracing the spread of cultural traits from South, Middle, and North America into and out of the West Indies. He sent Froelich G. Rainey and irving rouse, his first two graduate students, to the West Indies with this aim in mind. Like Hatt, they realized that they would first have to do chronological research. Rainey, assisted by Rouse, set up a sequence of local periods in Haiti, which, like Hatt's, consisted of a preceramic period followed by two ceramic periods. The first of the two was marked by local pottery, and the second by pottery in the Taino style resembling that encountered by Hatt in the Virgin Islands. Rainey then went to Puerto Rico where he was able to distinguish two ceramic periods comparable to those Hatt had found in the Virgin Islands (Rainey 1940, 1941).

Rainey named the two ceramic periods in his Haitian sequence after typical sites, as Hatt had done in the Virgin Islands, but preferred to call the two Puerto Rican periods *Crab* and *Shell* in recognition of the fact that such food remains were dominant in their respective assemblages. He was ahead of his time in calling attention to this shift in the local diet, but Rouse found when he continued the Puerto Rican research that ecofacts such as food remains do not provide an adequate basis for chronological research because their presence in archaeological assemblages depends upon their availability and crabs and edible shellfish are limited to the coasts of large islands such as Puerto Rico. In his doctoral dissertation, therefore, Rouse (1939) substituted the names of typical sites for *Crab* and *Shell,* following the example of Hatt in the Virgin Islands and Rainey in Haiti.

Rouse also synthesized the three established sequences into a regional chronology and continues to refine and expand this chronology as new information becomes available, adding other local sequences to his charts as they have been formulated (Fig. 2).

the use of chronological charts as many Caribbeanists assumed that the newly developed techniques of measurement rendered the charts obsolete. Experience has shown, however, that neither is sufficient by itself. The results of the two procedures need to be checked against each other in order to identify and eliminate invalid dates and to improve the accuracy of the charts.

The charts and dates have been called measures of absolute time because their temporal values remain the same throughout the regions covered. Caribbeanists also work with measures of relative time known as *ages*, which vary from place to place. Five ages are distinguished: lithic, which is marked by stone chipping; archaic, by the addition of stone grinding; ceramic, by the first appearance of pottery; formative, by the development of ball and dance courts; and historic, by the introduction of writing. These ages have an irregular distribution when inserted in the chronological charts because the innovations that define them took place at different times in different places (Fig. 2).

Culture-Historical Research

Chronological charts, dates, and ages play a number of roles in research on the final two levels of interpretation. They may be used at the start of a project to identify sites, artifacts, and other information pertinent to the problem under study and to retrieve these data from the ground or from storage. To assist in doing the latter, the Yale Peabody Museum, which is now computerizing its Caribbean collections, is adding the name of the local period when each item was produced to the information already recorded about the nature of the item and the locality from which it came (Hill and Rouse 1994).

More important, the chronological systems have added a new dimension to the study of the history of cultural traits envisaged by Osgood when he founded the Yale Caribbean program. They have made it possible to reconstruct the trajectories of traits as they spread from period to period as well as from area to area and to study the changes that took place en route. For example, prior to the construction of chronological charts and the advent of radiometric dating, it was assumed that the custom of building ball and dance courts had diffused from Mexico to the Greater Antilles because there are superficial similarities between the courts in the two regions. Thanks to chronological research, local archaeologists have been able to show that the Antillean courts originated in Puerto Rico during the latter part of the first millennium a.d. and spread east and west from there without ever reaching Jamaica or central and western Cuba, the parts of the Antilles closest to Mexico. The courts became simpler as they spread (González Colón 1984; Rouse 1992, 112-116).

West Indian scholars originally assumed that all their finds had been produced by the ethnic groups who inhabited the area in the time of Columbus, that is, by the Guanahatabeys (also known as Ciboneys), Igneris, Tainos, and Island-Caribs (Map 3). For example, Heye attributed all of the Lesser Antillean artifacts in his Museum of the American Indian to the Island-Caribs. And when the Swedish archeologist Sven Lovén wrote his scholarly summary of West Indian archaeology and ethnology in the 1930s, he began it with a statement that all four ethnic groups had come full-blown from either North or South America (Lovén 1935, 2). That assumption relieved him of the necessity of studying the evolution of the groups' cultures, since that would have taken place before they reached the islands. He only needed to concern himself with the histories of individual traits.

Lovén's assumption soon began to be contradicted by the results of chronological research. Some sequences of local periods in the Greater Antilles have now been extended back to ca. 4000 b.c. (Rouse 1992, Fig. 14), and the ethnic groups encountered by Columbus could hardly have retained their separate identities over such a long period of time. Consequently, we must distinguish the historic ethnic groups from their prehistoric ancestors and predecessors.

Ethnic groups are defined in terms of sociocultural criteria, which are difficult to infer from prehistoric remains-hence the position of sociocultural research at the end of the sequence of stages under discussion here. In the absence of adequate knowledge of sociocultural criteria, Caribbeanists have formulated prehistoric

The descendants of the British, Danish, Dutch, and French colonists who settled alongside the Spaniards in the northern part of the West Indies are less interested in their Taino predecessors because the latter had disappeared before they arrived. These people prefer to study the remains of their own ancestors. In Jamaica, where the present population is almost entirely African-American, much work is being done on the slave quarters on sugar plantations and on the dwelling sites of escaped slaves.

Conditions are different in the Windward Islands, which are closer to South America. For several centuries after the extinction of the Tainos, the Island-Caribs continued to live there on islands not yet colonized by Europeans. So far, attempts to locate their remains have been unsuccessful.

While conserving the ruins of the first European settlement in South America, at Nueva Cadiz on Cubagua Island, Venezuela, Cruxent identified and excavated the quarter occupied by Indian slaves the Spaniards had brought there to dive for pearls (Rouse and Cruxent 1963, 134-138). The Indian quarters in the mission sites of Martinique, Trinidad, and Venezuela have received less attention. The subject does not greatly interest the modern inhabitants of those places because they do not trace their descent from the aborigines.

Sociocultural Research

On the final level of interpretation, Caribbeanists have shifted their attention from the peoples who produced the local cultures to the societies who used them (Watters 1976, 6). In doing so, they have focused on the societies' activities.

These scholars have been attracted to the study of societies by the presence of chiefdoms among the Tainos in the Greater Antilles and the Caquetios in western Venezuela (Spencer and Redmond 1992; Wilson 1990). Indeed, the term *chief* comes from the Taino language. The remains of the Tainos and their ancestors provide an opportunity to examine the rise of chiefdoms in isolation, uninfluenced by direct contact with previously developed chiefdoms or states.

Bernardo Vega (1980) once tried to trace the boundaries of the Taino chiefdoms by correlating them with the limits of the latest archaeologically defined peoples and cultures in Hispaniola, but he had little success. The two kinds of units appear to have had different distributions and to equate them is like treating apples as oranges.

Better results have been achieved by using the direct historical method, that is, by deriving models of the Taino chiefdoms from the ethnohistoric evidence and projecting the models back into prehistory along the Tainos' ancestral line. The historic chiefdoms consisted of relatively large groups of villages, each with its own chief, that owed allegiance to hierarchies of district and regional chiefs (Wilson 1990). The historic chiefdoms were also marked by ceremonial centers (i.e., clusters of ball and dance courts), elaborate burials, special types of ornaments, and intensive trade. Study of the spatial and temporal distribution of these criteria in the Greater Antilles during prehistoric time indicates that the local chiefdoms began to evolve during the late ceramic age and reached maturity in the formative age (Fig. 2).

Citing archaeological evidence that Bahamian villages were divided into halves, Keegan and Maclachlan (1989, 615-616) have theorized that if and when these halves split apart and became separate villages, they may have retained their affiliations and, as a result, have come to be ruled by district chiefs. The two scholars note that the Spaniards encountered such an incipient chiefdom on Aklin Island in the southern Bahamas and hypothesize that continued evolution farther south in Hispaniola would have led to the emergence there of regional chiefs and, hence, of the full chiefdoms encountered by Columbus.

The probability that their conclusions are correct is heightened by the fact that they obtained them by

working within the direct line of ancestry of the Tainos as established on the previous, culture-historical level of interpretation. Without knowledge of this ancestry, the sociocultural researchers would have been prone to error. For example, in a separate study Keegan (1992, 17-18) assumed that the Dominican Republic sequence of Musiepedro (also known as

posibles origenes (un estudio interpretativo). Santo Domingo: Museo del Hombre Dominicano.

Cartailhac, Emile (Edouard Phillipe)

(1845-1921)

Emile (Edouard Phillipe) Cartailhac was born in Marseilles, France. He became a geologist and worked with Edouard and Henri Filhol at the Musée d'Histoire Naturelle in Toulouse, and it was those two men who encouraged his interest in prehistory. In 1866, Cartailhac moved to Paris where he was influenced by French prehistorians gabriel de mortillet and henri breuil. Cartailhac and Mortillet were the founders

of the International Congress of Anthropology and Prehistoric Archaeology, which held its first meeting in Neuchâtel, Switzerland, in 1866. In 1869, Cartailhac bought the journal founded by Mortillet, *Materiaux pour l'histoire naturelle et primitive de l'homme,* an important publication for promoting prehistory and anthropology. Cartailhac edited and published the journal until 1890 when it was amalgamated with the *Revues d'Anthropologie and d'Ethnologie* to form *L'Anthropologie.*

Cartailhac is most famous for his role in the authentication of Paleolithic cave art. In the late nineteenth century quantities of moveable Paleolithic pieces of art, engravings, and sculptures on bone, ivory, and antler wood were exhumed from prehistoric sites along with animal and human bones and stone tools. These cave sites were occasionally decorated with engravings and representations on their walls and ceilings, and the idea that early prehistoric humans could create art as well as stone tools was rejected by Cartailhac and many other archaeologists, who argued that this cave art was neither old nor authentic. By the beginning of the twentieth century, however, this view began to be debated as more discoveries of carvings and cave paintings were made at sites that were clearly from the Upper Paleolithic period. The study of ethnology had grown, and there was now evidence of this kind of art, some of it contemporary, all over the world.

In 1902, Cartailhac and Breuil rediscovered and explored the magnificent cave of altamira in Spain. First found in 1879 by a local landowner and his daughter, the cave had been considered a forgery, rejected as an example of prehistoric art, and neglected. Visiting it certainly changed Cartailhac's mind-perhaps the

cave's vastness, the fact that it was so obviously and beautifully painted, or the fact that the animals it portrayed were so identifiably extinct-had such force that he wrote “Mea Culpa of a Skeptic” that same year in which he apologized and recognized the authenticity of Paleolithic cave art. Breuil and Cartailhac went on to explore the cave of Niaux in the Ariège in 1906.

Carter, Howard (1874-1939)

Born in London, the son of a talented painter and illustrator, Carter grew up in Norfolk. At the age of fifteen he first visited the country home of Baron Amherst of Hackney, whose important collection of Egyptian antiquities were to influence and inspire Carter's interest in archaeology. Baron Amherst was a supporter of the Egyptian Exploration Fund and it was via this connection that Howard Carter was hired

as a draftsman and copyist by the Archaeological Survey of Egypt. He received some training in Egyptology and hieroglyphics at the british museum before leaving for Egypt in 1891.

Howard Carter (left) at the entrance of Tutankhamun's tomb in Luxor, 1922

(Ann Ronan Picture Library)

Carter proved his worth as a competent and committed archaeological draftsman, going on to join sir flinders petrie at excavations at El-Amarna in 1892. Here Carter received training as an excavator from the best Egyptologist of his time. Carter's rapidly growing proficiency as an excavator and site manager, as well as an illustrator and photographer, was recognized when he was appointed to the post of chief inspector of antiquities in Upper Egypt and nubia in 1900. During the four years he spent in this position Carter undertook important conservation work but was left little time to excavate. However he was able to carry out detailed surveys of the Valley of the Kings, eventually locating the tombs of Thutmosis I and Queen Hatshepsut.

In 1904 Carter became chief inspector of Lower Egypt, but due to a diplomatic row he left the antiquities service and supported himself as an archaeological illustrator and draftsman, buying and selling in the antiquities trade and acting as a guide for wealthy visitors to the Valley of the Kings. In 1909 Carter was hired as expert assistant by Lord Carnarvon, who had decided he would like to try excavating in the Valley of the Kings. The two excavated other sites in Egypt for five years before they were allowed to work in the Valley of the Kings from 1914. World War I put their project on hold; then from 1918 to 1922 they searched the valley for a promising site. By this time Carnarvon had become disenchanted, and by 1922 he had decided this would be their last year. In November Carter telegraphed him in Britain to return: “At last have made wonderful discovery… a magnificent tomb with seals intact…”

Carter's long training in the practical business of excavating tombs, as well as his skill in recording their contents, made him an ideal person to undertake the task of clearing and documenting the tomb of tutankhamun. But his lack of formal education, his uneasiness about his social position, his obstinacy, and his lack of diplomacy were problematic. Tutankhamun's tomb transformed him from being an unknown journeyman excavator to a great archaeological discoverer. Clearing and cataloguing the finds changed archaeology in Egypt forever, and strife between Carter and the Antiquities Department lasted for decades. Carter's greatest gift to Egyptology and posterity was not a monumental scholarly work or new insights into the nature of ancient Egyptian life, but the eight years he spent organizing and supervising the work of a large team of photographers, conservators, and illustrators who patiently catalogued and recorded the contents of the tomb of this minor Pharaoh.

When work on the tomb finally finished in 1932 Carter spent much of his time in Luxor dreaming of discovering the tomb of Alexander the Great, or in London going about his business in the antiquities trade. He received few academic and public honors. He died in London in 1939.

Casa Grande

Casa Grande, located on the Gila River between Phoenix and Tuscon, Arizona, is a large Hohokam Classic-period ruin. Casa Grande is Spanish for Great House, and this structure is part of a large site with numerous compounds. Prehistoric occupation of the Southwest spans 12,000 years, and Casa Grande is the type-site (an exemplary site; the best example of a type of site) for the Hohokam Classic Period, a.d. 1100 to 1300. Named the first federal reservation for a prehistoric ruin in the United States, Casa Grande Ruins National Monument, the site includes a great house, ball court, and many compounds. No other great houses have been found, although two others may have been built between the Salt and Gila rivers.

The archaeology of Arizona has a long, complex history of exploration and excavation by amateurs and professionals. During the time of discovery in Arizona, research was aided by private funding, the creation of national monuments, and university research institutions. In

1935 several prominent publications were started across the United States: *american antiquity*, the *Journal of the Society for American Archaeology,* and *The Kiva.* Casa Grande Compound A was excavated in the early 1900s by Jesse Walter Fewkes of the newly formed Bureau of American Ethnology. Organized archaeological research began in 1927 with harold s. gladwin's expedition to Casa Grande to conduct stratigraphic excavation, which revealed evidence of two peoples and two potteries on the site. Gladwin founded the Gila Pueblo Archaeological Foundation, which is credited with consolidating the Hohokam research to a definite culture. In 1930 Emil W. Haury became Gladwin's assistant director, and his subsequent report on the Snaketown site defined Hohokam culture.

The particular housing style of Casa Grande is distinctive for the Hohokam Classic period. Casa Grande walls were built of piled-up adobe that was then dried and sometimes smoothed, polished, and plastered. The roof was made of juniper, pine, fir, and mesquite wood. The house had a lower story that was filled in, creating a mound, second and third stories with five rooms, and a top story with a single tower-like room. A compound was created by building walls surrounding the house.

Research on the Hohokam period reveals dramatic changes in architecture, pottery, and funeral customs. Changes have been attributed to causes as varied as drought, culture collapse, and migration. As in most southwestern sites, control of water is essential to survival. Casa Grande's location is a key to its function. Located at the end of an irrigation canal, it may be that the farmers controlled the water from the canal.

Catherwood, Frederick (1799-1854)

Frederick Catherwood and john lloyd stephens brought the great indigenous American civilizations of Central America to the attention of the world in the 1840s. Not only were Catherwood's detailed drawings evidence of this great unknown culture, but they also remain valuable sources for details of Maya glyphs.

Catherwood was born in London, trained as an architect, and became an accomplished artist and architectural draftsman. He spent many years traveling in Greece and the Near East studying archaeological sites and drawing ruins. He and the antiquarian Robert Hay worked together on one of

the first attempts to record Egyptian temples and monuments.

Catherwood returned to England, where the exhibition of his Near Eastern drawings brought him to the attention of the American adventurer John Lloyd Stephens, who had himself spent many years touring the archaeological sites of Greece, the Near East, and Egypt. The two developed a friendship based on their shared interest in archaeological exploration. It was Catherwood who alerted Stephen to two small books on the ruins of Central America, and together they began to plan an expedition to this unexplored region. Catherwood joined Stephens in New York where he had established a successful architectural practice. In the meantime Stephens wrote and published *Incidents of Travel in Arabia Petraea* in 1839 and another book about Greece, Turkey, Russia, and Poland, both of which became best-sellers and made him the fortune that was to finance an archaeological expedition to Central America.

The exotic ruined temples in the steamy jungles of Central America had, by this time, been noted by French explorers and artists such as Guillermo Dupaix and Jean Frederic Waldeck, and had provoked some interest in New York and Europe. In 1839, after Stephens managed to secure a useful presidential appointment as a diplomatic minister in Central America, the pair traveled to belize. The physical difficulties

Caton-Thompson, Gertrude

(1888-1985)

Born in London and educated in Eastbourne, Caton-Thompson was from an upper-middle-class family, and the early death of her father made her financially independent for the whole of her life. Until World War I she enjoyed an active social life in London and the country, and she traveled, describing her trips to Italy and Egypt during this time as the source of her later interest in archaeology.

Gertrude Caton-Thompson

(Hulton Getty)

In 1917 she was employed by the Ministry of Shipping and promoted to a senior secretarial post in which she attended the Paris Peace Conference. She declined a permanent appointment in the civil service and in 1921, aged 33, began her archaeological studies under Margaret Murray, Dorothea Bate and Sir w. m. flinders petrie at University College London. Caton-Thompson joined Petrie's excavations at abydos in Upper Egypt in 1921 and Murray's excavations in Malta in 1922. She spent the next year at Newnham College, Cambridge, attending courses in prehistory, geology, and anthropology.

In 1924 she returned to Egypt to work with Petrie and Brunton at Qau. While they investigated the cemetery, Caton-Thompson excavated the predynastic settlement site at Hemamieh and discovered the Badarian civilization. With Guy Brunton she wrote *The Badarian Civilization* (1928).

In 1925, accompanied by the Oxford geologist Elinor Gardner, Caton-Thompson began the Archaeological and Geological Survey of the northern Fayum, one of the first interdisciplinary surveys on settlement patterns and sequences in Egypt. Between 1927 and 1928 she excavated and worked with Gardner in northwestern Egypt on the desert margins of Lake Fayum, discovering two unknown Neolithic cultures that were later proven to be part of the Khartoum Neolithic. Their findings were published in *The Desert Fayum* (1934).

In 1929 Caton-Thompson was invited by the British Association for the Advancement of Science to investigate the great monumental ruins at great zimbabwe in southern Africa. She confirmed that these ruins belonged to an indigenous African culture and dated them to the eighth or ninth centuries a.d., producing evidence of Zimbabwe's links with Indian Ocean trade. One of her assistants on this project was the young Oxford graduate kathleen kenyon. Caton-Thompson's conclusions were published in *The*

Zimbabwe Culture (1931). In 1930 she and Elinor Gardner collaborated again on excavations of prehistoric sites at the Kharga Oasis. These were the first Saharan oasis sites to be excavated, and the first in a large research program on the investigation of the Paleolithic of

North Africa, culminating in the book *Kharga Oasis in Pre-history* (1952).

Caton-Thompson's last excavations in 1937 were of the fourth and fifth centuries b.c. Moon temple and tombs at Hureidha in the Hadhramaut of southern Arabia (now Yemen). These were the first scientific excavations in southern Arabia, and she was accompanied on this trip by Elinor Gardner and Dame Freya Stark. Their findings were written up in *The Tombs and Moon Temple of Hureidha, Hadramaut* in 1944.

Between 1940 and 1946 Caton-Thompson was president of the Prehistoric Society, the only woman to hold this position. In 1944 she was elected a fellow of the British Academy and became a fellow of University College, London. She retired from field work after World War II, but continued to research and visit excavations in East Africa. In 1946 she was awarded the Huxley Medal of the Royal Anthropological Institute, and in 1954 the Burton Medal from the Royal Asiatic Society. In 1954 she was made an honorary fellow of Newnham College Cambridge, and received an honorary Litt.D. from Cambridge University. Between 1946 and 1960 she was a governor of the School of Oriental and African Studies in London. In 1961 she became a founding member of the British School of History and Archaeology in East Africa (later the British Institute in East Africa) and served on its council for ten years, becoming an honorary member. Although Caton-Thompson was widely regarded as being an archaeologist of formidable skill and determination, she never sought a position in a museum or a university. It has been rumored that she was once offered the prestigious Disney chair of archaeology at the University of Cambridge and that she refused it. It is true that her personal wealth allowed Caton-Thompson the freedom to work outside the constraints of an institution, and there can be no doubt that she used this advantage to make highly significant contributions to the archaeology of Africa and Arabia.

Caylus, Comte de

(1692-1765)

Anne-Claude-Philippe de Tubières-Grimord, Comte de Caylus, was an antiquary and dilettante of the early-eighteenth century who traveled widely engaging in excavation (especially in Asia Minor) and observation. French art historian Alain Schnapp (1996, 238-242) has noted that Caylus, through an extensive system of contacts built up through patronage and a common interest in the ancient past, was able to conceive of the goals of the antiquary more broadly than others before him.

Committed to publication (especially his seven-volume *Recueil d'antiquités égyptiennes, étrusques, greques, et romaines* published between 1752 and 1757) and careful illustration and observation, Caylus developed a rational basis for the description and classification of the large number of objects in his collection, and in doing so, he influenced the course of French antiquarian studies in the eighteenth century.

Antonini) bear witness to the location of the town on the *Aquileia-Emona-Poetovio* road. The Roman town name is recorded on over a hundred inscriptions and on numerous milestones.

The town covered an area of about sixty-five hectares and had about 10,000 inhabitants at its peak during the second and third centuries when, to a large extent, it retained its Celtic character. The autochthonous component was reflected in onomastic material, the worship of Celtic divinities such as Epona, Noreia, Celeia, etc., and in the archaeological remains. Celeia did not exhibit a regular insular layout, because it developed out of a pre-existing settlement. Houses were located along roads, some of which were paved in the town's center and, in some sections, lined with colonnades. Excavations have revealed houses that were adorned with mosaics and frescos, dated from the first to the fourth century. A second-century Roman temple was located on the southern edge of the town. The forum, as yet not excavated, was probably situated in the southwestern part of the town.

Cemeteries were located in the western, southern, and northern parts of the town, along roads leading to emona, Neviodunum, and Poetovio. Marble vaults for some of the local eminent politicians can also be found some fifteen kilometers west of Celeia, where their estates were situated. The town wall was built after the great flood of the river Savinja at the end of the third century. The town was the seat of a diocese in the Early Christian period (fifth and early sixth centuries a.d.). A church decorated with richly colored mosaics, donatorial inscriptions, and a baptisterium were recorded, dating from this period. After the fall of the Roman Empire, the town was abandoned and its former inhabitants sought refuge in isolated upland settlements.

The first reports of the collection and protection of Roman monuments in Celje date from the end of the fifteenth century. Some of the monuments were incorporated into buildings and churches during the sixteenth through the eighteenth centuries. The foundation of the Municipal Museum (*Mestni muzej*) in 1882 helped to protect extant monuments and led to the first organized archaeological excavations of the site in 1889.

Celts

Ancient Sources

The name *Keltoi* (Celts), probably a corruption of another Greek word, *Galatoi*, was first used by Greek writers in possibly the early sixth century b.c. Avienus, in his *Ora maritima* written in the fourth century a.d., claimed to be using sources dating from the sixth century b.c., including a sailing manual known as the *Massiliot periplus.* Avienus referred to Great Britain as Albion and Ireland as Iernè, and he also mentioned Ligurians in southern France being pushed southward into Iberia by Celts.

Around 500 b.c., Hecataeus of Miletus, writing on the Phocaean Greek settlement at Massalia (Marseilles), placed it in the land of the Ligurians while identifying nearby Narbo (Narbonne) as Celtic. In 480 b.c., Herodotus, with a rather jumbled geographical sense, recorded that *Keltoi* were to be found at the headwaters of the Danube, near the city of Pyrene on the Turkish coast, and west of the Pillars of Hercules (Gibraltar). By this period, there is archaeological evidence of goods traded by Greeks to peoples in france and by Etruscans (as exemplified by a wealthy woman's grave of the late sixth century found at Vix on the river Saône in central France), so first-hand information from Greek

travelers would have been available. Although it seems highly doubtful that any one term was applied universally to the indigenous peoples of Europe north of the Alps, it seems only sensible to use two names almost interchangeably, following Julius Caesar, who wrote in the mid-first century b.c. of the inhabitants of what is now central France that the Romans called them Gauls, but they called themselves Celts.

In the mid-sixth century b.c., Greek exchange links with “barbarian” centers north of

In the mid-sixth century b.c., Greek exchange links with “barbarian” centers north of

In 279 b.c., groups of Celts invaded Greece and attacked the sanctuary of Apollo at Delphi, and may even have sacked it, but they were driven out. Some settled in the Balkans, where the Celtic capitol of Tylis was established somewhere in what is now Bulgaria, while others crossed into Anatolia (now central Turkey), where they were known as Galatae, or Galatians. They proved to be destabilizing intruders until they were defeated in about 233 b.c. by Antigonos I, and later by his son Eumenes II, who in thanks dedicated a sanctuary to Athene Nikephoros where the famous statues of the *Dying Gaul* and the *Gaul Killing Himself and His Wife* were first displayed. Known now only from Roman copies made in the second century a.d., these statues originally formed part of a victory complex incorporating, on the temple's balustrade, a frieze of military trophies that showed weapons and armor that were comparable to those of contemporary central and western Europe.

The Renaissance and After

Many Greek and Roman sources refer to Celts, and some of them are not just geographical descriptions but also refer to physical appearance, social customs, and traits such as boastfulness. Many of these sources were lost in the upheavals of the fifth century a.d. and later following the collapse of the Roman Empire. It was not until the Renaissance and the fifteenth century a.d. that many of these sources once again became available in western and central Europe and were once again widely used by scholars.

An elaborate Battersea shield made in bronze in the first century b.c. by Celts and discovered in London

(The Art Archive/British Museum)

In Britain, this “rediscovery” of past societies led to the recognition of “ancient Britons” in the writings of antiquarians such as that of the first state archaeologist, william camden in *Britannia* 1586, and a century later, john aubrey's great but never published work, *Monumenta Britannica,* begun in 1663. It was observed that classical writers, in writing about Britain, had mentioned, not Celts, but “Pretanni.” In 1723, william stukeley (1687-1765), who helped found the society of antiquaries of london in 1717, entitled his unpublished draft of a study of the great Neolithic stone circle of avebury “The History of the Temples of the Ancient Celts.” Stukeley was both the great recorder of prehistoric antiquities, such as Avebury and Stonehenge, and also the ancestor of modern Druidism and “Celtomania.” edward lhwyd (1660-1709), assistant keeper and later keeper of the ashmolean museum in Oxford, England, the oldest public museum in Europe, identified Welsh, Irish Gaelic, Scottish Gaelic, and Gaulish as different variants of Celtic languages deriving from invaders. This was a brave claim even for its day since the question of the origins and subsequent insular developments of Celtic remains a fraught topic.

There are no surviving pre-Roman texts since presumed Continental early Celtic speakers, although aware of writing, chose to pass wisdom orally, and writing that does exist from northern Italy, Spain, and southern Gaul is restricted

to inscriptions. The earliest of these are in what is called a Lepontic script and dates to about 600 b.c. There is, in fact, much uncertainty as to whether there is, for example, any real evidence for the introduction of Celtic into the British Isles before the sixth century b.c., and there is absolutely no evidence of where or when Celtic speakers first reached Ireland.

Another problem concerns the traces of what have been claimed to be the Celtic or, following Pliny, the Celt-Iberian culture of central Spain. Arguments are divided between a settlement of the region from, and a much more complex admixture of various introduced elements with, the autochthonous population of the high Mesetas. Clearly, the Greek colonial settlements from the mid-first millennium played an important role, as can be seen in both metal types and pottery, although it is noticeable that objects typical of the late Hallstatt and la tène phases in central and western Europe are almost totally absent. By the third century, the Celt-Iberians had developed their own script.

In Continental Europe, pioneering Celtic studies were very much the product of the emerging democracies that accompanied the American and French Revolutions in the last quarter of the eighteenth century when there was a universal search for national roots. Rediscovery of the Celts, archaeologically speaking, took place at the time of the creation of romanticism, which was itself a child of new nationalisms. The Europe formerly divided by class changed to a Europe divided by ethnic solidarity and focused on the nation state while making obeisance to the rights of the masses. Among these romantic manifestations were the “translations” in 1762-1763 by James Macpherson of poems attributed to a completely fictitious third-century-b.c. poet, Ossian, which took Europe by storm. This bogus mythology was welcomed as the true “Celtic twilight” by painters such as Angelika Kaufmann and Jean-Auguste Dominique Ingres, who in 1812-1813 painted the *Dream of Ossian.* A little earlier, in 1802, Anne-Louis Girodet de Roussy Triosson, in his massive work presented to Emperor Napoleon, depicted Ossian welcoming into Valhalla the dead French heroes of the war of liberty against the Prussians.

Muddled mythologies apart, the beginning of a serious interest in folk music reflected in the number of “Scottish” compositions by composers such as Haydn, Beethoven, and Mendelssohn also point to the re-creation of the Scottish Celts as a symbol of the new Europe of “the age of the democratic revolution.” Within Britain, the rediscovery of this mythical Celtic past coincided with the destruction of the Scottish highlands after the 1745 Jacobite rebellion and its brutal repression by the Duke of Cumberland-and the end at that time of Scottish aspirations to independence. “Celts” or “Scots” could be enclosed between book covers or presented in genteel concert halls just as nature, no longer a threat in a period of urbanization and industrialization, could be domesticated and hung on walls as landscape painting.

In 1816, Danish archaeologist christian jürgensen thomsen published his three-age system of stone, bronze, and iron, and between 1846 and 1865, Johann Georg Ramsauer, surveyor of the imperial salt mines at Hallstatt in upper Austria, discovered a rich cemetery of about 1,000 graves associated with one phase of the prehistoric mines, dating from the seventh to fifth centuries b.c. Ramsauer claimed that the graves were Celtic, a matter still disputed although Hallstatt became the name generally applied to temperate Europe until the first half of the Iron Age. Because of the preservative effects of salt, much fabric, leather, and worked wood were also found in Hallstatt's three major areas of prehistoric mining. The mining techniques seem to have been borrowed from those used much earlier in mining the copper of the eastern Alps, with shafts extending up to 350 meters below the surface, and it was clearly a hazardous occupation. Although much of this material was discovered accidentally in the course of more recent mining activities, a major examination of the ancient mining system has been carried out by Fritz Eckart Barth, and Roy Hodson has applied modern statistical analyses to the contents of the cemetery.

Old Wealth, Modern Discoveries

The Hallstatt Iron Age is generally distinguished by its rich barrow burials, usually comprising

and while there was continuing debate as to whether these were relics of the Romans or of local Teutonic tribes, the presence in the graves of imports from the Mediterranean was recognized as being significant.

La Tène and the Rise of a New Power North of the Alps

During the fifth century b.c., the Hallstatt centers of power gradually waned, and there are signs that there was unrest: rich barrow burials were robbed, and princely centers, such as at Heuneburg, were destroyed. The old centers were apparently replaced in status by centers of power to the north and west, in the Champagne-Ardennes region of northern France and Belgium, in the iron-rich Hunsrück-Eifel region between the Rhine and the Mosel Rivers, and in Bohemia. The burial mounds of this period are smaller, there are fewer southern imports (and those are mostly Etruscan), and the types and styles of weapons and ornaments change. Lost wax casting was replaced by bivalve molds for bronze ware and the hammering and stamping of sheet gold. The style of decoration changed, too, from simple rectangular incised designs to the creation of fantastic beasts or ambiguous human heads on fibulae, neck and arm rings, belt hooks, horse harnesses, and chariot fittings in the fifth century b.c. This period lasted until the expansion of the Roman Empire over territories from Britain to Romania and from Italy to Jutland during the period from the late second century b.c. to the later first century a.d.

The first attempt to establish a relative chronology for the Iron Age was made by the Swede hans hildebrand in 1872. He was followed by the great French archaeologist gabriel de mortillet in 1875 and then by Otto Tischler in 1881, whose scheme was in turn refined by the Bavarian paul reinecke in a number of papers beginning in 1902. As a result, La Tène is still generally divided into early, middle, and late (or I, II, and III) in France, Italy, and Switzerland and into A, B (=I), C (=II), and D (=III) in Austria, Germany, the czech republic, and the rest of central and eastern Europe. Although this chronology, which is largely based on the analysis of cemetery evidence in southern Germany and western Switzerland, has undoubtedly been applied too readily to very different bodies of material, with the exception of the British Isles, it has not been superseded or challenged.

The site of La Tène is on the northernmost tip of Lake Neuchâtel in western Switzerland. The collector Hansli Kopp began gathering material from the lake in 1857, and the artificial lowering of the Jura Lakes system between 1868 and 1900 led to systematic excavation by Émile Vouga, beginning in 1885, and his son, Paul Vouga, commencing in 1906. After 1872, the site's name became accepted as designating the second phase of the Iron Age. Most of what was found in the Vougas' excavations was iron, wood, and wickerwork, including the piles of a collapsed bridge, iron swords, decorated scabbards, spearheads, shield bosses, fibulae, belt hooks, axes, knives, and shears. There were few or no female objects and virtually no pottery, glass, or bronze, but there was a considerable amount of cattle and horse bones and some human skeletal remains, including skulls with clear cut marks. With the exception of coins and iron swords and their scabbards, the bulk of material from La Tène remains scientifically unstudied, and the site is now largely assigned to the period of maximum Celtic expansion, with the La Tène C (III) tree-ring dating of wooden shields giving a date of 229 b.c. There is still disagreement as to whether it was a ritual site or a trading post.

From the earlier La Tène phase (ca. 500-300 b.c.), high-status graves provide evidence of long-distance trade, particularly in coral, amber, cowrie shells from the eastern Mediterranean, and even silk, but imports were fewer and generally comprised bronze Etruscan situlae (containers), with the importance of Etruria north of the Alps first being recognized by Herman Gunthe in 1871. The drinking service was still part of the funerary rite, but it now consisted of Etruscan bronze *stamnoi* (double-handled wine-mixing jars and bronze spouted flagons) and either imported or locally made Celtic imitations. One of these, with a close affinity to one discovered in a chariot grave at the salt-mining

complex at Dürrnberg-bei-Hallein

wealth and source of precious metal, as exemplified by the gold from the late-third-century Waldalgesheim chariot grave, increasingly-and of particular value to the archaeologist-coin types indicate local tribal areas, although with the expansion of trading between centers, coins of high value became distributed far beyond their point of origin.

Certain features of the *oppida,* which evolved in the course of the second century b.c. as tribal centers supported by open settlements and individual farmsteads, point to the evolution of urbanization for the first time north of the Alps. The degree to which this development may have been influenced by the nature of the town planning of contemporary Mediterranean society is a matter of debate, but it is clear from modern excavations of 200 or so sites in Hungary, the Czech and Slovak republics, Switzerland, Luxembourg, and France that there are considerably more variations than Caesar's general description might lead one to expect. Even so, the similarities in the association of the *oppida* and their attendant open sites with such activities as large-scale pottery making, smelting and the forging of iron, glass production, and the minting of coins remain as valid today as when first noted by French proto-historian joseph déchelette.

Déchelette excavated Mont Beuvray and was struck by the similarity in material from the French site and material obtained, largely unsystematically, at Stradonice in Bohemia and published in 1903 by Josef Píc, the head of the Archaeology Department of the National Museum in Prague. Déchelette translated Píc's excavation report and elaborated his own views in his massive *Manuel d'archéologie préhistorique, celtique et gallo-romain,* which was first published between 1908 and 1914 but in many ways has never been superseded.

Modern Research and the Case of the Vanishing Celts

A long series of excavation campaigns at Manching near the Bavarian town of Ingolstadt that commenced in 1938 marks the most thorough examination of an *oppidum,* although to date, only a fraction of the 380-hectare site with its roughly circular 7-meter-long *murus gallicus* (Gallic wall) has been examined. The site, a center of the Vindelici, the dominant tribe of the region until subjugated by Rome in 15 b.c., evolved from a series of settlements with their attendant cemeteries in the third century b.c. to the main enclosure, which evolved over a couple of generations during which time signs of burning indicate the strength of local rivalries. Inside the enclosure, regular habitation areas and industrial zones repeat patterns discovered elsewhere. Long-range trade and perhaps intermarriage are indicated by the occasional discovery of forms of female ornaments originating in the alpine region. Even more striking is the discovery of a model tree with ivy leaves made of gold-foil-covered wood whose parallels are with Italo-Greek gold work. The existence of a tree cult was recorded by classical historians.

Other evidence of later La Tène cult practices come from the vicinity of a number of square- or rectangular-banked enclosures, several with deep well shafts and square internal structures. At least some of the latter have been interpreted as temples, and among finds that seem to support their ritual use are the striking heraldic wooden animal figures from a well at Fellbach-Schmiden outside Stuttgart, which date to the late second or early first century b.c., and the somewhat older stone head of a Celt accidentally discovered in several pieces in a pit just outside a rectangular enclosure, which may have had a ritual purpose, at Ms˘ecké Zehrovice west of Prague.

In the nineteenth century, only in France was it possible to combine both Gauls and Romans in a construct of national identity-the Franks, who had given their name to the country, vanished below the horizon of popular interest. In other parts of Europe, however, the Celts, unlike Germans, Slavs, and Hungarians, were not associated with national governments nor, except in Ireland, with aspirations to separate nationhood. Since World War II, the Celts, with their widespread historical presence across

Europe, Turkey, and North Africa, have been seen as an antidote to the type of essential or genetically based racism that caused the Holocaust. As the precursors of national states, they seem to offer

Cesnola, Luigi Palma di

(1832-1904)

General Luigi Palma di Cesnola typifies the rapacious style of mid-nineteenth-century "archaeological" activity in the eastern Mediterranean. He had a varied and adventurous life, which included service in the American Civil War. Later, while resident in cyprus between 1865 and 1875 (and accredited as both the U.S. and the Russian consul), he arranged excavations at numerous sites and opened many thousands of Bronze and Iron Age tombs in the search for antiquities. The bulk of his vast collection of was eventually acquired by the Metropolitan Museum in New York City, and in return, Cesnola was appointed director of the museum in 1879. His methods both in the field and at the museum led to much criticism, especially regarding his practice of reconstructing statues from scattered pieces.

Chaco Canyon

Chaco Canyon is a natural canyon with thirteen major Native American ruins, which was named a National Historical Park in 1907. The park is located in the northwest quadrant of New Mexico. Chaco Canyon's abandonment by the Western Anasazi people remains one of the great mysteries of Southwestern prehistory. The abandoned sites contain large multistoried ruins along the Chaco River, a tributary to the San Juan River. The canyon sustained 1,500 years of prehistory and over a century of

scholarly research.

Chaco Canyon was first described by Gregg in 1844. Archaeological work was begun by Adolf Bandelier, then nels nelson (1914), edgar lee hewett (1906), Judd (1922), alfred kidder (1915), and Mera (1935). Work was later continued by Hayes (1975) and Judge (1976). Over the years, the major research questions considered (1) the origins of specific culture traits in modern Eastern Pueblos, (2) cause for abandonment before European contact, and (3) the role of environment in social organization for people who depend on agriculture.

Studies of change over time in Chaco Canyon are observed through changes in ceramic styles, architectural details, settlement patterns, migration, and social interaction. The semi-arid climate with unpredictable rainfall is a major component as well, and may have contributed to the abandonment of Chaco Canyon after crop failures. Climate study has been an essential part of research on Chaco Canyon. Modern patterns have been compared to ancient patterns through tree-ring dating, or dendroclimatological reconstruction. Fossil pollen (palynological) studies and temperature studies also contributed to reconstructing dwelling and growing cycles. Tree-ring data for Chaco Canyon during a.d. 650-1150 show more-than-average rainfall and then a drier-than-average time afterward. At that time the former adaptations to drought may no longer have been effective.

Champollion, Jean-François

(1790-1832)

Although he was to gain lasting fame as the person most responsible for the decipherment of Egyptian hieroglyphics, Champollion was famous long before Egypt. By the age of 16 he could speak and read six ancient oriental languages, in addition to Latin and Greek, and at 19 he became a professor of history at the university in Grenoble in France.

Jean-François Champollion

(Ann Ronan Picture Library)

The initial breakthrough in understanding ancient Egyptian hieroglyphics was the result of a study of the Rosetta Stone by a young English physicist, Thomas Young. The stone had been seized from the defeated French army in Egypt and presented by George III to the british museum. It was Young who realized that the stone was engraved with three versions of the same text-one in Greek, one in demotic Egyptian, and the last in ancient Egyptian hieroglyphs.

Champollion built on Young's work and took it further still, establishing an entire list of hieroglyphic signs and their Greek equivalents. Champollion recognized that some of the hieroglyphs were alphabetic, some were syllabic, and some were determinative, i.e., standing for a whole idea or object previously expressed. While his theories were bitterly disputed by other scholars at the time, this fundamental classification proved to be the key to understanding and translating this ancient writing system and contributed to the recognition of the study of linguistics as a scientific discipline.

Champollion became curator of the Egyptian collection at the louvre in 1826, conducting an archaeological expedition to Egypt in 1828. In 1831 the chair of Egyptian Antiquities was created especially for him at the College de France. In addition to an Egyptian grammar (1836- 1841) and an Egyptian dictionary (1842-1843), his works included *Précis du système hiéroglyphique* in 1824 and *Panthéon égyptien ou collection des personnages mythologiques de l'ancienne Egypt* in 1823-1825.

Chang, Kwang-chi

(1931-2001)

Born in Beijing, china, Kwang-chi Chang was the second child of Chang Wojun, a well-known Taiwanese historian. During his childhood years, Chang witnessed the corruption of the government, the suffering of ordinary people, and the invasion of the Japanese; he was also influenced by leftist ideology. Chang left Beijing for Taiwan with his family in 1946 when Taiwan was returned to China after its Japanese occupation. His experience in Beijing led him to develop a strong nationalist consciousness and sympathy for socialist beliefs, which later caused him to be jailed for a year as a political prisoner in Taiwan when he was eighteen. This experience apparently had a great impact on his decision to become an anthropologist in order to understand "why humans are the way they are" (Chang 1998, 75).

Chang was always a top student throughout his school years and was the favorite student of li chi (known as the father of Chinese archaeology for his contribution to the excavations at anyang) in the Department of Anthropology at Taiwan University. In 1955, Chang started his graduate studies in the Department of Anthropology at Harvard University, working with H. Movius, Jr., C. Kluckhohn, gordon r. willey, and L. Ward. After receiving a Ph.D. in 1960, he taught for many years at Yale University, where he established himself as a first-rate scholar in the discipline. In 1977 he returned to Harvard as the John E. Hudson Professor of Archaeology. He then became a member of the National Academy of Sciences in the United States and also served as vice-president of Academia Sinica in Taipei in the mid-1990s.

For decades, Chang's major contributions have bridged the gap between eastern and western archaeologists by presenting Chinese archaeology to anthropological circles in the western world. He, however, did not limit his interests to Chinese archaeology. During the 1960s and 1970s he stood at the forefront of U.S. anthropology with regard to archaeological theory and was a leader in general methodological debates in archaeology and in the study of settlement patterns. As a native of Taiwan, he was a major player in establishing the field of Taiwanese archaeology. From the 1980s, in addition to academic pursuits, he made a tremendous effort to build collaborative relationships with archaeologists in the People's Republic of China. In the 1990s, he overcame all political and administrative barriers to initiating the first Sino-American collaborative field project in China since the World War II. This project in Shangqiu, Henan, is dedicated to searching for the origins of the Shang dynasty, which has been a long-standing question haunting several generations of Chinese archaeologists (Ferrie 1995).

Over the years, Chang published numerous articles and monographs in English and Chinese, and the list of his publications is forty-one pages long (Murowchick 1999). His scholarly masterpieces include four editions of *Archaeology of Ancient China* (1963, 1968, 1977, 1986), *Shang Civilization* (1980), and *Art, Myth, and Ritual* (1983). These have been the most comprehensive and authoritative accounts of Chinese archaeology available in the English language for several decades, and they have been translated into many languages. His publications in Chinese have been equally influential. Presenting many fresh views of Chinese civilization, his *Six Lectures in Archaeology* (1986) and *The Bronze Age of China* (1983), both published in Beijing, have especially enlightened archaeologists in China.

In addition to archaeology, Chang had broad interests in many fields including art history, cultural anthropology, history, paleography, the anthropology of food, and sport. For four decades he "brought up" several generations of East and Southeast Asian archaeologists, and his former students are now spread over many parts of the world including North America, Europe, Asia, and Australia. Known to his colleagues, friends, and students as "K. C.," Chang was a kind, warm, sympathetic, hardworking, and charismatic man with great wisdom and an excellent sense of humor. His extraordinary

determination to overcome any difficulties in life is evident in his struggle with a devastating illness, which eventually claimed him in January 2001.

Chavín

Chavín is thought to have been a dominant culture in ancient peru between about 900 and 200 b.c. It was comprehensively defined by julio tello in the 1930s, but the nature and extent of the Chavín culture continues to be hotly debated. Although the core of Chavín culture can be discussed without difficulty at the type site of Chavín de Huantar, it now seems likely that Chavín art styles (particularly textiles) and larger-scale urban sites (found in the initial period and early-horizon deposits of sites in the northern highlands and the coastal areas of Peru) may have developed prior to the foundation of Chavín de Huantar. Thus, Tello's original conception of Chavín as being the progenitor culture of civilization in the Andes is now questionable.

Chichén Itzá

Chichén Itzá, one of the largest and most important of the Maya ruins, is located on the low, broad plain that forms the northern part of mexico's Yucatán Peninsula. This peninsula is composed of limestone (it is an ancient, shallow seafloor), and there is little surface water in the region: the rain soaks through the thin soil and forms caves below the surface. If the roofs of these caves collapse, sinkholes (*cenotes* in Spanish, from the Maya word *tz'onot*) are formed. Chichén Itzá has several of these sinkholes within the confines of the site. The term *Chichén Itzá,* which means “the mouth of the well of Itza,” is derived from the name of the largest of these sinkholes-the so-called Sacred Well. Chichén Itzá has been the source of considerable controversy over the years, largely involving the ethnic identity of the “Itza” and the two rather distinct architectural and art styles that exist at the site. Even the chronology of the site has long been in dispute. Traditionally, Chichén Itzá's history has been divided into two major phases. In the earlier phase (ca. a.d. 800-1000) the site was purely Maya, and its buildings were in a regional style called Puuk (Puuc). Then, around a.d. 1000, the site was taken over by a group whom some identified as the “toltecs,” from the site of Tula some 70 kilometers north of Mexico City. The Toltec foreigners (according to this traditional view of Chichén Itzá history) gained control of the site through conquest, and they controlled much of the northern part of the Yucatán Peninsula until shortly after a.d. 1200.

There are several problems with this reconstruction, which is still common in popular literature. For example, the dedication date (carved in Maya hieroglyphs) of the Great Ballcourt at Chichén Itzá was 18 November 864-impossibly early for a building argued to be one of the sites's quintessentially “Toltec” buildings. Additionally, “Maya” architecture and art at Chichén Itzá are not as clearly separated and consistently overlain by “Toltec” architecture and art as was once thought. The current view is that there is considerable overlap between the two styles, although how much overlap is still a source of dispute, as is the absolute chronology of the site. It has been argued by some that Chichén Itzá may represent a kind of “cosmopolitan style” of art and architecture, borrowing freely from several areas for inspiration.

Further, the art and architecture of Chichén Itzá seems to reflect a different order of government at this northern Yucatán site. There are none of the grandiose portraits of individual kings that are the hallmark of the kingdoms to the south. Rather, the hieroglyphs of Chichén Itzá describe a multiplicity of contemporary individuals, and the site's art shows parades of lords: it appears that the site may have been ruled by some sort of council rather than a single succession of kings.

Chavín

Chavín is thought to have been a dominant culture in ancient peru between about 900 and 200 b.c. It was comprehensively defined by julio tello in the 1930s, but the nature and extent of the Chavín culture continues to be hotly debated. Although the core of Chavín culture can be discussed without difficulty at the type site of Chavín de Huantar, it now seems likely that Chavín art styles (particularly textiles) and larger-scale urban sites (found in the initial period and early-horizon deposits of sites in the northern highlands and the coastal areas of Peru) may have developed prior to the foundation of Chavín de Huantar. Thus, Tello's original conception of Chavín as being the progenitor culture of civilization in the Andes is now questionable.

Chichén Itzá

Chichén Itzá, one of the largest and most important of the Maya ruins, is located on the low, broad plain that forms the northern part of mexico's Yucatán Peninsula. This peninsula is composed of limestone (it is an ancient, shallow seafloor), and there is little surface water in the region: the rain soaks through the thin soil and forms caves below the surface. If the roofs of these caves collapse, sinkholes (*cenotes* in Spanish, from the Maya word *tz'onot*) are formed. Chichén Itzá has several of these sinkholes within the confines of the site. The term *Chichén Itzá,* which means “the mouth of the well of Itza,” is derived from the name of the largest of these sinkholes-the so-called Sacred Well. Chichén Itzá has been the source of considerable controversy over the years, largely involving the ethnic identity of the “Itza” and the two rather distinct architectural and art styles that exist at the site. Even the chronology of the site has long been in dispute. Traditionally, Chichén Itzá's history has been divided into two major phases. In the earlier phase (ca. a.d. 800-1000) the site was purely Maya, and its buildings were in a regional style called Puuk (Puuc). Then, around a.d. 1000, the site was taken over by a group whom some identified as the “toltecs,” from the site of Tula some 70 kilometers north of Mexico City. The Toltec foreigners (according to this traditional view of Chichén Itzá history) gained control of the site through conquest, and they controlled much of the northern part of the Yucatán Peninsula until shortly after a.d. 1200.

There are several problems with this reconstruction, which is still common in popular literature. For example, the dedication date (carved in Maya hieroglyphs) of the Great Ballcourt at Chichén Itzá was 18 November 864-impossibly early for a building argued to be one of the sites's quintessentially “Toltec” buildings. Additionally, “Maya” architecture and art at Chichén Itzá are not as clearly separated and consistently overlain by “Toltec” architecture and art as was once thought. The current view is that there is considerable overlap between the two styles, although how much overlap is still a source of dispute, as is the absolute chronology of the site. It has been argued by some that Chichén Itzá may represent a kind of “cosmopolitan style” of art and architecture, borrowing freely from several areas for inspiration.

Further, the art and architecture of Chichén Itzá seems to reflect a different order of government at this northern Yucatán site. There are none of the grandiose portraits of individual kings that are the hallmark of the kingdoms to the south. Rather, the hieroglyphs of Chichén Itzá describe a multiplicity of contemporary individuals, and the site's art shows parades of lords: it appears that the site may have been ruled by some sort of council rather than a single succession of kings.

Who were the Itza, the people who are said to have ruled Chichén Itzá? Later descriptions

PREV NEXT

call the Itza foreigners and tricksters and portray them as “lewd” and unable to speak fluently. This depiction clearly indicates that they were foreigners-but whether they were Toltecs from Tula (the traditional view) or some other group has remained a subject of debate. Much evidence points to the southern Gulf of Mexico region where Mexicanized Maya groups lived and honed their skills as some of Mesoamerica's greatest long-distance traders. More recently, evidence has arisen to indicate that the Itza might have been refugees from the internecine warfare of the southern Maya lowlands in the late-classic period. The name *Itza,* in fact, shows up in classic-period texts from Motul de San José, a site not far from Tikal, so we know that some Itza lived and ruled there. Maya chronicles describe a long series of migrations from the Itza homeland until these people founded and settled in Chichén Itzá.

Dominating the site of Chichén Itzá are the buildings arranged on a huge platform that is 450 by 600 meters in area. Near the center of this platform is the so-called Castillo, or Castle, the tallest temple-pyramid at the site. On the western edge of the platform is the largest ballcourt in Mesoamerica. The Great Ballcourt is richly decorated with imagery symbolizing the Mesoamerican mythology of creation and the sacred charter of government, as well as murals that document the wars of conquest that gave the victors the right to rule.

Chichén Itzá is also famous for its Sacred Well, which was used as a place of ritual offerings by the Maya even after the site was abandoned. The well has been dredged several times, and thousands of archaeological pieces have been recovered. These include huge numbers of carved jade artifacts; wooden objects such as scepters, weapons, and idols; ceramics; balls of resin incense; human bones; and bells, disks, and figurines of gold. Chichén Itzá in general and the Sacred Well in particular were used as places of pilgrimage well into the Spanish colonial period, much to the consternation of the Spanish priests and administrators.

According to legend, the city fell through sorcery and trickery, but almost certainly its demise was due to fighting among rival lineages. Maya chronicles from the Spanish colonial period say that in a.d. 1221, the ruler of Chichén Itzá was defeated by the ruler of the nearby, emergent city of Mayapan and that the Itza were driven from their capital. Today Chichén Itzá is one of the most frequently visited archaeological sites in Mexico. It is a dramatic location, with broad vistas punctuated by some of the most grandiose pyramids and decorated temples in the entire Maya area.

Maya Civilization

Childe, Vere Gordon

(1892-1957)

vere gordon childe, the most celebrated archaeological synthesizer and theorist of his generation, was born in North Sydney, Australia, 14 April 1892. He graduated from Sydney University in 1913 with first-class honors in Latin, Greek, and philosophy. At Oxford University in England, his interest in European prehistory was aroused by a desire to locate the homeland of the Indo-Europeans. He returned to Australia in 1916 and became involved in anticonscription and Labour politics, serving from 1919 to 1921 as private secretary to John Storey, the Labour premier of New South Wales.

After the defeat of the Labour government of New South Wales in 1921, Childe returned to the study of European prehistory, paying special attention to the Balkans. In 1925, he published *The Dawn of*

European Civilization, a milestone in the development of culture-historical archaeology. Childe combined the concept of "the archaeological culture," refined by the German archaeologist gustaf kossinna to try to trace the histories of specific peoples in the archaeological record, with the diffusionism of the Swedish archaeologist oscar montelius. Montelius believed that in prehistoric times technological skills had spread to Europe from their place of origin in the Middle East. Like his Oxford mentors, arthur evans and john myres, Childe stressed the creativity with which Europeans had utilized this knowledge.

Childe was the Abercromby Professor of Prehistoric Archaeology at the University of Edinburgh from 1927 to 1946 and professor of European

archaeology and director of the Institute of Archaeology at the University of London from 1946 until he retired in 1956. Throughout these years he carried out numerous archaeological excavations and surveys in Scotland and also visited many excavations in Europe and the Middle East.

Although Childe was primarily a European prehistorian, for the rest of his life he sought a better understanding of cultural change. Beginning with *The Most Ancient East* (1928), he sought to delineate the revolutionary impacts that the development of agriculture and bronze working had on various parts of the Middle East and Europe. Instead of treating technological innovation as an independent variable that brought about cultural change, he sought to trace the reciprocal relations between it and specific environments, economies, and political systems. He saw changes occurring in a multilinear, not a unilinear, fashion.

In 1935, Childe visited the Soviet Union. Although he disapproved of the dogmatism imposed on Soviet archaeologists, he was impressed by the attention being paid to how ordinary people lived in prehistoric times and by Marxist interpretations of cultural evolution. In *Man Makes Himself* (1936) and *What Happened in History* (1942), Childe examined, from an evolutionary perspective, how elites and inflexible belief systems could halt economic and social progress but only at the cost of undermining a society's ability to compete with more progressive neighbors.

After World War II, disillusionment with the declining quality of Soviet archaeology led Childe to acquire a more profound understanding of Marxism as an analytical tool and to try to apply it to the interpretation of archaeological data. He attempted to reconcile the observation that all human behavior is culturally mediated with a materialist view of causality. In *Prehistory of European Society* (1958), he stressed that social and political organization provided the framework within which all archaeological data could most productively be understood.

Troubled by failing health and fearing that incipient senility was preventing him from devising new procedures for inferring social organization from archaeological data, Childe, jumped to his death from a cliff in the Blue Mountains of Australia on 19 October 1957.

Chile

Prescientific Period (1400-1830)

Pre-Columbian society described the past as a series of mythical epochs, and this idea was documented at the time of European contact by the first chroniclers of the sixteenth century. Even today, some ethnic minorities can retell the ancient epic stories about their origins. There are descriptions dating from the sixteenth century of “excavations” of Indian tombs in search of buried treasure or motivated by curiosity abut the rituals of Indian “paganism.” Of great importance for the study of pre-Columbian society are the numerous ethnohistoric documents generated by the Spanish administration during the period of Indian resistance. In fact, from the examination of these records, architectonic, ritual, and material culture traits have been explained and are of prime importance in the reconstitution of archaeological events.

During the sixteenth century, the Spanish encountered colossal ruins in the middle of a living Inca society

that were evidence of a distant past. The invaders' medieval worldview, along with their creationist dogmas and limited biblical chronology, did not stimulate the need to systematically record such ruins. However, some chroniclers proposed that ancient hunters must have carried out the first peopling of the Americas. Others, such as Father Lozano, writing in the early seventeenth century, devoted himself to the study of the origin of the Indians of the New World and West Indies *(Orígen de los indios del Nuevo Mundo e Indias Occidentales).*

Between the eighteenth and nineteenth centuries, various European travelers and scientists on neocolonial and scientific explorations visited the New World, and their accounts provide

Chile

Prescientific Period (1400-1830)

Pre-Columbian society described the past as a series of mythical epochs, and this idea was documented at the time of European contact by the first chroniclers of the sixteenth century. Even today, some ethnic minorities can retell the ancient epic stories about their origins. There are descriptions dating from the sixteenth century of “excavations” of Indian tombs in search of buried treasure or motivated by curiosity abut the rituals of Indian “paganism.” Of great importance for the study of pre-Columbian society are the numerous ethnohistoric documents generated by the Spanish administration during the period of Indian resistance. In fact, from the examination of these records, architectonic, ritual, and material culture traits have been explained and are of prime importance in the reconstitution of archaeological events.

During the sixteenth century, the Spanish encountered colossal ruins in the middle of a living Inca society

that were evidence of a distant past. The invaders' medieval worldview, along with their creationist dogmas and limited biblical chronology, did not stimulate the need to systematically record such ruins. However, some chroniclers proposed that ancient hunters must have carried out the first peopling of the Americas. Others, such as Father Lozano, writing in the early seventeenth century, devoted himself to the study of the origin of the Indians of the New World and West Indies *(Orígen de los indios del Nuevo Mundo e Indias Occidentales).*

Between the eighteenth and nineteenth centuries, various European travelers and scientists on neocolonial and scientific explorations visited the New World, and their accounts provide

important descriptions that can be linked to archaeological data. We know of several excavations in the Atacameño territory further south; an Inca fortress in Tagua was explored, and between 1851 and 1900 a series of unscientific excavations *(huaqueos)* in search of "mummies" or dehydrated corpses and their associated assemblages took place at a cemetery on the Loa River. The collections recovered from these excavations were shipped to museums in Paris, Madrid, Oslo, and New York.

The written accounts of explorers and scientists proved to be of great value, as they constituted the archaeological and ethnohistoric foundation from which an archaeological discourse could be nurtured. During the 1970s, Jorge Hidalgo presented the first proposal for a scientific Chilean ethnohistory and thus became the pioneer of the discipline of archaeology in Chile.

Prescientific Pioneers (1830-1890)

In Europe in 1836, christian jürgensen thomsen published his classic three-age system and thus inaugurated archaeology as a scientific discipline sustained by Darwinian evolutionism. Thomsen's scheme paralleled the geological concept of sir charles lyell of a greater temporal depth for humanity and was framed within the context of the natural sciences. As a result, two explanatory proposals for human history were postulated. The first propounded the diversity of all living organisms as a consequence of the earth's antiquity in a gradual evolutionary process. The second was a stratigraphic proposition, which defined an "extended chronology" in accordance with the great French anatomist and paleontologist Georges Cuvier's postulates and surpassing the biblical limits of 6,000 years.

In this postcolonial intellectual environment, recently opened up by universal philosophical reason, European scientific currents of thought made an impact on the debates between Chilean liberals and conservatives. They determined the dispute between "progress" and "backwardness."

After the mid-nineteenth century, the endorsement of the new scientific doctrines of evolutionism and positivism constituted the mission statement of the "modern" intellectual vanguard. A pioneer in this movement was Rodolfo A. Phillipi, an Austrian exile in Chile whose academic background in the natural sciences (medicine, botany, and zoology) influenced his archaeological observations as an employee of the Chilean government. Another important participant was Letelier, who was not religious and a firm empiricist. Letelier advocated an end to the "short biblical chronology" in favor of a more "extensive" chronology. He went even further and proposed a "prehistory of America," which would become a reality six years later with the publication of the monumental work of José T. Medina.

Toward the end of the nineteenth century, the French archaeologist jacques boucher de perthes successfully combined paleontology, geology, and archaeology with stratigraphic methods to create the scientific foundations of the discipline of archaeology, which enabled it to leave behind its antiquarian antecedents. Boucher de Perthes's proposals reached the New World via evolutionism, but there was no archaeological evidence akin to the spectacular findings in the Old World. Although Indian "megalithic ruins" were common in the Americas, and these exotic and abandoned ruins motivated a series of notable expeditions during the nineteenth century, Chile remained a far away place with limited archaeological attraction.

The natural sciences were influential in the founding of the important Museum of Natural History in Santiago (1830), a similar one in Valparaiso (1876), and a southern replica at Concepción (1902). These museums, the result of modern European ideas, researched and presented the whole evolutionary-biological circuit from fossils to static displays of Indian artifacts, which were regarded as some sort of more recent fossils.

The first scholar to value the archaeological past of Chile was the historian and bibliographer José T.

Medina. His analysis, although not strictly linked to the naturalism in vogue, covered all of the national territory except for the north of the state, which was the subject of an ongoing dispute with peru and bolivia. He compiled major ethnohistoric sources to make sense of the various indigenous entities of an ethnological and archaeological

PREV NEXT

expeditions had revealed a horizontal perspective without systematic prospecting. The construction of a respectable image for the national state of Chile had begun. This state sought an understanding of the vernacular, as an instrument of legitimization and as the new non-Indian national symbol, but with no links to the indigenous populations who lived on the fringes and margins of civilization.

The Scientific Systematic Embryo (1890-1919)

Scholars began to place themselves within a naturalistic and inductive-descriptive theoretical-methodological paradigm based on the principle that all qualities are measurable. Since there was no systematic program of archaeological study, archaeologists were self-taught, with enthusiasm and French romanticism making the still largely unknown ethnic and archaeological potential attractive. Expeditions were sponsored by museums of natural sciences, scientific societies, incipient universities, etc. A series of excavations and ethnographic and ethnolinguistic salvage projects were organized under the banner of different evolutionary perspectives (autochthonous versus diffusionist), resulting in the first cultural taxonomies and physical anthropology measurements. During this time, to satisfy the taxonomic obsession of researchers, Indians were forced to live out their lives in museums, thus guaranteeing access to their remains once they died.

Interest in ethnography and physical anthropology increased with the founding of the German Scientific Society directed by Phillipi and the Scientific Society of Chile, of French ideological inclination, directed by A. Obrecht and with the establishment of such institutions as the national museums of natural history and the incipient University of Chile. Thus, an embryo of anthropological studies that would hierarchically structure the intellectual life of Santiago, Valparaiso, and Concepción became apparent.

The evolutionary-positivist paradigm of the natural and empirical sciences initially caused the development of archaeology as a scientific discipline. However, in Europe, this paradigm confronted the metaphysical idealism of the German philosopher Wilhelm Friedrich Hegel, from which the materialist thesis would emerge, which would eventually have an impact in Chile. The so-called early-twentieth-century cultural history and the North American cultural relativist schools emerged as reactions on the part of Euro-American idealists to late-nineteenth-century positivism.

The debate centered on evolutionists versus anti-evolutionists, between the followers of Lamarck and Charles Lyell and the supporters of Georges Cuvier and Alexander von Humboldt. The former were adherents of chrono-stratigraphic reconstructions and their relationship to anthropological vestiges; the latter were followers of a creationist school that lacked sequential profundity. Argentinean evolutionists like Ambrosetti, Debenedetti, Outes, and Lehmann-Nitsche were frequently cited in Chile by the first systematic scholars such as Latcham and max uhle. The same was not the case for the works of Moreno, Bormeidter, and others, which lacked the properly documented, or chronologically arranged, data that were essential for the comparative method, which was in vogue at the beginning of the twentieth century.

However, orthodox Argentinean evolutionists led by the Ameghino brothers were unaware of the precise nature of the Paleolithic artifacts embedded in Miocene strata. During the International Congress of Americanists in Buenos Aires in 1895, ales hrdlicka shattered the largely autochthonous and hyperevolutionist Ameghinian thesis that had dated Argentinean artifacts and human fossil remains back to the Tertiary period. As a consequence, the antiquity of human occupation in Chile would be substantially reduced during this period, to shorter chronologies that remained impervious to substantial changes.

Another trans-Andean debate characteristic of this period was related to the northern Andean regions of

argentina and Chile. Monuments are conspicuous in these regions, and the Inca presence was well documented in the preceding period. The debate concerned the nature of the Inca as civilizing agents. Under the banner of pseudonationalism, “Peruvian” influence was denied, particularly in those territories that

school of Vienna, which was characterized by religious anti-evolutionist and overtly racist views. The group's work was also inspired by the translations of Oyarzún (Orellana 1979), the writings of Koppera and Schmidt and other classics by Ratzel Frobenius and fritz graebner, culminating in the Argentinean studies of Imbelloni, Bórmida, and Menghin.

Adherence to the culturalist current by Chilean intellectuals at the beginning of the twentieth century becomes understandable because in Argentina at the same time the opposite Ameghinist thesis was in vogue. During this period in Chile, all work that legitimized the superiority of certain peoples and races over others was very popular.

During the first decade of the twentieth century, while those scholars who closely adhered to the cultural-history school produced descriptive and speculative studies, other scholars made systematic contributions to the production of a documented database. Between 1900 and 1938 there was a methodological crisis caused by the abandonment of stratigraphic-naturalistic principles in favor of the hasty excavations of Indian tombs with the sole purpose of recovering artifacts to fill state museums. It has been acknowledged that these excavations were unsystematic and that no refined methods were applied to clarify cultural history in terms of pre-Inca sequences and developments in regional diversity. At the same time, from at least 1911 on, scholars in other countries were using stratigraphic methods, but the application of these methods was not popular in Chile where, with the exception of the northern and southern confines of the country, chronological frameworks were not thought to provide reliable sequences and contexts.

In this milieu, Uhle and Latcham made major contributions to the discipline. These two archaeologists were the products of German and British academic environments, which they would later incorporate with Euro-American influences. Max Uhle based his research in Chile (from 1911 to 1919) on the cultural-history paradigm. His pan-Andean archaeological perspective and his cutting-edge methods, synthesized into the Euro-American stance, enabled him to carry out contextualized excavations that made him the forerunner of modern empiricists. He enhanced the chronological, sequential, and distributive adjustments between peripheral and core cultures, based on the extension of the Tiwanaku and Inca guiding horizons, and as a result he wrote the first pre-Columbian cultural history, with its very own methods. Uhle's results remained in use until their harmonious integration into the modern investigations of junius bouton bird (1943) and even more recent investigations (Schaedel 1957).

During the first two decades of the twentieth century, then, various distant events had an impact in Chile. The first systematic physical anthropology studies began under Ales Hrdlicka, and the peopling of the Americas was established as a post-Pleistocene event (w. h. holmes). However “ancient” Paleolithic stations were recorded at Taltal in northern Chile, which helped to continue the debate on the earlier origins of humans in the Americas. The first stratigraphic excavations were carried out, and Max Uhle began to work in South America, where he was regarded as the father of Andean archaeology.

The Ameghinian School had been discredited to the point of oblivion by the application of stratigraphy, the discovery of rock art, the excavation of cemeteries, and the recovery of surface collections from ancient workshops. Initial excavations were in the desert, where monumental sites were more visible and profuse, in order to supply collections for state museums and private collectors. These excavations were undertaken with ethnohistoric sources rather than archaeological field-recording methods in mind. The scholars were erudite bibliographers who witnessed the erosion of any great antiquity for humans in the Americas, and in this context, Uhle's innovative role was decisive for the success of Chilean archaeology.

Transitional Interface (1919-1961)

Uhle's theories and practice were followed by the majority of Chilean senior researchers such as Ricardo Latcham (1928, 1938), who adopted his chronological sequence in spite of the fact

the work of Bird and Uhle through the use of a modern chronological, ecological, and adaptive analysis in the northern half of the country. Meanwhile, W. Mulloy's proposals about Easter Island drew Chile even closer to North American methodologies, and in this context, the Center of Anthropological Studies became the generator of scientific groundwork groups in Chile led by Carlos Munizaga, Francisco Reyes, Alberto Medina, Jorge Kaltwasser, Bernardo Berdichewsky, Ximena Bunster, Mario Orellana, Gonzalo Figueroa, and Juan Muziaga, the founder of scientific physical anthropology in Chile. Although Osvaldo Menghin's visit to this center clarified matters and methods related to issues of parietal (rock and cave) art, the Patagonian sequence, and his exploration in the south-central part of the country, his cultural-history proposals did not become popular.

A scientific movement originating in the provinces linked up with the scientific circle of the capital. This movement had its antecedents in the foundation of museums in Valparaiso, Viña del Mar, Angol, Punta Arenas, and La Serena, of which the Museum of Archaeology of La Serena constituted the most prestigious center of research and periodical publications. Like the museum in La Serena, the Museum of Viña del Mar was a front-line research center when it began using the excavation methods of "contextual cross-sections" and "determination of original floors" in 1955. In 1957, R.P. Le Paige founded the Archaeological Museum at the Casa Parroquial de San Pedro Atacama, and in 1959, Percy Dauelsberg founded the Regional Museum of Arica. During the following period, a process of regionalization took place in Chilean archaeology.

North American diffusionist explanations had ceased to be satisfactory explanations for the peopling of the Americas before 1961. The idea that all forms of progress and civilization were dispersed to marginal areas from Mesoamerican and Andean heartlands came under serious critical scrutiny. Psychological explanations of the past became inadequate, and the hierarchical ordering of differences began to compete with the search for regularities. This was a response to an inductivist approach that led more to descriptivism per se and resulted in a growing awareness that a dialectic deductive-inductive approach was needed, which would move closer to theories that would provide the next generation of archaeologists with better research objectives for sites and collections.

Professional Scientific Development (1961-)

The American ethnologist and archaeologist julian steward had an enormous influence on the generation of the 1950s and 1960s through the publication of his book the *Handbook of South American Indians*, but there were also other major influences. Carlos Ponce, working with a team of national colleagues, was applying stratigraphic excavation methods at Tiwanaku; Luis Lumbreras excavated Chavín and proposed a critical reading of the North American-Andean literature; Stig Rydén finished his monograph on Chile and Bolivia; and in Argentina, Alberto Rex González published his chrono-stratigraphic work. These young scholars, who kept in permanent contact with each other, were the authors of publications that became compulsory reading for the archaeological generation of the 1950s and 1960s. Many new technical and methodological strategies would emerge from this interrelationship, such as Childean evolutionism and a reevaluation of "garbage collections" as opposed to *belles pieces*, or great art objects. Most important, the chronological archaeology that would set this generation apart began, and the first modern and reliable synthesis of regional sequences emerged.

During the first decade of the twentieth century, reactions against unilineal evolutionism were channeled through the diffusionist school, which was inclined toward the hierarchical transmission of change rather than conservative social structures. The important issue for this school was the determination of cultural "emission" and "reception," which denied local creativity or the existence of autochthonous evolutionary developments mature enough to assimilate and internally process change. There was a growing need to look for more pluralist theses, which would complement Boasian ideas that firmly opposed the idea of

the biological inferiority of the American Indian and the evolutionary

of the preceding years had to be dealt with. There was a need for more locally based theoretical paradigms and for the optimization of the formation of academic groups. Various theoretical approaches, such as the cognitive, historicist, structuralist, neopositivist, symbolist, materialist, and postprocessualist approaches, have been helpful and will continue to be useful in maximizing the interpretative options of past events. In this context, the changing perspectives of the present range from a genetic neodiffusionism to a static deductive localism, from morphological discourse to the legitimization of computerized verification per se, and from an aversion to globalizing materialistic views to sterile descriptivism.

Some analytical models have recently surfaced in Chile that offer unequivocal signs of theoretical and methodological advancements. For example, the fact that the peopling of the coast of the country took place at such an early date (10,000 years ago) has reopened the relevant issue related to the articulation of two synchronic socio-adaptive processes: the Andeanization and maritimization of Chilean society.

Aside from the reconstitution of the general and specific behavior patterns and the ideological perceptions of the human phenomenon, there were also utopian aspirations to attract the younger generations of investigators to the quest for a vision of the society of the future. The aspirations of the newest generations of archaeologists are geared toward finding jobs and toward more specialized knowledge but with less alienating theory. In this sense, their propositions are perceived as consistent and well documented. Thus, it is now necessary to employ postgraduate archaeologists and to generate a museological (museum studies) policy that will contribute to a new educational strategy.

Epilogue

We should expect the emergence of “other” archaeologies later on, related to the 500 years of recent existence: colonial, industrial, subaquatic, urban, and forensic archaeology. The last is of particular importance as can be seen by detailed expert assessments made public during the judicial processes surrounding the “disappearances” that occurred during the military regime.

Another expected outcome would be the optimization of current knowledge about the original inter-American cultural processes, through the 30,000 to 12,000 years of human occupation, making it more difficult to divide it into two areas of study: prehistory and history. In a similar vein, it would be appropriate to find an approach with the discipline of history based on theories, methods, and techniques proper to archaeology in order to elucidate a reconstitution of the greater history of the Latin American peoples both before and after the linkage to the history of the west. In this context, we should strive to advance toward an appropriate paradigmatic synthesis, which would integrate the best of the proposals on particularities and regularities, in an explicit discourse directed toward those peoples who, until now, have received only the official and elitist histories.

I am describing an archaeology incorporated into a scientific and multidisciplinary history of the peoples of the Americas, a history that would go beyond its “intellectual” orientations, not forgetting its social meaning and its objectivity, to a proper understanding of the complexity of past and present human behavior. In today's world, when many people proclaim that history is defunct, archaeologists and their “extended chronologies” are the best equipped to attempt to change this apathy to a historic utopia, one that ascends from the depth of human nature and aspires to the sustainability of human society in search of the ideal of transformations that are more just and ecumenical.

China

The birth of modern Chinese archaeology in the early twentieth century was a product of the introduction of western scientific methods, the rise of nationalism, and the search for the cultural origins of the nation. These three factors have had a continuing influence on the development of the discipline, with the consequence that archaeology in China has been firmly placed in the general field of history. Its research orientations and interpretations have been significantly affected by the different political agendas of the nation-especially the ever-changing concept of nationalism in particular eras.

Formative Period (1920s-1940s)

The beginnings of modern archaeology in China can be traced to 1928, when the Institute of History and Philology, Academia Sinica, launched the excavation of Yinxu, a capital city

PREV NEXT

of the late Shang dynasty, at Xiaotun in anyang, Henan Province. This was the first state-sponsored archaeological project in China, and fifteen seasons of excavation took place between 1928 and 1937 (when the Sino-Japanese War broke out). This series of excavations at Anyang was not a random occurrence but was preceded by several lines of cultural, political, and technological development, which served as the foundation for the establishment of archaeology as a new discipline.

Archaeological Sites in China

Historical Context of Chinese Archaeology

There has been a tradition of interest in antiquarianism throughout Chinese history. Many antiquities were thought to possess a divine nature, and some bronze vessels were regarded as symbols of power and authority. This tradition encouraged the collecting and recording of ancient artifacts and, at the end of the nineteenth century, led directly to the discovery and decipherment of oracle bone inscriptions of the Shang dynasty. The discovery of the original

Beginning of Modern Chinese Archaeology

Although the scientific field methods used by the western archaeologists enlightened Chinese scholars, the general western research orientations were not considered satisfactory. Paleolithic and Neolithic remains were thought by Chinese scholars to be too remote to be connected directly to early Chinese history (Li 1968). Andersson's proposal, which traced the origins of the Yangshao culture to the Near East, was even less appealing. As one scholar complained, “the foreign archaeologists in China do not pay any attention to the material which represents indigenous Chinese culture, but are only interested in the remains which indicate cultural connections between China and the West” (Fu 1996, 191).

Excavations in Anyang

During the 1920s, a group of Chinese scholars who had received training in modern archaeology at western universities returned to their homeland embued with a great nationalist spirit. The first was li chi, a Ph.D. trained in physical anthropology at Harvard University, and he, with others, launched a series of archaeological research projects in 1926. Excavations in anyang from 1928 to 1937, organized by Li Chi in his position at the Institute of History and Philology, Academia Sinica, were the first attempts to search for indigenous Chinese cultural origins through archaeology.

The excavations in Anyang yielded numerous material remains, including hundreds of bronze objects, nearly 25,000 pieces of inscribed oracle bones, bronze workshops, palace and temple foundations, and large royal tombs. These discoveries proved the site to be a capital city of the late Shang dynasty and for the first time provided archaeological evidence confirming the existence of an ancient indigenous Chinese culture (Li 1977).

The excavations in Anyang not only marked the beginning of modern field archaeology conducted by Chinese scholars in China but also became a field station where many leading Chinese archaeologists were trained. Most associates of Li Chi who worked in Anyang (such as Tung Tso-pin, Kao Ch'ü-hsun, Shih Chang-ju, Liang Siyong, Guo Baojun, Yin Da, and xia nai) became the first generation of Chinese archaeologists and dominated the field for decades on both sides of the Taiwan Strait (Chang 1986b).

In spite of the success of the archaeological work in Anyang, there was still a gap in the evidence of material cultures between the historical Shang dynasty and the Neolithic Yangshao, as the latter was then regarded as a cultural diffusion from the Near East. Chinese scholars were still dissatisfied with the general notion that predynastic cultures in China were derived from ripples of influence extending from the West. Fu Sinian (1934) made the objection that the study of Chinese history by foreigners was mainly focused on Sino-foreign relationships, which was only a “semi-Chinese” *(ban Han)* endeavor. However, he continued, the more important issues to be studied were those “completely Chinese” *(quan Han),* that is, concerned with building the basic structure of Chinese history.

Discovery of the Longshan Culture

The cultural disconnection between Yangshao and Anyang encouraged archaeologists to search for the direct progenitor of the Shang, and the general consensus among archaeologists and historians was that the most likely area was in eastern China. After work at Anyang was halted around 1930 owing to civil war, the excavation team moved its operations to Chengziyai in Longshan township, Shandong Province, where Wu Jinding's previous preliminary surveys revealed potential archaeological discoveries (Fu 1934; Li 1990).

The excavations at Chengziyai were more fruitful than the excavators had expected. Distinctive from the Yangshao painted pottery, the black pottery from Chengziyai was similar to the Neolithic remains found at Hougang in Anyang, which lay directly beneath the Shang cultural remains. Uninscribed oracle bones

found at Chengziyai provided an even more direct link between the Longshan and Shang cultures. The Longshan culture of black pottery in the east (representing indigenous Chinese culture) thus came to be viewed as a system independent of the Yangshao culture of painted pottery in the west (thought to be the result of

Discovery of the Longshan Culture

The cultural disconnection between Yangshao and Anyang encouraged archaeologists to search for the direct progenitor of the Shang, and the general consensus among archaeologists and historians was that the most likely area was in eastern China. After work at Anyang was halted around 1930 owing to civil war, the excavation team moved its operations to Chengziyai in Longshan township, Shandong Province, where Wu Jinding's previous preliminary surveys revealed potential archaeological discoveries (Fu 1934; Li 1990).

The excavations at Chengziyai were more fruitful than the excavators had expected. Distinctive from the Yangshao painted pottery, the black pottery from Chengziyai was similar to the Neolithic remains found at Hougang in Anyang, which lay directly beneath the Shang cultural remains. Uninscribed oracle bones

found at Chengziyai provided an even more direct link between the Longshan and Shang cultures. The Longshan culture of black pottery in the east (representing indigenous Chinese culture) thus came to be viewed as a system independent of the Yangshao culture of painted pottery in the west (thought to be the result of

foreign diffusion). Chinese archaeologists hoped that "if we can trace back the distribution and development of the black pottery culture at Chengziyai, most problems in the formative period of Chinese history would be resolved" (Li 1990, 193). Therefore, as Li Chi further pointed out, this discovery not only identified a homeland for a part of the Shang culture but also made a major contribution to knowledge about the origins of Chinese civilization.

Excavations at Doujitai in Shaanxi Province

While the Academia Sinica headed by Li Chi was working in Henan and Shandong, the National Beiping Academy, led by Xu Xusheng, carried out excavations at Doujitai in Shaanxi Province in 1934-1937. The intention was to search for the prehistoric origins of the Zhou dynasty. su bingqi, who later became the paramount senior archaeologist in China, participated in this project and established his first research achievement on ceramic typology, focusing on changing forms of the *li* vessels (Falkenhausen 1999a; Su 1948). Su regarded *li* as a vessel form that was a diagnostic for ethnic affiliations and Chinese civilization. His approach turned into a model in an archaeological methodology for several generations of Chinese students to follow.

Western Origin, Dual Origins, and Indigenous Origin of Chinese Civilization

The origins of Chinese culture have been a most sensitive issue in Chinese archaeology. Upon his discovery of the Yangshao culture, Andersson determined to find the route of eastward cultural diffusion in northwestern China. Based on his findings in the Gansu region, Andersson established a sequence of ceramic cultures that perfectly supported his hypothesis. According to this sequence, the Yangshao culture was preceded by the indigenous Qijia culture in western China, so the western origin of Yangshao pottery became logical.

The discovery of the Longshan culture in the 1930s changed the paradigm of the solely western origin for Chinese civilization inferred from Yangshao painted pottery. The Longshan culture, which was characterized by black pottery, was thought to represent the indigenous Chinese culture, which arose in eastern China and was contemporary with, but independent of, the Yangshao culture in western China. As a result, a new concept for the dual origins of Chinese civilization was put forward: while the Yangshao culture diffused from west to east, the Longshan culture moved from east to west. The two traditions were thought to have encountered one another and mixed, and later became the progenitor of the Shang civilization (Chang 1999a; Chen 1997, 217-227, 276-281; Liang 1959). This proposition dominated archaeological circles until the 1950s.

During the Sino-Japanese War (1937-1945) and the subsequent civil war (1945-1949), major archaeological projects were halted although some fieldwork was still occasionally carried out in peripheral regions. Xia Nai participated in the Academia Sinica's expedition in the northwestern part of the country, where his excavations yielded stratigraphic evidence indicating that the Qijia culture was in fact later than the Yangshao culture. This conclusion challenged Andersson's sequence of prehistoric cultures in western China and therefore his theory on the western origin of the Yangshao culture. Xia Nai's victory over Andersson on this issue became legendary and inspired Chinese archaeologists for decades.

During this formative period of the discipline, Chinese archaeologists struggled to achieve two primary objectives: to defend their belief in the indigenous origins of Chinese culture against foreign diffusionism and to reconstruct a reliable cultural history based on material remains in order to clear up the uncertainties in textual records that had been attacked by historical revisionists known as "the doubters of antiquity." These objectives, in turn, determined the nature of archaeology as an enterprise closely aligned to the ethnic nationalism that was centered on the Han Chinese.

Development of Archaeology in the People's Republic of China

When the Communist Party took over China in 1949, the archaeologists in the Institute of History and Philology at the Academia Sinica were split into two groups. Li Chi and several of his colleagues moved to Taiwan while Xia Nai and

PREV NEXT

foreign diffusion). Chinese archaeologists hoped that "if we can trace back the distribution and development of the black pottery culture at Chengziyai, most problems in the formative period of Chinese history would be resolved" (Li 1990, 193). This conclusion challenged Andersson's sequence of prehistoric cultures in western China and therefore his theory on the western origin of the Yangshao culture. Xia Nai's victory over Andersson on this issue became legendary and inspired Chinese archaeologists for decades.

During this formative period of the discipline, Chinese archaeologists struggled to achieve two primary objectives: to defend their belief in the indigenous origins of Chinese culture against foreign diffusionism and to reconstruct a reliable cultural history based on material remains in order to clear up the uncertainties in textual records that had been attacked by historical revisionists known as "the doubters of antiquity." These objectives, in turn, determined the nature of archaeology as an enterprise closely aligned to the ethnic nationalism that was centered on the Han Chinese.

Development of Archaeology in the People's Republic of China

When the Communist Party took over China in 1949, the archaeologists in the Institute of History and Philology at the Academia Sinica were split into two groups. Li Chi and several of his colleagues moved to Taiwan while Xia Nai and

PREV NEXT

Liang Siyong stayed on the mainland. Xia Nai was the one who eventually gained the most international recognition in the discipline (Falkenhausen 1999b). For the rest of the twentieth century, archaeological fieldwork, research, and training developed rapidly, but dramatic fluctuations occurred as a result of various political waves. Archaeological activities can be divided into three periods: before, during, and after the Cultural Revolution (1966-1977).

Archaeology before the Cultural Revolution (1950-1965)

Soon after the founding of the People's Republic of China in the 1950s and early 1960s, archaeologists were in great demand by the state as the country underwent tremendous construction. In 1950, the Institute of Archaeology, led primarily by Xia Nai, was established under the Academia Sinica (AS), which changed its name to the Chinese Academy of Social Sciences (CASS) in 1977. The Archaeology Program, headed by Su Bingqi, was set up in 1952 under the Department of History at Beijing University. These two institutions were the leading forces at that time in conducting archaeological research and in training young archaeologists. Many provinces also set up archaeological institutes or management of cultural relics bureaus, which were primarily involved in salvage archaeology.

In addition to Beijing University, two other universities (Northwestern and Sichuan) also started archaeology programs to train students, and the number of professional archaeologists multiplied from a mere handful before 1949 to more than 200 by 1965. The first C-14 laboratory was set up in 1965 at the Institute of Archaeology, and it was soon followed by a second one at Beijing University. The first archaeological journals, the so-called three great journals-*Kaogu* [Archaeology], *Kaogu xuebao* [Acta Archaeologica Sinica], and *Wenwu* [Cultural Relics]-were established in Beijing.

Paleolithic Archaeology

paleolithic archaeology was carried out by the Institute of Vertebrate Paleontology and Paleoanthropology at the Academia Sinica. The number of excavated Paleolithic sites increased from three locations before 1949 to more than a dozen distributed in many parts of the country. Excavations at Zhoukoudian were resumed after the 1950s, and to date, that site has yielded hominid fossils of more than forty individuals dating from 550,000 to 250,000 years ago, more than 100,000 stone artifacts, and a large number of mammalian fossils. In addition, cranial remains of *Homo erectus* dating to 700,000 years ago were discovered in Lantian, Shaanxi Province, and two incisors of *Homo erectus* dating to 1.7 million years ago were found in Yuanmou, Yunnan Province. Homonid fossils and stone implements belonging to archaic *Homo sapiens* and *Homo sapiens sapiens* have been found in many locations over northern and southern China (Chen 1999b; Wu and Olsen 1985).

Neolithic Archaeology

Most fieldwork projects in the 1950s were carried out in the Yellow River valley in connection with hydraulic construction in the region. The excavations at Miaodigou in Shanxian, Henan Province, were a breakthrough and completely changed the proposition of dual origins for Chinese civilization. Archaeologists identified a ceramic assemblage, named the Miaodigou Phase II, that represented a transitional culture between Yangshao and Longshan (Institute of Archaeology, Academia Sinica 1959). This discovery clarified the relationship between the Yangshao and Longshan cultures as successive rather than contemporaneous. Chinese civilization, therefore, seems to have been derived from a single source-the Yangshao culture, which originated in the central plains region (Chang 1963; Chen 1999c).

It should be noted that the first attempt to interpret ancient Chinese history with a Marxist model of social evolution can be traced back to guo moruo's *A Study of Ancient Chinese Society* (1930). Under the Communist regime, and influenced by Soviet archaeology, many Chinese archaeologists wanted to

employ the Morgan-Engels evolutionary theory in archaeological practice, and this Marxist interpretation of Chinese history was then seen as a new mission for the discipline in addition to the search for Chinese cultural origins. The most successful application

Neolithic Archaeology

Most fieldwork projects in the 1950s were carried out in the Yellow River valley in connection with hydraulic construction in the region. The excavations at Miaodigou in Shanxian, Henan Province, were a breakthrough and completely changed the proposition of dual origins for Chinese civilization. Archaeologists identified a ceramic assemblage, named the Miaodigou Phase II, that represented a transitional culture between Yangshao and Longshan (Institute of Archaeology, Academia Sinica 1959). This discovery clarified the relationship between the Yangshao and Longshan cultures as successive rather than contemporaneous. Chinese civilization, therefore, seems to have been derived from a single source-the Yangshao culture, which originated in the central plains region (Chang 1963; Chen 1999c).

It should be noted that the first attempt to interpret ancient Chinese history with a Marxist model of social evolution can be traced back to guo moruo's *A Study of Ancient Chinese Society* (1930). Under the Communist regime, and influenced by Soviet archaeology, many Chinese archaeologists wanted to

employ the Morgan-Engels evolutionary theory in archaeological practice, and this Marxist interpretation of Chinese history was then seen as a new mission for the discipline in addition to the search for Chinese cultural origins. The most successful application

of this evolutionary scheme in archaeology was the analysis of a Yangshao site at Banpo near Xi'an, Shaanxi Province. The excavations, led by Shi Xingbang, revealed a large portion of a Yangshao settlement. Based on burials and residential patterns, the Banpo Neolithic village was described as a matrilineal society in which women enjoyed high social status and in which “pairing marriage” was practiced (Institute of Archaeology, Academia Sinica 1963). Such statements soon became standard in many interpretations of Neolithic sites dating to the Yangshao period, and the classic evolutionary model was commonly accepted among Chinese archaeologists.

Archaeology of the Three Dynasties: Zia, Shang, and Zhou

Shang archaeology was still a focus of research. Anyang resumed its importance as a center of archaeological excavations and yielded royal tombs, sacrificial pits, craft workshops, and inscribed oracle bones. These finds enriched the understanding of the spatial organization of the site (Institute of Archaeology, Chinese Academy of Social Sciences 1994). In the early 1950s, Shang material remains that could be dated to a period earlier than Anyang were first recognized at Erligang, near Zhengzhou, Henan Province. A fortified Shang city belonging to the Erligang phase was then found at Zhengzhou. The enormous size of the rammed-earth enclosure (300 hectares in area) and abundant remains found at the site (craft workshops, palace foundations, and elite burials) indicated that it may have been a capital city before Anyang (Henan Bureau of Cultural Relics 1959). This discovery encouraged archaeologists to search for the earliest remains of the Xia and Shang dynasties.

Inspired by ancient textual records, Xu Xusheng led a survey team in western Henan Province to explore the remains of the Xia dynasty. His endeavor soon proved fruitful when the team discovered a large Bronze Age site at Erlitou in Yanshi (Xu 1959). The Erlitou site was dated earlier than the Erligang phase, and subsequent excavations yielded a large palatial foundation, indicating the high rank of the site. The site was then designated as the type site of the Erlitou culture, which preceded the Erligang phase of the Shang (Institute of Archaeology, Chinese Academy of Social Sciences 1999).

The discovery of Erligang and Erlitou generated considerable debate on many issues: whether Erlitou was a capital city of the Xia or the Shang, which phases of the Erlitou culture belong to the Xia or the Shang cultures, and which capital cities named in ancient texts corresponded to Erligang and Erlitou. Most arguments were made on the basis of textual records that were written thousand of years after the existence of the Xia and Shang and reinterpreted by many individuals afterward. As people used different textual sources, which frequently contradicted one another to support their opinions, these debates have continued for decades without reaching a consensus (Dong 1999).

Between the mid-1950s and early 1960s, excavations at Fengxi, Chang'an, Shaanxi Province, revealed a large Bronze Age site, and it was determined that the site was the location of the capital cities of the western Zhou: Feng and Hao. These finds established the cultural sequence and chronology of the Zhou archaeological record (Institute of Archaeology, Academia Sinica 1962).

(Image Select)

Archaeological research during this period primarily focused on the central plains of the Yellow River valley, where a clear sequence of cultural development could be traced from the Yangshao to the Longshan to the three dynasties.

PREV NEXT

Many Neolithic sites in southern China were also found and excavated, such as Beiyinyangying near Nanjing, Qianshanyang in Zhejiang Province, and Qujialing in Hubei Province. These sites, however, yielded neither a material assemblage as old as the Yangshao culture, which was viewed as the earliest Neolithic culture, nor a continued sequence illustrating a regional cultural development. They were regarded as the peripheries of the central plains with minor significance for Chinese civilization. Such a paradigm of ancient Chinese cultural development was accepted by archaeologists in China and abroad, not only because of the limitations of the archaeological findings, but also because the traditional view of Chinese civilization focused on the central plains.

Archaeology during the Cultural Revolution (1966-1977)

Similar to other disciplines in academic institutions, archaeology stalled during the early part of the Cultural Revolution. Research and teaching were replaced by insurrection, and most junior members of archaeological institutes and students in universities were busy criticizing senior archaeologists and professors. However, excavations never completely stopped as continued construction projects always required salvage archaeology.

It was also soon recognized by the leaders of the Cultural Revolution that archaeology could serve as an instrument of propaganda for political purposes. Sending museum exhibitions of archaeological findings to foreign countries was considered useful in improving China's international relationships and promoting China's image as a great civilization. Moreover, the highly developed material culture from ancient times could reconfirm the Chinese people's national pride, and the wealth discovered from elite burials could be used for the education of the people in terms of class consciousness. Cultural relics unearthed in the People's Republic of China were displayed for the first time in Paris and London in 1973 in order to demonstrate the glory of the Chinese civilization and the achievements of archaeology in the new China (Xia 1973). Elaborately constructed architecture, burials, and artifacts were interpreted as testimony of class repression and exploitation of the poor by the rich.

To meet the new demands, the three major archaeological journals-*Kaogu, Kaogu xuebao,* and *Wenwu,* which were discontinued in 1966-resumed publication in 1972. *Wenwu* turned into a very popular magazine, as most journals with intellectual contents in social sciences had been stopped. Between 1972 and 1977, eight new archaeology programs were established in universities (Shanxi, Jilin, Nanjing, Xiamen, Shandong, Zhengzhou, Zhongshan, and Wuhan) in order to train much needed archaeologists for the rapidly expanded discipline (Chinese Archaeology Association 1984, 227-236).

Excavations of Neolithic sites were carried out in many regions, such as Dawenkou in Shandong Province, Cishan and Honghuatao in Hebei Province, Jiangzhai in Shaanxi Province, Liuwan in Qinghai Province, Daxi in Sichuan Province, Caoxieshan in Jiangsu Province, Hemudu in Zhejiang Province, Sanyuangong in Hunan Province, and Shixia in Guangdong Province. These sites provided rich information for the understanding of prehistoric development in different regions. In addition, by 1977 the radiocarbon laboratories in the Institute of Archaeology and Beijing University had published four sets of C-14 dates, providing some very early absolute dates from Neolithic sites outside the central plains, which revolutionized archaeological research.

The discoveries of several Neolithic sites in southern China were especially important. The Hemudu site in the lower Yangzi (Yangtze) River valley yielded the earliest evidence of rice cultivation in China, as radiocarbon dates pointed to a period as early as the Yangshao culture. The Hemudu culture seems to have been succeeded by a series of Neolithic assemblages, referred to as Majiabang, Songze, and Liangzhu, which formed a continued cultural sequence in the region. These new data seriously challenged the traditional view, which regarded the central plains as the only center for the development of Chinese

civilization. For the first time, the notion of a single origin of Chinese Neolithic culture needed to be reconsidered (Xia 1977) in

light of the fact that southeastern China may have played an important role in the development of Chinese civilization (Su 1978).

The discoveries that made the most newspaper headlines during the Cultural Revolution were elite tombs that had been discovered accidentally (Qian, Chen, and Ru et al. 1981). In 1968, for example, western Han royal tombs belonging to the prince Liu Sheng and his wife Douwan (ca. 113 b.c.) were found in Mancheng, Hebei Province. Among some 4,000 grave goods, two jade burial suits, each made of more than 2,000 jade wafers of different shapes tied with gold thread, were the most astonishing finds (Institute of Archaeology, Chinese Academy of Social Sciences, and Hebei 1980).

In 1972, an elaborately furnished western Han burial at Mawangdui in Changsha, Hunan Province, was unearthed. After removing many layers of clay, charcoal, wooden chambers, coffins, and silk garments, a corpse, nearly 2,000 years old, of the lady Dai, was revealed. The body was in perfect condition with no sign of decomposition, and the 138.5 melon seeds preserved in her esophagus, stomach, and intestines indicated the lady's last meal shortly before her death (Hunan Provincial Museum and Institute of Archaeology 1973).

In 1976, archaeologists excavated a very well-preserved Shang royal burial, tomb number five, in Anyang. Based on bronze inscriptions found in the burial, the tomb was determined to have belonged to one Fuhao, who was referred to as a consort of King Wuding in oracle-bone inscriptions. In addition to the large number of bronze and jade artifacts unearthed from the tomb, this discovery was significant because, for the first time, a named individual in oracle-bone inscriptions was identifiable in an archaeological context (Institute of Archaeology, Chinese Academy of Social Sciences 1980).

The discovery that attracted the most international attention was the underground terracotta army found in 1974 at the mausoleum of the first emperor of the Qin dynasty (221-206 b.c.), Qinshihuangdi, at Lishan, Lintong, Shaanxi Province. Deposits located to the east of the mausoleum include four large pits, three of which contain more than 7,000 life-sized terracotta warriors and horses. In the same year as the discovery, pit number one, the largest of four, which measures 12,600 square meters in area and 4.5-6.5 meters in depth (Shaanxi Institute of Archaeology 1988) was excavated. Five years later, the first on-site museum was built over the pit so that visitors could look down over railings at the rows of clay warriors and horses as well as at the processes of excavation of the site. Excavations have continued ever since, and three pits have been covered by on-site museums, attracting millions of visitors from all over the world. The mausoleum was listed as a World Heritage Site by the United Nations Educational, Scientific, and Cultural Organization in 1987.

In spite of numerous new discoveries, archaeological theoretical interpretations during the Cultural Revolution were dry and dogmatic, an inevitable consequence of the political climate of the era. Tightly controlled foreign policies eliminated the exchange of information between China and western countries, and the only theoretical frameworks applicable at the time were Marxism and Maoism. Mortuary and settlement data obtained from many Neolithic sites were commonly used to support Morgan-Engels or Marxist-Leninist propositions such as the emergence of private property, class differentiation, the practice of matrilineal or patrilineal social organizations, and the formation of the state as the result of class conflict. In some publications, which were purely data descriptions, Marxist and Maoist slogans were routinely inserted into the contents but appeared superficial and far-fetched. The lack of fresh theoretical approaches prevented archaeologists from engaging in critical discussions, and the rapid accumulation of archaeological data also forced scholars to become preoccupied with constructing the sequence of material culture rather than with theoretical thinking about it. Chinese archaeology, therefore, largely remained artifact oriented.

Archaeology in the Post-Cultural Revolution Era (1978-)

After the Cultural Revolution, the relatively relaxed political atmosphere and the practice of

economic reform promoted new developments on all fronts of Chinese archaeology. Salvage excavations conducted by regional archaeological institutes have been the most in demand, as a decentralized economic system stimulated construction projects across the country. Support from the central government has been shrinking, and most provincial institutes have become financially dependent on salvage archaeology. By 1978, a total of eleven universities had developed archaeology programs, training hundreds of archaeologists each year. These new graduates soon became the backbone of local archaeological institutes. The number of archaeological periodicals had multiplied from “the great journals” to a list of some 140 periodicals on archaeology-related subjects by 1991, most of which are published on a local level (Falkenhausen 1992). As a result, provincial archaeological institutions became increasingly independent of control by the Institute of Archaeology in Beijing with regard to administrative, academic, and financial aspects (Falkenhausen 1995).

Policies of economic reform have also opened China's doors to the world. Scholarly exchange between China and western countries has been encouraged, and western archaeological methods and theories have been brought in. Archaeologists in China found themselves facing new challenges from the outside world. During the 1980s and 1990s, as Deng Xiaoping was searching for a way for China to become a Chinese-style socialist country, archaeologists were struggling to find a way to make an archaeology with Chinese characteristics. There have been some increased nationalist feelings among many Chinese intellectuals, partially in reaction to the rapidly changing relationships between China and the rest of the world, and archaeology in this era has been strongly influenced by new concepts of nationalism.

As an enormous amount of archaeological data on all periods has been accumulated since the end of the Cultural Revolution, and three major topics have become the focal points of Chinese archaeology: the origins of early humans, the origins of agriculture, and the origins of civilization.

Paleolithic Archaeology and the Multiregional Model of Human Evolution

By the 1990s, more than sixty sites containing human fossils had been recorded as well as many more sites that have yielded Paleolithic artifacts. As world Paleolithic archaeology has been engaged in the debate between “the out-of-Africa” and “the multiregional-development” schools, evidence from China has become crucial. The majority of Chinese archaeologists and paleontologists support the multiregional development model, arguing for an independent system of evolution from *Homo erectus* to *Homo sapiens* in East Asia (e.g., Wu 1995). Some have gone even further and attempted to find evidence of the earliest hominids in China. The argument for indigenous evolution in east Asia is primarily based on two factors. First, similar to Weidenreich's observation, paleontologists continue to find morphological characteristics that are shared by hominid fossils and modern populations in the same region. Second, archaeologists have defined regional lithic traditions throughout the Paleolithic period in China that appear to be distinct from those in Africa and Europe (Chen 1999b).

The driving force for archaeologists has been to find evidence of the earliest hominid remains and the missing links in the developmental progress of modern humans in China. New evidence remains promising for the current evaluation and debate about human evolution. In 1984, for instance, a nearly complete skeleton of archaic *Homo sapiens* was found at Jinniushan (Gold Ox Hill) in Liaoning Province in 1984. The fossils were dated to 310,000-160,000 years ago, making the skeleton one of the earliest examples of this taxonomic group. Some typical morphological features of the skull are observable in earlier hominids and modern populations in the region, which seems to fit a model of local evolution (Chen, Yang, and Wu 1994).

It should be noted, however, that some recent claims about the early hominids might be problematic and lack credibility in light of the data; it has been suggested that some archaeologists have been too eager to

find the first man-made stone tool in China (Lü 2000). In 1985, cranial remains of *Homo erectus* associated with

stone tools were found at Longgupo in Wushan (now belonging to Chongqing), Sichuan Province. The stratum containing the hominid fossils was dated to 2 million years ago, which makes the Longgupo fossils the earliest example of *Homo erectus* in China. The reliability of the dates, however, is open to question (Huang and Ciochonetal 1995).

Even before visiting the Zhoukoudian site, Lewis Binford and Chuan Kun Ho challenged the long-established conclusions that Peking Man controlled fire and that the Zhoukoudian cave was the home of Peking Man (Binford and Ho 1985). Many Chinese archaeologists were outraged, and Jia Lanpo, one of the excavators of Zhoukoudian, defended Peking Man's reputation with great passion (Jia 1991). The strong reaction from the Chinese archaeological community is understandable when the issue is placed in the context of rising nationalism in China. Within the framework of the regional evolutionary model, Peking Man appears to have been regarded as one of the direct, but remote, ancestors of the nation.

The Origins of Food Production

When the Hemudu site (ca. 7000 b.p.) in the lower Yangzi River Valley was excavated in 1974, it was claimed that the large quantity of rice remains found there was the earliest evidence of domesticated rice in the world. However, rice production at Hemudu was in a somewhat advanced stage, and the origin of rice cultivation was still an open question. In the 1980s, rice remains dated to 8000-9000 b.p. were found at Pengtoushan and several other sites in the middle Yangzi River Valley, which was regarded as a possible center for the origins of rice domestication. The great potential of finding the earliest evidence of rice production in southern China attracted both Chinese and western archaeologists, and more excavations employing new methods and techniques-including flotation, phytolith analysis, and isotopic analysis-were carried out in the 1990s. Consequently, rice remains dated to 8000-9000 b.p. or earlier were found at Jiahu in southern Henan Province, Bashidang and Yuchanyan in Hunan Province, and Xianrendong and Diaotonghuan in Jiangxi Province (Chen 1999a; Lu 1999).

Excavations at the cave sites Xianrendong and Diaotonghuan, conducted by a Sino-American collaborative project led by Yan Wenming and Richard MacNeish, yielded long sequences of cultural development, suggesting that rice domestication can be traced back to a period as early as 10,000-11,000 b.p., followed by the earliest pottery making in 9000-10,000 b.p. (MacNeish and Libby 1995; Zhao 1998). The origin and rapid expansion of rice cultivation from the Yangze River Valley may imply the introduction of languages and genes from southern China to broader territories in adjacent regions (Higham and Lu 1998). Southern China may have also been one of the places where the earliest pottery was invented (Chen 1998). These findings have certainly promoted the significant role that China has played in world history.

The Origins of Civilization

The years since 1980 have witnessed a radically changed view of the development of Chinese civilization in archaeology, with a shift from the concept of a central-plains-centered tradition to that of a multicentered parallel development. This change was not simply a product of political propaganda, and it did not happen overnight. It has gradually emerged and crystallized as the result of a complex interplay of several factors. These include voluminous new archaeological discoveries made in areas outside the central plains, traditionally regarded as the core area of Chinese civilization; the recognition of diversified regional cultural traditions based on these new findings; a changing view of nationalism in recent years; and increased confidence in the credibility of the textual record.

New Archaeological Discoveries

Since the end of the Cultural Revolution numerous archaeological discoveries have been made-most of them in areas outside the central plains. In southern China, new evidence indicates that this region not only had its own indigenous origins of Neolithic traditions (earliest rice and pottery) but that it evolved into complex societies at same time as, if not earlier than,

stone tools were found at Longgupo in Wushan (now belonging to Chongqing), Sichuan Province. The stratum containing the hominid fossils was dated to 2 million years ago, which makes the Longgupo fossils the earliest example of *Homo erectus* in China. The reliability of the dates, however, is open to question (Huang and Ciochonetal 1995).

Even before visiting the Zhoukoudian site, Lewis Binford and Chuan Kun Ho challenged the long-established conclusions that Peking Man controlled fire and that the Zhoukoudian cave was the home of Peking Man (Binford and Ho 1985). Many Chinese archaeologists were outraged, and Jia Lanpo, one of the excavators of Zhoukoudian, defended Peking Man's reputation with great passion (Jia 1991). The strong reaction from the Chinese archaeological community is understandable when the issue is placed in the context of rising nationalism in China. Within the framework of the regional evolutionary model, Peking Man appears to have been regarded as one of the direct, but remote, ancestors of the nation.

The Origins of Food Production

When the Hemudu site (ca. 7000 b.p.) in the lower Yangzi River Valley was excavated in 1974, it was claimed that the large quantity of rice remains found there was the earliest evidence of domesticated rice in the world. However, rice production at Hemudu was in a somewhat advanced stage, and the origin of rice cultivation was still an open question. In the 1980s, rice remains dated to 8000-9000 b.p. were found at Pengtoushan and several other sites in the middle Yangzi River Valley, which was regarded as a possible center for the origins of rice domestication. The great potential of finding the earliest evidence of rice production in southern China attracted both Chinese and western archaeologists, and more excavations employing new methods and techniques-including flotation, phytolith analysis, and isotopic analysis-were carried out in the 1990s. Consequently, rice remains dated to 8000-9000 b.p. or earlier were found at Jiahu in southern Henan Province, Bashidang and Yuchanyan in Hunan Province, and Xianrendong and Diaotonghuan in Jiangxi Province (Chen 1999a; Lu 1999).

Excavations at the cave sites Xianrendong and Diaotonghuan, conducted by a Sino-American collaborative project led by Yan Wenming and Richard MacNeish, yielded long sequences of cultural development, suggesting that rice domestication can be traced back to a period as early as 10,000-11,000 b.p., followed by the earliest pottery making in 9000-10,000 b.p. (MacNeish and Libby 1995; Zhao 1998). The origin and rapid expansion of rice cultivation from the Yangze River Valley may imply the introduction of languages and genes from southern China to broader territories in adjacent regions (Higham and Lu 1998). Southern China may have also been one of the places where the earliest pottery was invented (Chen 1998). These findings have certainly promoted the significant role that China has played in world history.

The Origins of Civilization

The years since 1980 have witnessed a radically changed view of the development of Chinese civilization in archaeology, with a shift from the concept of a central-plains-centered tradition to that of a multicentered parallel development. This change was not simply a product of political propaganda, and it did not happen overnight. It has gradually emerged and crystallized as the result of a complex interplay of several factors. These include voluminous new archaeological discoveries made in areas outside the central plains, traditionally regarded as the core area of Chinese civilization; the recognition of diversified regional cultural traditions based on these new findings; a changing view of nationalism in recent years; and increased confidence in the credibility of the textual record.

New Archaeological Discoveries

Since the end of the Cultural Revolution numerous archaeological discoveries have been made-most of them in areas outside the central plains. In southern China, new evidence indicates that this region not only had its own indigenous origins of Neolithic traditions (earliest rice and pottery) but that it evolved into complex societies at same time as, if not earlier than,

stone tools were found at Longgupo in Wushan (now belonging to Chongqing), Sichuan Province. The stratum containing the hominid fossils was dated to 2 million years ago, which makes the Longgupo fossils the earliest example of *Homo erectus* in China. The reliability of the dates, however, is open to question (Huang and Ciochonetal 1995).

Even before visiting the Zhoukoudian site, Lewis Binford and Chuan Kun Ho challenged the long-established conclusions that Peking Man controlled fire and that the Zhoukoudian cave was the home of Peking Man (Binford and Ho 1985). Many Chinese archaeologists were outraged, and Jia Lanpo, one of the excavators of Zhoukoudian, defended Peking Man's reputation with great passion (Jia 1991). The strong reaction from the Chinese archaeological community is understandable when the issue is placed in the context of rising nationalism in China. Within the framework of the regional evolutionary model, Peking Man appears to have been regarded as one of the direct, but remote, ancestors of the nation.

The Origins of Food Production

When the Hemudu site (ca. 7000 b.p.) in the lower Yangzi River Valley was excavated in 1974, it was claimed that the large quantity of rice remains found there was the earliest evidence of domesticated rice in the world. However, rice production at Hemudu was in a somewhat advanced stage, and the origin of rice cultivation was still an open question. In the 1980s, rice remains dated to 8000-9000 b.p. were found at Pengtoushan and several other sites in the middle Yangzi River Valley, which was regarded as a possible center for the origins of rice domestication. The great potential of finding the earliest evidence of rice production in southern China attracted both Chinese and western archaeologists, and more excavations employing new methods and techniques-including flotation, phytolith analysis, and isotopic analysis-were carried out in the 1990s. Consequently, rice remains dated to 8000-9000 b.p. or earlier were found at Jiahu in southern Henan Province, Bashidang and Yuchanyan in Hunan Province, and Xianrendong and Diaotonghuan in Jiangxi Province (Chen 1999a; Lu 1999).

Excavations at the cave sites Xianrendong and Diaotonghuan, conducted by a Sino-American collaborative project led by Yan Wenming and Richard MacNeish, yielded long sequences of cultural development, suggesting that rice domestication can be traced back to a period as early as 10,000-11,000 b.p., followed by the earliest pottery making in 9000-10,000 b.p. (MacNeish and Libby 1995; Zhao 1998). The origin and rapid expansion of rice cultivation from the Yangze River Valley may imply the introduction of languages and genes from southern China to broader territories in adjacent regions (Higham and Lu 1998). Southern China may have also been one of the places where the earliest pottery was invented (Chen 1998). These findings have certainly promoted the significant role that China has played in world history.

The Origins of Civilization

The years since 1980 have witnessed a radically changed view of the development of Chinese civilization in archaeology, with a shift from the concept of a central-plains-centered tradition to that of a multicentered parallel development. This change was not simply a product of political propaganda, and it did not happen overnight. It has gradually emerged and crystallized as the result of a complex interplay of several factors. These include voluminous new archaeological discoveries made in areas outside the central plains, traditionally regarded as the core area of Chinese civilization; the recognition of diversified regional cultural traditions based on these new findings; a changing view of nationalism in recent years; and increased confidence in the credibility of the textual record.

New Archaeological Discoveries

Since the end of the Cultural Revolution numerous archaeological discoveries have been made-most of them in areas outside the central plains. In southern China, new evidence indicates that this region not only had its own indigenous origins of Neolithic traditions (earliest rice and pottery) but that it evolved into complex societies at same time as, if not earlier than,

the central plains. Southern China also witnessed highly developed Bronze Age cultures with characteristics distinctive from those of the central plains. Several Neolithic walled settlements have been found in the middle and upper Yangzi River Valley, and one found at Chengtoushan in Hunan Province (ca. 4000 b.c.) is the earliest example of a walled settlement in China.

Distinctive elite tombs filled with large quantities of jade objects on artificially made earth mounds have been discovered in the Liangzhu culture in the lower Yangzi River Valley, and the high level of craftsmanship reflected in jade manufacture and the construction of large burial mounds have led some archaeologists to argue for the existence of early states in the Liangzhu culture (ca. 3200-2000 b.c.). Sacrificial pits containing large numbers of bronze figurines, life size or bigger, have been discovered at Sanxingdui in Sichuan Province in the upper Yangzi River Valley, revealing a previously unknown kingdom with a highly developed bronze culture contemporary with the Xia and Shang dynasties. A large tomb filled with hundreds of bronze and jade objects was found at Dayangzhou in Jiangxi Province in the middle Yangzi River Valley, which indicates the existence of an advanced bronze culture with strong indigenous characteristics along with influences from the central plains.

In northeastern China, the Neolithic tradition now can be traced back to the Xinglongwa culture (6100-5300 b.c.) in Liaoning and Inner Mongolia, which may have demonstrated a fully developed agricultural society. Complex societies seem to have evolved around 3500 b.c. in this region, as is indicated by the construction of a large public edifices in the late Hongshan culture, especially at the Niuheliang site, which yielded stone monuments with well-furnished elite burials and remains of a large architectural foundation associated with life-size female figurines (known as the Goddess Temple). This broad region later became the homeland of pastoralism and nomads whose interaction with agricultural populations dominated the political arena in the following millennia. These astonishing discoveries changed the traditional view, which regarded peoples outside the central plains as barbaric and uncivilized.

In eastern China, including Shandong and northern Jiangsu Provinces, archaeologists discovered the earliest Neolithic assemblage at Houli in Shandong Province (ca. 6200-5600 b.c.), which was followed by the Beixin, Dawenkou, and Longshan cultures, forming another regional tradition of cultural development. Many elaborately furnished elite burials and more than a dozen walled settlements dated to the Dawenkou and Longshan periods (ca. 4100-2000 b.c.) have also been found, generating more claims for the emergence of state-level societies in the Neolithic period in this region.

In the central plains, primarily including the middle Yellow River, the Fen River, and the Wei River Valleys and regarded as the center of Chinese civilization, archaeological discoveries seem to demonstrate a cultural tradition that may not have been much more advanced than those on “the peripheries” during the Neolithic period. As in other regions, the Neolithic traditions of the central plains can be traced to the Peiligang culture 7000 b.c., which was followed by a continued development of the Yangshao and Longshan cultures. Although rich elite burials dated to the Longshan period have been discovered at Taosi in Shaanxi Province and walled settlements belonging to the late Yangshao and Longshan have been found in Henan Province, these features are not unique and are certainly not earlier than those in other regions (for brief information on the major discoveries in the Neolithic period and the three dynasties, see Ren and Wu 1999; Wang 1999). Diversified regional cultural traditions are easily observable based on these new data, which have encouraged new interpretations concerning the origins of civilization.

Multiregional Development of Civilization in China

Initiated by Su Bingqi, a research model known as *quxi leixing*-the regional systems and local cultural

series-was proposed in the early 1980s (Su and Yin 1981; for a review of Su's framework see Wang 1997). The model is based mainly on ceramic assemblages, with an emphasis on the independent development of and interaction among different regional cultural traditions. The *quxi leixing* concept was intended to provide a methodological framework for the reconstruction

of Chinese prehistory, as it shifted away from the center-periphery model to a multiregional approach to the development of Chinese civilization.

As stated by Su Bingqi (1991), after 10,000 b.p., six relatively stable regional divisions *(quxi)* formed within the area embraced by historical China. The six regional cultures are further divided into a number of local phases *(leixing).* Each of these regions, according to Su, had its own cultural origins and developments and interacted with the others in the developmental processes of Chinese civilization. Yan Wenming suggested a similar model as "the unity and variability of Chinese prehistoric culture," seeing the central plains as the center of the flower and cultural traditions and the surrounding areas as layers of petals (Yan 1987). Instead of giving equal weight to all regional cultures implied in Su's hypothesis, Yan's model emphasizes the leading role of the central plains in the movement toward civilization while acknowledging the existence of elements of civilization in the peripheries in prehistory.

The general trend shifting from a monocentered to a multicentered development of Chinese civilization, as Lothar von Falkenhausen (1995, 198-199) observed, is also reflected in the four editions of the *Archaeology of Ancient China* by kwang-chih chang, which have been the most comprehensive and authoritative sources of Chinese archaeology in English for decades. In the first three editions, published in 1963, 1968, and 1977, the central plains was seen as the nucleus from which complex society and dynastic civilization rose. In the fourth edition, published in 1986, this view was replaced by the concept of "a Chinese interaction sphere," covering a geographic dimension much broader than the central plains, which formed the foundation for the development of the three dynasties (Chang 1986b, 234-242). Such a change of paradigm in Chinese archaeology seems to integrate very well with a new perspective in the reconstruction of national history.

Nationalism, National History, Legends, and Origins of Civilization in Archaeology

Since its birth, Chinese archaeology has had one clear objective: to reconstruct national history. The concept of nation, and thus of national history, however, has changed over time, as the tasks of reconstruction have been inevitably affected by new perspectives of national history.

As the state has attempted to bring China's multi-ethnic population into a viable political entity since the1950s, the concept of the Chinese nation has become equivalent to that of the state, best described by Fei Xiaotong (1989) as a single entity with multiple components *(duoyuan yiti).* According to Fei, China as a nation (a substance without self-consciousness) has gradually come into existence through thousands of years. This formative process was amalgamative, with a dominant core constituted first by the Huaxia and then by the Han people. However, the cultural interaction between the Huaxia-Han and other groups was not a one-way diffusion but a mutual influence. This national entity now, according to Fei, includes all nationalities (more than fifty) and covers the entire territory of modern China. It seems that this new concept of nationalism fits relatively well with the archaeological *quxi leixing* paradigm and, in particular, with "the unity and variability" hypothesis. Evidently, the archaeological and sociological models mutually support each other in constructing national history.

With increased knowledge of regional archaeological cultures, scholars have developed a strong willingness to construct cultural history based on archaeological material remains and the historical record. There has been a tendency to identify archaeological cultures and phases, sites, and even artifacts directly with specific ancient groups of people or places named in legends or historical literature. The continuing debates on the cultural identification of several Bronze Age cities-such as Erlitou, Erligang, and, most recently discovered, Yanshi Shang city near Yanshi and Xiaoshuangqiao near Zhengzhou-best exemplify this attempt. By doing so, archaeological assemblages (mainly pottery typology) become historically meaningful, although the logical connections between the two sets of

information-ceramic typology and ethnic affiliation-have not been made explicit.

The phrase “five-thousand-year history of civilization” has been commonly used in China

to summarize national history, and archaeology is pledged to trace the origins and to demonstrate the processes of this history. Since recorded dynastic history did not begin until about 2000 b.c., much effort has been made to connect regional Neolithic cultural developments with the activities of predynastic legendary kings and sages in order to fill the time gap of 1,000 years. Attempts have also been made to link certain cultural achievements with the dawn of civilization, such as the manufacture of jade objects and the construction of large ceremonial monuments, which are traceable to the Neolithic period.

As a consequence, not only are legends read as reliable history and used to interpret Neolithic archaeology, but the origins of Chinese civilization are pushed back 1,000 or more years to match counterparts in mesopotamia and Egypt (Su 1988, 1997). In the early twentieth century, when the *yigupai* questioned traditional texts, they hoped that archaeologists would uncover reliable ancient history from the field. For many archaeologists today, these legendary accounts are like blueprints for reconstructing prehistory, and the *yigupai* have become the target of criticism (Li 1994).

A state-directed project in the 1990s pushed this endeavor to its peak. In a visit to Egypt, Song Jian, the state counselor *(guowu weiyuan),* was introduced to a detailed chronological record of dynastic Egypt that started from 3100 b.c. Dissatisfied with the Chinese dynastic chronology, which is not only 1,000 years later but also less precise than that of Egypt, Song Jian called for a project to reconstruct an accurate chronology of the three dynasties so that Chinese civilization would be comparable to Egypt's (Song 1996). This project, known as the Xia-Shang-Zhou Chronology Project, was officially launched in 1996. For nearly four years, some 170 experts in history, archaeology, astronomy, and radiocarbon-dating technology were involved in the project, focusing on nine primary research topics, which were further divided into thirty-six subtopics. The budget was about 17 million yuan (US$2.1 million), and archaeology certainly benefited from such a generous financial commitment from the state, which supported some major excavations. The project achieved four objectives (Jiang 1999):

1. 1. to provide accurate dates for a time period from the conquest of the Shang by the Zhou to the beginning of recorded chronology in 841 b.c.
2. 2. to determine relatively accurate chronology for the late Shang period
3. 3. to define a relatively detailed time frame for the early Shang period
4. 4. to outline a basic time frame for the Xia dynasty

The chronology of the three dynasties has indeed become more precise and detailed than before, but the project has not made Chinese civilization temporally comparable with some older civilizations in other parts of the world.

Encouraged by the achievement of the Xia-Shang-Zhou Chronology Project, a new research organization, the Center for the Study of Civilization, was recently established in the Department of Archaeology at Beijing University. Archaeologists are now determined to find the ultimate origins of Chinese civilization, which ought to be embedded in the Neolithic cultures (Center for the Study of Ancient Civilization, Beijing University 1999).

International Collaborative Research in China

Since the 1980s, scholarly exchange between China and foreign countries has increased dramatically. It has also moved on from exchanging ideas at international conferences to conducting field research. In 1991, the Chinese National Bureau of Cultural Relics released a document on policies for Sino-foreign

collaborative research in archaeology (National Bureau of Cultural Relics 1992), which, after more than forty years, reopened the door to foreign archaeologists wanting to working on Chinese archaeology.

Many collaborative projects have been carried out in recent years in regions across the country, international scholarly exchange has introduced western theories to China, and these theories have, to some extent, enriched research orientations and interpretations. New methods and technologies have been introduced in fieldwork and laboratory analyses, including, to name a few, the use of the flotation method in recovering macrofaunal and macrofloral remains;

Christy, Henry

(1810-1865)

Born in London into a wealthy stockbroking Quaker family, Christy became such a successful banker that by 1850 he was able to spend more time pursuing his antiquarian interests and traveling. His trips to Scandinavia in 1852 and 1853 visiting museums provoked his interest in prehistory.

In 1856 his interest in ethnology took him to North America and mexico, where he befriended and traveled with anthropologist edward tylor (1832-1917). Together they visited and studied the ruins of teotihuacán, Xochichalco, and Cholula.

In 1862 Christy began funding and working with French paleontologist édouard lartet (1801-1871) exploring the caves of Vezere in southwestern France. They discovered the sites of Gorge d'Enfer, laugerie haute, la madeleine, le moustier, and les Eyzies, all of which had an enormous impact on contemporary understanding of the French Paleolithic. From evidence at Le Moustier, the Mammoth and Great Cave Bear periods were recognized as contemporaneous. From evidence at La Madeleine,

the Reindeer age was better understood. Christy also funded work with Lartet in the Perigord (Dordogne) region that provided evidence for the existence of Paleolithic cave art. Much of the material found became part of the Musée des Antiquites Nationales at Saint Germain-en-Laye. Lartet (one of the giants of the history of prehistoric archaeology) was immensely fortunate in his association with Christy and their partnership made a fundamental contribution of the first rank to our understanding of human prehistory.

Christy was editing a volume of their results when he died. *Reliquiae Aquitanicae* (1875), a classic in European Paleolithic archaeology, was completed at the expense of Christy's estate by geologist Thomas Jones.

Clark, Sir Grahame

(1907-1995)

Grahame Clark is by general consent the only British prehistorian of the twentieth century whose importance rivaled that of vere gordon childe. His career spanned almost the whole century as well as the emergence of modern archaeology. His first book was published in 1932, and his last appeared in 1992. Clark went

up to Peterhouse College, Cambridge, in 1926 completed his Ph.D. in 1930. His dissertation was later published as *The Mesolithic Age in Britain* (1932). Miles Burkitt supervised Clark's doctorate, but it was probably dorothy garrod, an active excavator, who had a greater influence on him. Clark lectured in Cambridge from 1935 to 1952 when he became Disney Professor of Archaeology. He retired from the chair in 1974 but actively wrote and researched until his death. The list of his publications is phenomenal.

While Disney Professor, he employed eric higgs and david clarke and created an exciting environment for students from Britain and other parts of the world at Cambridge University. These contacts and a significant program of overseas excavations were the result of Clark's interest in world prehistory.

Clark's long career covered more ground that that of almost any other archaeologist of the twentieth century. He is not identified with the analysis of one kind of archaeological material, nor indeed with an interest that is restricted to one aspect of prehistory. Clark has been universally linked with the Mesolithic site of Star Carr in Yorkshire in England. However, even that work should be viewed in the larger context of Clark's overall career, for it was but one element on a broad canvas, prepared over the decade before excavation and retouched and developed many years later. Clark frequently switched his focus and interest; he would introduce ideas and study topics and then move on.

Although Clark was not regarded as a founder of “the new archaeology,” at least some of its concepts were present in his writings during the 1950s. He did not carry the radiocarbon revolution to its conclusion, although he had used early radiocarbon results to demonstrate that the northern and western European Neolithic was far older than previously supposed. Clark moved on to consider hunter-gatherer landscape use and suggested the hierarchical taxonomy of human groupings in the Paleolithic northern European plain. It was left to others to identify these as biologically based mating networks, and meanwhile, Clark was engaged in the investigation of cultural diversity. His last book, *Space, Time and Man* (1992), discussed the human ability to conceive of and organize time and space in ways that other species cannot.

Clark, J. Desmond

(1916-)

John Desmond Clark is preeminent among twentieth-century archaeologists working in Africa. More than any other individual he has shaped African prehistory, and his visions have established or structured almost all of the prehistoric research now under way on that continent. Desmond Clark was born in London and attended Christ's College, Cambridge, where he studied archaeology and anthropology under Miles Burkitt and grahame clark, who taught him the importance of the paleoenvironment in archaeology and how changes in that environment might influence human behavior.

In 1937, Clark went to work in Northern Rhodesia (now Zambia) as secretary of the Rhodes-Livingstone Institute in Lusaka and as curator of the Rhodes-Livingstone Memorial Museum in Livingstone. He reorganized the museum, created thematic exhibits of both archaeological and ethnological materials, and wrote an accompanying handbook. The museum proved to be popular with local people and schoolchildren and after World War II attracted foreign tourists visiting nearby Victoria

Falls. Later the museum was to be the site of Clark's annual Winter School in Archaeology. Clark also established the National Monuments Commission to protect archaeological sites in Northern Rhodesia.

During the 1930s, Clark was one of the few professional archaeologists in southern Africa. He began his fieldwork with the geologist Basil Cook from Johannesburg, and his study of the stone tools and fossils of the Old Terrace gravels of the Zambezi River in Northern Rhodesia resulted in his first publication in 1939. He obtained a research grant to do additional excavations at Mumbwa, and a 1942 report recorded a sequence of Stillbay, Rhodesian Wilton, and

PREV NEXT

context and to write, edit, or coordinate insightful syntheses such as *Prehistory of Africa* (1970) and the *Atlas of African Prehistory* (1967).

Clarke, David Leonard

(1936-1976)

David Leonard Clarke, a British archaeologist, never directed a major excavation but was noted for his outstanding contributions to theoretical archaeology. He studied the ceramic vessels of the Beaker assemblage of the third millennium b.c. in Europe and gained his accreditation as an archaeologist more in the Continental museum tradition than in the British excavation mode. Clarke remained in Cambridge, England, all his professional life, and his career spanned only ten years from the completion of his Ph.D. to his sudden death in 1976.

He is famous for radicalizing British archaeology, and in *Analytical Archaeology* (1968), Clarke argued that archaeology must become a science by developing an explicitly archaeological theory based on general systems theory. Clarke argued that the variability in cultural assemblages required attention. Cultural assemblages varied-there were no discrete cultures, only overlapping suits of slightly different collections of items-and the artifacts varied as well. Concentrating on the special but calling it typical, in the sense of the unique and supposedly diagnostic, could lead to conclusions quite different from those reached when looking at the most common or typical forms. The variability in specific types of objects was a fascinating insight into the obvious. Variability of form suggested to Clarke a past of unceasing fluctuation. He believed that what was possible for biology should be feasible for culture, with variability lodged within a taxonomic frame for ordering the allocation of entities to classes, not directed to a systematic operational concern with the causes and effects of variability.

His second profound contribution to archaeological theory was the recognition of the critical importance of scale in our understanding of the past and the different scales of phenomena within it. If archaeology was to be systematic, as Clarke wished, it was not difficult to envisage that the established rigor and precision should be extended to include precise statements about magnitude and variability. Clarke's great insight was that by extension, the rigor of acquiring data should also be applied to its interpretation.

Clarke wanted to find the taxonomic system that meshed all archaeological phenomena together, coinciding, by accident or intent, with “natural” categories of culture, and doing for archaeology what the sixteenth-century Swedish biologist Carolus Linnaeus had done for biology. Even without a high-level theory, a system of classification that coincided with a natural taxon would allow coherent research propositions, just as it did for biology before the modern synthesis. The addition of variation to the description of archaeological entities should lead toward a proper theory of culture. In this respect, Clarke had something in common with “the new archaeologists” in the United States. The correct procedure, whether based on Hempellian logic in the U.S. scheme or taxonomy in Clarke's scheme, was intended to produce good and appropriate theories.

The quandary at the core of Clarke's agenda is the absence of a systematic high-level theory about what matters-an explanation of the nature of human behavior. This weakness was common to the entire

program of the new archaeology, and it still is a fundamental limitation of archaeological theory. No current paradigmatic position in archaeology has overcome this quandary.

Clarke, David Leonard

(1936-1976)

David Leonard Clarke, a British archaeologist, never directed a major excavation but was noted for his outstanding contributions to theoretical archaeology. He studied the ceramic vessels of the Beaker assemblage of the third millennium b.c. in Europe and gained his accreditation as an archaeologist more in the Continental museum tradition than in the British excavation mode. Clarke remained in Cambridge, England, all his professional life, and his career spanned only ten years from the completion of his Ph.D. to his sudden death in 1976.

He is famous for radicalizing British archaeology, and in *Analytical Archaeology* (1968), Clarke argued that archaeology must become a science by developing an explicitly archaeological theory based on general systems theory. Clarke argued that the variability in cultural assemblages required attention. Cultural assemblages varied-there were no discrete cultures, only overlapping suits of slightly different collections of items-and the artifacts varied as well. Concentrating on the special but calling it typical, in the sense of the unique and supposedly diagnostic, could lead to conclusions quite different from those reached when looking at the most common or typical forms. The variability in specific types of objects was a fascinating insight into the obvious. Variability of form suggested to Clarke a past of unceasing fluctuation. He believed that what was possible for biology should be feasible for culture, with variability lodged within a taxonomic frame for ordering the allocation of entities to classes, not directed to a systematic operational concern with the causes and effects of variability.

His second profound contribution to archaeological theory was the recognition of the critical importance of scale in our understanding of the past and the different scales of phenomena within it. If archaeology was to be systematic, as Clarke wished, it was not difficult to envisage that the established rigor and precision should be extended to include precise statements about magnitude and variability. Clarke's great insight was that by extension, the rigor of acquiring data should also be applied to its interpretation.

Clarke wanted to find the taxonomic system that meshed all archaeological phenomena together, coinciding, by accident or intent, with “natural” categories of culture, and doing for archaeology what the sixteenth-century Swedish biologist Carolus Linnaeus had done for biology. Even without a high-level theory, a system of classification that coincided with a natural taxon would allow coherent research propositions, just as it did for biology before the modern synthesis. The addition of variation to the description of archaeological entities should lead toward a proper theory of culture. In this respect, Clarke had something in common with “the new archaeologists” in the United States. The correct procedure, whether based on Hempellian logic in the U.S. scheme or taxonomy in Clarke's scheme, was intended to produce good and appropriate theories.

The quandary at the core of Clarke's agenda is the absence of a systematic high-level theory about what matters-an explanation of the nature of human behavior. This weakness was common to the entire

program of the new archaeology, and it still is a fundamental limitation of archaeological theory. No current paradigmatic position in archaeology has overcome this quandary.

Classification

Classification is the most fundamental of all interpretive activities, not only in archaeology but also in all of science. There comes a time, sooner or later, when the sheer accumulation of

data requires its subdivision into groups before any other analytical or interpretive procedures can be undertaken. In archaeology, this has been true in the case both of artifacts and of cultures. As a result, archaeological classification has a long history, and in the broadest sense it probably dates back to the beginnings of archaeology itself. Beginning in the early nineteenth century, scientific classification developed hand in hand with scientific archaeology.

Preliminary Considerations and Definitions

If classification is the most fundamental of interpretive activities in archaeology, it is also one of the most complex and one of the most controversial. There are, to begin with, two quite different kinds of archaeological classifications, respectively, of artifactual finds and of "cultures" (variously also designated as horizons, patterns, aspects, etc.). The procedures involved are so different for both cases, and the characteristics of the classifications themselves so different, that their histories must be considered separately. There are, in addition, classifications of such things as house types, burial types, and decorative styles that fall somewhere between artifact classifications and culture classifications. They are classifications of abstractions rather than of concrete things, but they are confined in each case to one particular kind of abstraction while culture classifications are based on a whole range of abstractions involving different kinds of evidence.

Culture classifications are akin to, and in some sense derived from, the historian's traditional practice of periodizing the past-as, for example, into successive phases that are called Tudor, Jacobean, and Restoration. In archaeology, however, culture classifications attempt to encompass and to summarize both the spatial and the temporal variability of archaeological remains, creating units of analysis that are believed to represent the normative culture of a certain specific region during a specific interval of time. The Fort Ancient Culture of the Ohio River Valley and the Tripolye Culture of Neolithic Eastern Europe are examples of culture classification. Very frequently these schemes have a genetic character akin to that in language classification; that is, they recognize "parent" and "daughter" cultures in a chronological sequence.

Artifact classifications are usually nongenetic. They are however enormously variable, depending partly on the nature of the material being classified. The two most common kinds of artifact classifications are those of pottery and lithics (especially projectile points), but the salient features that are considered in the two cases are quite different. Pottery classifications are usually designed for use with small fragments; as a result, they place emphasis on stylistic and componential features rather than on overall form, which often cannot be determined. Projectile point classifications, on the other hand, are designed for use on whole specimens or large fragments and are based largely on criteria of form. The variables to be considered in classification also depend on what characteristics have been found to be temporally or chronologically significant; for example, color in the case of most pottery classifications but not in most lithic classifications.

However, the most important differences among artifact classifications depend on the purposes for which they were developed. A major distinction can be made between basic or essentialist classifications, which are designed to yield information about the material being classified, and instrumentalist classifications, in which the classified material is used for some purpose external to the material itself, such as the dating of archaeological sites. Essentialist classifications are often developed for the instruction of a wider public, for example, through museum displays and popular books, while instrumentalist classifications are developed only for "in-house" use among archaeologists and find expression chiefly in technical monographs. There are also purely ad hoc classifications whose only purpose is convenience: very often, to permit the description of a large and diverse mass of material in a limited number of monograph pages (see Adams and Adams 1991, 157-168). Most archaeological

bead classifications seem to fall into this last category.

Many, but not all, artifact classifications are typologies-here defined as classifications that have been made for the specific purpose of sorting

entities into discrete categories for purposes of statistical treatment. In such a system, the categories must be mutually exclusive and not overlap, so that each individual artifact or shard is assigned to one and only one category. Moreover, the set of categories must be comprehensive so that there is “a pigeonhole for every pigeon.” These features are not necessary in a classification that is made only for communication purposes; such a system may consist of a set of norms that overlap at the boundaries (see Adams and Adams 1991, 76-90). Typological classification is a relatively recent feature of scientific archaeology and is important chiefly when typological data are to be used quantitatively, or statistically. Consequently, it is a feature of artifact classifications rather than of culture classifications.

Reconstructing vases at the British Museum

(Gamma)

Many but not all classifications, both of artifacts and of cultures, have a hierarchical feature; that is, the smallest classificatory units are grouped into larger and more inclusive units in the same way that biological species are grouped into genera. This feature is especially prevalent in pottery classifications like the “type-variety system” that has been widely used in North and Central America (Smith, Willey, and Gifford 1960; Wheat, Gifford, and Wasley 1958). Such hierarchical classifications will be here designated as taxonomies.

Renaissance and Enlightenment Foundations

The archaeology of today is an outgrowth of what was earlier called antiquarianism. It is usually said to have had its beginnings in the Renaissance period, fifteenth to sixteenth centuries, when royal and noble patrons paid for field excavations in Italy and Greece that would yield objets d'art for their private collections. Before long, the antiquarian fever spread to England, where its focus shifted from classical antiquity to the megalithic remains of late prehistory. The objects recovered from these early diggings were displayed in “cabinets of curiosities”-often a whole room or several rooms in a nobleman's palace might be devoted to such displays. Later, a great many of the collections found their way into museums; indeed, they formed the original nuclei of some of Europe's earliest museums.

Every collector developed his or her own system for displaying the collected antiquities, as, a little later, did the museums that inherited them. Although none of these systems have survived, we may assume that at least some of them involved primitive, ad hoc classifications, perhaps according to the materials employed, artistic similarities, or places of finding. This type of ad hoc classification, while it has been partially superseded by other and purportedly more scientific systems, has by no means disappeared from archaeology. For example, it is still a common practice to divide up the total assemblage of material to be described in an archaeological monograph according to the material employed, so that there are separate chapters on pottery, objects of stone, objects of bone, and the like.

If the Renaissance was preeminently an era of discovery and collecting, the Enlightenment-essentially coeval with the eighteenth century-was above all an era of systematization. The dominant concern during the Enlightenment was to bring order and system to the mass of materials and facts that had been collected, not only in the natural world but in the social and political spheres as well. This effort resulted in a proliferation of botanical, zoological, and geological classifications, best exemplified by the "system of nature" developed by the Swedish botanist Carolus Linnaeus in the eighteenth century (Linnaeus 1735). At the same time, the moral philosophers, especially in France and in Scotland, developed logically coherent social and political schemata, including what came to be known as the three-stage schema of prehistory. This framework envisioned successive hunter-gatherer, pastoral, and agricultural stages in human development and was proposed almost simultaneously by Turgot in France and by Ferguson and Millar in Scotland (Meek 1976).

In the broadest sense, the classificatory methods of Linnaeus and other naturalists provided a methodological foundation for the later development of artifact classification while the three-stage schema of the moral philosophers was equally basic, at least conceptually, to the subsequent development of culture classification. However, the real development of classification as an essential, rather than merely an incidental, feature of archaeology had to wait for the beginnings of scientific archaeology, which came about only when the true antiquity of the human race began to be recognized. That recognition was one of the signal achievements of the nineteenth century.

The Beginnings of Scientific Archaeology

Scientific archaeology arose from the recognition that material remains from the past can be sources of information as well as of aesthetic enjoyment. Once that happened, scientific classification followed more or less inevitably. Artifacts began to be classified first and foremost with an eye to the information they could yield, information about themselves and about their makers and their times.

Scientific advances in archaeology have often begun in areas where the archaeological record was scantiest; where, in other words, careful and precise investigation was required to extract any information from the little that has survived from the past. This was undoubtedly the reason why European scientific archaeology, including classification, had its beginnings in Scandinavia, a region that was outside the realm both of classical antiquity and of the prehistoric megalith builders. Scandinavians at the outset of the nineteenth century were gripped by the same spirit of nationalism that affected nearly all European peoples, and like many of the others, they began to regard prehistory as an essential part of their national heritage. Without major architectural monuments or conspicuous objets d'art, however, they had a much more difficult job recovering that heritage than their neighbors in the more southern countries. It was in that context that scientific archaeology had its beginnings, mostly in denmark.

The Danes pioneered in the development of both culture classification and artifact classification. In the beginning, the two went hand in hand, but with the dominant concern always on the classification of cultures, since that was an essential step in the reconstruction of national prehistory. Artifact classification

was ancillary, or instrumental; that is, it was undertaken, not to learn about the artifacts themselves, but to

define the artifact types that were diagnostic attributes of each particular culture. There was a special interest in those types that could be recognized as "index markers" for particular cultural periods, akin to the "index fossils" of the geologist and the paleontologist. This instrumentalist function remains an important consideration in artifact classification to the present day, particularly in the Old World.

The Development of Culture Classification in the Old World

As far back as 1776, Scandinavian scholars had recognized that in their countries there were some archaeological sites that yielded only stone-cutting tools, others had both stone and copper, and still others had stone, copper, and iron (Daniel 1967, 90). In the early nineteenth century, Vedel Simonsen wrote specifically of a Stone Age, a Copper Age, and an Iron Age as stages in the prehistory of Scandinavia (Simonsen 1816-1819). It was christian thomsen, however, who first gave wide publicity to what has come to be called the three-age system when he arranged all of the prehistoric collections in the newly opened Danish National Museum into separate Stone Age, Bronze Age, and Iron Age assemblages in 1819. In order to achieve this comprehensive separation, he studied not only the cutting tools but also all of the different prehistoric remains at his disposal, including such things as pottery and ornaments, classifying them as Stone, Bronze, or Iron Age according to the contexts in which they occurred. The three-age system was thus from the beginning both a culture classification and a kind of artifact classification.

Thomsen's contribution to the three-age system was basically museum oriented, and it was left to several colleagues, most notably jens jacob worsaae, to give it wider recognition through published works (especially Worsaae 1843). For some time, however, there was resistance to the scheme in other countries, where scholars tended to regard it as a strictly Scandinavian phenomenon. In the competitive nationalist spirit of the times, they were perhaps hoping to discover uniquely different cultural sequences for their own countries. Still, by the 1850s, discoveries in England, Ireland, and Switzerland had convinced at least some scholars that the scheme had a wider validity. A little later it was found to accord perfectly with the worldwide schemata of cultural evolution proposed by sociologist Herbert Spencer (1855), ethnologist John Lubbock (lord avebury)(1865), anthropologist Lewis Henry Morgan (1877), and other pioneer evolutionists, and its acceptance became universal. Indeed, it has remained at the foundation of nearly all cultural classification systems in Europe and the Near East to the present day.

The three-age system could be regarded as a mere periodization, exemplifying a procedure that had long been common among historians. However, it was also the first archaeological culture classification insofar as it created a set of mutually exclusive categories to which both sites and artifacts were to be assigned.

French prehistorians, working in the middle of the nineteenth century, made an important addition to the three-age system when they recognized the existence of two stone ages: an earlier period characterized by the exclusive use of chipped stone tools and a later period having also ground and polished tools. In *Pre-historic Times,* first published in 1865, the English prehistorian John Lubbock gave these phases the formal names by which they are still known: Paleolithic, or Old Stone Age, and Neolithic, or New Stone Age.

It was also the French prehistorians of the later nineteenth century who first revealed the great variety of Stone Age cultures and the very long time span that they had occupied. édouard lartet, excavator of many Paleolithic sites in the Dordogne and Vezere regions of France, offered a four-stage periodization based on the kinds of mammal bones that were found in the sites: first aurochs and bison, then reindeer, then mammoth and woolly rhinoceros, and finally, cave bear. However, this periodization was soon superseded by the more comprehensive Stone Age classification of gabriel de mortillet, which, like the

earlier classificatory systems of Thomsen and Lubbock, was based on the internal evidence of distinctive artifact types rather than on the external evidence of paleontology.

PREV NEXT

to suggest an overall periodization into which they would all fit. His periodization encompassed four stages for the Neolithic and five stages for the Bronze Age (Montelius 1903). Other scholars working at about the same time subdivided the prehistoric Iron Age into two phases. The Montelius scheme combined and elaborated upon the features of the Thomsen and de Mortillet classifications in that culture periods were defined both by the materials employed in tool manufacture and by diagnostic characteristics of the tools themselves. In effect, the new method substituted diagnostic assemblages for individual diagnostic tool types as the basis for the definition of cultures and culture periods. This approach, which Montelius called "the typological method," has since been widely employed by European prehistorians although it has come in for substantial criticism in the recent past.

Although the cultural chronologies of Montelius and his colleagues, like those of Thomsen and de Mortillet, were based on the recognition of supposed continent-wide similarities, those similarities were attributed for the first time to cultural diffusion rather than to evolutionary processes. This new perspective went hand in hand with the general adoption of the concept of culture among both ethnologists and prehistorians at the end of the nineteenth century. Different prehistoric assemblages were now seen as representing the work of ethnically distinct peoples who had continually borrowed ideas from one another. At least in the Neolithic and Bronze Ages, widespread cultural similarities were now seen mostly as the result of those borrowings.

The Montelius chronology of roman-numbered Neolithic (I-IV) and Bronze Age (I-V) stages is still occasionally employed by European prehistorians insofar as it provides a handy set of typological-chronological pigeonholes into which particular cultures can be placed. However, modified versions of the scheme have a much more basic role in the classification of Aegean and Near Eastern cultures, where scholars still routinely assign sites and cultures to the Early, Middle, or Late Bronze Age and to numbered subdivisions of these periods.

Although the general typological method of Montelius has remained in use among European prehistorians to the present day, no one since Montelius himself has proposed an overall, formal schema for the classification or periodization of European and Near Eastern prehistory. The nearest thing to overall synthesis is found in the works of English archeologists gordon childe (1925) and grahame clark (1952), but both of those scholars made use of the culture classifications already in use rather than proposing new ones.

A new and highly formal methodology for the development of culture classifications was proposed in 1968 by david clarke (1968, 187-398). In the broadest sense, it represented a refinement of the typological method in which artifacts were to be clustered into types, types into assemblages, and assemblages into cultures using highly rigorous criteria of inclusion at each level. However, this discussion was purely programmatic. Clarke did not go on to propose an actual classification based on his system, nor did the Soviet prehistorians who discussed and debated the methods of culture classification in rather similar terms during the same period (Klejn 1982). The time/space grid of European prehistory that remains in actual everyday use among prehistorians is still very largely an extension of the ones created initially by Christian Thomsen, de Mortillet, and Montelius, and it is based on their typological methodology.

The underlying conceptual model for Old World Paleolithic classification has always been chronological and evolutionary while the underlying model for Neolithic and Bronze Age classification has been mostly geographical and diffusionist. It may be noted that the same is generally true in the classifications of African Paleolithic and Neolithic cultures, which have been undertaken almost entirely by European-trained scholars (Trigger 1989, 135-138).

Culture Classification in the New World

Although the classification of prehistoric cultures in Europe and the Near East was always overshadowed by a concern for chronology and a belief in evolutionary progress, these factors

akin to the European three-age system, though paying more attention to ecological factors. This schema has proved useful for the evolutionary pigeonholing of specific prehistoric cultures, but it makes no effort to express historical relationships among them, as the Gladwin and McKern systems are intended to do.

The Gladwin and McKern systems remain almost the only efforts to introduce anything like formal or rigorous systematics into the classification of New World cultures, and neither has come into general use. Insofar as formal methods have been employed, they have largely been devoted to the differentiation of sequential phases within the same culture (e.g., Pueblo I-V) rather than to the differentiation of spatially distinct cultures. Overall, archaeological culture classification in the Americas remains mostly an ad hoc process, guided by no rigorous rules, and the same is true for Europe and Africa. There is a continuing, largely unexamined premise that preceramic cultures are defined most importantly by projectile point types and ceramic cultures, by pottery types. The establishment and acceptance of a particular culture, and of its successive phases, is still very much a matter of dialogue among the relevant specialists, resulting eventually in a general agreement on norms and boundaries.

Although there has been a great deal of highly sophisticated debate about the epistemology as well as the methodology and the utility of artifact classification, there has been relatively little debate concerning culture classification. There is, rather, a general recognition that archaeological cultures are for the convenience of the archaeologist so that the question of their “reality” does not arise.

The Development of Artifact Classification

Scientific artifact classification developed initially as an adjunct to culture classification. The early prehistorians, like Thomsen and de Mortillet, were not really interested in tools and pots as evidence of activities, technologies, or thought patterns but only as identifiers of chronological horizons. The objective in artifact classification was to identify those types that could be associated specifically with the Stone, Bronze, or Iron Age and could help in the allocation of sites to one or another of those periods. Individual types were of course defined on the basis of formal characteristics, but they were then grouped together on the basis of chronological contexts rather than the internal evidence of form or function.

So long as they were undertaken for purposes of culture definition and of site attribution, artifact classifications were dominated by the concept of “the index fossil.” That is, primary attention was given to those artifact types that were found to be diagnostic of specific periods. On the other hand, artifact types that were considered nondiagnostic were often ignored. Thus, for example, Mediterranean archaeologists gave names and definition to a few pottery types, like Minyan Ware, that had a high degree of historical significance, but a great many other and more ubiquitous pottery wares went unnamed. In the same way, North American prehistorians developed comprehensive and highly detailed classifications of projectile points, but nothing comparable was done for the more generalized stone tools like scrapers and choppers.

A long step forward was taken when Montelius introduced the typological method in the latter part of the nineteenth century. Using this procedure, cultures and chronological horizons were defined on the basis of total assemblages rather than of a few diagnostic types, and as a result, artifact classifications became more comprehensive. There was not, however, any attempt to introduce formal systematics into the classifications.

Not all nineteenth-century artifact classifications were instrumentalist. The problem confronting the museum curator was fundamentally different from that of the field archaeologist, since a museum's mission is to inform or entertain the public rather than to answer culture-historical questions. Moreover, a

great many museum collections had been donated by amateurs, with little or no accompanying provenience information. This was especially true in the case of arrowhead collections, which have always had a special fascination for Americans. As a result,

other scientific propositions, should be regarded as propositions to be tested (Hill and Evans 1972). As a result, there was a renewed emphasis on formal systematics, exemplified especially in the work of David Clarke (1968, 187-229), Robert Dunnell (1971), and Dwight Read (1974).

The renewed emphasis on formality and rigor led to an important methodological innovation: the use of statistics and the definition of types by attribute clustering rather than by object clustering (Spaulding 1953). The archaeologists' traditional procedure of partitioning a body of collected material into types through visual inspection and the observation of similarities was now thought to be too intuitive. Instead, a list was to be made of all the attributes of size, shape, color, and so on that were exhibited by all the objects in a collection individually. Types were then to be defined by clusters of attributes that occurred together with a frequency greater than chance, as revealed through the use of accepted statistical measures. Such a procedure would, in theory, result in "finding the joints in nature" and would eliminate all subjective judgment and all historical interpretation from the process of classification. The attribute-clustering approach carne to be known as "agglomerative" in contrast to the older method of partitioning, which was called "divisive."

In the beginning, the major difficulty in statistically based classification lay in the enormous number of separate calculations that had to be made in order to determine the randomness or nonrandomness of a nearly infinite number of attribute combinations. That difficulty was overcome in the 1970s, however, through the use of computers. There followed a decade of experimentation with computerized systems of classification, which, it was hoped, would finally achieve the elusive goal of automatic classification (see especially Whallon and Brown 1982). Before long, the search for automatic and absolutely "natural" classification became an end in itself, rather than a means to an end, and as such it considerably outlived the new archaeology paradigm that had given it birth.

It was eventually realized, however, that the goal of automatic classification was not practically attainable. The coding of more and more variables simply resulted in the generation of more and more types; far more than were useful for any practical purpose. Indeed, the ultimate logical outcome of computerized classification was a series of classifications in which every object constituted a separate type. In the end, there was a general, though not universal, acknowledgment that types that were not produced for any specific purpose were also not useful for any specific purpose.

As a result there has been, since the early 1980s, a considerable loss of faith in the possibilities of computerized classification and, with it, a loss of interest in the subject of classification in general. The postmodern fashion of the 1990s represented in many ways a reversion to the perspective of the 1940s, once again condemning formal typological constructs precisely because they had been made to serve the archaeologists' own purposes.

The successive changes of direction and of interest that have taken place since 1940 have resulted in far more theoretical and programmatic literature than actual, in-use classifications. The concern of most authors has been to propose new methods of classification rather than to develop actual classifications based on those methods. Insofar as the new methods have been put to practical use, it has been almost entirely at the level of individual assemblages. There has been, as a result, a proliferation of ad hoc classifications, each archaeologist developing his or her own system as a way of dealing with, and publishing, his or her own finds. For the most part, these individual systems have not proved capable of generative use and have not passed into what might be called the public domain. The archaeological type concepts and typological systems that remain in general, region-wide use are still very largely those that were developed, chiefly for the instrumentalist purpose of culture classification, more than half a century ago.

Other Archaeological Classifications

Although the vast majority of archaeological classifications are concerned either with cultures or with artifacts, there are also classifications

of house and building types, of burial types, of petroglyph and pictograph types, and of artistic styles. Some of these classifications, like some of the artifact classifications, predate the beginnings of scientific archaeology. As far back as the 1750s, william stukeley devised a classification of British earth mounds and megalithic monuments. A generation later, richard colt hoare and william cunnington proposed a fivefold classification of English barrow types. In North America, antiquaries caleb atwater in 1820 and Squier and Davis in 1848 proposed classifications of earth mound types.

The classification of houses and of burials has always gone hand in hand with culture classification, much as did the classification of artifacts before the 1930s. Indeed, the various monument types designated by Stukeley, Colt and Cunnington, and Atwater were initially regarded as the primary diagnostics for the recognition of different cultural periods. Later, house types took their place along with pottery and projectile points as defining characteristics of the various Neolithic cultures of the Old World, as well as of prehistoric American cultures. The importance of house types in culture classification is particularly evident in the U.S. Southwest, where each of the major cultures (Anasazi, Hohokam, Mogollon, and Hakatayan) is characterized by its own distinctive form of dwelling, as are the different developmental phases in some of the cultures. Burial types on the other hand have played an especially important role in defining the early cultures of the Nile Valley, where evidence of housing is largely lacking. In nubia, at the beginning of the twentieth century, george a. reisner recognized and differentiated a whole succession of previously unfamiliar ancient cultures on the basis of burial types alone (Reisner 1909).

Unlike artifact classifications, the classifications of house types and burial types have never really been decoupled from the larger objective of culture classification. Although prehistoric dwellings have been extensively studied from the standpoint of function and of ecology, their formal partitioning into types still serves mainly for the identification of cultures and of horizons. The case is somewhat different, however, in the classification of petroglyphs and pictographs, since many of these cannot be associated with specific peoples or time horizons. Classifications of rock art therefore tend to be more strictly formal and essentialist, based strictly on the exhibited characteristics of the drawings. There is not, however, any one generally accepted classification, or system of classification, of rock art. Every region has its own scheme based on its own distinctive body of material.

Theory versus Practice: The Typological Debate

As long as the basic aim in artifact classification was to define cultures and sequences, the actual procedures involved in the classification were generally regarded as nonproblematical. Artifact types were accepted or rejected on the grounds of their recognizability and their utility or nonutility for the reconstruction of culture history, and the question of their objective reality or meaningfulness to their makers did not arise. Debate often occurred over the legitimacy or the utility of individual types, but it did not touch upon the general methods or the purposes of classification itself.

However, the major shifts of interest that occurred after 1940 gave rise not only to new approaches to classification but also to an extensive and often heated dialogue about the nature and the meaning of classification itself. In one form or another, this discussion persists down to the present day, particularly in North America, where it has been given the name, “the typological debate.” The accumulated body of theoretical and programmatic literature is enormous, yet it bears surprisingly little relationship to what goes on in the practical domain, and it must therefore be discussed independent of actual field practice.

The most fundamental issue that has been debated concerns the “naturalness” or “artificiality” of types, which was raised initially in the context of the “functional revolution” in the 1940s but in one guise or another continues to be debated down to the present day. There is general agreement that “artificial” (i.e., instrumentalist) types can be created that are useful

Claustra Alpium Iuliarum

Claustra Alpium Iuliarum is a late Roman defensive system in western slovenia, northwestern Croatia, and northeastern italy. The term *Claustra Alpium Iuliarum* was first found in the texts of the Roman officer and historian Ammianus Marcelinus, who wrote in the fourth century a.d., and it was frequently used by many other ancient writers. The name Julian Alps was used in ancient times for the mountainous ridge extending from the Gail River valley (Carynthia in southern Austria) in the north to the mountain of Ucka (Istria in northwestern Croatia) in the south. Today, the name Claustra Alpium Iuliarum is normally applied to the remains of partially explored walls and fortifications in this region.

PREV NEXT

When constructing the defensive system, the Romans took advantage of the difficult terrain between the Roman towns of Tarsatica (Rijeka in northwestern Croatia), Tergeste (Trieste in northeastern Italy), Emona (Ljubljana in central Slovenia), and Forum Iulii (Cividale in northeastern Italy). The defensive system aimed at controlling all land routes and passages from the Balkans to Italy, and it consisted of a series of barrier walls in valleys and signal towers, small fortifications, and *castella,* or forts, which were built using prehistoric and early Roman constructions. As an organized military system, it belongs to the third and fourth century a.d., but some parts were used later as well.

Colombia

Among the most important sources for modern Colombian archaeologists are the writings of the Spanish conquistadores. The documents left by these soldiers, priests, administrators, and specially appointed chroniclers of the Indies of the sixteenth and seventeenth centuries are used in various ways: to complement the later periods of local or regional archaeological sequences, as a tool for interpreting the function or significance of archaeological sites or aspects of culture, and, finally, in conjunction with twentieth-century ethnographic studies used to build evolutionary type classifications of cultures. Perhaps that is why the sixteenth century is taken as a starting point by some of the authors who have dealt at length with the history of the discipline (Duque 1965, 1967, 1970; Burcher 1985; Londoño 1989; Uribe 1979; Jaramillo 1994). The works of these authors are the main sources for this entry.

A number of the sixteenth- and seventeenth-century writers-the priest Juan de Castellanos in his *Elegies of Illustrious Men of the Indies,* Friar Pedro Simón in his *Historical Notices of the Conquests of Terra Firme in the West Indies,* and Lucas Fernández de Piedrahita, author of the *General History of the New Kingdom of Granada*-had antiquarian interests. Their writings included discussions of the peopling of the new continent and of related factors such as changes in sea level. The importance of their work, however, is somewhat diluted by the unavoidable biblical frame of reference, for some of them were convinced that American Indians were the descendants of the Lost Tribes of Israel. (Unless otherwise stated, Spanish is the original language of the publications and journals mentioned in this entry; full bibliographical details can be found in Bernal [1970], Enciso and Therrien [1996], and Bermeo [1990]).

The systematic looting of Indian tombs was one way in which the Spaniards obtained the gold that they coveted and that was the driving force behind the conquest. Means of recognizing tombs by marks on the surface and ways of distinguishing rich graves from poorer ones were frequently described; in his *Historical Compilation,* for example, Friar Pedro de Aguado described the rich tombs of the lower Sinú River basin as well as those of the Muisca area, in the upland plateau of the Eastern Cordillera (a mountain range).

Early on, the Spanish crown issued laws to ensure its share of the profits from the looting of shrines and tombs, and lawsuits and quarrels between crown and church over the possession of gold idols obtained in these places were not infrequent. Regrettably tomb looters remained a step ahead of antiquaries and later archaeologists during the centuries that followed. This was the case with San Agustín in the upper reaches of the Magdalena River, the country's most famous archaeological region, through which the Spaniards passed in the sixteenth century. At that point monolithic sculpture was already a feature of the

past, and the statues, within artificial mounds, were not visible. By the eighteenth century, when Friar Juan de Santa Gertrudis visited the region, looting had started. His *Marvels of Nature* was the first written account of the region, although he described monuments as images of Catholic religious dignitaries "sculpted by the devil." He traveled extensively in the southwestern part of New Granada (as the country was known by that time) and wrote about the ancient burials of various parts of it.

Colt Hoare, Sir Richard

(1758-1838)

Born into an aristocratic banking family, Colt Hoare was financially independent and thus able to pursue a career of leisure. After the premature death of his wife he assuaged his grief by traveling around Europe for two years, a journey that stimulated his interest in monuments and antiquities. He returned to Britain to become Baron Hoare in 1787, then continued his European travels, visiting archaeological sites and drawing them for the next three years, until the French Revolution made it impossible to remain on the continent.

It was this impasse that caused him to visit Wales, England, and Ireland, drawing the monuments of his own country. Between 1812 and 1821 he illustrated and published the two-volume *Ancient History of North and South Wiltshire* and the *History of Ancient Wiltshire.* These contained accounts of Stonehenge and avebury, of Roman roads and sites, and of hundreds of barrows that he had explored with his protégé william cunnington. These books can be seen as the first attempts at recording the archaeology of a particular region.

Colt Hoare was a fellow of the Royal Society and the society of antiquaries of london, and he wrote numerous books, printed for private circulation, on history, architecture, and the archaeological sites, artifacts, and monuments of Europe, England, Wales, and Ireland. He financed his own archaeology team-composed of Cunnington, draftsman Philip Crocker, and special workmen-and he believed that excavations should be able to answer questions about the past. Unfortunately the answers to the big questions, such as who it was who actually built the monuments he caused to be excavated or recorded, remained elusive.

Colt Hoare saw himself as a historian, with his arguments based on facts and not on speculation, as were those of william stukeley. He was one of the first of the new generation of Romantic aristocratic gentlemen who were travelers, adventurers, artists, and journalist-writer-historians who were also keen barrow diggers. Such antiquaries featured strongly in the pursuit of the understanding of the past during last years of the eighteenth and the early nineteenth centuries, their position both chronologically and ideologically somewhere in between the antiquarians of the Enlightenment, and the professional archaeologists of the mid-nineteenth century.

Computer Applications in Archaeology

The application of computers to deal with archaeological problems has evolved from the statistical applications of the late 1950s and early 1960s to the current information technology (IT) approach. The development of ever-more user-friendly computer technology has encouraged the adoption of computers among a wider range of archaeologists than just those interested in quantitative analysis. It has been argued that the growing popularity of computer use is mainly owing to the fact that it can facilitate enormously the dissemination of archaeological information to a more generalized public at a relatively low cost. Some archaeologists have even seen the adoption of IT in archaeology as a subdiscipline in its own right. A series of specialized journals and regular meetings attest to

this trend, for example, the annual Computer Applications and Quantitative Methods in Archaeology Conference, which, after more than twenty-five years, attracts a growing number of archaeologists from around the world.

This trend has been characterized as a step forward to the ultimate full-fledged embracing of IT by archaeologists. In an evolutionary scheme akin to the Danish archaeologist c. j. thomsen's three-age system, the evolution of computer applications in archaeology can be considered as follows: the 1960s were the age of exploration; the 1970s, the age of implementation; the 1980s, the age of exploitation; and the 1990s, the age of information.

Quantitative Applications

In the 1960s, the age of exploration, statistics represented the main practical application of computers to archaeology. The facts that the statistical packages used were developed for mainframe computers and that archaeologists interested in this type of analysis had to have certain knowledge of the programming languages limited the generalized adoption of computers to a certain extent. Nevertheless, toward the second half of the 1970s, there was a noticeable shift in how archaeologists approached their data.

Archaeologists became aware of the need to present and analyze their data in a numerical form, and this shift was fostered by the development of radiocarbon dating, on the one hand, and the development of easier programming languages-e.g., Fortran-on the other. Although statistical applications experienced a decline in the mid-1980s, perhaps as a reaction against the alleged scientism of processual archaeology on the part of postprocessual archaeologists, the development of commercial statistical packages for the personal computer (PC), along with the impact of multivariate statistics, provoked a resurgence of this approach in the 1990s. Overall, it can be said that statistics has remained a favored computer-based application in archaeology throughout time.

Equally favored since the 1970s has been the use of computers in database management. Originally designed to keep museum and site inventories on mainframe computers, the development of PC-based programs (e.g., Dbase, Access) has sparked interest in this application. Currently, the development of metadata (i.e., data that documents information about datasets while allowing the expedient transfer and sharing of data between users) has opened the possibility of having access to the enormous resources contained in museum collections and site reports from other research institutions.

Artificial Intelligence and Expert Systems

The 1980s witnessed the emergence of what was presaged as being a revolutionary approach to archaeological problem solving: artificial intelligence (AI) and expert systems. Simply described, AI is a system by which computers are programmed to process data following a rationale similar to that of the human brain. In other words, the goal was to teach computers how to “think” like people. An outcome of AI was the development of expert systems, or programs that can replicate the combined knowledge of human experts addressing a specific problem in order to solve it. By mimicking the advice-giving capabilities of human experts, expert systems can offer intelligent advice or make an intelligent decision about how to solve a problem.

The proponents of this new methodology believed the multidisciplinary nature of the archaeological issues provided the ideal environment in which expert systems could thrive. However, despite the initial clamor and success stories in other disciplines, expert systems have not been fully embraced by archaeologists. Its critics argued that despite the expedient access to expert knowledge that expert systems offered, their main drawback lay in their limited or nonexistent ability to reproduce the uniquely human capabilities of common sense, creativity, and learning. Furthermore, some archaeologists

expressed concern that an overreliance on expert systems could be detrimental to the development of archaeological theory.

Attempts to overcome some of the limitations were undertaken, but apparently the momentum was lost. Expert systems gained a moderate level of popularity in archaeology toward the latter part of the 1980s but eventually lost favor and have been practically abandoned,

Artificial Intelligence and Expert Systems

The 1980s witnessed the emergence of what was presaged as being a revolutionary approach to archaeological problem solving: artificial intelligence (AI) and expert systems. Simply described, AI is a system by which computers are programmed to process data following a rationale similar to that of the human brain. In other words, the goal was to teach computers how to “think” like people. An outcome of AI was the development of expert systems, or programs that can replicate the combined knowledge of human experts addressing a specific problem in order to solve it. By mimicking the advice-giving capabilities of human experts, expert systems can offer intelligent advice or make an intelligent decision about how to solve a problem.

The proponents of this new methodology believed the multidisciplinary nature of the archaeological issues provided the ideal environment in which expert systems could thrive. However, despite the initial clamor and success stories in other disciplines, expert systems have not been fully embraced by archaeologists. Its critics argued that despite the expedient access to expert knowledge that expert systems offered, their main drawback lay in their limited or nonexistent ability to reproduce the uniquely human capabilities of common sense, creativity, and learning. Furthermore, some archaeologists

expressed concern that an overreliance on expert systems could be detrimental to the development of archaeological theory.

Attempts to overcome some of the limitations were undertaken, but apparently the momentum was lost. Expert systems gained a moderate level of popularity in archaeology toward the latter part of the 1980s but eventually lost favor and have been practically abandoned,

although this by no means implies that they are completely defunct, and it would not be surprising to see them reemerge.

Computer Graphics

It is apparent that the increasingly accessible prices of hardware and the development of more user-friendly software have greatly promoted the use of computers by archaeologists to address all sorts of issues. It is owing to this availability that we have witnessed a dramatic adoption in the application of computer graphics and virtual reality (VR) techniques for the display and analysis of archaeological data. Computers have long offered obvious advantages to archaeological documentation in the recording of excavation plans, artifact illustration, and the processing and presentation of results from scientific analysis, and these advantages are augmented by the ability to apply computer-generated graphics in reconstructive models of archaeological sites and structures. In this field, VR has had a considerable impact on how archaeological data is displayed.

Reconstruction of a man's face from the skull using digital technology

(Gamma)

The basic components of VR have been developed since the early 1960s, but the limitations of the available hardware at that time made its use prohibitive, except for those institutions that could afford it, like the military. Nonetheless, the ongoing developments of computer technology and decreasing prices have allowed a more widespread access to this technique. However, the embracement of VR has not been an easy process. The complexity of the graphics needed to reproduce the real world hindered its full acceptance for some time. The first attempts at VR renderings ended up being a disappointing imitation of reality, and the initial hype it created soon simmered down. As a response to this early rejection, current VR systems are more likely to attempt to “simulate” rather than imitate reality, which means that VR graphics will represent models of reality, not reality itself. There is a qualitative difference in this conception since simulated objects are ideal mathematical constructs that are displayed outside reality; consequently, the need for fully immersive systems is removed.

Another initial problem of VR graphics was that performance was dependent on the type of computer platform being used and the level of technical expertise of the user. To cope with these limitations, more-accessible programming languages have been developed since the mid 1990s-such as Virtual Reality Modeling Language (VRML) and Quick Time Virtual Reality (QTVR)-which are intended to become the standard languages for interactive simulations on the worldwide web.

Despite the simplification of the programming language, the production of computer-generated graphics is still a complex process comprising two stages: the modeling and the rendering. In the former, the geometric characteristics of the objects to be created are specified. In the latter, the model created is converted into pictures of the objects, which are then displayed from different perspectives. Simple objects can be created using “primitives,” simple predefined geometric shapes, e.g., cubes, spheres, cones, and cylinders. More-complex objects like landscapes or complex buildings cannot be properly modeled with primitives, and in these cases, the simplest building block used is a face of a polygon, and thousands of individual faces may be required.

The results thus obtained can indeed be impressive,

but the ongoing issue is whether archaeologists using this technology are merely obtaining pretty pictures or whether these graphic renderings will be of any assistance in the process of deriving better interpretations of the data. That computer-generated graphics can offer much more to archaeology than just pretty pictures is a position that has been adopted by various enthusiasts of these techniques. The insight that can be gained in terms of the social and political relationships reflected in the use of space, and even the construction of detailed models of the actual excavation process of archaeological sites for educational and analytical purposes, have been highlighted as obvious advantages.

What is immediately apparent is that computer graphics can increase public attention with regard to archaeology. The models represent a powerful and persuasive means of conveying to a much wider public the ideas and interpretations that the archaeologist distills from the data. For museums, computer graphics offer the possibility to enhance the way in which collections are presented to the public, for computer-generated graphics can allow the visitor to view the site from various perspectives-a bird's-eye view, walk around it, walk inside it-and thus obtain a more comprehensive impression of how the site may have been seen by its original users. Equally important, three-dimensional documentation of heritage structures can offer great advantages for the referencing and archiving undertaken by government agencies in charge of managing cultural resources.

Computers and Archaeological Knowledge

Although the creation of impressive images and the expeditious and effective manipulation of huge databases are without doubt of great appeal, archaeologists who embrace this technology should proceed with caution. They have to be aware that the sophisticated presentation of data may blind the uncritical eye to the fact that only a minuscule part of the whole may have been captured-and that it may represent our own subjective perception of that reality.

The very nature of the interpretative illustrations of archaeological sites and monuments generated by computer graphics has sparked an increasing amount of discussion. These discussions have centered mainly on the implicit assumption that the images are an all-inclusive, accurate interpretation of the past while, in fact, they may lack a rigorous scientific basis and perhaps represent more of the artist's impression.

It is undeniable that information technology is making groundbreaking contributions to archaeology, but it is not known how exactly this “new” technology impacts archaeological theory and what the consequences will be in terms of production and the dissemination of knowledge. Since the first incorporation of the computer as an analytical tool, in the midst of the paradigmatic shift that the processual archaeology was generating, there was an awareness on the part of some people of the growing need to have dual and simultaneous advances in method and theory.

The relationship between technological development and theory development is akin to what has been identified by some scholars as the interaction between tools and problems. Archaeologists now have access to a revolutionary tool that can handle enormous quantities of data, the computer, but tools can acquire a life of their own, computers in the information age may even come to dominate an entire period of thought. Throughout the history of science we see instances in which the solution to specific problems was delayed by the lack of appropriate tools to address the relevant issues. On the other hand, the availability of certain tools has allowed us to perceive problems, and formulate questions, that otherwise might have remained unidentified. This improved perception can lead to the formulation of new questions that may have a considerable impact on the development of our theoretical underpinnings.

The challenge of this age of information according to its proponents is the “democratization” of

knowledge. In other words, not only will the information age facilitate communication among scholars, but it is hoped that it will actually promote international cooperation in archaeological issues.

The democratization of knowledge is an issue that looms large in the minds of those archaeologists who are fully engaged in bringing archaeology up to speed in the information age. It has

been noted that since its insertion in the social sciences in the nineteenth century, archaeology has been part of a paternalistic civilizing process. In this sense, the Internet offers the great possibility of radical changes in the hierarchical structure of archaeological knowledge. In the view of these specialists, the growing accessibility to the Internet poses new possibilities in the dissemination and creation of new knowledge, thus making it more difficult for the academy (those professionals inside of universities) to have exclusive control of it.

Costa Rica and Nicaragua

In her history of Central American archaeology, doris stone observed that "early archaeology in lower Central America was primarily a part of exploration; sites and surface finds were discovered and described by observant travellers, engineers (and) art historians" (1984, 13). It is true that in the earlier days of exploration and initial investigation-the early and mid-twentieth century-Central American archaeologists were widely traveled and conversant with the prehistoric sites and artifacts of more than one, and frequently all, of the Central American countries. For example, Harvard archaeologist Samuel Lothrop worked in guatemala, el salvador, Nicaragua, Costa Rica, and panama, and one of his final publications was a synthesis of lower Central America. Harvard ethnologist Herbert Spinden worked in El Salvador and mexico, but also wrote extensively about Costa Rica and Nicaragua. Harvard student Doris Stone worked in Costa Rica and Honduras, but has also published widely about the prehistory of other countries in the isthmus.

Of present-day researchers, perhaps only Payson Sheets, who excavated in Panama, Costa Rica, and El Salvador and conducted survey activities in Nicaragua, or Ronald L. Bishop, who conducted extensive analytical programs with jade and ceramic data from Panama, Costa Rica, Nicaragua, Honduras, El Salvador, and Guatemala, approach this breadth of coverage.

Beginning in the early twentieth century, regional syntheses included Costa Rica and Nicaragua (*see* Joyce 1916; Spinden 1917; Lothrop 1966; Baudez 1970; Willey 1971; Stone 1972, 1977; Ferrero 1977). Joyce's synthesis was based on museum collections, while Lothrop, Baudez, gordon willey, Stone, and Ferrero reflected the gradual growth of the archaeological database; their regional syntheses became increasingly data-based through time.

A number of summary volumes on research in the area have appeared since 1980 (*see* Lange and Stone 1984; Lange 1984; Lange, Sheets, Martinez, and Abel-Vidor 1992; Lange 1992; Graham 1993). In addition to regional overviews, the publications have more complete bibliographic resources for Costa Rican and Nicaraguan archaeology. An annotated bibliography of Central American archaeology and pre-Columbian art is in preparation.

Improved transportation and logistical conditions, as well as changes in archaeological paradigms,

methodologies, and analytical possibilities, have affected Nicaraguan and Costa Rican archaeology, just as they have elsewhere. Where entire regions were once available only by horse, mule, on foot, or by dug-out canoe, there are now paved roads. Expanding populations and new communities provide communications and other support in what were once vast empty spaces. Where the dating of ceramic types, or entire sites, was once dependent on cross-association with the better-studied adjacent areas on the southern and eastern frontier of the Maya lowlands, radiocarbon dating has provided a firm chronological basis.

This entry places the history of Costa Rican and Nicaraguan archaeology within the broad outlines established for American archaeology (Willey and Sabloff 1993). However, archaeologists who are nationals of Central American

countries often see the development of Latin American archaeology as having its roots in the intellectual history of that region. As Fonseca (1992, 13-15) noted (translation mine):

The archaeological tradition that has most influenced Latin America, and therefore Costa Rica, is that of North America.... [A]s inheritors of European ethnocentrism, the colonizers of North America reserved the concept of history to the study of their own origins, and the related origins of those peoples who influenced the development of their culture (in this case Native Americans).… The history of archaeology has acquired different characteristics from country to country, and from region to region. In Costa Rica, archaeologists recently began to explain our ancient history.

This tendency to identify with "our" native ancestors, and to see their remains as the roots of the national heritage, persists even though the Spanish eliminated as much as 95 percent of the indigenous population.

Furthermore, the contrasting histories of the national political systems in Nicaragua and Costa Rica have greatly impacted the development of archaeology. With longer-term stability in the university and museum systems (reflecting stability in the broader political, social, economic, and cultural dimensions of society) Costa Rica has a larger and more mature corps of archaeologists (and auxiliary museum and collaborative specialists such as botanists, chemists, etc.) than does Nicaragua.

Nicaragua

Archaeologically, this is by far the least known of the Central American republics. While there was a great deal of nineteenth century interest, and detailed summaries (Lange et al. 1992; Arellano 1993) have been written, Nicaragua is still little known, particularly in the north and east (see map).

Central American Archaeological Survey Areas

The Non-Scientific/Speculative Period, 1492-1840

Numerous early accounts by Spanish chroniclers contain limited descriptions of gold- working, settlement patterns, subsistence practices, and religious activities. These reports were utilized by late-nineteenth and early-twentieth-century researchers to speculate about external cultural contacts and influences, which were presumed to have been primarily Mesoamerican. These same data, and more recent historical overviews and secondary sources (*see* Radell 1969; MacCloed 1973; Newson 1987; Incer 1990) are being utilized by contemporary researchers to test models of social organization, to supplement archaeological data in the development of cultural-historical sequences, and to define patterns of localized development and regional interaction.

Scientific Research, 1840-Present

Classificatory and Descriptive Period, 1840-1914.

Ephraim G. Squier, who had been educated as an engineer, was the United States charge d'affaires to the republics of Central America during the mid-nineteenth century. He published (1852) still-important baseline data on the stone statuary and petroglyphs of Isla Zapatera and other islands in Lake Nicaragua.

Another traveler, Frederick Boyle, described the area of Chontales, and reported seeing pot-hunters destroying sites and tombs. Boyle not only wrote down his travel observations, but was also, according to Stone (1984, 25), "the first to notice the difference between the monoliths of Chontales, Niquiran, and others in Nicaragua… Boyle also illustrated Luna Ware, shoe vessels, and stone faces from Ometepe and Zapatera islands, Mombacho, and Chontales."

Earl Flint and J.F. Bransford conducted some of the first documented excavations in Nicaragua, and their collections are now in the smithsonian institution and in the peabody museum at Harvard University. Flint presented the first scientific report on the famous footprints of Acahualinca, but unfortunately assigned them an excessively speculative age of more than fifty thousand years! Bransford was with a U.S. Navy medical group and took advantage of being in Nicaragua to explore certain aspects of its prehistory. His report described work on Ometepe Island and in the isthmus of Rivas, and illustrated both one of the earliest (Bocana Zoned Incised) and latest (Luna Polychrome) ceramics types known from the area.

Carl Bovallius was a Swedish naturalist who recorded drawings of statues, petroglpyhs, and artifacts, primarily from Zapatera Island. Already in the nineteenth century this island had become a standard stop on the archaeological tour. Karl Sapper also traveled through the area and filed cursory reports on the sites and artifacts he encountered. As a geographer, his environmental and physical descriptions are perhaps of even greater interest.

Classificatory and Historical Period, 1914-1940.

While Herbert Spinden never actually conducted archaeological research in either Nicaragua or Costa Rica, his interest in Central American and Mayan archaeology inspired him to suggest models that influenced other scholars who did work in the two countries.

As Doris Stone (1984, 17) noted: “Spinden… broadened Lehmann's concept of the archaeological culture center to include three provinces of lower Central America (a) northern Honduras east of La Ceiba and eastern Nicaragua north of Rivas and west of the forest zone; (b) southern Nicaragua; and (c) northern Costa Rica, subdivided into six sections.” While based on linguistic data that were not universally accepted at the time, Spinden's model was the first careful attempt to divide prehistoric Nicaragua and Costa Rica into cultural/geographical areas.

Chronological Concerns, 1914-1949.

While the historical period ends in 1940 with Willey and Jeremy Sabloff's scheme, it lasted until into the early 1960s in Nicaragua, where there was a distinct time lag in the development of scientific archaeological research and the establishment of national and regional cultural chronologies. In other parts of Latin America (Mexico, peru, etc.) chronological sequences had been developed since the 1920s.

Samuel K. Lothrop did not excavate during his sojourn in Costa Rica and Nicaragua in the 1920s. Like Bransford, he originally went to the area as an employee of the United States government, and took advantage of the slow pace of official business to pursue his interests in archaeology. He attempted to relate his descriptive corpus of ceramics to known chronologies from southern mesoamerica and Mexico, and, perhaps more importantly, created a two-volume visual museum (Lothrop 1926) of the pre-Columbian ceramic art of Nicaraguan and Costa Rica.

In Nicaragua, a locally defined cultural historical sequence began to emerge only at the very end of the 1950s, when the Institute for Andean Research's “Program on the Inter-relationship of New World Cultures” permitted Gordon Willey and Albert H. Norweb to survey and test a number of sites on the isthmus of Rivas. Wolfgang Haberland also contributed to the development of the Nicaraguan chronological framework with his work on Ometepe with Peter Schmidt in the early 1960s. This also created the first example of methodological contrast, with Hno. Hildeberto Maria carrying on thematic studies on rock art and petroglyphs at the same time that Haberland and Schmidt were conducting their cultural-historical research.

Willey, Norweb, and Haberland's work also marked the beginning of the qualitative imbalance between Costa Rican and Nicaraguan research, with the Nicaraguan sequences being primarily dependent on cross-dating with the better chronometrically controlled sequences (*see* Appendix III; Lange and Stone 1984) from Costa Rica. After thirty years, additional chronometric data from Pacific Nicaragua were obtained by Salgado at the Ayala site in 1992-93 (see below).

Context and Function, 1940-1960.

After thirty years, additional chronometric data from Pacific Nicaragua were obtained by Salgado at the Ayala site in 1992-93 (see below).

Context and Function, 1940-1960.

There was little archaeological activity in Nicaragua during

this period, although various authors continued to publish on the trinity of stone statuary, footprints, and petroglyphs.

The Beginning of the Explanatory Period, 1960s.

In the development of Nicaraguan archaeology, the concerns with context and function of the preceding period were combined with the first efforts at explanation. In addition to their chronology building efforts, Haberland and Schmidt also contributed to the explanation of certain aspects of the archaeological record including shamanism and specialized site use, such as the Concepcion volcano site, El Respiradero.

The Explanatory Period: New Data and Interpretations, 1960s and 1970s.

Lydia Wyckoff continued chronology building on the Pacific Coast, while Richard Magnus initiated the first survey and stratigraphic testing on the Atlantic watershed and produced the first chronological sequence for that region. He also searched for data to explain coastal adaptation and to interpret possible connections with other cultural areas. Magnus was instrumental in bringing Nicaraguan nationals such as Silvia Montealegre Osorio, Anibal Martinez, and Franzella Wilson into active participation in archaeological research. In 1973 and 1974, Neil Hughes salvaged mortuary remains and related ceramic and ecological data from a sewer installation in downtown Managua.

Karen Olsen Bruhns initiated a project to study the interrelationships of various styles of Chontales statuary, but lacked a firm chronological linkage between the statues and the established ceramic sequence. She also conducted some work on Zapatera Island in conjunction with the statuary research.

The Explanatory Period: Continuing Methodological and Theoretical Innovations, 1970s-1980s.

Healy (1980) analyzed part of the collections from Willey and Norweb's efforts and significantly refined the typology and sequence from the Rivas area of Nicaragua. Nonetheless, the gap between the time of excavation and the time of analysis and publication clearly transcends the era of emphasis on chronological sequence and local/regional cultural histories and the era of more expansive, if somewhat less precise, model building and systematic explanation.

The first intensive effort to train Nicaraguan nationals in archaeology occurred during the first years of the revolutionary Sandinista government (1979-1985). Most of the archaeologists currently working for the National Museum of Nicaragua received their first opportunities during this era. Various rescue projects were conducted at different sites, primarily on the Pacific Coast by Rigoberto Navarro, Anibal Martinez, Edgar Espinoza, Ronaldo Salgado, Rafael Gonzalez, and Jorge Zambrana. The initial development of a national park system also provided brief protection for important sites such as Isla el Muerto, Isla Zapatera, and Isla Ometepe in Lake Nicaragua. A group from the Milwaukee Public Museum recorded the important petroglpyhs from Isla el Muerto. Much of this research was motivated by the interest and dedication of Amelia Barahona, then director of cultural patrimony.

In 1983, Frederick W. Lange, Payson D. Sheets, and Anibal Martinez carried out a rapid reconnaissance of sites on the Pacific coast of Nicaragua, as well as some sites to the east of lakes Managua and Nicaragua. These studies produced a better map of local Nicaraguan prehistoric development, as well as gathering the obsidian and ceramic specimens that integrated Nicaraguan data with similar databases from southern Mesoamerica and northwestern Costa Rica.

Other important projects carried out by the National Museum of Nicaragua in the 1980s included excavations at the colonial site of Leon Viejo, and at other sites in the Managua urban and Pacific coastal regions. In 1987, Mario Molina and Jorge Levano developed a master plan for the management

of the Leon Viejo site. The economic situation that developed during the 1980s made archaeological research increasingly opportunistic and salvage oriented.

These projects were dependent almost exclusively on foreign funding and initiatives, although they were required to involve Nicaraguan counterparts in the fieldwork. Primary among these was the French Archaeological

this period, although various authors continued to publish on the trinity of stone statuary, footprints, and petroglyphs.

Sheets, and Anibal Martinez carried out a rapid reconnaissance of sites on the Pacific coast of Nicaragua, as well as some sites to the east of lakes Managua and Nicaragua. These studies produced a better map of local Nicaraguan prehistoric development, as well as gathering the obsidian and ceramic specimens that integrated Nicaraguan data with similar databases from southern Mesoamerica and northwestern Costa Rica.

Other important projects carried out by the National Museum of Nicaragua in the 1980s included excavations at the colonial site of Leon Viejo, and at other sites in the Managua urban and Pacific coastal regions. In 1987, Mario Molina and Jorge Levano developed a master plan for the management

of the Leon Viejo site. The economic situation that developed during the 1980s made archaeological research increasingly opportunistic and salvage oriented.

These projects were dependent almost exclusively on foreign funding and initiatives, although they were required to involve Nicaraguan counterparts in the fieldwork. Primary among these was the French Archaeological

this period, although various authors continued to publish on the trinity of stone statuary, footprints, and petroglyphs.

The Beginning of the Explanatory Period, 1960s.

In the development of Nicaraguan archaeology, the concerns with context and function of the preceding period were combined with the first efforts at explanation. In addition to their chronology building efforts, Haberland and Schmidt also contributed to the explanation of certain aspects of the archaeological record including shamanism and specialized site use, such as the Concepcion volcano site, El Respiradero.

The Explanatory Period: New Data and Interpretations, 1960s and 1970s.

Lydia Wyckoff continued chronology building on the Pacific Coast, while Richard Magnus initiated the first survey and stratigraphic testing on the Atlantic watershed and produced the first chronological sequence for that region. He also searched for data to explain coastal adaptation and to interpret possible connections with other cultural areas. Magnus was instrumental in bringing Nicaraguan nationals such as Silvia Montealegre Osorio, Anibal Martinez, and Franzella Wilson into active participation in archaeological research. In 1973 and 1974, Neil Hughes salvaged mortuary remains and related ceramic and ecological data from a sewer installation in downtown Managua.

Karen Olsen Bruhns initiated a project to study the interrelationships of various styles of Chontales statuary, but lacked a firm chronological linkage between the statues and the established ceramic sequence. She also conducted some work on Zapatera Island in conjunction with the statuary research.

The Explanatory Period: Continuing Methodological and Theoretical Innovations, 1970s-1980s.

Healy (1980) analyzed part of the collections from Willey and Norweb's efforts and significantly refined the typology and sequence from the Rivas area of Nicaragua. Nonetheless, the gap between the time of excavation and the time of analysis and publication clearly transcends the era of emphasis on chronological sequence and local/regional cultural histories and the era of more expansive, if somewhat less precise, model building and systematic explanation.

The first intensive effort to train Nicaraguan nationals in archaeology occurred during the first years of the revolutionary Sandinista government (1979-1985). Most of the archaeologists currently working for the National Museum of Nicaragua received their first opportunities during this era. Various rescue projects were conducted at different sites, primarily on the Pacific Coast by Rigoberto Navarro, Anibal Martinez, Edgar Espinoza, Ronaldo Salgado, Rafael Gonzalez, and Jorge Zambrana. The initial development of a national park system also provided brief protection for important sites such as Isla el Muerto, Isla Zapatera, and Isla Ometepe in Lake Nicaragua. A group from the Milwaukee Public Museum recorded the important petroglpyhs from Isla el Muerto. Much of this research was motivated by the interest and dedication of Amelia Barahona, then director of cultural patrimony.

In 1983, Frederick W. Lange, Payson D. Sheets, and Anibal Martinez carried out a rapid reconnaissance of sites on the Pacific coast of Nicaragua, as well as some sites to the east of lakes Managua and Nicaragua. These studies produced a better map of local Nicaraguan prehistoric development, as well as gathering the obsidian and ceramic specimens that integrated Nicaraguan data with similar databases from southern Mesoamerica and northwestern Costa Rica.

Other important projects carried out by the National Museum of Nicaragua in the 1980s included excavations at the colonial site of Leon Viejo, and at other sites in the Managua urban and Pacific coastal regions. In 1987, Mario Molina and Jorge Levano developed a master plan for the management

of the Leon Viejo site. The economic situation that developed during the 1980s made archaeological research increasingly opportunistic and salvage oriented.

These projects were dependent almost exclusively on foreign funding and initiatives, although they were required to involve Nicaraguan counterparts in the fieldwork. Primary among these was the French Archaeological

Mission under the auspices of CEMCA (Centre d' Études Mexicaines et Centramericaines), headquartered in Mexico City. Beginning in 1984, Dominique Rigat and Franck Gorin worked first in the Chontales area east of Lake Nicaragua, and later in the Lake Managua basin in the north central part of the country. These projects contributed to the goal of a national inventory of archaeological sites that is being supported by the Organization of American States, and in Chontales they recovered stone statuary from a dateable context. The research also contributed significantly to our understanding of differences in regional settlement patterns, and in the distribution of imported obsidian, locally available lithic materials, southern Mesoamerican ceramics, and Greater Nicoya ceramics.

Navarro (1993) and Espinosa (1993) have provided brief reviews of some of the projects from the 1980s and the early 1990s.

Recent Developments, 1990s.

The first years of the 1990s make it clear that the greatest era of research in Nicaraguan archaeology lies in the future. A Swedish archaeological project, under the direction of Lars Radin, embarked on a first-ever detailed mapping project of Zapatera Island. Laraine Fletcher from Adelphi University (New York) is meeting both national site inventory and settlement pattern and chronological sequence development in unknown areas with a project in the Esteli-Somoto area in north central Nicaragua. Nicaraguan archaeologists (Ronaldo Salgado, Jorge Zambrana, Edgard Espinosa, and Rafael Gonzalez) are participating actively in both of the projects, and gradually assuming increased analytical and reporting responsibilities.

Silvia Salgado, a Costa Rican graduate student at SUNY-Albany, obtained dissertation funding from the National Science Foundation to initiate a project at the Ayala site, near Granada. While she was also able to refine the early part of the regional sequence, her main emphasis was on site hierarchies and internal site organization. She also recovered southern Honduran ceramics that further blurred the poorly defined boundaries between the northern edge of “Greater Nicoya” and the southern “frontier” of Mesoamerica.

Nicaraguan archaeologists, as well as some of the foreign archaeologists working in Nicaragua, participated in a National Science Foundation-sponsored conference on the future of research in Greater Nicoya in Costa Rica in May of 1993. The Organization of American States funded the first training course for archaeologists in Nicaragua, from February to June of 1993. The course was extremely successful and benefited from participation by university professors and students and employees of other government institutions in addition to the national museum. Arellano (1993) has edited a volume recapitulating the last thirty years of archaeological research in Nicaragua.

None of the universities in Nicaragua currently offers a degree in archaeology and there are no university-employed archaeologists. The National Museum of Nicaragua employs four archaeologists, all of whom have been trained “on the job” working with foreign archaeological projects; none of the four has a degree in anthropology/archaeology. Of similar concern is the lack of a national archaeological journal (such as *Vinculos,* published by the National Museum of Costa Rica) to provide a local outlet in Spanish of Nicaraguan research, and to educate the government and the public about the importance of protecting and studying the nation's cultural heritage. Despite this somewhat gloomy reality some progress is being made by dedicated archaeologists, working under difficult circumstances.

Costa Rica

Costa Rican archaeology has experienced greater development than has archaeology in Nicaragua. The shift from reliance on foreign archaeologists to a primary dependence on country nationals has largely

been completed in Costa Rica. Various authors (*see* Arias 1982; Corrales 1987; Fonseca 1992) have examined the development of archaeology in Costa Rica, and in this section their approaches are merged with the Willey and Sabloff framework. For example, Arias (1982, 4; translation mine) observed that:

Costa Rica

Costa Rican archaeology has experienced greater development than has archaeology in Nicaragua. The shift from reliance on foreign archaeologists to a primary dependence on country nationals has largely

been completed in Costa Rica. Various authors (*see* Arias 1982; Corrales 1987; Fonseca 1992) have examined the development of archaeology in Costa Rica, and in this section their approaches are merged with the Willey and Sabloff framework. For example, Arias (1982, 4; translation mine) observed that:

An analysis of the theoretical and methodological changes that have occurred in Costa Rican archaeology is not a easy task… the models that have been used up to now are the Cultural Historical model and the Cultural Process model, with an additional period that we might call the pre-paradigm period in which there was no theoretical model to guide archaeological investigation.

The Non-Scientific/Speculative Period, 1492-1840

Arias (1982, 4) referred to this as the Pre-Paradigm Period, characterized by the speculations of early chroniclers and conquistadors and later travelers who wrote about the "life-styles" of the unknown peoples they encountered. They reported customs that were strange, exotic, and foreign to the rapidly dominant European culture.

Scientific Research, 1840-Present

The Classificatory-Descriptive Period, 1840-1914.

This period includes Fonseca's (1992, 15) "period of the pioneers of Costa Rican archaeology" (1850-1925) in which he mentions both Anastasio Alfaro and Carl V. Hartman as being inseparable from the pioneer archaeological effort. Alfaro was trained in museum work at the Smithsonian Institution, "excavated" at the site of Guayabo de Turrialba, and in 1887 founded the National Museum of Costa Rica. Hartman, a Swedish botanist like Bovallius, provided some of the first knowledge of mortuary patterns in Costa Rica, conducting research at both Las Mercedes on the Atlantic watershed and at Las Guacas on the Nicoya peninsula. His practice of carefully recording excavation contexts produced volumes of information that are still of great use.

Taking a broader approach, Arias classified the entire period from 1840 to 1960 as the "synchronic descriptive period," which focused on describing cultures as composed of particular norms and customs, but without an emphasis on temporal change or interrelationships between groups.

Echoing Fonseca's statement, Stone (1984, 27) suggested that Anastasio Alfaro could be considered "the father of Costa Rican archaeology." I would narrow that accolade slightly to a more specific recognition as the father of "museum archaeology" in Costa Rica.

Both Bransford and Flint, previously mentioned in the section on Nicaragua, crossed briefly into northwestern Costa Rica and recorded data from the areas of the Bay of Culebra and the Bay of Salinas, respectively. This was an early reflection of the historical and political unity of the Rivas and Nicoya areas, and an early indication of the relative unity of "Greater Nicoya," a concept later further developed by Lothrop (1926), Norweb (1964), and Lange (1971).

The Classificatory-Historical Period, 1914-1940.

In the local Costa Rican sequence, this correlates roughly with Fonseca's (1992, 15) "Period of Synchronic Description" (1925-1960). Certain aspects of the previous period continued, as reflected in the studies of Jorge Lines and the early publications of Doris Stone and Samuel Lothrop, but overall there was little archaeological activity.

Chronological Concerns, 1914-1940.

As in Nicaragua, in Costa Rica we see a time lag in the development of local chronological sequences when compared with such developments in other parts of the Western Hemisphere. Until the early 1960s, Costa Rican archaeology was dependent on cross-dating with external sequences.

Context and Function, 1940-1960.

During this period Carlos Aguilar Piedra began to train as an archaeologist with studies in Mexico and at the University of Kansas, and in 1953 became professor of archaeology and the main force behind the development of the archaeology program at the University of Costa Rica. He conducted research at the highland site of Retes in the 1950s and sparked public interest in Costa Rican archaeology with the discovery of wooden artifacts preserved beneath a volcanic ash fall. He is the father of modern archaeology in Costa Rica.

This also was the period during which modern

As in Nicaragua, in Costa Rica we see a time lag in the development of local chronological sequences when compared with such developments in other parts of the Western Hemisphere. Until the early 1960s, Costa Rican archaeology was dependent on cross-dating with external sequences.

Context and Function, 1940-1960.

During this period Carlos Aguilar Piedra began to train as an archaeologist with studies in Mexico and at the University of Kansas, and in 1953 became professor of archaeology and the main force behind the development of the archaeology program at the University of Costa Rica. He conducted research at the highland site of Retes in the 1950s and sparked public interest in Costa Rican archaeology with the discovery of wooden artifacts preserved beneath a volcanic ash fall. He is the father of modern archaeology in Costa Rica.

This also was the period during which modern

chronological knowledge of southern Costa Rica, and the close and across-the-border relationship of this area to western Panama.

Beginning of the Explanatory Period, 1960s.

Arias (1982, 4) described Kennedy's developed sequence for the Reventazon Valley and Aguilar's sequence for the Guayabo de Turrialba region as the beginnings of the concern with chronology. Matthew W. Stirling also contributed important chronological information to our knowledge of the Atlantic watershed.

In 1969, Lange conducted research in northwestern Costa Rica and broadened the application of the Coe and Baudez chronological sequence. Assuming more of a cultural and ecological approach, he focused on relationships of riverine and coastal adaptation and challenged the long-held assumption that there had been strong Mesoamerican influence in this region.

Explanatory Period: New Data and Interpretations, 1960s and 1970s.

Fonseca (1992, 15) designated the period between 1960 and 1975 a “Period of Descriptive Chronology,” an accurate representation of local developments in Costa Rica. He also observed (1992, 16) that this was the period in which the diachronic concept of cultures and societies was finally accepted. At the same time Aguilar and Snarskis developed chronological sequences for the Central Valley and Atlantic watershed, and Sweeney completed analysis of some of Coe's earlier work in northwestern Costa Rica. All of these efforts resulted in there being at least a broad chronological framework for the entire country.

Explanatory Period: Continuing Methodological and Theoretical Innovations, 1970s-1980s.

Arias (1992, 5) classified this explanatory period as still part of the process of consolidation and as principally characterized by the concern for the explanation of sociocultural processes, with an emphasis on human ecology. Citing Binford, Arias commented that regional studies were the most appropriate means of studying social processes and cultural change, while also noting that it was necessary to continue to develop chronological sequences as an aspect of, but not the principal objective of, research. She also noted the important transition from speculating about to explaining Costa Rica's past. This transition still largely remains uninitiated, and local newspapers still give credence to wildly speculative explanations about particular sites and cultural historical relationships.

For Fonseca (1992, 15) this was the “Period of Diachronic Explanatory Models.” Inspired by the administration of Costa Rican President Daniel Oduber (1974-1978) and National Museum of Costa Rica director Luis Diego Gomez, the first two major site surveys and hypothesis testing projects were initiated. The Bay of Culebra project focused on the development of coastal adaptation in northwestern Costa Rica, and the Guanacaste-San Carlos Project was designed to study the relationships between the Pacific and Atlantic watersheds. Michael J. Snarskis continued with testing and mapping numerous large architectural sites on the Atlantic.

Hector Gamboa was head of the department of anthropology and history at the National Museum of Costa Rica during this period. His understanding of Costa Rican prehistory and his great diplomatic skills, which helped to blend the interests of foreign and national researchers, were essential to the growth in research in Costa Rica during this time.

Oscar Fonseca obtained his M.A. in anthropology from the University of Pittsburgh in 1977 and returned to Costa Rica to assume a pivotal role in the further development of the anthropology and archaeology teaching program at the University of Costa Rica. The University of Costa Rica also began

an intensive reevaluation of the site of Guayabo de Turrialba, and used this to support the field training of a whole generation of young Costa Rican students. During this time, Oscar Fonseca, Luis Hurtado de Mendoza, Michael Snarskis, and to a lesser extent Lange supported a significant increase in archaeological training at the university. Unfortunately, the number of available jobs quickly was outpaced by the number of students graduating from the university. Costa Rica has been slow to see the advantages of adding archaeologists to the staffs of the Ministry of Tourism, the National Park Service, the Ministry of Housing, and the like.

In 1977, Costa Rican author Luis Ferrero published the first detailed summary of Costa Rican prehistory. In conjunction with the beginning of the publication of the journal *Vinculos* by the National Museum of Costa Rica in 1975, Ferrero's volume complemented the important function of placing essential data, in Spanish, about Costa Rican prehistory in the hands of Costa Rican students and public.

In the early 1980s Robert Drolet initiated the Boruca Dam-Rio Terraba project in southern Costa Rica, and research on the Bay of Culebra continued under a cooperative arrangement between the National Museum of Costa Rica and the University of California, Los Angeles. Payson Sheets initiated the Lake Arena project in the cordillera of Guanacaste and demonstrated the utility of applying remote sensing technology to Costa Rican archaeology. Winifred Creamer conducted an extensive survey and testing program on the Gulf of Nicoya.

The late 1970s and 1980s saw the definitive transition to vesting principal research responsibilities with Costa Rican archaeologists at the University of Costa Rica and at the National Museum of Costa Rica. Aida Blanco conducted research at the site of Ochomogo in the central highlands, and collaborated with Maritza Gutierrez and Silvia Salgado in the rescue archaeology of the Cenada market site in the metropolitan San Jose area. Magdalena Leon focused on the archaeology of the metropolitan area. Ricardo Vazquez conducted research at the central highland site of Agua Caliente. Sergio Chavez, Ana Cecilia Arias, Maureen Sanchez, Myrna Rojas, Carlos Valdesperras, and Floria Arrea conducted research at central valley sites. Francisco Corrales and Ifigenia Quintanilla developed long-term research in the Central Pacific region, and Olman Solis conducted microsettlement research at one of the sites in the area. Blanco and Juan Vicente Guerrero conducted extensive rescue operations at the La Ceiba in Guanacaste. Marlin Calvo, Leidy Bonilla, and Silvia Salgado mapped and tested a salt production site on the south shore of the Bay of Culebra.

Some of these projects were rescue oriented, while some were pure research in orientation (*see* Lange and Norr 1986). Corrales (1987) has discussed this transition in more detail. Of particular importance were the expansion of research efforts into the Central Pacific coastal region and greatly increased efforts in the Central Valley.

Recent Developments, 1990s.

The construction on the Bay of Culebra tourist project began, and research directed by Ellen Hardy was conducted under a contract between the Ministry of Tourism and the National Museum of Costa Rica. There were also signs that the long waiting Boruca Dam impoundment was under reconsideration. Jeffrey Quilter has continued Drolet's research in the Rio Grande de Terraba region, and Aida Blanco is both conducting research and directing a regional museum in the San Isidro region.

In addition, Ifigenia Quintanilla is developing a greatly expanded contextual database for one of Costa Rica's best known prehistoric enigmas, the stone balls of the Diquis region. The French team of Claude Baudez, Sophie Laligant, Natcha Borgnino, and Valerie Lauthel conducted stratigraphic research in the Diquis area that helped to refine the sequences developed by Lothrop and Haberland. John Hoopes has initiated long-term research in the Golfito area.

In an ongoing collaboration between rescue and academic archaeology, the National Museum is also involved in a massive salvage project in the area of the Cañas-Liberia irrigation project in the northwestern region. Research by University of Costa Rica archaeologists is largely restricted to the Central Valley, and the teaching program at the university has been weakened by the departure of some key professors and by a shift in emphasis by the social science division of the university. While not an archaeologist, Adolfo Constenla is making important linguistic contributions (1991) to our understanding

of the period immediately preceding the Spanish invasion.

The 1990s saw the first steps toward collaboration between the archaeologists of Costa Rica and Nicaragua. In 1993 they participated in a National Science Foundation-sponsored workshop to discuss the future of research in

Greater Nicoya and in the first training course for young archaeologists to be sponsored in Central America by the Organization of American States.

Conclusion

In this entry, Costa Rica and Nicaragua have been dealt with as two separate entities. In terms of the history of archaeology as it has been practiced in the two countries, this is perhaps the best method. However, in terms of reflecting the prehistory of the two countries, it creates artificial barriers. Nicaragua and Costa Rica share prehistoric cultural communalities along both the Pacific and Atlantic coasts, and Costa Rica has communalities with Panama in the south; Nicaragua with Honduras and El Salvador in the north.

These communalities were recognized by some of the more observant early explorers and archaeologists. These have more recently been concretely demonstrated by instrumental analyses of jade and ceramics conducted by Ronald L. Bishop of the Conservation Analytical Laboratory of the Smithsonian Institution, and obsidian analyses conducted by Fred Stross and Frank Asaro of the Lawrence Berkeley Laboratory at the University of California.

Not only in reviewing the history of Costa Rican and Nicaraguan archaeology but also in foreseeing its future we see the long-term need for balance between cultural and historical studies and the testing of systems and models. There are still vastly unknown areas of Central America (the Nicaraguan and Costa Rican segment of the map is reproduced on page 374) for which we still need the most basic cultural and historical data with which to formulate problems of broader and more general interest.

The history of Nicaraguan and Costa Rican archaeology began with the explorations of early travelers, developed with the assistance of foreign archaeologists, and is gradually becoming the primary responsibility of country nationals. The late 1970s and the early 1980s were a golden age for the development of national archaeology in both countries. In Costa Rica this momentum has been maintained, while in Nicaragua it has stalled temporarily.

Nicaragua and Costa Rica are on the verge of developing the basis for collaboration that is essential for regional studies and for approaching many of the cultural and historical problems that need to be researched. It is hoped that when the next history of the archaeology of these two countries is written, a heightened level of cooperation between the universities, museums, and professional communities will be one of the highlighted themes.

Cotter, John L.

(1911-1999)

One of the pioneers in establishing historical archaeology in North America, John L. Cotter had an earlier career in prehistoric studies. As a graduate student, he helped excavate the famous Paleo-Indian site of Lindenmeier in Colorado (1934-1936) and the Clovis typesite at Blackwater Draw, New Mexico (1936-1937). After receiving his master's degree in anthropology from the University of Denver in 1935, he worked extensively in the southeastern United States, especially in Kentucky and along the Natchez Trace Parkway in Mississippi. Administratively, he also had experience in southwestern prehistory, serving during the 1940s as the National Park Service supervisor for the Tuzigoot National Monument in Arizona.

Cotter's primary contribution was helping to establish historical archaeology in North America. In 1953, he was assigned by the National Park Service to jamestown, virginia (the first permanent English settlement in America in 1607), and there he directed-with the help of Edward B. Jelks, Louis Caywood, Joel

Shiner, and Paul Hudson-three seasons (from 1954 to 1956) of extensive fieldwork. In 1958, this project and the earlier pioneering excavations on the site by j. c. harrington (1936- 1941) were described and published in Cotter's classic work, *Archaeological Excavations at Jamestown, Virginia.*

After working at Jamestown, Cotter returned to Philadelphia, where he had previously done graduate work at the University of Pennsylvania (1936-1937), and completed his doctorate in anthropology there in 1959. Although almost fifty years old, he set out to use the city and its institutions to build his newly adopted specialization. His primary employment was as the northeast regional archaeologist (1957-1970) for the National Park Service office in the city, but it was his secondary affiliations with the University of Pennsylvania and its University Museum that gave him a broader base for building American historical archaeology. Cotter worked in three different but equally constructive settings: as an educator, as an active field archaeologist, and as a professional organizer for the discipline.

In 1960, at the invitation of the new Department of American Civilization at the University of Pennsylvania, Cotter taught a class entitled “Problems and Methods of Historical American Archaeology,” the first academic class anywhere in the United States and elsewhere to carry the designation, “historical archaeology.” For almost twenty years he taught a series of courses that introduced students to this new subject, and because the city itself was the site explored, he helped to create urban historical archaeology in America. In 1992, he coauthored with Daniel G. Roberts and Michael Parrington *The Buried Past: An Archaeological History of Philadelphia,* the first such synthesis for a major U.S. city.

Much earlier, in January 1967, he was one of a small group of established scholars who assembled in Dallas, Texas, and founded the Society for Historical Archaeology. Cotter served as the society's first president (1967) and coedited the initial volume of its journal, *Historical Archaeology.* Twice he invited the new society to meet in Philadelphia, first to celebrate the county's bicentennial (1976) and six years later to mark the city's three-hundredth anniversary (1682-1982).

Shortly before his death, the Society for Historical Archaeology created the John L. Cotter Award in Historical Archaeology to honor his memory and to recognize the achievements of researchers (including students) at the start of their professional careers.

Crawford, O.G.S.

(1886-1957)

O. G.S. Crawford was born in India and grew up with aunts in England. He took an Oxford degree in

geography, and the subject of his short thesis was a field survey of archaeology in the Andover district of England. He went to the Sudan to excavate with the Wellcome expedition until World War I began; then he served in the Royal Flying Corps as an observer, was shot down, and became a prisoner of war.

After supplying archaeological details to correct revised editions of Ordnance Survey maps, Crawford was appointed in 1920 as the survey's first archaeological officer, a post he held until his retirement in 1946. Visible monuments and earthworks had been recorded since the survey's first mapping of Britain early in the nineteenth century, but Crawford extended and developed this work into a much fuller record of the nation's visible archaeology, drawing on both scattered or systematic records in other institutions and new field surveys. As well as providing better archaeological notice in the ordinary maps, he surveyed for and drew up a remarkable series of period maps, beginning with *Roman Britain* (1924), the best being, in Crawford's own view, the two sheets of *Britain in the Dark Ages* (1935).

"What I want is simple, clear-minded stuff that any intelligent fool can understand.") This approach is not usually theoretical in a self-consciously explicit way, but still it is not unsystematic.

Contemporaries saw Crawford as a distinctive individualist with a strong and independent spirit. Wheeler told with relish the scandal that echoed around archaeological Wales when Crawford received Welsh archaeologists visiting his excavation wearing *shorts*-"Thereafter for thirty seven years he was one of my closest friends, and his boyish glee in calling the bluff of convention never left him." Crawford's autobiography is full of tales of conflict between his free spirit and the bureaucratic systems of the Ordnance Survey.

Crawford's later work *Archaeology in the Field* (1953) shows him drifting away from his early principles, and his last work, *The Eye Goddess* (1957), is alarmingly lacking in that robust good sense and clear attention to good chronology that before had been the Crawford style. In 1955, however, Crawford wrote a good autobiography, *Said and Done.*

Cunningham, Alexander

(1814-1893)

Alexander Cunningham went to India from England as an army engineer in 1833 and fell, as a young man, under the influence of james prinsep, who had undertaken the task of reorienting the research interests of the members of the Asiatic Society of Bengal founded in 1784. The society was the focal point of European research activities in India, and under Prinsep's secretaryship these interests veered from mere literary speculations to field investigations.

By the mid-1830s, Cunningham was assisting Prinsep with his research, in particular with the study of Kharosthi, the principal ancient script of the Indian northwest. Until 1842, as his publications show, Cunningham was interested principally in the study of coins and seals-some of them Roman-that were then being found in profusion in the northwestern part of India. He never lost this early interest in scripts

and coins, and his publications, such as *Inscriptions of Asoka* (1877), *Coins of Ancient India from the Earliest Times down to the Seventh Century a.d.* (1891), and *Coins of Mediaeval India from the Seventh Century down to the Muhammadan Conquests* (1894), are eloquent testimony to its persistence in his life.

Another major line of investigation pursued by Cunningham was in the area of ancient Indian architecture. He published a detailed study of ancient temples in Kashmir in the *Journal of the Asiatic Society of Bengal* in 1848 and followed that work with *The Bhilsa Topes,* a study of the Buddhist stupas at Sanchi and in its neighborhood (1854); *The Stupa of Bharhut* (1879); and *Mahabodhi, or the Great Buddhist Temple under the Bodhi Tree at Bodh-Gava* (1892).

Cunningham also contributed a great deal to the elucidation of various historical problems related to ancient India, and his analyses of dynastic issues in his Archaeological Survey of India Reports constitute the primary evidence of this contribution. Another of his abiding interests was the study of ancient Indian historical geography based on both archaeological surveys and textual material. This study culminated in the publication of *The Ancient Geography of India* (1871).

However, it is for his Archaeological Survey of India Reports that Cunningham maintains a

permanent place in the history of Indian archaeology. Of the twenty-three volumes published in this series between 1862 and 1887, twelve were written by Cunningham himself, two were written by him in collaboration with an assistant, and the rest were written by his three assistants in the Archaeological Survey of India-J. D. Beglar, A.C.L. Carlleyle, and H.W. Garrick. As far as the archaeology of the area between the northwestern hills and Bengal is concerned, these reports constitute a major source of information even today.

The Archaeological Survey of India was established by the government of India in 1861 mainly owing to Cunningham's persuasion. He became its first director-general/director on his retirement from military service. After four years the survey was disbanded to be reestablished in 1870-1871, with Cunningham again in charge. He retired from this duty in 1885. His main interest in archaeology was topographical, and he followed the routes traveled by Alexander the Great and two famous Chinese pilgrims, Hiuen Tsang (seventh century a.d.) and Fa-Hian (fifth century a.d.), and identified and described ancient sites along the way. Some of the most important ancient city sites of India owe their identifications to him. He was not much of an excavator, but he mapped out sites on a scale that has not yet been equaled in India.

Cunnington, William

(1754-1810)

A middle-class cloth merchant who, like his wealthy patron, sir richard colt hoare, developed a passion for excavating English barrows and graves. He lead Colt Hoare's archaeology team, and with draftsman Philip Crocker surveyed a huge part of Wiltshire, locating ancient sites and earthworks. It was Cunnington who supervised the excavation of some 379 barrows and who ensured that observations were recorded accurately and carefully. He also divided barrows into five types and used stratigraphy to identify primary and secondary burials. While coins were used to date some barrows, Cunnington argued that it was possible that graves with only stone artifacts in them might be earlier than those that contained metal ones. Notwithstanding these advances in fieldwork methods and in the analysis of artifacts neither Cunnington nor his patron Colt Hoare was able to convincingly demonstrate a relative chronology for these English monuments.

Curtius, Ernst

(1814-1896)

Curtius was born in Lubeck and studied philology and philosophy in Bonn, Gottingen, and Berlin. In 1837 he traveled to newly independent greece and visited the site of Olympia, the excavation of which was to become his lifelong work. He returned to Germany and obtained his doctorate in Halle in 1841. In 1844 he was appointed tutor to the German Crown Prince, the future Emperor Friedrich III, and professor of classical philology in Berlin. In the same year he published his most important work, a

two-volume description of the Peloponnese, which was the result of his travels in the 1830s.

In 1856 Curtius returned to Gottingen as professor of classical philology and archaeology. He published *Griechische Geschichte,* which became the most widely read Greek history written in German, republished five more times. In 1868 he moved to Berlin as professor of classical archaeology. heinrich schliemann's successes at Troy led to German government support of Curtius's long-planned excavation of Olympia. In 1874 he signed an agreement with the Greek government that not only allowed German scholars exclusive rights to excavate Olympia, but also provided for the exhibition of finds at the site. This was the first government-supported excavation in Greece, and it became a model for other countries who wished to work there and respect Greek antiquities and the right of the Greek government to keep them. Curtius also helped to found the German Archaeological Institute (deutsches archäologisches institut) in Athens.

Olympia was excavated between 1875 and 1881 (and again from 1936 to 1941 and since

permanent place in the history of Indian archaeology. Of the twenty-three volumes published in this series between 1862 and 1887, twelve were written by Cunningham himself, two were written by him in collaboration with an assistant, and the rest were written by his three assistants in the Archaeological Survey of India-J. D. Beglar, A.C.L. Carlleyle, and H.W. Garrick. As far as the archaeology of the area between the northwestern hills and Bengal is concerned, these reports constitute a major source of information even today.

The Archaeological Survey of India was established by the government of India in 1861 mainly owing to Cunningham's persuasion. He became its first director-general/director on his retirement from military service. After four years the survey was disbanded to be reestablished in 1870-1871, with Cunningham again in charge. He retired from this duty in 1885. His main interest in archaeology was topographical, and he followed the routes traveled by Alexander the Great and two famous Chinese pilgrims, Hiuen Tsang (seventh century a.d.) and Fa-Hian (fifth century a.d.), and identified and described ancient sites along the way. Some of the most important ancient city sites of India owe their identifications to him. He was not much of an excavator, but he mapped out sites on a scale that has not yet been equaled in India.

Olympia was excavated between 1875 and 1881 (and again from 1936 to 1941 and since

1952). Excavations revealed the layout of Greece's most important and largest religious shrine, locating the temple of Hera, the great altar of Zeus, and the Olympic stadium. The only major surviving sculpture by Praxiteles, “Hermes carrying the infant Dionysus,” was also unearthed at the site. Model techniques of excavation and stratigraphy were employed at the site, and the amount of valuable sculptural, numismatic, and epigraphic material found was very great. The results were edited by Curtius in five volumes. While Curtius's primary achievement was his organization and editing of the excavations at Olympia, he also inspired many scholars with his love of Greece and its past.

Cushing, Frank Hamilton

(1857-1900)

Cushing was born in Pennsylvania and grew up near Albion in New York State. His poor health as a child resulted in a circumscribed but intense education in the fields and woods of his immediate environment. It was during his explorations that Cushing was to find the Indian arrowhead that stimulated his lifelong interest in ethnology. At eighteen he studied natural science at Cornell University and wrote an article about the natural history of his neighborhood in New York. This was published by the smithsonian institution, whose staff were so impressed that they offered him a job.

In 1879 Cushing was appointed to the new Bureau of American Ethnology, which was closely connected to the Smithsonian Institution. Under the directorship of geologist and explorer john wesley powell (1834-1902) the Bureau became the center for anthropological research in North America. While its mandate was to study the ethnography and linguistics of Native American people so as to better administer Indian affairs, the bureau also had a considerable impact on the development of North American archaeology.

The bureau maintained the view that there there was no real difference between indigenous American peoples in the nineteenth century and their prehistoric ancestors. In an environment that denied indigenous American peoples their histories, archaeologists gained insights into the past by working closely with ethnologists and modern native people. In this way prehistoric archaeology was defined as a branch of anthropology.

Cushing and his Bureau colleague J.W. Fewkes (1850-1930) pioneered this approach, known as the direct historical method. They used ethnographic parallels to interpret, by analogy, the activities of prehistoric people. Cushing was so interested in the processes by which the artifacts he found were made that he became a master of indigenous technologies, arts, and crafts.

His outstanding achievements include his studies of the Zuni Pueblo Indians, made over the five years that he lived with them, his explorations of ancient pueblos in the Salt River Valley in Arizona, and his investigations of the ancient inhabitants of Key Marco, Florida. His *Zuni Creation Myths* (1896) and *Zuni Breadstuff* (1920 republished) remain ethnological classics.

Czech Republic

Background

The Czech Republic lies in central Europe and since the sixth century a.d. has been inhabited by Czechs who speak a Slavic language but whose culture has been more Western European in style since the Middle Ages. At that time the territory, almost identical with its present frontiers, formed the Kingdom of Bohemia, part of the Holy Roman Empire of the Middle Ages. Later it was integrated into the Austrian Empire, and in 1918 it gained new independence under the name of Czechoslovakia. It became an island of western-type democracy in the 1930s, when all the surrounding countries were ruled by authoritarian or fascist regimes. In an act of appeasement Czechoslovakia was given to Adolf Hitler by the west European powers in 1938. It was occupied by Germany in 1939, and at the end of World War II the Great Powers decided at Yalta that Czechoslovakia should belong to the Russians after the war. It remained formally independent, becoming a Soviet satellite state. After a short period of liberalization in the 1960s it was occupied by the Soviet army in 1968 to stop what seemed to be a development toward democracy. It regained full independence in

antiquity, remains firmly within a tradition that emphasizes excavation, description, and culture-historical explanation. Its greatest strength lies in this primary concern for data and a well-established tradition of substantial site reports providing the basis for explanations of all kinds.

Czech Republic

Background

The Czech Republic lies in central Europe and since the sixth century a.d. has been inhabited by Czechs who speak a Slavic language but whose culture has been more Western European in style since the Middle Ages. At that time the territory, almost identical with its present frontiers, formed the Kingdom of Bohemia, part of the Holy Roman Empire of the Middle Ages. Later it was integrated into the Austrian Empire, and in 1918 it gained new independence under the name of Czechoslovakia. It became an island of western-type democracy in the 1930s, when all the surrounding countries were ruled by authoritarian or fascist regimes. In an act of appeasement Czechoslovakia was given to Adolf Hitler by the west European powers in 1938. It was occupied by Germany in 1939, and at the end of World War II the Great Powers decided at Yalta that Czechoslovakia should belong to the Russians after the war. It remained formally independent, becoming a Soviet satellite state. After a short period of liberalization in the 1960s it was occupied by the Soviet army in 1968 to stop what seemed to be a development toward democracy. It regained full independence in

1989 during the process of the disintegration of the Soviet empire, and it is now striving to revitalize contacts with western democracies that were severed in 1938. The eastern part of Czechoslovakia, Slovakia, chose independence in 1992, so what remained is the Czech Republic. From the geographic point of view and also historically, the Czech Republic has been divided into two parts: the west is called Bohemia, the east, Moravia.

The archaeological record of both Bohemia and Moravia began in the early Paleolithic period. It was richly structured into settlement sites, cemeteries (both "flat" and those with surviving barrows), hoards, fortifications, ritual monuments, and so forth. The number of sites runs to the thousands, and most of them are polycultural. Settlement sites, whose mutual distance is from 1 to 3 kilometers in many instances, mostly consist of underground features filled with cultural deposits full of shards (since the Neolithic period), animal bones, and other finds, but there are few superimposed layers. "Pagan" graves preceding the ninth century a.d. usually contain grave goods (pottery, stone, bronze, and/or iron artifacts). In consequence of the rich artifactual record, most of the post-Mesolithic sites can be classified with the accuracy of plus or minus 100 years. All these circumstances create very good conditions for detailed archaeological research.

The Beginnings of Archaeological Interest

The Czech chronicler Kosmas, who died in a.d. 1125, mentioned a barrow near Prague where a lege ndary Czech military leader of the ninth century should have been buried. This is an early example of the interpretation of an archaeological monument. Similarly, Václav Hájek of Libočany, writing in 1541, believed that the Marcomanian king Marobuduus (first century a.d.) had his seat at Závist near Prague, a place that is now known as a late-la tène period oppidum (fortified town). His interpretation was nearly correct from the chronological point of view, which may have been a matter of chance, but it should be kept in mind that Hájek was unusually good at inventing details when historical evidence failed him; apparently he had a good model of the past.

The first exact field observation was that of Karel Škréta, a painter who in 1668 made a drawing of the siege of Libice, an early medieval stronghold in Bohemia. Although he placed the historically attested battle of the tenth century into the eastern part of the site (with a gothic church, etc.), he also faithfully recorded the empty western part, consisting of bare fields surrounded by a simple rampart. One flat place in the fields has been described by Škréta as "ruins"; this is exactly where excavations of the 1950s unearthed the ground plan of a tenth-century church lying in the center of the original stronghold. All this is not very surprising to those who know that peasants of the late-medieval period (and much earlier times) correctly identified long-deserted earthworks as ancient forts and barrows as ancient graves. Many Iron Age hill-forts carry the name *Hradiště*, which means hill-fort in Czech; this also applies to cases where the ramparts are barely visible.

The first recorded collection containing archaeological objects was that of the Bohemian King Rudolph II, who was also a Roman emperor. It was kept in the royal palace in Prague and enriched by the king himself by means of excavations of a Bronze Age cemetery in Silesia, which in Rudolf's time belonged to the Kingdom of Bohemia. The excavation took place in 1577, and Rudolph unearthed one of the vessels with his own royal hands.

The Romantic Period

As in most European countries, archaeological activities in Bohemia and Moravia greatly increased in the romantic period from the end of the eighteenth century onward. The main idea was the belief that prehistory as recovered by archaeology was a backward projection of history, with the same "nations"

and the same habits as recorded in the earliest written documents. There was no knowledge of the great antiquity of the human race; in fact, very few people ever considered the question of what preceded the Celtic, Germanic, and Slavic “nations” in central Europe. Therefore, the romantic query did not demand any systematic handling of the archaeological finds, which were simply believed to be illustrations of ancient history.

1989 during the process of the disintegration of the Soviet empire, and it is now striving to revitalize contacts with western democracies that were severed in 1938. The eastern part of Czechoslovakia, Slovakia, chose independence in 1992, so what remained is the Czech Republic. From the geographic point of view and also historically, the Czech Republic has been divided into two parts: the west is called Bohemia, the east, Moravia.

The archaeological record of both Bohemia and Moravia began in the early Paleolithic period. Similarly, Václav Hájek of Libočany, writing in 1541, believed that the Marcomanian king Marobuduus (first century a.d.) had his seat at Závist near Prague, a place that is now known as a late-la tène period oppidum (fortified town). His interpretation was nearly correct from the chronological point of view, which may have been a matter of chance, but it should be kept in mind that Hájek was unusually good at inventing details when historical evidence failed him; apparently he had a good model of the past.

The first exact field observation was that of Karel Škréta, a painter who in 1668 made a drawing of the siege of Libice, an early medieval stronghold in Bohemia. Although he placed the historically attested battle of the tenth century into the eastern part of the site (with a gothic church, etc.), he also faithfully recorded the empty western part, consisting of bare fields surrounded by a simple rampart. One flat place in the fields has been described by Škréta as "ruins"; this is exactly where excavations of the 1950s unearthed the ground plan of a tenth-century church lying in the center of the original stronghold. All this is not very surprising to those who know that peasants of the late-medieval period (and much earlier times) correctly identified long-deserted earthworks as ancient forts and barrows as ancient graves. Many Iron Age hill-forts carry the name *Hradiště*, which means hill-fort in Czech; this also applies to cases where the ramparts are barely visible.

The first recorded collection containing archaeological objects was that of the Bohemian King Rudolph II, who was also a Roman emperor. It was kept in the royal palace in Prague and enriched by the king himself by means of excavations of a Bronze Age cemetery in Silesia, which in Rudolf's time belonged to the Kingdom of Bohemia. The excavation took place in 1577, and Rudolph unearthed one of the vessels with his own royal hands.

The Romantic Period

As in most European countries, archaeological activities in Bohemia and Moravia greatly increased in the romantic period from the end of the eighteenth century onward. The main idea was the belief that prehistory as recovered by archaeology was a backward projection of history, with the same "nations"

and the same habits as recorded in the earliest written documents. There was no knowledge of the great antiquity of the human race; in fact, very few people ever considered the question of what preceded the Celtic, Germanic, and Slavic “nations” in central Europe. Therefore, the romantic query did not demand any systematic handling of the archaeological finds, which were simply believed to be illustrations of ancient history.

eighteenth century, but it rose to importance in the nineteenth. A nice example in this regard involved the forgeries of allegedly early-medieval manuscripts written in Czech that were "discovered" in 1817 and 1819. Being well written, they influenced one part of Czech archaeology until the beginning of the twentieth century, as many influential historians and archaeologists accepted them as facts (e.g., P.J. Šafařík in 1836 and later F. Palacký, J.L. Píč, and others).

The romantic paradigm of archaeology faced a crisis when it became clear that it was unable to answer its own questions, in spite of the fact that the number of finds substantially increased. This development, however, did not take place in a vacuum: it was stimulated by changing ideologies reflecting changing social structure. It is often believed that the rise of the middle class and the beginning of the industrialization of the country can be held responsible for the development. Details of the complicated processes that took place within the society of the nineteenth century have not yet been sufficiently studied.

The Beginning of Formalism

The beginning of archaeology has often been identified with the creation of the first formal system of archaeological finds (the three-age system). It may not be chance that this attitude toward the "beginning" of archaeology came from modern archaeologists who themselves were proponents of formal (typological) archaeology. The romantic period seemed to them to be unscientific, apparently because it relied so heavily on models derived from outside (from history). There is no obvious reason, however, why the beginning of archaeology should be set as late as the introduction of the three ages.

The three-age system was well known and adopted in Czech lands soon after it was proposed in denmark. J.E. Vocel, the first Prague professor of archaeology, was its partisan, and J.V. Hellich, a custodian of the archaeological collection at the National Museum in Prague, used it in a handbook on Czech archaeology, written in 1943. The opposition of German specialists to the three-age system, however, could not be entirely dismissed and resulted in a conditional adoption of the ideas of the three ages by some Czech archaeologists.

It is worth noting that Vocel tried to subdivide the Bronze Age on the basis of the chemical composition of bronze artifacts. This is an example of how early formal archaeologists were still looking for chronologically sensitive attributes of artifacts before finding them in terms of shape and decoration. The romantic paradigm did not end abruptly with the three-age system, as it was permanently regenerated by the nationalism of the nineteenth century, which was especially active in central Europe. It was only at the end of the century that the national ambitions of at least some nations of the central European states (including those of the Czechs) were satisfied and they became more or less politically stable. This created the necessary conditions for an almost complete (but temporary) abandonment of romantic and nationalist concepts.

Developed Formal Archaeology

The three-age system was not entirely satisfactory, not only because of persisting nationalism but also because some countries had many archaeological finds that showed a good deal of formal variability that could not be explained by means of the three basic periods. By the end of the nineteenth century Bohemian and Moravian archaeology had its basic classificatory framework, going far beyond the three-age system, and this framework did not change substantially afterward.

This achievement was the logical consequence of the greatly enlarged effort of many Czech archaeolo gists in the second half of the nineteenth century who excavated new sites and tried to classify their finds into more detailed subdivisions. The final form of the achievement is connected with the names of Lubor

Niederle, Karel Buchtela, Inocenc L. červinka, and Jaroslav Palliardi (mainly for the Neolithic period). The first two archaeologists based their classification on the monumental collections of the National Museum in Prague, which were greatly enriched by Josef L. Píč and his friends. Píč, an unusually active curator of

eighteenth century, but it rose to importance in the nineteenth. A nice example in this regard involved the forgeries of allegedly early-medieval manuscripts written in Czech that were "discovered" in 1817 and 1819. Being well written, they influenced one part of Czech archaeology until the beginning of the twentieth century, as many influential historians and archaeologists accepted them as facts (e.g., P.J. Šafařík in 1836 and later F. Palacký, J.L. Píč, and others).

This development, however, did not take place in a vacuum: it was stimulated by changing ideologies reflecting changing social structure. It is often believed that the rise of the middle class and the beginning of the industrialization of the country can be held responsible for the development. Details of the complicated processes that took place within the society of the nineteenth century have not yet been sufficiently studied.

The Beginning of Formalism

The beginning of archaeology has often been identified with the creation of the first formal system of archaeological finds (the three-age system). It may not be chance that this attitude toward the "beginning" of archaeology came from modern archaeologists who themselves were proponents of formal (typological) archaeology. The romantic period seemed to them to be unscientific, apparently because it relied so heavily on models derived from outside (from history). There is no obvious reason, however, why the beginning of archaeology should be set as late as the introduction of the three ages.

The three-age system was well known and adopted in Czech lands soon after it was proposed in denmark. J.E. Vocel, the first Prague professor of archaeology, was its partisan, and J.V. Hellich, a custodian of the archaeological collection at the National Museum in Prague, used it in a handbook on Czech archaeology, written in 1943. The opposition of German specialists to the three-age system, however, could not be entirely dismissed and resulted in a conditional adoption of the ideas of the three ages by some Czech archaeologists.

It is worth noting that Vocel tried to subdivide the Bronze Age on the basis of the chemical composition of bronze artifacts. This is an example of how early formal archaeologists were still looking for chronologically sensitive attributes of artifacts before finding them in terms of shape and decoration. The romantic paradigm did not end abruptly with the three-age system, as it was permanently regenerated by the nationalism of the nineteenth century, which was especially active in central Europe. It was only at the end of the century that the national ambitions of at least some nations of the central European states (including those of the Czechs) were satisfied and they became more or less politically stable. This created the necessary conditions for an almost complete (but temporary) abandonment of romantic and nationalist concepts.

Developed Formal Archaeology

The three-age system was not entirely satisfactory, not only because of persisting nationalism but also because some countries had many archaeological finds that showed a good deal of formal variability that could not be explained by means of the three basic periods. By the end of the nineteenth century Bohemian and Moravian archaeology had its basic classificatory framework, going far beyond the three-age system, and this framework did not change substantially afterward.

This achievement was the logical consequence of the greatly enlarged effort of many Czech archaeologists in the second half of the nineteenth century who excavated new sites and tried to classify their finds into more detailed subdivisions. The final form of the achievement is connected with the names

of Lubor Niederle, Karel Buchtela, Inocenc L. červinka, and Jaroslav Palliardi (mainly for the Neolithic period). The first two archaeologists based their classification on the monumental collections of the National Museum in Prague, which were greatly enriched by Josef L. Píč and his friends. Píč, an unusually active curator of

the National Museum, promptly published his finds, which enabled his opponents to use them to discredit his arguments. Although he tried to work independently in creating a nonformal and more or less romantic paradigm of his own, Niederle (then already a professor of prehistoric archaeology at Charles University in Prague) was well aware of the parallel work being done elsewhere in Europe, which, however, he and Buchtela did not accept unconditionally. With the exception of some supposedly romantic points primarily concerning several assumed migrations, their paradigm was formal, that is, based on shape, decoration, and similar characteristics, as observed on individual artifacts. červinka, working in Moravia and closely following Niederle and Buchtela, based his views on the collections of a number of local archaeologists, and Palliardi built on excavations of his own.

In spite of the fact that there were romantic elements in the works published around the turn of the twentieth century, such works were basically not nationalist, for their main problems were connected not with the "nations" known in central Europe at the beginning of written history but with the formal aspects of the archaeological record.

These achievements, however, were not isolated in Europe, and they were not the first of their kind. By the 1870s many archaeologists in other parts of Europe (oscar montelius in Sweden was the most prominent representative of the current) began to look for finer divisions of the archaeological record, inspired, directly or indirectly, by Charles Darwin's evolutionary theories (which, however, explained the variability of nature). Their work was unusually successful, leading to detailed chronological schemes, one part of which (for the Bronze Age and the beginning of the Iron Age) is still used. The studies were undertaken mainly in Scandinavia and later in Germany in the period from 1890 through 1910. They are generally known under the name *typology*, as the chronological schemes were constructed on the basis of the "evolution" of archaeological types (usually a parallel evolution of several types for each period).

The contribution of Czech lands to these schemes has already been mentioned. Czech archaeologists not only created typological sequences for their own regions but also supplied important parts of the evidence on which other specialists could build. An important Czech contribution to the typological endeavor, which deserves to be mentioned in more detail, was achieved by the Moravian archaeologist Jaroslav Palliardi, who proposed a detailed chronology (with twelve phases) of the Moravian Neolithic and Eneolithic periods. The conclusions he arrived at by the end of the nineteenth century are still valid; they were, in fact, so much ahead of their time that they were not developed further until the late 1950s. This was partly caused by the fact that their final form only appeared when the views of gustaf kossinna, a prominent German professor of philology, started to occupy the minds of official archaeologists. Although Palliardi demonstrated that the individual Neolithic and Eneolithic cultures represented consecutive chronological phases, Kossinna's adherents considered them to be more or less contemporaneous groups covering different ethnic wholes. However, it clearly followed from Palliardi's chronology that "Nordic elements," such as the funnel beakers, appeared very late in the Moravian sequence and therefore could not be considered responsible for the appearance of civilization throughout Europe, as maintained by Kossinna. Palliardi's findings contradicted Kossinna (and even his nonradical followers) to such a degree that almost no archaeologist had the courage to mention them.

The First Half of the Twentieth Century

The three-age system and the recognition of the "diluvial" age of humans that followed had one great nonformal consequence: it became clear that humankind was of great antiquity, and it was to be expected that the "nations" known at the beginning of written history could not account for everything in the past; after all, much history was not mentioned in any written documents. This idea was taken up by a number of archaeologists, first of all by Kossinna, who began to look for ancient Indo-Europeans and their origins in the archaeological record. Formal archaeology was so successful in drawing

PREV NEXT

that could be used by everybody, and the newly founded State Archaeological Institute promised to become a center for heritage management. As will be explained shortly, these undeniable achievements were lost in the postwar socialist period.

The Socialist Period

Ideologically, the socialist period began just after World War II as nationalist propaganda stressed the allegedly close relationship between Czechs and Russians. This propaganda found immediate reflection in archaeology: archaeology was expected to demonstrate the eastern connections of the Czech nation, proving that the "Slavs" arrived very early from the east. This point was directed against the Germans, with whom the Czechs have, in fact, more in common than with the Russians. Most archaeologists did not recognize the ideological background of these views and actively participated in the officially supported boom of "Slavic archaeology" especially if no explicit ideological statements were required, and there were no direct nationalist implications. This period ended in 1968; thereafter anything "Slavic" became ideologically untenable because it was a reminder of the Russian military invasion. There was a subperiod just after the mid-1960s, preceding the liberalization of 1968, when achievements of Czech scientists in general were evaluated on the basis of references in the West: the regime recognized that it could not rely on reports put out by the party bureaucracy that ruled the institutes.

Contrary to the expectations of many western archaeologists, Marxism never became a widespread topic in Czech archaeology. However, statements on theory running against Marxist ideology would have been punished, something that automatically put an end to all discussions of major theoretical issues. Any theoretical debate had to have the usual dogmatic form, full of quotations from Karl Marx (see Neustupný 1967), but there were not many publications of this sort. Marxism was completely dropped after 1968, as some of its ideas apparently seemed dangerous to the communist ruling class; all that remained was the usual Marxist political rhetoric. But the situation in West Germany-where, despite the absence of Marxist ideological pressure, there was no discussion of theory in the 1950s through to the 1980s-makes it uncertain whether theoretical issues would have been raised by Czech archaeologists of that period if there had not been any communist regime. Marxist philosophy, however, had one positive effect in that every university student had to study the works by Marx and Friedrich Engels. Consequently, many students became acquainted with some kind of philosophy and a sort of anthropology, although a part of the related reading was purely political (see Neustupný1991).

As real archaeological theory, being ideologically controlled, was dangerous to touch, most archaeologists refused to go near it. It was also dangerous to write positively about anything coming from the West. To proclaim oneself to be a "New Archaeologist," for example, was a risk that nobody took. In this situation many archaeologists preferred nontheoretical topics within the tradition of formal, typological archaeology; the main problems discussed in archaeological writings were chronology and cultural influences, assumed to come predominantly from the southeast. At the same time, the large-scale contemporaneity of prehistoric cultures was taken for granted, and this, of course, opened the door to the equation of archaeological cultures with ethnic units; the assumption of many migrations was a logical result. This kind of archaeology may have been a protest against the communist regime because it was utterly nonideological (see Kuna 1993), or at least not favorable to socialism, whereas an active engagement in communist ideology was otherwise required in any other sphere of life. New Archaeology and the beginnings of postprocessual archaeology were largely missed in this deformed intellectual environment.

In this way it happened that Czech archaeologists became very good at typological chronology (cf. Krumphanzlová 1972), and their detailed schemes created in the 1950s and 1960s are still valid; they became the basis for local sequences all over central Europe. Either

PREV NEXT

they were applied directly or they stimulated similar schemes to originate elsewhere as parallels. Czech archaeologists have also achieved positive results in the study of the natural environment and the spatial structure of sites. Problems involving the latter concern ensued not only from theoretical considerations but also from the unusually large rescue excavations that took place, by and large in northwestern Bohemia. This region was the only one to have an effective rescue team (a branch of the Prague Academy Institute) as early as the end of the 1950s; tens of hectares were continuously stripped and covered by rescue excavations in front of open coal mines, leading to the creation of an unusually rich archaeological record (see Neustupný 1994).

In the 1950s and 1960s archaeology was lavishly supported by the state for ideological reasons, and major amounts of money went to large-scale excavations. This, however, was done at the expense of rescue work, museums, and universities, which were allotted very limited funds. Moreover, the large excavations, mostly led by the institutes of the Academy of Sciences, often remained unpublished for decades, so their great informative potential was partly wasted. But in spite of this, these excavations have brought much new knowledge, which has not yet been fully used. The support for excavations substantially diminished in the 1970s when they began to necessite a growth in rescue work paid by the developers.

The Postsocialist Period

The power structures introduced by the communists had a devastating effect on Czech archaeology. In the postsocialist period almost nothing was normal: how could it have been without the imposition of the all-pervasive party control? The party disappeared by 1989, but the institutions created for its maintenance partly remained. At the beginning of the period it seemed that the transition to a normal state would be fast and easy, but such hopes have not been realized, mainly because many individuals succeeded in keeping their microenvironments unchanged. The previous system has been replaced by liberal mechanisms of self-rule in the field of research. As Czech society as a whole is successfully and rapidly moving toward a market economy based on private property and toward western-type democracy, the state of Czech archaeology is likely to change in the future.

The "Prehistories" of the Czech Republic

There are many summary works on Bohemian, Moravian, and Czechoslovak prehistory, far more than in other countries. The likely reason for this is that Bohemia and Moravia are geographically well defined by mountains, having no or sparse archaeological finds in border areas; thus, it is not necessary to draw artificial limiting lines along modern frontiers while compiling archaeological evidence.

Leaving aside the purely antiquarian lists of monuments, the first summary books are those by J.E. Vocel (1845, 1853, 1866). They were followed by a series of books, beginning with the works of Buchtela and Niederle (Buchtela 1899; Niederle and Buchtela 1910) and leading to those of Schránil (1928), Böhm (1941), Neustupný (1946), Filip (1948), and Neustupný (1968). All these writings are based on similar methodological and theoretical grounds (formal typological approach, interest in influences and limited migrations, little interest in economy and social relations). The last-named book, however, was concerned with ecological evidence and issues.

New principles were introduced by Evžen and Jiří Neustupný in 1961. The influences and migrations were kept to a minimum, and economic and social questions were discussed on an unprecedented scale. In this sense their work went far beyond the typological paradigm. Bohemian archaeology was influenced by the two preceding books (especially by their systematic discussions of prehistoric economy and society and their summaries of the environmental evidence), but otherwise it remained

within the traditional typological current. The most recent attempt (Neustupný 1994), a textbook for schools, suppresses the typological detail and tries to explain the past in terms of the practical function, social meaning, and symbolic significance of the archaeological record.

The Organization of Archaeological Research

The first type of organization in which archaeology was performed on a professional or semiprofessional level was the museum. The National Museum in Prague (originally the Museum of the Kingdom of Bohemia) and the Moravian Museum in Brno, both founded in 1818, were followed by Olomouc (in northern Moravia) and other smaller museums that became centers of archaeological research, and they continued to be so during the second half of the nineteenth century. In addition to the large museums many local museums were opened in which amateur archaeologists were especially active at the end of the nineteenth and in the first half of the twentieth centuries.

The second centers of archaeological research were the universities. The Charles University in Prague, founded in 1348, has had a chair of Bohemian antiquities since 1850. Jan Erazim Vocel, a partisan of the three-age system who compiled a book on Bohemian antiquities (Starožitnosti země české, 1866), was its first professor of archaeology. In 1898 Lubor Niederle was appointed the first professor of prehistoric archaeology, and since that time the chair has been occupied permanently (except during World War II, when Czech universities were closed by the Germans). Yet though Charles University educated several professional archaeologists, most of them in the second half of the twentieth century, it never became the center of Czech archaeology. It did not perform any major excavations, and its staff was always limited to a very few persons. Nonetheless, it produced a number of outstanding professional archaeologists on a high level. The Brno University in Moravia has had a chair of prehistoric archaeology since 1933, and in many respects it has been more active archaeologically than Charles University in Prague. At present archaeology is also taught at a number of smaller universities, but none of them has a chair of archaeology.

The network of museums and universities was supplemented by the State Archaeological Institute in 1919 (with a Brno branch in 1941). Originally, the institute was a small body occupied mainly with fieldwork. It became the core of the Archaeological Institute of the Czechoslovak Academy of Sciences, founded in accordance with the Russian template in 1953. As a result of that move any hopes of Czechoslovakia getting an institution to take over the care of archaeological monuments and rescue excavations vanished.

The foundation of the Czechoslovak Academy of Sciences was a part of the program to unify the Soviet empire by building comparable structures everywhere; the goal in creating this institute was to easily control the sphere of science and humanities from one communist party center. This meant an incredible degree of centralization, with more than half of all Czech archaeologists directly attached to this institute (others were attached indirectly). The Prague Archaeological Institute had some 200 employees in 1989, and there was another but smaller institute in Brno. Museums and universities were not allowed to grow in this phase, and in the first twenty years there was no body responsible for rescue excavations (later, this responsibility was partly assumed by the Academy Institutes). All theoretical activities were supposed to be done by the academy, whose leading position in the field of science was embodied in law. Directors of the institute became the rulers of Czech archaeology.

The socialist regime fostered people of mediocre intellect in general, and most of those in archaeology were not exceptions to this rule. To achieve anything after the Russian invasion of Czechoslovakia, one had to be a member of the Communist Party or a secret police agent. Individuals in both these categories were active in archaeology. For the most part only children of reliable party members were allowed to study “ideological” subjects, and archaeology was considered to be one of them. In view of these facts it is surprising that a fair number of talented people escaped the attention of the party and became good archaeologists. This often happened at the cost of them joining the party. After the “capitalist revolution” in 1989, several groups of archaeologists, doing mostly rescue work, separated

from the Institutes of the Academy in 1993. But otherwise the situation had

D

Daniel, Glyn

(1914-1986)

Glyn Daniel grew up in the Vale of Glamorgan in southern Wales, was educated at Barry Grammar School, then went to St. John's College, Cambridge, on a scholarship in 1932. He switched from geography to archaeology and was at St. John's all the rest of his life.

Daniel's first research on the megalithic monuments of the British Isles was later enlarged by studying their cousins in France and across Europe as a whole. His work was published as *The Prehistoric Chamber Tombs of England and Wales* (1950) and *The Prehistoric Chamber Tombs of France* (1960). It was a large task, in the late 1930s, simply to collate knowledge of the chamber tombs and then to relate them to their sister monuments scattered across western Europe.

Working within the "moderate-diffusionist" framework for European prehistory associated particularly with the work and name of vere gordon childe, Daniel devised a scheme (1941) for a dual colonization of western Europe by megalith builders: a passage-grave tradition originating in the eastern Mediterranean and a gallery-grave tradition originating in the western Mediterranean, which between them explained the pattern in northwest Europe, the region where the diffusionist impulse had spread the habit of megalithic building. Like other schemes diligently built to explain European prehistory with slight and ambiguous chronological evidence, this one collapsed in the 1950s when calibrated radiocarbon chronology showed that the northwest European megaliths, especially those in Brittany, were earlier than, or as early as, their supposed ancestors in Mediterranean lands. Instead, Daniel was able to enjoy the role that his native Wales played in originating a style and craft of stone-building through Atlantic Europe that was older than the pyramids of Egypt.

It seems in retrospect that it was not helpful to concentrate research on megaliths as a defined class on their own. The techniques of building with great blocks are much the same everywhere, because the engineering options are few, so similarities of form can only be weak proof of cultural affinity or any direct historic connection. Recent study has instead preferred to integrate examination of the megaliths with evidence from nonmegalithic contexts of the same periods. Even that is still not an easy task because the artifactual evidence that can be used in dating is even now often slight or uncertain; it was certainly impossible to find it a good basis for systematic megalithic study in the prewar and preradiocarbon era.

In 1943, Daniel published *The Three Ages,* a study of the Scandinavian development in the early nineteenth century of a Stone Age/Bronze Age/Iron Age division of early European archaeology, the key insight in ordering the artifacts that made studying prehistory possible in that century. This was the first of many studies by Daniel in the history of archaeology, including *A Hundred Years of Archaeology* (1950), *The Idea of Prehistory* (1962), *The Origins and Growth of Archaeology* (edited, 1967), and *A Short History of Archaeology* (1981), that set out the essentials of the nineteenth-century story especially as they have now come to be generally understood. Implicit in this important part of Daniel's writing, though not unnecessarily emphasized, is the insight that we do not excavate the simple *facts* of

D

Daniel, Glyn

(1914-1986)

Glyn Daniel grew up in the Vale of Glamorgan in southern Wales, was educated at Barry Grammar School, then went to St. John's College, Cambridge, on a scholarship in 1932. He switched from geography to archaeology and was at St. John's all the rest of his life.

Even that is still not an easy task because the artifactual evidence that can be used in dating is even now often slight or uncertain; it was certainly impossible to find it a good basis for systematic megalithic study in the prewar and preradiocarbon era.

In 1943, Daniel published *The Three Ages,* a study of the Scandinavian development in the early nineteenth century of a Stone Age/Bronze Age/Iron Age division of early European archaeology, the key insight in ordering the artifacts that made studying prehistory possible in that century. This was the first of many studies by Daniel in the history of archaeology, including *A Hundred Years of Archaeology* (1950), *The Idea of Prehistory* (1962), *The Origins and Growth of Archaeology* (edited, 1967), and *A Short History of Archaeology* (1981), that set out the essentials of the nineteenth-century story especially as they have now come to be generally understood. Implicit in this important part of Daniel's writing, though not unnecessarily emphasized, is the insight that we do not excavate the simple *facts* of

ancient matters. Archaeological knowledge depends also on the attitudes and values of the inquirer; the advances in the developing history of archaeology came from new opportunities that resulted from changing frames of ideas as well as from new field discoveries.

In 1952, Daniel participated in an archaeological quiz show on British (BBC) television, *Animal, Vegetable, Mineral?* and soon became its chairman. For each show, three experts (of whom sir mortimer wheeler was the regular performer with the best style and panache) would examine mystery objects from a museum collection and try to identify just what they were and where they came from. The program was an unprecedented success in the "strange and heady days" of early British television, and Daniel was voted "Television Personality of the Year" in 1955. Looking now at the few minutes of black-and-white film that survive, it is not easy to see why the program caught the public imagination so. Rather than allowing himself to be pulled further into the television world, Daniel stayed with archaeology and later was much involved in the guidance of the long-running BBC archaeology series *Chronicle*.

In 1955, Daniel began to edit a new series of books for Thames and Hudson, *Ancient People and Places,* which ran to over 100 volumes, and in 1957, he succeeded o. g. s. crawford as editor of the journal *antiquity*. As a journal and book editor, knowledgeable in the ways of television and with a lively sense of what was new and exciting, Daniel had great importance (not always visible) from the 1950s onward; in the modern phrase, he was a great "networker." Knowing everyone, always interested in the gossip as to who had found what and said what, he had an influential hand in many useful innovations, and much was done, written, and published that might not have occurred without his cheery and steel-centered encouragement. A long series of his students went on from St. John's to successful careers in archaeology; Glyn was especially proud of 1962 when Barry Cunliffe, Colin Renfrew, and two other members of St. John's all got first-class degrees. Cambridge recognized Daniel's diverse service, in his college as well as in the university, and that his work was much broader than the conventional research of a narrow academic career by electing him Disney Professor of Archaeology in 1974, in succession to sir grahame clark. When Daniel retired in 1981, he was succeeded by his student Lord Renfrew.

Daniel published an excellent fat autobiography, *Some Small Harvest,* which is full of lively and telling stories, in 1986, the year of his retirement after thirty years of editing *Antiquity* and the year of his death. He was survived by his wife, Ruth, production editor for *Antiquity* and the less public partner in a celebrated Cambridge double act for the forty years since their marriage in 1946.

Dart, Raymond Arthur

(1893-1988)

Born near Brisbane, Queensland, Australia, Dart graduated from the University of Queensland in 1913 with a science degree. He studied medicine at the University of Sydney and after completing his master's degree in anatomy, and his medical degree in 1917, joined the Australian Medical Corps in France and England from 1918 to 1919. After the war he worked with sir grafton elliot smith, demonstrating anatomy at University College London, and then in 1920 won a Rockefeller Foundation fellowship to the United States. He first studied at the University of Cincinnati but then spent most of his time in the

anatomy department at Washington University in St. Louis, Missouri. In 1922 Dart became professor of anatomy and dean of the medical school at the University of Witwatersrand in south africa, and he built up these institutions until 1943, creating the Raymond Dart Collection of Human Skeletons while teaching there. He retired in 1958 but continued to work as an honorary professorial research fellow at the Bernard Price Institute for Palaeontological Research in Witwatersrand for six months of the year and as professor at the Avery Postgraduate Institute in Philadelphia, U.S.A., for the other six months, until the age of ninety-three. The Institute

Dasgupta, Paresh Chandra

(1923-1982)

P. C. Dasgupta was primarily an art historian interested in the early historic terracottas and later sculptures of West Bengal before he was made the director of the West Bengal State Directorate of Archaeology and Museums in Calcutta in the early 1960s. His subsequent career is an excellent example of how important a role even amateurs can perform in modern archaeology, especially in the Third World, by their sheer enthusiasm.

Stone Age sites had been known in West Bengal before, but the number of discoveries Dasgupta made in this field far outstripped any significant work done earlier. One of his sites, Susunia, is undoubtedly the only major primary Acheulian site in eastern India, rich in both faunal and lithic remains. Interestingly, his amateurism meant that he was instrumental in preventing the full potential of the site from being realized because he employed a large number of workmen to only pick up artifacts. Neolithic-Chalcolithic sites were well understood in many other parts of India by 1960, but nothing was known of them in West Bengal. Dasgupta soothed regional pride by finding a large number of them over a wide area, and although he did not do justice to the major site he excavated in this context, that of Pandu Rajar Dhibi, his report (Dasgupta 1964) was for many years the only definitive publication on the stratigraphy of such a site in West Bengal.

Dasgupta's department soon built up what was to become the largest archaeological collection from Bengal. The museum that was established after he had retired in the late 1970s reflects his enormous enthusiasm and support for Bengal archaeology, and those who work in the region will always feel indebted to him.

Dating

Establishing the age of objects, landscapes, or contexts is one of the primary tasks of the archaeologist. It has also proved to be among the most difficult. Archaeology's twin roots in the humanities and in sciences such as geology and paleontology provided two types of answers to the question, how old? Although antiquarians, historians, and philosophers long pondered the history of people before writing, it was only in the nineteenth and twentieth centuries that the discipline of archaeology was able to make great strides in developing reliable means of assigning age and chronological relationship.

From the humanities, particularly through the study of material culture, archaeologists have developed schemes of relative dating based on the close analysis of the forms and functions of artifacts. In this endeavor strong links with classification (taxonomy) and typology were forged that depended on the development of consistent rules for describing artifacts and the contexts in which they were found. The earliest relative chronologies, such as the three-age system, were founded upon description, taxonomy, and the development of typology. But in the absence of a means to establish relative age, such classifications and typologies were, in essence, ahistorical and potentially circular in their logical forms.

Geology and paleontology provided the basis of a solution. The principle of relative dating (that is, establishing that one thing is relatively older or younger than another thing) was based on the notion of

stratigraphy. In this sense it was understood that following the law of superposition (by which what is on the top is assumed to be younger than what is on the bottom), the relative ages of artifacts could be established on the basis of their relative positions within a stratigraphic profile. Advances in the degree to which antiquarians and archaeologists in the nineteenth century understood the principles of stratigraphy (and site formation) were matched by an increasing sophistication in the ways in which they were able to apply them.

The work of Scandinavian archaeologists such as jens jacob worsaae, sophus müller, and oscar montelius and Egyptologists such as w. m. flinders petrie was particularly significant in the development of the relative-dating technique of seriation. These advancements were supported by painstaking research into the

since its development by willard libby in 1952. Radiocarbon dating has become the most widely used absolute dating technology all over the world. Indeed, one of its very great strengths has been its capacity to create a "world prehistory"-a framework within which archaeologists could compare what was happening in parts of the world that had, at that time, little or no shared history (Bowman 1990). However, virtually from the time the technique was first applied to archaeological contexts, practitioners have recognized and worked to correct limitations in the technology-an effort that has led to the development of a thriving industry in dating research and the education of archaeologists in the business of collecting samples and interpreting dates. After some fifty years of research we now have enhancements of Libby's original technique that can deliver more accurate absolute dates over longer time periods.

Some limitations in radiocarbon dating have been overcome by the development of new technologies such as luminescence dating (Aitken 1985), which themselves have become the subjects of ongoing research. Given that dating is so central to the business of doing archaeology in the early twentieth-first century, any reputable undergraduate archaeology textbook contains exhaustive descriptions of techniques for dating materials as diverse as the enamel on teeth or the products of volcanic eruptions in the very remote human past. The identification of regular decay processes occurring in nature is an ongoing task designed to assist the archaeologist in obtaining absolute dates from seemingly intractable materials and to improve our confidence in the reliability and precision of such dates. Notwithstanding the great success achieved by dating specialists in the twentieth century, we should never forget that although the development and application of the technologies is important, the task of making sense of them remains firmly in the province of the archaeologist.

Davis, Edwin Hamilton

(1811-1888)

Davis was born at Hillsboro in southern Ohio, a town surrounded by a number of circular, square, and octagonal earthworks that were the cause of much speculation. From his earliest years Davis was interested in the origins of the mounds and their builders. He graduated from the Cincinnati Medical College in 1837 and settled down to practice medicine in Chillicothe, Ohio, but his interest in the earthworks continued. Davis financed the surveying of 100 of these, and the stratigraphic excavation of others, by newspaper editor-turned-archaeologist Ephraim G. Squier. Consolidating their data with the findings of other researchers on prehistoric earthworks from all over the eastern united states, Davis and Squier co-wrote *Ancient Monuments of the Mississippi Valley* (1847), the smithsonian institution's first publication. It remains an important source of information for archaeologists to this day. Squier and Davis supported caleb atwater's Moundbuilder theory, and while this precluded speculation on the origins of mounds and earthworks, they did speculate on their possible uses.

Davis collected artifacts from the mounds that were regarded as surprisingly advanced artistically. Most of his collection was acquired by the Blackmore Museum in Salisbury, England, while a smaller part is in the American Museum of Natural History in New York City. Davis was professor of medicine at the New York Medical College from 1850 to 1860, and maintained his interest in archaeology, appearing as a regular lecturer on archaeology to various learned societies.

Dawkins, Sir William Boyd

(1837-1929)

Born in Shropshire, England, Dawkins studied geology at Oxford and after graduating in 1860 worked for the Geological Survey of England.

PREV NEXT

In 1869 he was appointed curator at the Manchester Museum and lecturer in geology at Owens College in Manchester. In 1874 the college became the Victoria University of Manchester (now Manchester University) and Dawkins became its first professor of geology, a position he held until his retirement in 1909.

Dawkins became interested in Paleoanthropology in 1859 when he helped the Rev. J. Williamson explore the Wookey Hole, a cave in the Mendip Hills in southern England, in search of evidence of early humans in England. At the same time william pengelly and hugh falconer were interpreting prehistoric material found at brixham cave in Devonshire to the same end. While in his first book, *Cave Hunting* (1874), Dawkins cautiously supported the idea of early human antiquity, by his second, *Early Man in Britain* (1880), he argued that human antiquity was only as old as the Pleistocene period (10,000 years ago). Dawkins believed that the mammalian extinctions at the close of the Tertiary period would have also included humans-if they had existed at all. Based on the fossil remains in river-drift terraces or cave sites, Dawkins argued that humans first appeared in Europe during the middle Pleistocene period. He criticized French archaeologist gabriel de mortillet for excluding regional variations in early human evidence, and went on to suggest that differences in assemblages might also be the result of tribal or ethnic variations, or of access to raw materials.

Dawkins maintained his position on human antiquity despite subsequent developments in Paleoanthropology, but remained active in scientific debates, including that of the great antiquity of Piltdown man. Despite regarding the arguments for Piltdown as “heresy,” he was to become close friends with Sir Arthur Keith, who at that time was vigorously supporting the finds from Piltdown.

Dawkins became a Fellow of the Geological Society in 1861 and received the Lyell Medal in 1889 and the Prestwich Medal in 1918. He was knighted in 1919.

Déchelette, Joseph

(1862-1914)

Déchelette is considered one of the first professional archaeologists in france, not only because he was paid by an institution to conduct his work, but also because his social and financial situation allowed him to devote himself full-time

PREV NEXT

to research on a European scale. His career was relatively brief-roughly fifteen years between 1899 when he retired from his manufacturing business and 1914 when he died as a result of action during World War I. Déchelette was a self-taught scholar, never belonging to the academic elite or sharing in its exclusive focus on classical archaeology. He was, both socially and intellectually, above the level of local scholars and amateurs, who were limited to their arrondissement or canton. He was a correspondent of the Institut de France and the Société des Antiquaires, a member of the Comité des Travaux Historiques, a divisional inspector of the Société Française d'Archéologie, and a conservator of the Antiquites et Objets d'Art du Departement de la Loire.

Déchelette's success in the field of protohistoric archaeology was no accident, and in the no-man's-land between history and prehistory he pioneered what innovations were possible at the frontier where different disciplines meet.

Faced with a fragmented discipline in which archaeological remains were interpreted in isolation, Déchelette gathered together scattered records, connected disparate data and defined a relevant method that would work for all the periods covered by archaeology. He acquired an encyclopedic knowledge that enabled him to tackle problems from a synthetic perspective. When the publisher Picard proposed a manual of national archaeology, Déchelette was the obvious person to do it, writing the four volumes of the *Manuel d'archeologie prehistorique, celtique et galloromaine* between 1908 and 1914.

Déchelette was also one of the first archaeologists to examine the structure of empirical archaeological information. His 1904 publication *Les vases ceramiques ornes de la Gaule romaine* probably gives the best account of his method. The analysis of decorative techniques coupled with the identification of categories of vases clarified the apparent chaos of the sherds and indicated the existence of a series of workshops ranked in time and space. It was thus possible to discern the general development of the ceramic industry in the Gallo-Roman era, which coincided with a gradual shift in the centers of production from northern Italy to the banks of the Rhine. On a more detailed level the study of the decorative motifs and the stamped forms allowed archaeologists to identify each workshop by the individual output of its potters. In turn researchers could then trace how techniques and decorative themes were transmitted from workshop to workshop or even from potter to potter. The next step could be an analysis of the changes in the iconographic repertory, thereby moving from a technochronological study of the archaeological materials to questions of economic history or historical anthropology.

Déchelette, the father of French protohistory, was not a creative genius. He was a conscientious worker who applied himself enthusiastically to his archaeological pursuits in his retirement as he had done to his career in manufacturing.

He was awarded the Legion d'Honneur and given an honorary doctorate by the University of Freiburg. He was a foreign member of the Academies of Madrid and Stockholm and a contributing member of the Deutsches Institut and of the Archaeological Societies of London, Edinburgh, Dublin, Copenhagen, Brussels, Prague, and Hamburg.

Although archaeology is a young science, it is rooted in a centuries-old tradition as part of the aristocratic passion for collecting. The princely collections of curios fashionable during the Renaissance also contained prehistoric artifacts. They were few in number, since excavations had not yet begun and treasure hunting was only practiced on a small scale in northern Europe. Objects recognized as archaeological were primarily monuments: grave mounds, dolmens and runic stones, and prehistoric remains were rare in this period. Until the end of the reign of King Christian IV, treasure trove material was regarded as a source of state income and melted down. Not until King Frederik III established his Kunstkammer (Chamber of Arts) in 1663 were treasure troves awarded antiquarian status and placed on exhibition.

This situation changed abruptly after the agrarian reforms of the 1780s, which increased the destruction of burial mounds. Although treasure and hoard finds turned up in newly cultivated areas and were more common, thousands of prehistoric remains were being destroyed. This alarming situation led to the establishment in 1807 of the Royal Commission for Antiquities and a national museum, housed in the loft of the Trinitatis Church in Copenhagen. Questionnaires were sent to all clergy and other interested private citizens to obtain a comprehensive survey of the nation's antiquities, and the results were published, but museum accessions were still few.

christian jürgensen thomsen, a merchant with no academic qualifications, was appointed secretary of the Royal Commission for Antiquities. He systematically rearranged the museum's collections, registered accessions, and in 1819 opened the museum to the public via free, weekly, guided tours that he conducted himself. In a short time the museum became an object of great interest throughout Scandinavia. During the fifty years (up to 1865) that Thomsen was in charge-ending as the director of five museums-the foundations of the collections were laid, and the number of accessions rose steadily (in Thomsen's time there were 540 each year). This led to the acquisition in 1832 of four to five rooms in the Christiansborg Palace and still more in 1838, occasioned by the visit of the Russian czar-prince. Finally, in 1854, the museum was housed in Prinsens Palace, where it is still to be found, having undergone extensive alterations and additions in the 1930s. A major factor in the progress of archaeology was Thomsen's principle that the collections should be open to everyone and that guided tours could instruct people about the past and create an interest in antiquities among all classes of society. Thomsen thus established a practice fundamental to all museums today.

In this period only a few random excavations were carried out. Finds were acquired primarily from the many destroyed burial mounds, and they were cataloged and exhibited. A lack of transportation prevented frequent field trips, and museum work was carried out on a part-time and unpaid basis until jens jacob worsaae received the first royal appointment to the position of inspector for ancient monuments. Great importance was attached to developing contacts with interested collectors and dealers, through the increasing popularity of archaeology at a time of a national economic depression, and the payment of rewards to the finders.

From 1855 onward a growing number of provincial collections were established. With the collecting activity of King Frederik VII as a model, many aristocratic private collections were established in the decades after 1850, and a corresponding number of private citizens' collections were begun in towns.

An expanding market for artifacts developed. In these decades the destruction of burial mounds reached a climax as a result of the new prosperity and the many subsequent advances in agriculture.

Worsaae became a museum curator in 1866 in the midst of this sudden expansion. He rearranged the collections, and the National Museum, having created new positions and received special grants, began a more systematic excavation

Although archaeology is a young science, it is rooted in a centuries-old tradition as part of the aristocratic passion for collecting. The princely collections of curios fashionable during the Renaissance also contained prehistoric artifacts. They were few in number, since excavations had not yet begun and treasure hunting was only practiced on a small scale in northern Europe. Objects recognized as archaeological were primarily monuments: grave mounds, dolmens and runic stones, and prehistoric remains were rare in this period. Until the end of the reign of King Christian IV, treasure trove material was regarded as a source of state income and melted down. Not until King Frederik III established his Kunstkammer (Chamber of Arts) in 1663 were treasure troves awarded antiquarian status and placed on exhibition.

This situation changed abruptly after the agrarian reforms of the 1780s, which increased the destruction of burial mounds. Although treasure and hoard finds turned up in newly cultivated areas and were more common, thousands of prehistoric remains were being destroyed. This alarming situation led to the establishment in 1807 of the Royal Commission for Antiquities and a national museum, housed in the loft of the Trinitatis Church in Copenhagen. Questionnaires were sent to all clergy and other interested private citizens to obtain a comprehensive survey of the nation's antiquities, and the results were published, but museum accessions were still few.

christian jürgensen thomsen, a merchant with no academic qualifications, was appointed secretary of the Royal Commission for Antiquities. He systematically rearranged the museum's collections, registered accessions, and in 1819 opened the museum to the public via free, weekly, guided tours that he conducted himself. In a short time the museum became an object of great interest throughout Scandinavia. During the fifty years (up to 1865) that Thomsen was in charge-ending as the director of five museums-the foundations of the collections were laid, and the number of accessions rose steadily (in Thomsen's time there were 540 each year). This led to the acquisition in 1832 of four to five rooms in the Christiansborg Palace and still more in 1838, occasioned by the visit of the Russian czar-prince. Finally, in 1854, the museum was housed in Prinsens Palace, where it is still to be found, having undergone extensive alterations and additions in the 1930s. A major factor in the progress of archaeology was Thomsen's principle that the collections should be open to everyone and that guided tours could instruct people about the past and create an interest in antiquities among all classes of society. Thomsen thus established a practice fundamental to all museums today.

In this period only a few random excavations were carried out. Finds were acquired primarily from the many destroyed burial mounds, and they were cataloged and exhibited. A lack of transportation prevented frequent field trips, and museum work was carried out on a part-time and unpaid basis until jens jacob worsaae received the first royal appointment to the position of inspector for ancient monuments. Great importance was attached to developing contacts with interested collectors and dealers, through the increasing popularity of archaeology at a time of a national economic depression, and the payment of rewards to the finders.

From 1855 onward a growing number of provincial collections were established. With the collecting activity of King Frederik VII as a model, many aristocratic private collections were established in the decades after 1850, and a corresponding number of private citizens' collections were begun in towns.

An expanding market for artifacts developed. In these decades the destruction of burial mounds reached a climax as a result of the new prosperity and the many subsequent advances in agriculture.

Worsaae became a museum curator in 1866 in the midst of this sudden expansion. He rearranged the collections, and the National Museum, having created new positions and received special grants, began a more systematic excavation

recording and excavation, resulting in the accumulation of essential new knowledge on both detailed and comprehensive levels. The composition of settlement layers was recorded in terms of its archaeology, geology, and botany. Crumbling skeletal remains were exposed in graves with a brush or recorded by means of phosphate analysis. The use of machinery to uncover large surface areas also added to the knowledge of the nature of settlements, since it thereby became possible to expose whole villages. In this way the work of the Settlement Committee (established by the Research Council) was extremely important. Excavation activity also increased with the setting up of the Fortidsmindeforvaltning (Administration of Ancient Monuments), which began the excavation of endangered sites, or rescue archaeology, as laid down in a revision of the Act of Conservation in 1969.

The last two decades of the twentieth century saw the interlinked expansion and development of rescue archaeology and museums. Museums in Denmark took over the practical responsibility of carrying out all rescue archaeology. This initially caused expansion, but since the mid-1980s there has been stagnation. Because so many museums were involved and because a good number of them were small, the demands of modern, large-scale rescue excavations could not be met, and the museums were not helped by legislation, basically unchanged since 1969, that left postexcavation work unfinanced and unpaid for by private developers. (This legislation is about to be revised in accordance with the Malta Convention of the European Parliament.) As a result a large number of young Danish archaeologists migrated to find work in other countries, especially Norway and Sweden. Because rescue archaeology is the motor of the archaeological environment in all industrialized countries, Danish archaeology is now at a watershed. Will it reform legislation and the framework of rescue archaeology and enforce a new dynamic? Or will it remain within the traditional framework of museum archaeology?

Research Objectives and Milieus

Thomsen began a scientific tradition that was as important as his museum work in the development of archaeology in that he created a milieu for archaeological research-a precondition for the development and continuity of every field of study. This goal was reflected in his comprehensive correspondence, in which he shared all his knowledge and experience and thereby decisively influenced the development of museums and archaeology in Scandinavia.

An important figure in the field of scholarship at that time was Thomsen's contemporary C. C. Rafn, who in 1825 was a founding member of the Society of Northern Antiquaries (it became a royal society three years later). Rafn was the prime mover in the society, which was to become the foremost scientific medium for Danish archaeology. Its growing membership, at home and abroad, helped to give Danish archaeology a prominent place during the middle and latter part of the nineteenth century. This was also the time when a special French edition of the society's annual publication was issued (at that time French was the main language of Danish archaeology). The society published Icelandic manuscripts, partly for scholars and partly for the general reader. This effort soon gave the society a sound economic footing, which was further enhanced by the 1837 publication of the international best-seller *Antiquitates Americanae.* The society's scholarly reputation, as well as its capital, increased steadily during the nineteenth century, partly because a growing proportion of its core membership consisted of scientists, heads of state, princes, and other prominent figures from all over the world. From 1832 on archaeology was represented in the periodical *Nordisk Tidsskrift for Oldbyndighed,* retitled *Antiquerisk Tidsskrift* after 1936. These journals were succeeded in 1866 by *Aarbøger for nordisk Oldkyndighed.* During their first few decades, however, they primarily served the study of history and philology. To change this situation required an improvement in the status of archaeology, reflected both in greater activity and in an archaeological objective defined in terms of social and cultural history. This change was brought about by Thomsen's followers in the years after 1850, with Worsaae as the guiding spirit.

The ground had already been prepared in the 1840s when the young Worsaae elegantly refuted

with the establishment of a new research center, have encouraged an expansion in this field. In addition, the computerization of the large national register of monument, sites, and finds during the 1980s led to developments in the application of modern methodological tools such as geographic information systems (GIS) in settlement archaeology. The other area of expansion has resulted from the establishment of two national research centers for settlement studies during the 1990s, which have helped to analyze and publish the results of settlement excavations and projects, such as the Thy project, the Als project, or the Saltbæk Vig project, all based upon international cooperation.

Archaeology in Society

A general and well-known feature of the archaeology of many countries is that, throughout its development, it has been part of national moral rearmament, and Denmark is no exception. The “fateful years” of 1807, 1848, 1864, 1920, and 1940 to 1945 are all reflected in the archaeological activity of the time, and prehistory in these years of crisis was frequently used as a symbol of national identity. After all, it was not only through museums and archaeological books that knowledge of archaeology spread. Most of the population learned about it second- or thirdhand-primarily through the literary tradition but also in an attenuated form through school textbooks, children's books, folk high schools, and so forth. In this way knowledge of prehistory and of the past in general reached a large section of society in a complex process of dissemination, during which it underwent several changes and was used in many disguises. The question is whether it is possible to discern behind these general tendencies any important changes in the social position of archaeology and its ideological affiliations. Was archaeology used? What was it used for and by whom? We can attempt to answer these questions in several ways. The records of the National Museum, for instance, show us the route from finder to museum and the fact that that route changed. The other route, from archaeologists out to different segments of society via literature, popular outlines, and the like, is also informative. Finally, the founding of museums and the active interest shown by people outside the circle of professional archaeologists provide us with more tangible information.

There seems to be no doubt that the Commission for Antiquities was set up as the indirect result of the Romantic movement and the national defeats of the time. There is also no doubt that during its first fifty years, archaeology in Denmark was a leisure pursuit of the educated upper class. So-called popular backing was found only on a small scale. The clergy and local government officials (magistrates and county prefects) played a crucial role by maintaining contact with the Museum of Antiquities during this early period. But it was the payment of rewards that counted among those people who actually made the finds, since their standard of living was miserably low throughout most of the nineteenth century. The educational ideas that were part of the archaeological effort were expressed by archaeologists and the educated upper class of government officials and landowners.

Those who were to become enlightened by the past were not themselves actively involved in this process. The initiatives came from the people at the top. Several attempts were made at the time to set up public archaeological collections in the provinces, often attached to a county library (i.e., as part of the educational effort). But they were only attempts. Both administratively and ideologically, archaeology remained an integral part of the period's autocracy.

In the interwar years between 1850 and 1864, five provincial museums were established in rapid succession: Ribe, Odense, Århus, Viborg, and Alborg. They were founded by the educated upper middle class of the towns and not by the social group with which they were most concerned-the local peasants-at a time when the towns were experiencing rapid population increases and economic expansion. By this point archaeology had won general recognition as an important branch of national history, which was further emphasized by King Frederik VII's active interest in the field. Moreover,

investigations were begun during these years at a number of national monuments, such as Jelling and Danevirke, and in Denmark's relationship

PREV NEXT

During the period 1975 to 2000 archaeology in Denmark was professionally consolidated. This effort was mainly linked to the expansion of local and regional museums. After a period of stagnation during the 1950s and 1960s, these institutions became the driving force in local cultural revivals. The modernization of Danish society increased the demand for and interest in local histories and identities, and museums successfully took on the job of meeting those needs. New grassroots movements formed local archives to supplement this development. History since industrialization became a major interest, as it presented a parallel story to the present-day transformations of society and landscape. And since 1985 public interest has increasingly focused on monuments and landscapes as part of a revitilization of local tourism and recreation.

Desor, Edouard

(1811-1882)

Born near Frankfurt, Germany, but of French origin, Edouard Desor played an important role in the development of archaeological research in switzerland after the middle of the nineteenth century. Desor's intellectual path was eventful. While studying law in Germany, his political activities in the liberal movement forced him into exile, first in Paris, then in Bern, Switzerland, where he met and developed a friendship with the naturalist Louis Agassiz, whom he then followed to Neuchâtel, Switzerland.

As the young master's right-hand man, Desor found himself among Agassiz's disciples and became immersed in the intense dynamic of research in what was a “scientific factory,” in the words of his friend Carl Vogt. He studied the natural sciences-geology, paleontology, and above all, glaciology-during some of the group's risky explorations in the Alps. In 1848, he followed Agassiz to the United States, where they fell out. While Agassiz was teaching at Harvard University, Desor undertook different geographical, geological, and zoological tasks and surveys for the U.S. government. Four years later he returned to

Switzerland to teach geology in Neuchâtel.

Desor's curiosity was universal, both in the natural sciences and in prehistoric research, which he only discovered in 1854 following the work of ferdinand keller on the lake dwellers. His easy social nature and his facility of expression, as much as his liking for travel, enabled him to be in constant contact with most Swiss and foreign prehistorians and naturalists. Thus, Desor chaired the first international congress of prehistory ("paleoethnology") in his adoptive town of Neuchâtel in 1866.

He inherited a considerable fortune after his brother died, which gave him financial security while he studied and published. It also allowed him to keep an open house for guests who wished to participate in scientific debates, and this venue became famous in Neuchâtel. He continued to be involved in politics, initially on behalf of the Radical (progressive) Party, which elected him president of the Swiss Federal Assembly.

Desor studied the palafittes, or pole dwellings, of Lake Neuchâtel, but he also studied

those of other lakes, both Swiss and foreign. He even started lake-dwelling research in northern Italy. His studies sought to clarify the differences between Neolithic and Bronze Age sites by defining reference corpora. He was one of the few people to question whether the so-called dwellings on water were warehouses rather than houses. He became interested in the problems of trade, and the relationships between land and lakeside dwellings, but, unlike most of his contemporaries, he always remained cautious about ethnic assimilations and peoples' migrations. Desor worked to familiarize Swiss scientists with Nordic Mesolithic and French Paleolithic research. He closely followed French archeologist gabriel de mortillet's work on the origins of man.

Desor is most famous for his work at the site of la tène in Switzerland, and he excavated several mounds in the Neuchâtel area. He was the first to propose a chronological division of the Iron Age (Desor 1865, 1866, 1868). He argued that the mounds (or tumuli), even without any iron objects, such as those at Favargettes, belonged to the earliest part of the Iron Age, like the Hallstatt sites, whereas the sites of La Tène, Tiefenau (Bern), and alesia (France) represented a second development, or a later Iron Age. Alesia provided a certain chronology, thus joining prehistory to history.

Desor made few detailed studies on precise subjects, but his insatiable curiosity encouraged him to try to find out all the facts he could about archaeology. With his open mind and his great scientific rigor, he considerably widened the field of prehistoric research.

Deutsches Archäologisches Institut (DAI)

The antecedents of the Deutsches Archäologisches Institut (DAI, German Archaeological Institute) lie in the Instituto di Corrispondenza Archeologica, which was founded in Rome in 1829 by a group of antiquarians, artists, and diplomats. The purpose of the institute was the promotion of the study of classical art, epigraphy, and topography. The Prussian crown prince (later King Friedrich Wilhelm IV) was its first patron, and in 1832, when Eduard Gerhard, the person most responsible for the creation of the institute left Rome for Berlin, the organization moved with him.

Beginning in 1859, the links between the institute and first the Prussian and later the German governments became closer until it became a government operation and the name was changed to the Deutsches Archäologisches Institut. Since the turn of the twentieth century, the

DAI has grown from a focus on Italy to encompass a German interest in the archaeology of Greece and the Middle East. As such, it has become a major source of finance and administration for German archaeological activity and is a highly respected publisher of field and laboratory research pursued under its auspices.

Dezman, Dragotin

(1821-1889)

The Slovenian archaeologist, natural scientist, and politician Dragotin Dezman (also known as Carl Deschmann) introduced and developed scientific and professional archaeology in slovenia. He first studied medicine, law, and natural sciences at Vienna University; was curator of the Provincial Museum of Carniola (Landes Museum fur Krain) in Ljubljana from 1852 to 1889; and in 1864 was made president of the Museum Society of Carniola and also a member of the Anthropological Society of Vienna.

As a natural scientist, Dezman devoted the first decades of his research and museum work almost entirely to his specialities: zoology, botany, and geology. However, in 1875 he discovered pile dwellings at the site of ljubljansko barje in Slovenia, and from then on he focused most of his work on prehistoric archaeology. From 1875 to 1877 he conducted several excavations of pile dwellings and uncovered some interesting artifacts such as wooden architectural remains, clay figurines, richly ornamented pottery, and the earliest metal finds in Slovenia. He published only short reports and notices of this work.

In the 1880s, he extended his prehistoric research to include the entire province of Carniola, the core province among Slovenian lands in the Austro-Hungarian Empire. He published the first syntheses on the prehistory of this province, “Prahistorische ansiedlungen und Begrabnisstatten” and “Zur Vorgeschichte Krains” in 1880 and 1891, respectively.

Dezman considered prehistoric archaeology to be a natural science founded on empiricist and evolutionist anthropological bases. He tried to follow the development of archaeology in Europe and to apply the best standards of those positivist disciplines to his work. For example, he was able to distinguish the la tène finds in Carniola only a year after the Iron Age was divided into the Hallstatt and La Tène periods. He maintained contacts with many of the most important institutions and scholars in central Europe and even beyond. He integrated the Provincial Museum into the international museum network, and after his important discoveries at Ljubljansko Barje, he organized the First Austrian Congress of Anthropology and Prehistory in Ljubljana in 1879. As an important personality in political and cultural life (mayor of Ljubljana 1871-1873, member of Parliament in Vienna 1873-1879), he succeeded in developing the new Museum Palace, which was officially opened in 1888. On that occasion he published a modern guidebook to the museum's collections, of which the prehistory collection was the most prominent.

Dikaios, Porphyrios

(1904-1971)

Porphyrios Dikaios studied archaeology in greece, Britain, and france. He was the curator of the Cyprus Museum from 1931 to 1960, acting director of the Department of Antiquities during World War II, and director from 1960 to 1963. He made major contributions to Cypriot archaeology through his excavations at numerous sites of many periods, the more important of which include Neolithic Khirokitia-Vouni

(1936-1946) and Sotira-Teppes (1947-1956), early-Bronze Age Bellapais-Vounous (1931- 1932), and late-Bronze Age enkomi (1947- 1957). His work on the earlier periods in cyprus, summarized in his contribution to the fourth volume of *The Swedish Cyprus Expedition,* is of particular significance, both in providing primary data and in the analytical and conceptual frameworks he developed, which still structure much current research. His substantial publication on the excavations at Enkomi remains the starting point for research on the later prehistory of the island.

Dolní Vestonice

Excavated by the Czech archaeologist Karel Absolon (1887-1960), Dolní Vestonice is a complex of six open-air sites in Moravia, czech republic, dating from the Upper Palaeolithic period (about 25,000 years ago). The site features an accumulation of bones from over 100 woolly mammoths, hearths, pits, evidence of round dwellings, and a number of burials. Subsequent work in the mid-1980s revealed more burials. The lithic technology (featuring burins, scrapers, and backed blades) is classified as Eastern Gravettian. Perhaps most remarkable of all is the abundance of fired clay, including one complete "Venus" figurine and the remains of two simple kilns, which together are the earliest evidence for pottery anywhere in the world.

Clay "Venus" from Dolní Vestonice, Gravettian, 24,800 b.c.

Domestication of Plants and Animals

The domestication of wild plants and animals (which is a characteristic of the Neolithic period in any given region) has been a worldwide phenomenon occurring independently in southwest Asia, parts of North, Central, and South America, china, and Africa. This change in human behavior arose following the trend toward exploration of a more broad-spectrum economy in the Mesolithic period (approximately 12,000 years ago), when people expanded their hunting and fishing repertoire to include previously unexploited species. Between 10,000 and 5,000 years ago, farming, pastoralism, and sedentism were being adopted on a large scale, although by no means universally.

Domestication of wild species results when humans take control of an animal's or a plant's reproductive cycle, causing genetic and phenotypic change. The degree of control people have over their environment can be measured on a continuum, ranging, for example, from herding wild animals to breeding them for specific preselected traits, and it can exist for hundreds of

(1936-1946) and Sotira-Teppes (1947-1956), early-Bronze Age Bellapais-Vounous (1931- 1932), and late-Bronze Age enkomi (1947- 1957). His work on the earlier periods in cyprus, summarized in his contribution to the fourth volume of *The Swedish Cyprus Expedition,* is of particular significance, both in providing primary data and in the analytical and conceptual frameworks he developed, which still structure much current research. His substantial publication on the excavations at Enkomi remains the starting point for research on the later prehistory of the island.

Dorpfeld, Wilhelm

(1853-1940)

Dorpfeld was employed as an architectural draftsman at the excavation of Olympia, under the supervision of the great German classical archaeologist ernst curtius. It was Dorpfeld who had shown heinrich schliemann around the site of Olympia in 1876, which Schliemann visited after he had been accused of amateur and unscientific excavation methods. Dorpfeld was familiar with the technical side of the excavations and so impressed Schliemann that he was eventually hired to work at the site of Troy, in Hisarlik in Turkey.

From 1882 to 1890, Dorpfeld was Schleimann's assistant. He began at Troy during Schleimann's third season of excavations, after Schliemann had once again been criticized by journalists and some archaeologists for being a treasure hunter and a fraud-and this despite the friendship of the great German archaeologist rudolf virchow. So Dorpfeld was employed for scholarly credibility, and wisely so as it turned out. He clarified the stratigraphy of the walls and allowed a better understanding of the evolution of the structures on the site. He corrected Schliemann's mistake of attributing the burnt layer to the second rather than the third layer from the bottom. Dorpfeld also discovered that the city continued outside the walls and was present in Hissarlik in March 1890 when the international panel of archaeologists assembled by Schliemann decided that the site was indeed the remains of ancient Troy.

Dorpfeld went on to assist Schliemann at the excavation of the city of Tiryns in the Peloponese from 1884 to 1885. The floor plan of the palace was uncovered and Dorpfeld discerned the floor plans of two buildings similar in structure to that of Temple A at Troy. He identified this architectural form as the Homeric megaron. The other major find at Tiryns were Mycenean wall-paintings. While the site was a disappointment to Schliemann, for Dorpfeld it was a great success, as it was he who located the architectural remains and the wall paintings.

In 1886 Schliemann and Dorpfeld excavated at Levadia, where they searched unsuccessfully for the site of the Oracle of Trophonius. They also returned to Orchomenos, where Dorpfeld cleaned out and drew up a more accurate plan of the tomb. Together they visited Crete to look at the site at Knossos-but Schliemann considered the rights to excavate the site to be too expensive.

Dorpfeld traveled with Schliemann to London to help mount a response to critics of the interpretation of their finds from Tiryns and escorted Schliemann's body from Naples, where he had died, back to Athens, where he was buried.

Succeeding Schliemann, Dorpfeld used more refined excavation methods, identifying nine levels and revising Schliemann's chronology and stratigraphy at Hissarlik, proposing that Troy VI, not Troy II, was the Homeric city. In 1893 and 1894 Dorpfeld confirmed the late Bronze Age date of Troy VI. He subsequently excavated on Levkas, which he identified as Homeric Ithaca, the home of Odysseus.

Douglass, Andrew Ellicot

(1867-1962)

Born in Windsor, Vermont, and a graduate of Trinity College, Connecticut, in 1889, Douglass joined the Harvard College Observatory, which marked the beginning of a long and eminent career concerned primarily with astronomy. Douglass helped to establish and operate three major astronomical

observatories-the Harvard College Observatory at Arequipa, Peru; the Lowell Observatory in Flagstaff, Arizona; and the Steward Observatory at the University of Arizona in Tucson-before he became involved in archaeology.

Douglass's interest in the effects of sunspots on terrestrial weather led him to investigate the annual growth layers of Arizona pines for variations in tree-ring width. He discovered a relationship between rainfall and tree growth, and between cyclical variations in tree growth and sunspot cycles. Looking for extensive tree-ring records to substantiate his theories, Douglass asked archaeologists in Tucson for pieces of wood from the ruins of a southwestern pueblo. Within a decade he was able to date some of these wooden remains back to a.d. 100, and others to a.d. 700, providing archaeology with a valuable tool for establishing an independent chronology. Douglass went on to develop the study of tree-rings into the science of dendrochronology. Tree-ring dating has made substantial contributions to archaeology in the Arctic, Britain, Central Europe, and the Mediterranean Basin. Douglass also provided dendro-climatic and dendro-environmental reconstructions for archaeology.

He retired from astronomy to found and direct the Laboratory of Tree-ring Research at the University of Arizona, which he helped to establish as the preeminent center for dendrochronological research.

Dubois, Eugene

(1858-1940)

Born in the netherlands, Dubois studied medicine at the University of Amsterdam until 1884. He worked as an assistant to the Anatomist Max Furbringer from 1881 until 1887, and lectured in anatomy from 1886 to 1887. Inspired by the work of Ernst Haeckel, Dubois resigned from the university and left for the Dutch East Indies (now indonesia) to search for evidence of early human beings. Haeckel had claimed that humankind had descended from a group of apes in Asia, and not in Africa as Darwin had suggested. This argument was based on a few anatomical resemblances between modern humans and the gibbons of island southeast asia.

Supported by the Dutch colonial government, Dubois searched for human ancestral remains in Java and Sumatra from 1888 to 1895. The skullcap, thighbone, and a few teeth of a *Pithecanthropus erectu*s, along with other fossils, were found near the village of Trinil on Java between 1891 and 1893. Dubois believed these remains, known as “Java man,” to be the missing link between apes and humans, and he returned to Europe to convince the scientific community of their importance.

Dubois's fossil finds were the first hominid remains to be accepted as material proof of human evolution, and a significant number of scientists regarded them as proof of a chain of connection between humans and their primitive ancestors. The debate about their significance led to the development of an evolutionary interpretation of extant European Neanderthal remains, leading to further development of the new science of paleoanthropology.

Dubois became professor of crystallography, mineralogy, paleontology, and geology at the University of Amsterdam in 1899 and withdrew from the debate on *Pithecanthropus*. He continued with paleontological and anatomical research, pioneering allometric relations between brain and body size in vertebrates and hominids. This work convinced him that vertebrate evolution had not proceeded in a linear nor a gradual way, but through quantum changes. He maintained that *Pithecanthropus* was the missing link between primates and hominids, and he would not accept that other pithecanthropine finds, made in Java in the 1930s by von Koenigswald, were much closer to *Homo sapiens* that he had

originally argued. He retired in 1929.

Duff, Roger Shepherd

(1912-1978)

Roger Duff was born in Invercargill on the south island of New Zealand and attended Otago University and Canterbury University College. Duff was introduced to Pacific ethnology and archaeology by Dr. H. D. Skinner, director of the Otago Museum and a well-known archaeologist. Duff became director of the Dominion Museum (now the National Museum) in Wellington, a position he held from 1948 to 1978.

Duff received a Doctor of Science Degree from the University of New Zealand in 1951 for his most famous work on the Moa-hunter period of Maori culture, which has since been reprinted numerous times. This monograph became the foundation for the integration of modern Maori and Polynesian history based on Duff's archaeological and ethnological understanding of the Pacific. In his analysis of material excavated from burial sites at Wairu Bar, Duff confirmed that the Maori Moa-hunters were truly Polynesian peoples, rather than Melanesian as had formerly been thought. Based on the highly developed stone-adzes Duff was later to describe eastern Polynesian culture as “Neolithic.”

Duff received a number of awards including the Smith Medal from Otago University for anthropological research and the Hector Medal from the Royal Society of New Zealand.

Dugdale, Sir William

(1605-1686)

The son of a Warwickshire gentleman, Dugdale became a lawyer. His interests in antiquities and local history were encouraged by local antiquarians William Burton, author of the *Description of Leicestershire,* and Sir Simon Archer, the owner of a historic collection relating to Warwickshire. During the 1630s and 1640s Dugdale researched the histories of Warwick county's families, and this brought him to the attention of the well-connected and aristocratic antiquarians of London, Sir Henry Spelman, Sir Christopher Hatton and Thomas, the Earl of Arundel. They invited him to London and eased his way into the world of national antiquarianism. They also encouraged him to research the monastic foundations of England with another antiquarian, Roger Dodsworth of Yorkshire.

Sir William Dugdale

(Hulton Getty)

To this end Dugdale was provided with access to records in the Exchequer and the Tower of London, major depositories of ancient documents dating back to the Middle Ages. The library of Sir Robert Cotton, another antiquarian, was also opened to Dugdale. His patrons recommended that he become a Herald, a position that included lodgings at the Office of Heralds in London and a small income. With the political crisis between Parliament and King James II, Dugdale was dispatched by Sir Christopher Hatton to record as many as possible of the coats of arms, inscriptions with details of kinship lines, and church records on stone, glass, brass, and paper, which the antiquarians knew would be targets for

destruction by the Puritans during the impending civil war.

In 1648, with the collapse of the Royalist cause, Dugdale went to France where he continued his research, but on French records about English monasteries. He returned to England to work with Dodsworth to complete their *Monasticon* and to publish his *History of Warwickshire*.

E

Easter Island

Occupied by people from polynesia at the extreme edge of their range in the early centuries a.d., Easter Island was named by a Dutch navigator by the name of Roggeveen during a visit to the island over Easter in 1722. It seems likely that this was one of the few contacts with the outside world that was made over the entire period of occupation of the island. Detailed archaeological research on Easter Island was begun by the Norwegian explorer Thor Heyerdahl in 1955, although the large statues (*moai*), the platforms (*Ahu*), the quarries, and the Rongorongo script had attracted attention earlier. An air of mystery (and some sadness) pervades Easter Island studies, but archaeologists now have a clear understanding of the means by which the famous statues were created and erected, the source of the island's original inhabitants, and the (devastating) environmental history of the island.

Ecuador

Pottery in the New World appeared first in the equatorial and subequatorial tropics. It developed next in the subtropics and, finally, in the temperate zones a few centuries before European contact. Archaeological teaching and research developed inversely. The subject was first taught north of the Tropic of Cancer in the United States, then south of the tropic of Capricorn in argentina and chile and, finally, in Ecuador. References to the pre-Columbian past began with reports by the early Spanish chroniclers who accompanied Francisco Pizarro on his voyages from panama to peru. This period of Ecuadorean archaeology, which was mainly ethnohistorical, lasted until the last two decades of the nineteenth century-roughly the same as that in any other area of the New World, corresponding to the speculative period defined by gordon willey and Phillip Phillips for U.S. archaeology.

In the late nineteenth century, Msgr. Federico González Suárez, the archbishop of Quito and a historian, wrote, as an appendix to his *History of Ecuador,* a volume entitled *Archaeological Atlas.* A professor of history at Quito University, he was the first of a generation of historians interested in the aboriginal history of his country. Others, including Carlos Manuel Larrea and Jacinto Jijón y Caamaño, also left their imprint on the archaeology of Ecuador. They conducted research in the Andean intermontane valleys and on the coast of Manabí and Esmeraldas Provinces. However, no serious effort was made to develop professional archaeologists in Ecuador until the 1980s.

During the nineteenth century European naturalists and geographers who visited the New World-such as William Bollaert (from 1860 to 1880), Anatole Bamps (from 1878 to 1888), and Alfons Steuble (from 1875 to 1888)-made the first collections of archaeological artifacts in Ecuador. (The latter's collections were studied by a young max uhle in Dresden from 1889 to 1890 and in 1892.) In the 1890s Marshall Saville from the George Heye Foundation carried out extensive excavations along the Ecuadorean

coast, and George Dorsey collected some Inca artifacts from La Plata Island, 36 kilometers southwest of Manta in Manabí Province, for the Field Columbian Museum during the Fourth Centennial Columbian Exhibition in Chicago. Jijón y Caamaño was later instrumental in bringing the German archaeologist Max Uhle to Ecuador, and he financed Uhle's research for nearly two decades (from 1920 to 1939). Beginning in the 1940s coastal archaeological research started to dominate Ecuadorean culture history. This trend needs to be explained for an understanding of the development of archaeological research in the hub of the northern Andean area.

Although small in size, Ecuador presents a great variety of environments and landforms. The upthrust of the Andes divided it into two lowland regions. The coast, west of the Andes, is separated into a Tertiary uplifted plain, bordered by the Pacific Ocean and ancient volcanic mountains. Between these mountains and the Andes, two large riverine basins began to fill with alluvium around 10,000 b.p., providing a western counterpart to the Amazonian jungle. A mantle of recent alluvium covers the Ecuadorian Upper Amazon, and in some areas it overlays ancient alluvial deposits, laid down before the Andean upthrust. The Ecuadorean Andes are divided into two intermontane valleys by the Cordillera Real. Its western valley reaches altitudes higher that 2,000 meters; the eastern valley averages 900 meters in altitude. The western valley is subdivided into smaller valleys that drain both eastward into the Upper Amazon and westward into the coastal lain and the Pacific Ocean.

Beginning in the Holocene the landscape of Ecuador marked by the Andean and coastal uplifts of the Tertiary period underwent great changes. Rapid deposits of recent alluvium modified the landscape of the Guayas and Amazonian basins. Deposits of lava and volcanic tuft caused by the intense volcanic activity in the northern Ecuadorean Andes also changed the early-Holocene landscape. And during the end of the Pleistocene and the beginning of the Holocene, severe climatic and sea-level shifts dramatically altered the landscape as well. Tropical savannahs changed into forests, and the coastline retreated as it gave way to the rising seas. The great mammals of the Pleistocene, which had lived in the area for nearly a million years, disappeared. These changes occurred 2,000 to 3,000 years after the arrival of the Paleo-Indians.

Active floodplain covers great spaces of the Ecuadorean lowlands, and alluvium is added to the Upper Amazon and to the Guayas basin each year. Meandering rivers churn up the alluvium, redepositing it and its cultural contents in newly created point-bar formations, complicating the stratified deposits in new landforms. The accumulated deposits cover the evidence for early occupation of these bottomlands. An example is the Valdivia II site at Colimes de Balzar (with two C-14 assays of 4770 + 210 b.p. or 3200 b.c. [corrected]). This site, buried under 8.20 meters of alluvium strata, shows interspacing by volcanic-ash deposits and habitation floors from several occupational periods. Late-Pleistocene remnants, dating between 18,000 and 10,000 b.c., should be much deeper.

In the northern Ecuadorean highlands, under a soft volcanic tuft about 3 meters deep, Pleistocene faunal remains can be found. A good example is the Paramo del Angel, north of the Chota Valley in Carchi Province, where the remains of several mastodons have been discovered at the bottom of erosion gullies. In the eastern lowlands, Pedro T. Porras found some chipped stone artifacts at Yasuní, apparently belonging to that period, but he did not report faunal associations of any kind. This lack of conclusive evidence is probably the result of unsystematic investigations in preceramic archaeology.

Some 10,000 years of archaeological evidence is buried in this stage. Grave robbers, antiquarians, and some archaeologists have unearthed shards that testify to a complex social-history process based on the exploitation of a landscape rich in ecological niches that supported some of the most diverse floras and faunas in the world.

The Evolution of Archaeology in Ecuador

In trying to systematize the progression of archaeological research in Ecuador, one may be tempted to use Willey and Phillips's classification

PREV NEXT

for New World archaeology, and in general it does fit. Most archaeological research in Ecuador has been conducted by Americans during several periods, representing the tendencies used as period indicators by Willey and Phillips. In a 1982 article entitled “100 Years of Ecuadorian Archaeology,” Donald Collier divided Ecuadorean archaeological research into four periods: the pioneer period, 1878-1899; the developmental period, 1900-1934; the transitional period, 1935-1952; and the florescent period, 1953-1980. Collier's article is chronological in intent and in some ways quantitative-qualitative, and it is useful for showing the increase in archaeological research in Ecuador up to 1980. It does not, however, consider the trends in archaeological research that have dominated Ecuadorean archaeology, and because it was published in the early 1980s, it missed the the recent period in which archaeology in Ecuador attained some degree of maturity.

Archaeology in Ecuador

Archaeological research in Ecuador can be best classified in the following manner. Following is my own thematic version of its development.

The First 350 Years

The initial reports of archaeological monuments in Ecuador appeared in the chronicles of the Spanish priest and soldiers accompanying Pizarro, in the chronicles of the sixteenth century, and in the *Visitas* of the seventeenth century. (Detailed descriptions by naturalists and geographers, who put together the first archaeological collections, came later.) The precursors of Ecuadorean archaeology had appeared. Concomitant with this, the looting of tombs for gold and archaeological materials began with the Spanish conquistadores, settlers, and colonial officials. The first Ecuadorean archaeological and ethnographical materials began to appear in European museums in the 1850s.

1880-1920: The Classificatory Period

This period is best defined by the classification in a museum in Dresden-by young linguist Max Uhle-of the archaeological materials collected by Alfons Steuble and Willhelm Reiss in Ecuador in the 1880s. During this time some local historians (such as Monsignor González Suárez) and foreign residents (such as the linguist Otto von Buchwald) also began to classify their archaeological finds in Ecuador. The collections made by George Dorsey and Marshall Saville in coastal Ecuador for the Field Columbian Museum and for the Museum of the American Indian (George Heye Foundation) were classified and published in the first decade of the twentieth century. About the same time, Paul Rivet and R. Vernau began their Ecuadorean research for the French Academy, and Uhle, who was already acquainted with the Ecuadorean materials collected by Steuble and Reiss in the previous period, arrived in Ecuador from Peru at the invitation of Jacinto Jijón y Caamaño. The two men began a fruitful, twenty-five-year research association that contributed to the development of the first systematic chronology for Ecuadorean archaeology, and together with Carlos Manuel Larrea they carried Ecuadorean archaeology into the culture-historical period.

As Ecuadorean archaeology progressed, grave looters in the southern Ecuadorean Andes began unearthing veritable treasure hoards, which were, for the most part, melted down to be sold as gold from the mines in the area. Saville managed to save a small part of one of the Sigsig/Gualaceo treasures, acquiring it for the Museum of the American Indian from Don Nicol's Ribadeneyra of Guayaquil.

1920-1950: The Culture-Historical Period

Following the momentum of Max Uhle and Jacinto Jijón's archaeological investigations, others individuals, such as G.H.S. Bushnell, Roaul D'Harcourt, and Paul Bergsøe, began conducting research in coastal Ecuador. Two young history and geography teachers, Carlos Zevallos Menéndez and Francisco

Huerta Rendón, followed suit, taking their senior students on archaeological field trips. At the beginning of World War II, Bushnell left Ecuador to fight for England, and U.S. anthropologists from the Andean Institute went to Ecuador to do archaeological work and help with the anti-Nazi war effort. Donald Collier and John V. Murra excavated in Cerro Narrío

for New World archaeology, and in general it does fit. Most archaeological research in Ecuador has been conducted by Americans during several periods, representing the tendencies used as period indicators by Willey and Phillips. In a 1982 article entitled “100 Years of Ecuadorian Archaeology,” Donald Collier divided Ecuadorean archaeological research into four periods: the pioneer period, 1878-1899; the developmental period, 1900-1934; the transitional period, 1935-1952; and the florescent period, 1953-1980. Collier's article is chronological in intent and in some ways quantitative-qualitative, and it is useful for showing the increase in archaeological research in Ecuador up to 1980. It does not, however, consider the trends in archaeological research that have dominated Ecuadorean archaeology, and because it was published in the early 1980s, it missed the the recent period in which archaeology in Ecuador attained some degree of maturity.

Archaeology in Ecuador

Archaeological research in Ecuador can be best classified in the following manner. Following is my own thematic version of its development.

The First 350 Years

The initial reports of archaeological monuments in Ecuador appeared in the chronicles of the Spanish priest and soldiers accompanying Pizarro, in the chronicles of the sixteenth century, and in the *Visitas* of the seventeenth century. (Detailed descriptions by naturalists and geographers, who put together the first archaeological collections, came later.) The precursors of Ecuadorean archaeology had appeared. Concomitant with this, the looting of tombs for gold and archaeological materials began with the Spanish conquistadores, settlers, and colonial officials. The first Ecuadorean archaeological and ethnographical materials began to appear in European museums in the 1850s.

1880-1920: The Classificatory Period

This period is best defined by the classification in a museum in Dresden-by young linguist Max Uhle-of the archaeological materials collected by Alfons Steuble and Willhelm Reiss in Ecuador in the 1880s. During this time some local historians (such as Monsignor González Suárez) and foreign residents (such as the linguist Otto von Buchwald) also began to classify their archaeological finds in Ecuador. The collections made by George Dorsey and Marshall Saville in coastal Ecuador for the Field Columbian Museum and for the Museum of the American Indian (George Heye Foundation) were classified and published in the first decade of the twentieth century. in Cañar Province, and Wendell Bennett conducted research around Cuenca and southern Azuay Province. As World War II came to a close, Hans Dietrich Disselhoff, a former German administrator in occupied Denmark, carried out archaeological research in Manantial de Guangala.

Meanwhile, gold-rich sites continued to be looted, and archaeological gold was melted and formed into ingots. Looters began to keep some of the ceramic and other artifacts, which they sold to a new breed of collectors-those who became interested in local culture-history. A Swiss businessman, Max Konantz, began his collection by buying from looters in the Cuenca area. Local landowners and farmers also started to collect archaeological artifacts.

1950-1965: The Historical Classificatory Period-The Advent of C-14

Bushnell published his coastal chronology in *The Archaeology of the Santa Elena Peninsula in South West Ecuador* (1951), and Collier and Murra published theirs for the cultures of the southern Ecuadorean Andes. However, because stratified materials were not always superimposed, Bushnell, like Jijón y Caamaño before him, inverted part of his sequence. However, Willard Libby's discovery of C-14 dating was soon conceived as the panacea that would cure all ailments in archaeological chronologies. Establishing a workable chronology was problematic prior to the application of radiometric (C-14) dating. Both Bushnell's coastal chronology and Collier and Murra's chronology of the Southern Ecuadorian Andes experienced difficulties.

With the advent of C-14 the emphasis on excavating archaeological deposits by their “natural stratigraphy” declined, and simpler means of excavation-artificial stratigraphy, for instance, by metric levels-became widespread, providing more secure archaeological sequences. A Guayaquil businessman turned archaeologist, Emilio Estrada, began to build a new chronology for the Ecuadorean coast. Estrada was later joined by Clifford Evans and Betty J. Meggers from the Smithsonian Institution, and together they built the basic chronology for Ecuador. It still stands today, with some addenda and modifications made by others. The single most important modification has been Betsy Hill's 1972-1974 refinement of the Valdivia from four to eight phases, and the more recent eleven-phase refinement by Marcos and Obelic in 1998. During this period the most significant contribution to the knowledge of the archaeology of the Ecuadorian coast derived from the excavations at San Pablo by Carlos Zevallos and Olaf Holm. Although they published only a preliminary report, their excellent excavation permitted a more comprehensive view of Valdivia society. Zevallos later published an article that correctly postulated the agricultural base for the development of Valdivia society.

Meggers and Evans introduced type frequency seriation into Ecuador. This was a laboratory-analysis method developed by James A. Ford for his excavations in the lower Mississippi, which went hand in hand with the excavation of arbitrary levels. The publication of information on Zevallos and Holm's excavations at San Pablo may well have convinced many archaeologists of the limitations of metric stratigraphy and type frequency seriation (*see* Classification; Dating).

Estrada convinced other aficionados to take part in the archaeological research in coastal Ecuador. Richard Zeller, prompted by Estrada, began a long love affair with Guangala sites in the Jabita River basin, north of the Santa Elena Peninsula. Olaf Holm, cooperating at first with Zevallos at San Pablo, moved to Joa in southern Manabí Province to study evidences of copper metallurgy, and in the eastern lowlands Estrada, Meggers, and Evans began supporting Fr. PedroI. Porras's archaeological research.

During this period archaeologists in Ecuador, following Konantz, began to supplement their excavations with collections, acquiring fortuitous finds from farmers as well as artifacts from merchants who bought from looters, known as *guaqueros*. Zevallos built the gold museum for the Casa de la Cultura de

Guayaquil by such acquisitions; the ceramic and other artifacts came from archaeological excavations he and his associates conducted. Estrada supplemented the collection of the Victor Emilio Estrada Museum, buying both whole

pots and other artifacts from guaqueros from Manabí. Although this method allowed researchers to supplement museum exhibitions with looted material validated by the archaeological data, it also set a trend that, with time, was exacerbated and became disproportionate, ultimately increasing the looting of archaeological sites.

1965-1974: Questioning Type Frequency Seriation

With the appearance in 1965 of the smithsonian institution's publication *The Formative Period of Ecuador: Valdivia and Machalilla Phases,* by Meggers, Evans, and Estrada, some archaeologists (Donald Collier, Jon Müller, Donald Lathrap, and Henning Bischof, among others) began to question the Jomôn origin for Valdivia, as well as the excavation method used and especially type frequency seriation.

Edward P. Lanning and his students from Columbia University began a research project in the Santa Elena Peninsula, contributing to the refinement of all cultural phases proposed by Estrada and in Meggers's *Ecuador*. Lanning's efforts were also directed at rescuing the excellent data published by Bushnell (1951). Zevallos cooperated with Lanning, and after that point he and his students began to use the stylistic seriation developed by John Rowe in his studies in the Ica Valley in Peru.

Toward the end of this period a florescent epoch for Ecuadorean archaeology commenced. José Alcina Franch and his students at the Universidad Complutense de Madrid began a series of research campaigns in Ecuador that would continue into the next period. Alcina made many contributions to the archaeology of Esmeraldas Province and the Inca site of Ingapirca in Cañar. At Cochasquí, north of Quito, a team from the University of Bonn, under the direction of Udo Oberem, restudied the site that had been excavated by Uhle in the 1920s. Karen Stothert, under the direction of Edward Lanning, began her research at the Vegas preceramic site, and Jorge G. Marcos located the Valdivia site of Real Alto and was pursuing his doctorate at the University of Illinois.

Guillermo Pérez Chiriboga-then president of the Central Bank of Ecuador-decided to create a gold museum at the bank when he realized that much of the gold bullion it bought had been archaeological gold. In some of the ingots he was able to see vestiges of the artifacts that had been melted down to form the bars. In creating the gold museum he intended to save archaeological gold from destruction, and he soon decided to broaden the scope of the museum to include all archaeological artifacts. Going beyond the initial concept, the Central Bank created the Museum for the Archaeology of Ecuador.

The museum fund was built on the acquisition of the Konantz Collection and a few other, smaller private collections. As it grew, its directors began to procure exceptional archaeological pieces from some guaqueros, and in time the negative effect of increased looting became apparent.

1974-1978: The Beginning of Explanatory Archaeology in Ecuador

In August 1974 an interdisciplinary team of archaeologists and other specialists from the University of Illinois-led by Donald W. Lathrap and his student Jorge Marcos-arrived in the Santa Elena Peninsula to begin research at Real Alto, the site that Marcos had discovered. This investigation marked the beginning of explanatory archaeology in Ecuador. Up to that time archaeologists had been content to describe their finds or to construct hypotheses based on routes and ways of diffusion. They also postulated possible social organization based only on their site finds and on prejudices about the level of society reached by the ancestors of the present native population in the area. Another form of prejudice was evident in regard to the environment. A heavily deforested area during the second half of the twentieth century was considered by many archaeologists as a model for the ancient environs of the Santa Elena Peninsula. At Real Alto environmental reconstruction, area excavation, biological and forensic studies of skeletal material, geologic studies of the Tablazo formation, quantification and use

patterns in milling stones, and ceramic modal and functional analysis represented a shift in the right direction. The excavation of the Cotocollao site in Quito by Peterson and Villalba, which

pots and other artifacts from guaqueros from Manabí. Although this method allowed researchers to supplement museum exhibitions with looted material validated by the archaeological data, it also set a trend that, with time, was exacerbated and became disproportionate, ultimately increasing the looting of archaeological sites.

1974-1978: The Beginning of Explanatory Archaeology in Ecuador

In August 1974 an interdisciplinary team of archaeologists and other specialists from the University of Illinois-led by Donald W. Lathrap and his student Jorge Marcos-arrived in the Santa Elena Peninsula to begin research at Real Alto, the site that Marcos had discovered. This investigation marked the beginning of explanatory archaeology in Ecuador. Up to that time archaeologists had been content to describe their finds or to construct hypotheses based on routes and ways of diffusion. They also postulated possible social organization based only on their site finds and on prejudices about the level of society reached by the ancestors of the present native population in the area. Another form of prejudice was evident in regard to the environment. A heavily deforested area during the second half of the twentieth century was considered by many archaeologists as a model for the ancient environs of the Santa Elena Peninsula. At Real Alto environmental reconstruction, area excavation, biological and forensic studies of skeletal material, geologic studies of the Tablazo formation, quantification and use

patterns in milling stones, and ceramic modal and functional analysis represented a shift in the right direction. The excavation of the Cotocollao site in Quito by Peterson and Villalba, which

began a few months later, followed, in a smaller way, this new trend.

Formally trained Ecuadorean archaeologists working in European and U.S. universities returned to Ecuador at the end of this period. Their impact would soon be felt in the progress of archaeology in their homeland. Examples of the research they started include the project known as Sacred Isles of Ecuador, during which the existence of long-distance maritime trade networks centered on the coast of Ecuador was discovered, and the excavation of the obsidian mine at Mullumica by Ernesto Salazar.

As archaeology progressed, pothunting and looting accelerated due to the increase in international demand and the market pressure created by the acquisition of looted archaeological art by local museums and collectors. The consequent loss of artifacts and sites through disturbance placed the heritage of Ecuador under great pressure.

1980: Formal Training in Anthropological Archaeology Begins

In 1980 the first formal program to graduate professional archaeologists opened at the Escuela Superior Politecnica del Litoral (ESPOL) in Guayaquil. Although the creation of the Institute of National Heritage (Instituto de Patrimonio Cultural) in 1979 had formalized archaeological research, achieving a national consensus on the importance of archaeology for Ecuador is still a pending assignment.

Historically, most Ecuadoreans, including some university and government officials, did not consider archaeology a scientific effort. It was regarded as an activity worthy of dilettantes, the rich, and a few dreamers. The professional archaeologist was seen as strange sort whose career was considered a hobby by most people of means and a job by the poor farmers who became looters as a means of offsetting the chronic scarcity of agricultural jobs.

Such conceptions are now changing. For a long time, however, there was strife between museum directors and museum research personnel. The former felt that archaeologists pulled only potsherds out of the ground, not the beautiful pieces brought to them by grave robbers. The latter wanted museum funds to be used for archaeological investigations, not the acquisition of archaeological art.

1981-1992: Hoarding Archaeological Art versus Archaeological Research

During the 1980s and early 1990s professional archaeologists, on the one hand, and museum directors and collectors, on the other, waged a war that was partially won by the archaeologists, for the national museums in Ecuador halted all forms of acquisition. However, the huge acquisition budgets were not redirected to research, and research funds continued to be meager. The difficulty lay in the fact that archaeology was and still is considered by the cultural elite to be a business for antiquarians and art merchants, rather than a career worthy of historians or anthropologists. Private and archaeological museum collections, including those of the national museums, have been acquired by purchasing from looters rather than through museum-financed archaeological research. Museum directors and collectors justify their actions by saying that they are keeping the archaeological pieces from leaving the country. However, a study made by archaeologists and economists for the Central Bank of Ecuador showed that the internal demand for archaeological art actually finances the looting that yields the small amount of excellent art that is exported clandestinely.

Archaeological research nevertheless grew over this period, thanks to international funding and to some national research funds provided by groups such as Foncultura, or the Social and Cultural Fund of the National Petroleum Company. Studies of the impact of development on archeaological sites were also started, with much of this research carried out by Ecuadorean graduates in archaeology.

1992-2000: Growing Pains-Toward Adulthood and Reproduction

During the last decade of the twentieth century, there was an increase in the number of Ecuadorean archaeologists working in their field, in spite of the economic crisis that affected most cultural and social programs in

PREV NEXT

began a few months later, followed, in a smaller way, this new trend.

During the 1980s and early 1990s professional archaeologists, on the one hand, and museum directors and collectors, on the other, waged a war that was partially won by the archaeologists, for the national museums in Ecuador halted all forms of acquisition. However, the huge acquisition budgets were not redirected to research, and research funds continued to be meager. The difficulty lay in the fact that archaeology was and still is considered by the cultural elite to be a business for antiquarians and art merchants, rather than a career worthy of historians or anthropologists. Private and archaeological museum collections, including those of the national museums, have been acquired by purchasing from looters rather than through museum-financed archaeological research. Museum directors and collectors justify their actions by saying that they are keeping the archaeological pieces from leaving the country. However, a study made by archaeologists and economists for the Central Bank of Ecuador showed that the internal demand for archaeological art actually finances the looting that yields the small amount of excellent art that is exported clandestinely.

Archaeological research nevertheless grew over this period, thanks to international funding and to some national research funds provided by groups such as Foncultura, or the Social and Cultural Fund of the National Petroleum Company. Studies of the impact of development on archeaological sites were also started, with much of this research carried out by Ecuadorean graduates in archaeology.

1992-2000: Growing Pains-Toward Adulthood and Reproduction

During the last decade of the twentieth century, there was an increase in the number of Ecuadorean archaeologists working in their field, in spite of the economic crisis that affected most cultural and social programs in

PREV NEXT

Ecuador. This trend was enhanced by an increase in archaeological impact studies, most of which were conducted by Ecuadorean graduates in anthropology and archaeology. However, although the demand for archaeologists increased, a perverse tendency developed in universities where careers were judged by cost-benefit parameters and archaeology or anthropology was not deemed as attractive to the university council as management or business studies.

A number of medium-sized projects to study Ecuadorian biodiversity and native development are now opening up new opportunities for archaeological research, and as a result there has been an increase in the demand for graduates in archaeology. This situation is a welcome preview of better days ahead at the outset of the third millennium.

Egypt: Dynastic

Introduction

The archaeology of Pharaonic Egypt spans three millennia (ca. 3100-332 b.c.) and encompasses a diverse body of artifacts, architecture, texts, and organic remains. Museums throughout the

his colleagues in the 1930s (see Powell 1973, 61, where Pendlebury is said to be part of "a new generation of archaeologists openly disapproving of what they regarded as the amateurish policies of the past").

Napoleon, Champollion, and the Problem of Integrating Textual and Archaeological Data

Just as it is difficult to ascertain the date at which European antiquarianism was superseded by archaeology (see Daniel 1967; Piggott 1989), it is difficult to be precise about the point at which the simple enthusiasm for Egyptian antiquities was transformed into something resembling the modern discipline of Egyptology. Most histories of Egyptian archaeology, however, see the Napoleonic expedition at the beginning of the nineteenth century as the first systematic attempt to record and describe the standing remains of Pharaonic Egypt. The importance of the *Description de l'Egypte,* the multivolume publication that resulted from the expedition, lay not only in its high standards of draftsmanship and accuracy but also in the fact that it constituted a continuous and internally consistent appraisal by a single group of scholars, thus providing the first real assessment of ancient Egypt in its totality.

However, the beginning of Egyptology as a complete historical discipline, comprising the study of both texts and archaeology, was made possible by the more deskbound endeavors of the French linguist jean-françois champollion. His decipherment of Egyptian hieroglyphs in 1822, closely followed by Thomas Young's decipherment of the demotic script in the late 1820s, transformed Egyptology almost overnight from prehistory into history. The translation of a whole range of documents, containing such information as the names of gods and kings as well as the details of religious rituals and economic transactions, soon enabled the field of Egyptology to take its place alongside the study of the classical civilizations. Champollion's discovery, however, had also set in motion an inexorable process of academic divergence between linguists and excavators, between historians and anthropologists.

From the moment that hieroglyphs, both hieratic and demotic, began to be translated, Egyptology was characterized by a constant struggle to reconcile the kinds of general socioeconomic evidence preserved in the archaeological record with the more specific historical information contained in ancient texts. Although the newly discovered knowledge of the texts had the potential to revive the very thoughts and emotions of the ancient Egyptians, it also introduced the temptation to assume that the answers to questions about Egyptian civilization could be found in the written word rather than in the archaeologist's trench. The purely archaeological view of Egyptian culture, as preserved in the form of buried walls, artifacts, and organic remains, would henceforth have to be seen in the context of a richly detailed corpus of texts written on stone and papyrus. The absence of written records in prehistoric archaeology may be frustrating, but it has undoubtedly allowed prehistoric archaeologists greater freedom to evolve new theories and hypotheses that are based purely on the surviving material culture. In Egyptian archaeology, as in other historical disciplines, the written word, with all its potential for subjectivity and persuasion, has a paradoxical tendency to obscure, and sometimes eclipse, the archaeological evidence (see Kemp 1984).

It is interesting, from the point of view of the dichotomy between texts and archaeology, to compare the history of Egyptian archaeology with that of Mayan studies, given that Mayanists appear to have experienced the reverse situation: their discipline was predominantly anthropological and archaeological until Mayan glyphs began to be deciphered in the 1980s, producing a sudden flood of texts that have significantly altered the perception of the Mayan culture. In some respects, the suspicion with which Mayan archaeologists initially regarded the historical information provided by their philological colleagues (see Coe 1992, 270-274; Schele and Miller 1986) is a mirror image of the reaction of many traditional text-based Egyptologists to the increasingly science-based and anthropological analyses of Pharaonic

Egypt produced by archaeologists in recent years. Both Mayanists and

Egyptologists are struggling to come to terms with the basic fact that writing tends to be the product of elite members of society whereas the bulk of archaeological data derives from the illiterate majority of the population. The solution lies in the successful integration of both types of evidence to produce a view of society as a whole.

A related problem in modern Egyptian archaeology is the increasing dislocation between the processes of change in the material culture and the traditional chronological system of dynasties, kingdoms, and "intermediate periods," which may now be approaching the end of its usefulness. The dynastic conventions have become firmly embedded in the literature, but many modern scholars would now question the historic validity of a distinction between Sixth or Seventh Dynasty or between "third intermediate period" and "late period." Excavations since the 1960s have gradually produced a rival and more archaeologically relevant chronological system based simply on changes in material culture and supported by a framework of stratigraphic analysis and radiometric dates (see, for instance, O'Connor 1974; Trigger, Kemp, O'Connor, and Lloyd 1985). Future chronologies of the pharaonic period will need to integrate political change with the socioeconomic and art-historical fluctuations observable in the archaeological record.

Wilkinson, Lepsius, and Mariette: Exploration and Conservation

The Napoleonic expedition was complemented both by the Franco-Tuscan expedition of 1828-1829 (led by Ippolito Rosellini and Champollion) and by the more piecemeal work of a growing number of European travelers in the late eighteenth and early nineteenth centuries. The British Egyptologist Sir John Gardner Wilkinson, for instance, spent twelve years in Egypt and nubia between 1821 and 1833. The publication of *The Manners and Customs of the Ancient Egyptians* in 1837 was to earn him his knighthood, but much of his work, including maps, plans, and drawings of sites that have now been lost or destroyed, remains unpublished. His contemporaries, including English travelers James Burton, Robert Hay, and Edward Lane, also left behind numerous sketches, notebooks, and unpublished manuscripts that have only recently begun to be researched.

The Prussian expedition of the 1840s, led by karl richard lepsius, was the next major step forward in terms of the accumulation of a basic archaeological database for Egypt (Lepsius 1849-1859). In many ways, the Napoleonic and Prussian expeditions set the pattern for Egyptology until well into the twentieth century, essentially initiating a quest for more and more information to be cataloged and assimilated into the frameworks of history and art history. From the point of view of data, Egyptian archaeology has always been something of a victim of its own success. The archaeological remains are so rich, diverse, and well-preserved that most Egyptologists have tended to be immersed in the processes of description and categorization, often at the expense of analysis and interpretation. In addition, much of the earlier work was biased by the fact that nineteenth-century archaeologists in Egypt were almost entirely concerned with the study of temples and tombs since those remains were considered most likely to yield the kinds of artistic and textual materials that most Egyptologists then regarded as the backbone of the discipline.

What is remarkable about the European expeditions to Egypt in the first half of the nineteenth century is the rapid pace with which new information was acquired, digested, and assimilated into the overall picture of the pharaonic period. In 1838, the French architect Hector Horeau published a "panorama" of Egypt that included an illustration showing the principal monuments of Egypt. The painting took the form of an imaginary view of the meandering course of the Nile River, with Alexandria and the Mediterranean coast in the foreground and the Temple of Isis on the island of Philae in the far distance. This pictorial view of Egypt, which incorporated the basic essentials of Egyptian architecture from the pyramids at Giza to the temples of eastern and western Thebes, is a good illustration of the speed with which the

bare bones of Egyptology were assembled. As early as the 1830s, Gardner Wilkinson was able

to present a wide-ranging and detailed view of ancient Egypt in his book on its manners and customs. Certainly there were inaccuracies, misconceptions, and omissions in the publications of the early nineteenth century, but in many respects the fundamentals were already known and the last one and a half centuries have arguably been more concerned with filling in the details than breaking new ground.

Although the greatest individual achievement in the history of Egyptology was undoubtedly the deciphering of hieroglyphs by Champollion, the birth of Egyptian archaeology owes a great deal to the work of another French Egyptologist, auguste mariette. Born and educated in Boulogne-sur-Mer in northern France, Mariette was inspired to take up Egyptology when he examined the papers bequeathed to his family by his cousin Nestor L'Hote, who had served as a draftsman on Champollion's Franco-Tuscan expedition. In 1850, Mariette was sent to Egypt to obtain papyri for the collection of the Louvre, where he had been employed to inventory the Egyptian inscriptions. Once in Egypt, however, he embarked on a career in excavation, beginning with a remarkable discovery of the Serapeum (the burial place of the sacred Apis bulls) at saqqara.

As a result of his prolific archaeological work at many different sites (including Giza, abydos, Thebes, and Elephantine), Mariette was appointed in 1858 to the office of first director of the Egyptian Antiquities Service (now known as the Supreme Council of Antiquities). In this post he was able to reduce the amount of plundering of Egyptian antiquities as well as to create the nucleus of a national archaeological collection (housed initially in a disused warehouse at Bulaq, the port of Cairo, and most recently at the Egyptian Museum in the center of Cairo). During the next twenty years he excavated at some thirty-five different sites and gradually expanded the national museum.

However, despite the efforts of Mariette and his successor Gaston Maspero, the plundering of ancient sites remained a common problem. Such important finds as the Deir el-Bahari cache of royal mummies and the El Amarna archive of cuneiform tablets were initially plundered by local people and only came to scholarly attention when items became available on the art market. Maspero's official discovery of the Deir el-Bahari cache in 1881 involved something of a detective story in which he traced a hieratic papyrus of the Twenty-first Dynasty pharaoh Pinudjem back to the Abd el-Rassul family in the Theban village of Gurna, the family that had first uncovered the mummies ten years earlier.

Flinders Petrie, George Reisner, and the Introduction of Scientific Archaeology

Between the period of organized plundering undertaken by such men as giovanni belzoni and Drovetti in the early nineteenth century and the excavations of French scholars Emile Amelineau and J.L. De Morgan in the 1890s, there was surprisingly little development in the techniques employed by Egyptian archaeologists. As John Wortham puts it in his history of British Egyptology: “Although archaeologists no longer used dynamite to excavate sites, their techniques remained unrefined” (Wortham 1971, 106).

The concept of “clearance,” as opposed to scientific excavation, was arguably one of the most insidious and retrogressive aspects of nineteenth-century archaeology in Egypt. The very word appeared to substantiate the fallacy that the sand simply had to be removed in order to reveal the significant monuments hidden below, thus helping to discourage the proper consideration of stratigraphic excavation and the appreciation of all components of a site such as sand, shards, mud bricks, and towering stone gateways as being equally important and integral elements of the archaeological record. The use of the term *clearance* also encouraged the feeling that the antiquities of Egypt simply needed to be exposed and displayed rather than being analyzed, interpreted, or reconstructed. From the 1880s onward, however, the emergence of more scientific approaches gradually discredited the practice, although it was many years before clearance techniques could be said to have been eradicated.

Two individuals, W.M. Flinders Petrie and george reisner, were primarily responsible for the modernization of archaeology in Egypt in

PREV NEXT

from cemetery N7000 have provided modern researchers with an extremely reliable anthropological database.

Although the achievements of Petrie and Reisner are comparatively well documented, there was another phase in the development of Egyptian archaeology that has received less attention. In the period between the two world wars, several field-workers in Egypt began to undertake projects that would now be described as experimental and ethno-archaeological. Reginald Engelbach, for instance, undertook a number of experiments in the study of stone procurement and processing (Engelbach 1923) while Winifred Blackman, the wife of the British Egyptologist A.M. Blackman, published a study of Egyptian peasants (Blackman 1927) that was distinctly innovative in its approach to the links between modern and ancient Egyptian culture. These methodological advances, however, were to be thoroughly eclipsed by the discovery of new spectacular treasures by archaeologists howard carter at Thebes and Pierre Montet at Tanis.

In 1922, Carter's discovery of the tomb of Pharaoh tutankhamun, almost exactly a century after Champollion's decipherment of hieroglyphs, opened the floodgates in terms of public appreciation and exploitation of ancient Egypt. Archaeology as a whole attracts a level of popular interest not usually associated with other, more deskbound disciplines such as physics or mathematics, and the study of ancient Egypt has a particularly strong grip on the popular imagination. Even before the discovery of the tomb of Tutankhamun, nineteenth-century poets and novelists, such as Percy Bysshe Shelley and Sir Rider Haggard, were presenting a romanticized view of Pharaonic Egypt that drew heavily on new information provided by adventurers and archaeologists.

There are no doubt many theses that might be written on the impact of Carter's discovery on the popular culture of Europe and America, but from a purely Egyptological point of view, it might be argued that it was something of a mixed blessing. Although both Petrie and Reisner had made other sensational discoveries at certain points in their careers, their principal achievement had been to establish Egyptology as a rigorous scientific discipline concerned with the pursuit of knowledge rather than objets d'art. Yet in one fell swoop, the discovery of Tutankhamun's tomb restored the popular view of Egypt as a treasure hunters' paradise in which sheer persistence might eventually be richly rewarded (after the initial euphoric days, Carter was to spend much of his life cataloging the funerary equipment he had discovered in the tomb). Egyptologists have since been dogged by a public willing them to find something even more exciting than an intact royal tomb, and they have often found that their scientific agenda is at odds with the popular desire for buried treasure. The other side of the coin, however, is the continued existence of a wide audience for Egyptological research, which helps to maintain a subject that might otherwise be a vulnerable minority discipline.

Settlement Prehistory and the “Nubian Campaign”: New Directions in Egyptian Archaeology

Most of the work accomplished by archaeologists in Egypt between the mid-nineteenth century and World War II was characterized by two distinct trends. First, the early work in particular was marked by a resolutely art-historic, object-oriented approach to the excavated data. Second, fieldwork was dominated by a preference for the study of religious and funerary architecture rather than the artifacts and architecture of daily life. Both of these tendencies effectively inhibited the intellectual development of Egyptian archaeology until the 1960s when two major influences-the study of the prehistory of the Nile Valley and the increased excavation of pharaonic towns-finally began to exert an influence on the subject as a whole.

Certain town sites had already been investigated by the travelers, antiquarians, and pioneering archaeologists of the early nineteenth century such as Sir John Gardner Wilkinson and Robert Hay. In

1826, for example, Wilkinson made a detailed survey of the Greco-Roman port of Berenice on the Red Sea, which had been discovered a few years earlier by Giovanni Belzoni. Both Wilkinson and Erbkam (Lepsius's

Now, however, the long-term excavations at sites such as Elephantine in Upper Egypt and Tell el-Dab'a in the eastern delta have provided a more reliable view of the gradual processes of urbanization by revealing successive strata of settlements spanning many centuries. The published evidence from Elephantine (Kaiser et al. 1988), for instance, charts the growth of the site from an Old Kingdom settlement of some 16,000 square meters to a congested late-period city covering more than 70,000 square meters. The excavations at Tell el-Dab'a (Bietak 1975, 1992) have revealed a detailed local socioeconomic history in which the Egyptian inhabitants of the first intermediate period (ca. 2134-2040 b.c.) were gradually supplanted by Asiatics during the second intermediate period (ca. 1640-1532 b.c.). The results of the scientific investigations at Elephantine, Tell el-Dab'a, and other sites have not only vastly increased the knowledge of Egyptian domestic economy but have also begun to show how Egyptian settlements changed over the course of time. The Egyptian urban database has therefore expanded sufficiently to allow the different chronological phases of urbanization in Egypt to begin to be discerned and studied separately (see Kemp 1977, 1989) so that the idiosyncrasies of individual sites and particular periods of urban growth can be clearly distinguished from overall trends.

The Growth of Science in Egyptology

Eric Peet's inaugural lecture as reader in Egyptology at Oxford University in 1934 concerned the "present state of Egyptological studies." Already acutely conscious of the impact of science on Egyptology, he suggested that "many of the questions, especially those of the origins of materials and the technical processes of the arts and crafts, which have puzzled us for years, will eventually reach definite solution through the resources of chemistry and the other sciences" (Peet 1934). He was no doubt mindful of the fact that only eight years earlier the Cairo-based British chemist Alfred Lucas had published the first edition of *Ancient Egyptian Materials and Industries,* a brilliant summary of the surviving evidence for Egyptian materials and crafts that effectively served as the essential manual for Egyptological science until the 1990s. Lucas had access to much of the material in the Cairo museum, which enabled him to publish data, chemical analyses, and bibliographical references for a great deal of the most important material excavated since the mid-nineteenth century, including the objects from the tomb of Tutankhamun.

Lucas may have been the first scientist to survey the whole range of available data from Egypt, but there were many earlier scholars who pioneered various procedures. The field of bio-anthropology, focusing principally on the study of human and animal remains, has been one of the most active areas of scientific research in Egyptology from the early nineteenth century until the present day (see David 1979, 1986; Davies and Walker 1993). The surgeon Thomas Joseph Pettigrew took part in the unwrapping and dissection of numerous mummies from 1820 onward, and in 1834 he published his *History of Egyptian Mummies* that was to serve as the most reliable volume on the subject until the X-raying work of Grafton Elliot Smith at the beginning of the twentieth century (Elliot Smith 1912). In 1896, the German researcher W. Konig was the first to make radiographs of Egyptian mummies, and two years later, Petrie published radiographs of mummies from his excavations at Deshasheh (Petrie 1898). These photographs are thought to be the earliest instance of the archaeological use of X-rays in Britain, and they were perhaps made by J.N. Collie, who was making pioneering medical X-rays at University College London in the same year. Most of the subsequent work on Egyptian mummies has concentrated on examinations of this type, but some of the most recent research has concentrated on molecular biology and the extraction of DNA (e.g., Goudsmit, Decker, Smit, Kuiken, Geelen, and Perizonius 1993; Nissenbaum 1992).

A growth area in the 1980s and 1990s was the study of human diet in Pharaonic Egypt, based principally on the analysis of surviving fragments of food from both domestic and funerary contexts.

Projects of this type have included studies of Egyptian bread and beer making, wine production, and meat processing. A

PREV NEXT

related area of research into Egyptian food technology is the analysis of organic residues in amphorae and other vessels, which is beginning to make a significant contribution to the understanding of trading patterns between Egypt, the Levant, and the Aegean.

Thanks primarily to willard libby's use of Egyptian antiquities as some of his earliest “guinea pigs” in the development of radiocarbon dating, Egyptian archaeologists have been able to take advantage of radiometric methods of dating since the 1950s. In the immediate aftermath of the emergence of dendrochronological curves for the calibration of radiocarbon dates, in the mid-1980s, Egyptology was again one of the yardsticks against which the method was tested (Hassan and Robinson 1987; Shaw 1985). There is broad agreement between the calibrated dates and the conventional pharaonic chronology, but there has never been a concerted attempt to date a wide range of materials from a number of different phases of Pharaonic Egypt (and there are still a small number of disconcerting anomalies, e.g., see Haas, Devine, Wenke, Lehner, and Wolfi 1987). The existing sets of Egyptian radiocarbon dates are too piecemeal (and in many cases too old or too unreliable) to form the basis of an independent radiometric chronological framework for comparison with the conventionally calculated dates.

Another important area of scientific progress in recent years has been the use of geophysical methods of prospecting pharaonic sites, including the use of such techniques as resistivity survey, proton-magnetometer survey, sonic profiling, ground-penetrating radar, and thermal imaging. In the Great Pyramid at Giza, for instance, in 1986-1987 the combined use of microgravimetry (a technique for measuring the relative densities of stone blocks) and the transmission of electromagnetic microwaves revealed the possible presence of hidden chambers behind the stone walls of the so-called king's and queen's burial chambers. On a less sensational level, resistivity surveys at Saqqara, Memphis, and El Amarna, during the 1980s and 1990s have proved particularly suited to Egyptian sites. Resistivity traverses have supplemented conventional survey techniques, which has allowed archaeologists both to select areas showing the greatest potential for excavation and to map major features, such as wells or enclosure walls, without actually having to remove the material under which they are buried (see, for instance, Leclant and Clerc 1988; Mathieson and Tavares 1993).

The processual, multidisciplinary strategies of fieldwork that are now largely taken for granted in Egyptology (and even in some fieldwork at funerary and religious sites, as in the application of Schiffer's “behavioral archaeology” to the excavation of a Theban tomb [see Polz 1987]) have their roots in the archaeology of Egyptian settlements and prehistoric sites. Many sites (e.g., Abydos, Memphis, El Amarna, Elephantine, and Tell el-Dab'a) have been the subject of long-term multidisciplinary research since the late 1970s, thus providing opportunities for the application of numerous innovative scientific approaches to the archaeological remains of the Pharaonic period, including the use of experimental and ethnoarchaeological work (e.g., Guksch 1988; Nicholson 1992).

Theoretical and Practical Problems in Egyptian Archaeology

The sheer consciousness of large amounts of still-unpublished or unexamined data seems to have discouraged archaeologists working in Egypt from experimentation with innovative techniques and fresh theoretical perspectives. Indeed, H.S. Smith sees the apparent theoretical and analytical stagnation of Egyptian archaeology as an inevitable result of the accumulation of vast amounts of relatively unsynthesized data. He argues that the relative lack of explicit method or theory in Egyptology might be an inherent problem for historical archaeologists generally: “Because of the complexity of most of the societies with which they deal, the vast scale of the records and remains known to exist, and the countervailing inadequacy of these to provide a complete cultural picture at any one moment or a complete development through time, historians and historical archaeologists tend to be less analytical in

approach, more catholic and less explicit in their assumptions" (Smith 1972, xi).

Egypt: Predynastic

The term *Predynastic* denotes Egypt before the historically recorded sequence of kings and dynasties that starts ca. 3050 b.c. (*see* egypt: dynastic). Although there is no official beginning to the Predynastic, in Egyptian archaeology the term usually refers to the period that follows the appearance, ca. 5000 b.c., of a Neolithic food-producing economy in the Egyptian Nile Valley proper (as distinct from the Sahara at large). Evidence for reliance on food production using domesticated plants and animals (principally sheep, goat, pigs, cattle, wheat, and barley) occurs late in the Nile Valley relative to the fertile crescent of the Near East, possibly suggesting that hunting/gathering remained viable for a longer time span in the rich environment of the Nile floodplain. Once adopted, however, food production is linked with a long-term process of population growth, sedentism, and increasing social complexity in Predynastic cultures in the Nile Valley. The study of Predynastic Egypt has primarily been focused on the development of a series of different cultures in both northern and southern Egypt during the course of the two millennia from ca. 5000 to ca. 3000 b.c. The Predynastic period culminated in a process of political and territorial conquest during the second half of the Fourth Millennium b.c. (ca. 3400-3050) that included the expansion of the southern Egyptian cultural tradition over the rest of the country. The emergence of a politically powerful elite, governmental institutions, royal artistic and architectural styles, and the hieroglyphic writing system can be traced during the terminal stages of the Predynastic period, setting the stage for Egypt's transition to the Dynastic period.

The study of Predynastic Egypt differs in certain ways from that of Dynastic Egypt. The lack of writing until the very end of the Predynastic means that archaeology of the Predynastic does not have at its disposal the written evidence that begins to be increasingly important with the transition to the Dynastic period. This difference is, however, not as pronounced as might appear to be the case since during many periods of Egypt's Dynastic history, the volume of written documents and inscriptions is a small and very selective corpus of material. The archaeology of Predynastic Egypt has been, in recent decades, one of the most rapidly changing areas of work in Egypt, with new insights and discoveries continuing to reshape understanding of the early origins of Egyptian civilization.

Although the concept of the Predynastic period fits well with modern ideas of the distinction between prehistory and history, it is important to recognize that the idea of the Predynastic has been rooted to a large degree in the Egyptians' own ideas of their earliest past. One of the central religious and political ideas of ancient Egypt was the concept of the *Sema-Tawy,* or "Unification-of-the-Two-Lands." The Egyptians organized their history into a sequence of royal dynasties (a version of this that was recorded by Manetho, a priest of the Ptolemaic period, being the basis for the Dynastic history we use today). The beginning of these dynasties was the unification (*Sema-Tawy*) of Upper (southern) and Lower (northern) Egypt by a king Menes, ca. 3100 b.c. Menes was the first pharaoh of the First Dynasty and

according to Egyptian tradition founded the capital city of Memphis near the southern apex of the Nile delta so he could live there and rule over this newly unified kingdom.

For many years it was believed that the tradition of the *Sema-Tawy* was a historical reality and scholars frequently followed ancient Egyptian tradition by defining the Predynastic period as Egypt before the unification by Menes. Evidence suggesting that the Egyptian hieroglyphic

was discovered in a deposit at Hierakonpolis by Quibell and Green in 1898. These objects may have originally been set up as dedicatory objects inside the early temple precinct of the god Horus at Hierakonpolis. The slate palettes are often decorated with scenes showing the defeat of chaotic forces, an important role of the pharaoh in Dynastic times. Some have scenes that are historical in nature. The most famous of these objects is the Narmer Palette, which depicts king Narmer defeating northern enemies. The Narmer Palette was long considered a record of the *Sema-Tawy* ("Unification-of-the-Two-Lands") by king Narmer (who thus has often been linked with Menes of Egyptian historical tradition). The majority of scholars now accept it as an object commemorating an important military victory of Narmer but not the actual Unification event. Other significant palettes and maceheads include the "Towns Palette," which bears city hieroglyphs associated with a series of different royal names, the "Scorpion Macehead," which has scenes of a king Scorpion possibly engaging in a foundation ceremony, and the "Narmer Macehead," which has scenes of king Narmer engaging in a royal religious ritual.

One widely discussed aspect of late Predynastic Egypt (Nagada II-III and Dynasty 0) is evidence for interaction with the contemporary culture of southern Mesopotamia. A number of late Predynastic (particularly southern Egyptian) objects display use of distinctively Mesopotamian artistic motifs (such as the Gilgamesh "hero" motif, serpent-headed quadrupeds, and boat scenes). These motifs occur on objects as diverse as the Hierakonpolis painted tomb (Tomb 100), the Narmer palette, and the ivory handle of a flint knife known as the Gebel el-Arak knife. It was long considered that Mesopotamian stimulus may have been a factor in Egypt's developing organization at the end of the Predynastic period. Most archaeologists working on Predynastic Egypt see this evidence as use of foreign artistic motifs by the developing elite of the Nagada III period, but do not see Mesopotamian inspiration as a prime catalyst in Egypt's developing complexity. The motivations behind contact between late Predynastic Egypt and Mesopotamia remain uncertain but may have included the trade for gold that occurred in the desert regions east of southern Egypt.

As archaeological work on Predynastic Egypt continues, in future years we can expect considerable new evidence that will further reshape our understandings of the rise of Egyptian civilization. The field is increasingly benefiting from the use of modern techniques such as remote sensing, physical dating, and analytical techniques. As the amount of evidence builds, the rise of complex civilization in the Egyptian Nile Valley during the crucial two millennia from 5000-3000 b.c. will become ever clearer.

Egypt Exploration Society

The Egypt Exploration Society is the principal British archaeological institute involved in excavations in Egypt. Before its founding in 1882, Amelia Edwards, an English novelist, visited Egypt in the winter of 1873-1874 and sailed the length of the Egyptian Nile. At that time, many of the ancient sites and monuments were

conserving tombs of Memphis officials of the New Kingdom, including the tomb built for tutankhamun's general Horemheb, who later became king himself.

In 1982, the society celebrated its centenary with a special exhibition at the British Museum and by launching a project, directed by David Jeffreys and Lisa Giddy, to survey and investigate the site of the capital city of Memphis. In recent years, a number of smaller-scale projects have been initiated, surveying sites such as the Wadi Abu Had in the eastern desert of Egypt and Gebel el-Haridi in Middle Egypt. In 1992, the society responded promptly to a call from the Egyptian Antiquities Organisation for archaeological assistance in recording sites in northern Sinai that were threatened by the construction of the El-Salaam Canal.

The results of the society's work in Egypt are published in various series of memoirs. The society also publishes the prestigious annual *Journal of Egyptian Archaeology* and, since 1991, a color magazine, *Egyptian Archaeology*, which presents articles on fieldwork and research in a more popular style.

The Egypt Exploration Society has offices and a library in London, and membership in the society is open to anyone with an interest in ancient Egypt. Lectures and social events are held in London and Manchester. In 1992, an office was opened in Cairo to provide support for field expeditions and an increased level of activities for members in Egypt.

El Salvador

The first descriptions of archaeological sites in El Salvador were by nineteenth-century visitors from North America and Europe. Excavations of architectural centers, including Quelepa, Cihuatan, Tazumal, Campana San Andres, and Los Llanitos, went hand in hand with an interest in defining the spatial distribution of Maya-, Lenca-, and Nahua-speaking Pipil ethnic groups reported from the sixteenth century. Modern research has been concerned with clarifying the relations of the earliest sites with early Mesoamerican cultures, exploring the effects of volcanism and the possibility of migration out of and into the country following major eruptions,

PREV NEXT

and technologies of the Zapotitan basin. An unanticipated by-product of the focus on vulcanism was the discovery at Ceren of buildings and fields buried during eruption, preserving fragile organic remains and the relative contextual associations between items. Excavation and analysis of these materials, interrupted by the deepening of civil war in El Salvador in the 1980s, was resumed in the early 1990s.

Contemporary processual archaeology has greatly advanced the goal of establishing basic chronological control (see Sheets 1984). Projects have contributed valuable data on specific sites long noted as important, and they have introduced refined excavation techniques and a variety of specialized technical analyses. But other aspects of archaeology remain undeveloped. A focus on Mesoamerican contacts has limited the amount of attention directed to the eastern part of El Salvador, and data on this region are insufficient to begin to suggest models for interaction with neighboring Central American countries. Even in the better-studied western and central regions of the country, site-centered research and the often unique characteristics of sites limit the interpretation of internal developments.

Salvadoran archaeology continues to suffer from a lack of reliable regional data on settlement for most of the country. In addition to the Zapotitan basin, the Cerron Grande salvage project conducted in the valley of the Lempa River is the only major survey completed to date. The latter project is also notable in that it represents a national initiative following a period during which archaeology was primarily carried out by North Americans. Along with the end of civil war in El Salvador, the development of national archaeological programs may begin to address the existing gaps in Salvadoran archaeology.

Elgin, Lord

(1766-1841)

Bruce Thomas Elgin was born into the line of the earls of Elgin and Kincardine in 1766, attended Harrow and Westminster schools, and studied at St Andrew's University in Scotland, and then in Paris. In 1771 he succeeded as earl on the death of his elder brother, and was a representative peer of Scotland from 1790 to 1807 and from 1820 to 1840.

Lord Elgin

(Hulton Getty)

Elgin's career began in the army in 1785; he became major-general in 1809 and general in 1837. He also became a diplomat. In 1790 he was appointed envoy in Brussels, and in 1795 envoy extraordinary in Berlin. But it was through his appointment in 1799 to the embassy of the Ottoman Porte of Constantinople (now Istanbul), that he was to become famous.

PREV NEXT

classes, and for filling the museums of western Europe.

Without the official permission of the Turkish government Elgin began to assemble what is now know as "the Elgin marbles," a collection of pedimental sculptures from the Parthenon and from the Athenian temple of Nike Aperos and various antiquities from mainland Greece and Asia Minor. Part of this collection was sent to England and shipwrecked in transit, taking three years and great expense to salvage. Other pieces continued to be smuggled out of Greece from 1803, when Elgin left his position in Constantinople, until at least 1812, when it is recorded that eighty cases of antiquities arrived in England.

Elgin displayed his collection initially in his London residence and later at Burlington House, where its acclaim by artists and scholars tended to overcome any qualms about its provenance. The English nation was gripped with a fervor for Greek art, which was soon to be replaced by a similar one for everything Egyptian, even though this time the French got there first. Initially criticized for the dubious methods of its procurement, the collection was soon deemed to be of such significance that the House of Commons recognized Elgin's ownership and purchased his marbles, at a greatly undervalued price, for the british museum, where they remain to this day-notwithstanding continued requests by the Greek government that they be repatriated.

Tim Murray

Emery, Walter Bryan (1903-1971)

Born in Liverpool, England, Emery was apprenticed to a firm of marine engineers when he decided instead to study Egyptology at the Institute of Archaeology in London (1921- 1923). Between 1923 and 1924 he joined the egypt exploration society's excavations at el amarna. In 1924 he was appointed director of the Liverpool expedition to clear up and restore the New Kingdom tomb of Ramose and the tombs of other nobles in the necropolis at Thebes. It was during this task that Emery was able to visit the tomb of tutankhamun while it was being excavated.

In 1924, once more employed by the Egypt Exploration Society, he participated in the excavation of the Buchis bulls at Armant. In 1928 he was appointed by the Egyptian Antiquities Service to direct the Second Archaeological Survey of nubia. For six years he traveled all over southern Egypt excavating sites. These included the particularly rich site of Ballana near the border with Sudan. Here Emery found the fourth- to sixth-century a.d. royal burial mounds that became a significant part of the collections of the Cairo Museum. From 1935 until 1939 when he enlisted in the army, Emery excavated the 1st to 3rd Dynasty tombs at saqqara for the Egyptian government. He stayed in Egypt for the war, eventually becoming a lieutenant-colonel and director of military intelligence. Excavations at Saqqara resumed in 1945 until 1946, but then halted when he accepted a post as first secretary at the British embassy in Cairo.

In 1951 Emery was elected the Edwards Professor of Egyptology at University College, London, and in 1952 he returned to Saqqara with the Egypt Exploration Society once again, this time to complete the excavation of the tombs of the 1st Dynasty. After the Suez Crisis and in 1956, Emery and the Society began to work in the Sudan, excavating the Middle Kingdom fortress town of Buhen, which dated from 1970 b.c. He advised both the Egyptian and Sudanese Antiquities Services throughout the UNESCO campaign to save the monuments of Nubia and arranged for Buhen to be moved to Khartoum.

In 1964 Emery returned to Saqqara when he excavated the sacred animal necropolis of Memphis and its temple site-a rich hoard of animal mummies, bronze figures, temple furniture, and documents from the sixth to the first centuries b.c. He died in 1971 and is buried in Cairo.

Emona

The Roman town of Colonia Iulia Emona in what is now Ljubljana, the modern capital of slovenia, was founded on the site of a prehistoric settlement and situated on a highly important

strategic point that controlled the main route from italy to the Balkans. Written sources for the period of the second and first centuries b.c. report that the first people to live there were members of the Celtic tribe Taurisci.

Roman Emona was situated on an important road coming from Aquileia, Poetovio, and Siscia and riverine routes on the river Sava, and the town fully exploited its strategic and commercial position. According to a construction inscription found in Ljubljana, Emona was founded between a.d. 14 and 15. For a long time, Emona was believed to have developed from the Roman legionary camp of the Legio XV Appolinaris, which was stationed in this area until around a.d. 14 when it was transferred to Carnuntum near Vienna. However, recent studies by j.šašel have cast doubts on that thesis. One of the major arguments for the prior existence of the legion's camp is Emona's rectangular town plan. The town's walls measured 523 meters by 425 meters, and they were fortified with twenty-eight towers and four reinforced gates. An important early Christian complex was built in northwestern part of the town in the fourth century a.d.

The beginning of an interest in the antiquities of Emona (mainly epigraphic) can be traced to the fifteenth century. Rich epigraphic monuments and historical studies had long been the main focus of scholars from the seventeenth century and were published by German historian T. Mommsen, who was in charge of the “Limeskommission” set up in 1892 to investigate Roman remains. The establishment of the Provincial Museum in 1821 and the Museum Society in 1839 in Ljubljana gave an important impetus to the historical and archaeological research of the Roman town. In 1879, A. Mullner, the curator of the Provincial Museum, published a monographic study of Emona. In *Archaologische Studien aus Krain* he wrongly located Emona at Ig, a village some 10 kilometers south of Ljubljana. However, in 1898, Mullner started to excavate the Roman cemeteries in Ljubljana.

The first large excavations of the cemeteries began in the period between 1904 and 1907, and after almost 100 years of archaeological research and excavations, the Emona cemeteries are now among the largest excavated in the Roman Empire. Since 1635, when the first grave was reported, there have been more then 3,000 documented Roman graves in cemeteries situated outside the town and along the roads to Aquileia, Siscia, and celeia. Excavations of the settlement were initiated by the Provincial Museum, and between 1909 and 1912, almost one-third of the town was excavated. Walter Smid, the curator of the museum, published his results in *Jahrbuch fur Altertumskunde* in 1913.

The next large excavations were carried out by a city museum in the 1960s and 1970s as a result of extensive city development. The most important result of these excavations was the discovery of the early Christian center, comprising an administrative center, rich residential buildings, and town infrastructure.

Enkomi-Ayios Iakovos

Enkomi-Ayios Iakovos on the east coast of cyprus is the largest and most extensively excavated late-Bronze Age site on Cyprus. Early excavations by the british museum (1896) concentrated on the rich tombs, and it was subsequently recognized that they had been constructed within houses and open spaces inside the city walls. Additional work at the cemetery was undertaken by the Cyprus Museum by j. l. myres (1913), R. Gunnis (1927), and the Swedish Cyprus Expedition. Major excavations by porphyrios dikaios (1947-1957) and a French team directed by Claude Schaeffer (1934, 1947-1974) concentrated on the settlement. The Turkish occupation of northern Cyprus has precluded further research at the site since 1974.

Extensive excavations revealed a large walled city laid out on a grid plan. There are numerous

private and public building complexes, fortifications, and sanctuaries, including the Sanctuary of the Horned God and the Sanctuary of the Ingot God. Rich finds from both the settlement and the tombs include many high-status items imported from abroad or influenced by foreign prototypes. The latter include Mycenaean, Levantine, and Egyptian artifacts, as Cyprus was drawn into the international world of the eastern Mediterranean in the second half of the second millennium b.c. Processes of secondary state formation in Cyprus at the beginning of the late Bronze Age saw Enkomi develop as the earliest city on the island, and it maintained its preeminence when other polities developed later in the period.

Ephesus

Ephesus, an ancient city on the Ionian coast of turkey, was once a major port. It was famed in ancient times for the magnificent (and huge) temple of Artemis, and after the original burned down in 356 b.c., it was replaced by an even more magnificent building, which became one of the Seven Wonders of the World. Because of its importance throughout Hellenistic and Roman times, Ephesus boasted many major buildings and was an important center for sculpture production. Although it continued to be important into the Byzantine era, the site was progressively reduced in size and significance until it was abandoned in the eleventh century a.d.

Temple of Hadrian, Ephesus,Turkey

(Ann Ronan Picture Library)

Archaeological excavation began in Ephesus under John Wood (between 1863 and 1874), and the English had the signal fortune of excavating the Artemision (the temple precinct) in 1904, a feat that involved d. g. hogarth. However, it has been the Austrians who have made the most significant impact on the site. Beginning in 1895, under the auspices of the Austrian Archaeological Institute, they have excavated there for over a century.

Etruscan Archaeology

The Etruscans inhabited italy in the region known as Etruria (modern Tuscany, upper Latium, and parts of Umbria), from around 1000-900 b.c. into the first century b.c. Traditionally, Etruscan archaeology has been a multidisciplinary pursuit. Experts in the field seek to unite evidence on Etruscan language, history, society, religion, myth, art, and architecture with more strictly archaeological data concerning topography, settlement patterns, cemeteries, construction techniques, inscriptions, ceramics, and metalwork. The global approach is epitomized in the writings of Massimo Pallottino (d. 1995), who is universally acknowledged as the greatest of all Etruscan scholars.

Scholarship on the Etruscans began in the fifteenth and sixteenth centuries in connection with the pride and curiosity of Italians who were investigating the origins of their cities. They quickly recognized that many towns had Etruscan beginnings, and in some cases, they gave special emphasis to their own Etruscan ancestry-for example, the Medici of Florence (Cipriani 1980). Much of this research on the Etruscans was philological and art historical, drawing on Greek and Roman writers not only for Etruscan history but for such matters as the design of Etruscan temples, described by Vitruvius in the later first century b.c. (*De architectura* 4.7) or the nature of Etruscan terracotta sculpture and small bronzes, noted by Pliny the Elder in the first century a.d. (*Natural History* 33.158; 34.34). Pliny also gave a detailed account of the tomb of Lars Porsenna (*Natural History* 26.91), king of Etruscan Clusium (Chiusi).

Epigraphical evidence was recorded and evaluated in the Renaissance by Sigismondo Tizio of Siena (d. 1528), who compiled the first known Etruscan vocabulary list, and by Annio of Viterbo (d. 1502), who unfortunately was prone to enhance or even completely fabricate inscriptions in his home territory (Weiss 1988). Much more admirable scholarship is found in the report by the Renaissance artist and writer Giorgio Vasari on the discovery of the famed bronze Chimaera in 1553 in his native Arezzo (now in the Archaeological Museum in Florence). He concluded that the statue was Etruscan on the basis of the letters inscribed on its leg and was able to identify the beast through numismatic comparisons.

Some of the early scholars on the Etruscans were not Italians. The French savant Guillaume Postel, in *De Etruria regionis… originibus, institutis, religione, et moribus* (1551), lent his support to some of the more preposterous ideas of Annio, such as the notion that the Etruscans could be traced back to Noah. In the seventeenth century, the German archaeologist and antiquarian Athanasius Kircher visited an Etruscan tomb near Viterbo and left an amazing account of how he was told by a local guide that the stone-carved chambers and beds were actually made for underground cave dwellers. This misinterpretation can be forgiven in light of the scarce knowledge of Etruscan topography at the time.

The most important study of the Etruscans in the seventeenth century, by the Scotsman Thomas Dempster (Haynes 2000), was in fact written with little direct knowledge of archaeological sites. Dempster's famous *De Etruria regali libri septem* (Seven Books on Etruria of the Kings) is based on information from classical sources about the origins, customs, history, cities, and language of the Etruscans. Written for the Medici Cosimo II (d. 1621), the work was not published until over a century later by the English bibliophile Thomas Coke, who purchased the manuscript in Florence. The work appeared in 1726 (though the date of publication is listed as 1723-1724) and contains notes by the Florentine scholar Filippo Buonarroti (Galli 1986) and ninety-three illustrations. Buonarroti's archaeological commentary added immensely to the value of Dempster's work, including, for example, reports on some of his own systematic survey of tombs near Civita Castellana.

The publication of *De Etruria regali* was both a symptom and a cause of an absolute mania for the Etruscans that developed in the eighteenth century (de Grummond 1986, 39-40). On a fairly superficial

level, this mania found its way into decorations of English country houses and provided the name “Etruria” for the neoclassical ceramics factory of Josiah Wedgwood in England. In Italy, a patriotic fervor for this Italian civilization emerged, and the Etruscans were

European Mesolithic

What Is the Mesolithic?

In 1932 grahame clark defined the Mesolithic as the period "between the close of the Pleistocene and the arrival of the Neolithic arts of life" (J. G.D. Clark 1932, 5). This is the definition adhered to by the majority of those who study the period, and it is how the term will be used here. It is a deliberately loose definition, referring only to a somewhat imprecise period of time rather than to a rigorously defined cultural stage separate from what preceded and succeeded it. However, not all who study the period accept this definition. Some agonize about links with the Paleolithic and insist that the period should be referred to as the Epipaleolithic (e.g., Rozoy 1989); others, mainly in eastern Europe, consider that ceramics and claimed sedentism mean that the later part of the period should be termed "Neolithic" (e.g., Dolukhanov 1979). The Mesolithic thus has the dubious distinction of being the only major period in European prehistory whose very name is a matter of dispute among its students.

The Place of the Mesolithic in European Prehistory

The Mesolithic was the last of the major periods in European prehistory to be named. christian j. thomsen 's three-age system of Stone, Bronze, and Iron Ages was published in 1836. The first age was divided into the Paleolithic (of glacial age) and the Neolithic (of postglacial age) by Sir John Lubbock (later known as lord avebury) in 1865. The term *Mesolithic* was first used in 1872, but it was not systematically applied until the early years of the twentieth century (J. G.D. Clark 1980; Rowley-Conwy

1996).

That the period was not recognized for so long is rooted in the history of archaeology in the nineteenth century. Prior to 1858 prehistoric archaeology scarcely existed. After that date it emerged from a fusion of two distinct lines of study. On the one hand were geologists, who studied nonhuman aspects of the distant past; on the other were historical archaeologists, who studied material culture in the context of historically documented societies. Before 1858 these two groups had nothing in common: it was not believed that humans lived at the same time as the glacial deposits and bones of extinct animals that the geologists studied, so the geologists had nothing to say on the subject of early human societies. The historical archaeologists claimed the pre-Roman "Celtic" period but made little in the way of a systematic attempt to study it. william pengelly's excavations at brixham cave in 1858 demonstrated the contemporaneity of humans and extinct mammals in a glacial climate, a position generally accepted by 1863. This brought humans into the area studied by geologists, and most of the early Paleolithic specialists had a geological background. Meanwhile, the historical

European Mesolithic

What Is the Mesolithic?

In 1932 grahame clark defined the Mesolithic as the period "between the close of the Pleistocene and the arrival of the Neolithic arts of life" (J. G.D. Clark 1932, 5). This is the definition adhered to by the majority of those who study the period, and it is how the term will be used here. It is a deliberately loose definition, referring only to a somewhat imprecise period of time rather than to a rigorously defined cultural stage separate from what preceded and succeeded it. However, not all who study the period accept this definition. Some agonize about links with the Paleolithic and insist that the period should be referred to as the Epipaleolithic (e.g., Rozoy 1989); others, mainly in eastern Europe, consider that ceramics and claimed sedentism mean that the later part of the period should be termed "Neolithic" (e.g., Dolukhanov 1979). The Mesolithic thus has the dubious distinction of being the only major period in European prehistory whose very name is a matter of dispute among its students.

The Place of the Mesolithic in European Prehistory

The Mesolithic was the last of the major periods in European prehistory to be named. christian j. thomsen 's three-age system of Stone, Bronze, and Iron Ages was published in 1836. The first age was divided into the Paleolithic (of glacial age) and the Neolithic (of postglacial age) by Sir John Lubbock (later known as lord avebury) in 1865. The term *Mesolithic* was first used in 1872, but it was not systematically applied until the early years of the twentieth century (J. G.D. Clark 1980; Rowley-Conwy

1996).

That the period was not recognized for so long is rooted in the history of archaeology in the nineteenth century. Prior to 1858 prehistoric archaeology scarcely existed. After that date it emerged from a fusion of two distinct lines of study. On the one hand were geologists, who studied nonhuman aspects of the distant past; on the other were historical archaeologists, who studied material culture in the context of historically documented societies. Before 1858 these two groups had nothing in common: it was not believed that humans lived at the same time as the glacial deposits and bones of extinct animals that the geologists studied, so the geologists had nothing to say on the subject of early human societies. The historical archaeologists claimed the pre-Roman "Celtic" period but made little in the way of a systematic attempt to study it. william pengelly's excavations at brixham cave in 1858 demonstrated the contemporaneity of humans and extinct mammals in a glacial climate, a position generally accepted by 1863. This brought humans into the area studied by geologists, and most of the early Paleolithic specialists had a geological background. Meanwhile, the historical

archaeologists were pushing their studies back in time, bringing postglacial farming societies within their domain (Van Riper 1993; Grayson 1983; Gräslund 1987).

Although formally united as "prehistoric archaeologists" after 1863, the two groups of researchers still had little in common because of their different temporal foci and methods, and to an extent the division persists to the present day. In the later nineteenth century the jewels in the crowns of the two groups were, on one side, caves, containing complex stratigraphic sequences, stone tools, animal bones, and (if the researchers were lucky) spectacular paintings, and, on the other side, beautiful items of metal and jewelry, much pottery, and many visible monuments.

It is thus understandable that the Mesolithic, being postglacial but preagricultural and producing neither cave paintings nor monuments and metalwork, belonged nowhere and therefore had a difficult birth. Its very existence was denied by scholars such as French archaeologist gabriel de mortillet, whose "hiatus theory" claimed that Europe was unoccupied between the cave painters and the crop planters. This ignored events in denmark, where, as early as 1851, scholars recognized that certain shell heaps were the rubbish middens of a postglacial but preagricultural people (Steenstrup 1851); Havelse Mølle has the distinction of being the first recognized settlement of the period that would later be called Mesolithic.

Despite the repudiation of the hiatus theory, the Mesolithic period did not compare favorably to the Paleolithic and Neolithic periods. This was because of the Victorian evolutionary view that human progress moved through a series of ever higher "levels" of civilization. The hunter-painters of the Paleolithic were considered sufficiently impressive to be precursors to the agricultural barbarians of pre-Roman Europe. By contrast, the Mesolithic, with a simplified and diminutive technology and little or no art, looked like an uninteresting period of cultural retrogression. This view continued well into the twentieth century, not least of all in the dominating works of vere gordon childe. In the first edition of *The Dawn of European Civilization,* Childe wrote that "the contribution of [the mesolithic] to European culture is negligible. The hiatus is only recreated" (1925, 3). In the sixth and final edition of *The Dawn,* he was still writing of "cultures that are termed mesolithic because in time-but only in time-they occupy a place between the latest palaeolithic and the oldest neolithic cultures" (1957, 35).

The rest of this entry will examine the transformation of Mesolithic archaeology from the study of a retrogressive cultural stage into the study of hunter-gatherer adaptations in a diverse and changing landscape. Because of the extent of the change, the Mesolithic is arguably the best arena in which to examine changes in the theory and practice of European archaeology in the twentieth century.

From Hiatus to Behavior

The archetypal artifact of the Mesolithic is the microlith (the word simply means "small stone"). Larger items exist, but most Mesolithic sites contain numerous microliths, and many typological studies have been undertaken. Microliths amount to small blanks that may be mounted in a variety of tools. They are occasionally found as parts of arrowheads, such as the well-known example from Loshult in Sweden that used two, one as tip and one as barb (this item is widely illustrated, see, e.g., J.G.D. Clark 1975, fig. 12). Up to a dozen at a time are found mounted on larger spearheads or daggers (e.g., J.G.D. Clark 1975, fig. 43). None have been found in Europe mounted as sickles or other implements connected with plants, but their potential role in this connection has been stressed (J. G.D. Clarke 1976, fig. 2).

In 1932 Grahame Clark synthesized the British material in *The Mesolithic Age in Britain,* and he extended this to the mainland in *The Mesolithic Settlement of Northern Europe* (1936). He argued that the major Mesolithic event was the spread of the Capsian-derived Tardenoisian culture into a Europe peopled by local groups descended from different Upper Paleolithic cultures. The Mesolithic

cultures were interpreted as peoples, and the history of the Mesolithic was the history of their interactions and developments (J. G.D. Clark 1932, 93 ff.). The axe-using

Maglemosians occupied the lowlands of northern Europe, whereas the Tardenoisians had no axes and occupied sandy and hilly regions; the Maglemosians produced some art and made bone tools, whereas the Tardenoisians did neither (J. G.D. Clark 1936). The behavioral view that has replaced this argument derives from work in two main fields: archaeology and ecological anthropology. These will be examined in turn.

Archaeology

The upland-lowland cultural dichotomy came under strain in Britain during the 1960s. Radley and Mellars (1964) pointed out that microliths in the two zones were very similar and that axes were occasionally found in the uplands. On the mainland similar results were published (Geupel 1973; Newell 1973). Most would now see the differences as reflecting behavior and preservation rather than cultural variation. Acid conditions have destroyed bone at the upland sites. Varying proportions of artifacts are found in both upland and lowland areas, and these are thought to reflect varying activities. The rarity of axe/adzes in the uplands probably reflects the thinner woodland in these regions (J. G.D. Clark 1972, 1973; Jacobi 1978; Mellars 1976a).

A second element in the understanding of the Mesolithic was dating. During the 1970s the radiocarbon revolution reached the Mesolithic, and the mainland Mesolithic was divided into three main technological phases. Phase 1 was characterized by a high proportion of obliquely blunted points among the microliths. This is conventionally thought to have started at the Pleistocene-Holocene boundary at 10,000 b.p. (see further discussion in later passages). Phase 2 began around 8800 b.p. and was typified by smaller microliths, such as triangular and lanceolate forms. Phase 3 began around 7850 b.p. and was marked by artifacts made on broader blades, among which trapeze-shaped microliths were the most numerous. This phase ended with the appearance of the Neolithic period (for major reviews, see Kozlowski 1975, 1976; Rozoy 1978).

Work in Britain identified an early phase corresponding to phase 1 on the mainland, characterized by the same microlithic forms and ending at the same time; the industries are termed “broad blade.” Britain's later phase, termed “narrow blade,” was similar to the mainland phase 2. The blade and trapeze industries of mainland phase 3, however, never reached Britain. By the time this phase appeared on the mainland, Britain had been isolated by the rising postglacial sea, and the narrow gap was apparently sufficient to inhibit the spread of trapeze industries (Jacobi 1973, 1976; Mellars 1974, 1976b; Switsur and Jacobi 1979).

A third strand of relevant archaeological work has been spread over a much longer period and concerns organic remains of various kinds. This strand has been important in countering the early view that the Mesolithic was both technologically and artistically impoverished. The formation of peat bogs has led to superb conditions of preservation in some parts of Europe. The bows that shot the microlith-tipped arrows have turned up at several major settlements, including early-Mesolithic Holmegård in Denmark (illustrated in S.H. Andersen and Nielsen 1982, 22) and late-Mesolithic Ageröd V in sweden (Larsson 1983a, figs. 32, 33). Barbed bone and antler points are common; major concentrations were found at Star Carr in England (nearly 200 points, see J.G.D. Clark 1954, figs. 47-64) and at Mosegården III in Denmark (over 300 points, see K. Andersen 1983). At Mosegården III they were found spread across an area about 1,000 by 300 meters, not directly associated with a settlement but on the bed of a former lake. Nearby settlements contain many fish bones, and some of the Mosegården III examples were found point downward, suggesting they were mounted as leisters and lost during fishing (K. Andersen 1983, 155-173). At Star Carr they were found concentrated in just a few square meters at the edge of the settlement, but the settlement produced no fish bones (J. G.D. Clark 1954, fig. 5); this suggests they were cached and intended for use against land mammals and would therefore have been mounted as

spears (Legge and Rowley-Conwy 1988, 95).

Larger, more complex fish-catching items are also known. The famous seine from Antrea in Karelia was some 30 meters long and 1.5 meters

high (J. G.D. Clark 1975, 223-224). Other nets are known, as well, such as those from Sventoji 2B in lithuania (Rimantiené 1992, fig. 4) and Friesack in Germany (Gramsch 1987, pl. 25-26). Basket fish traps made of wickerwork are also known, for example, from Ageröd V in Sweden (Larsson 1983a, 62-69) and several sites in Denmark (Becker 1941). Larger fish traps made of fixed stakes are known from Tybrind Vig and Lystrup in Denmark (S. H. Andersen 1987a, fig. 155, and 1996, figs. 3 and 4) and Sventoji 1A in Lithuania (Rimantiené 1992, fig. 5). In addition, organic items for use in transport are known; these include canoes, one from Tybrind Vig in Denmark measuring 9.5 meters in length (S. H. Andersen 1987a, 275-276), and a ski fragment from Sarnate in latvia (Zvelebil 1979, 214). Such items have *not* survived from the Upper Paleolithic.

Among the organics are various items with artistic designs and motifs. Visibility of art thus covaries with the degree of organic preservation. Denmark probably has provided more artwork than any other country (J. G.D. Clark 1975; S.H. Andersen 1980). The site of Tybrind Vig must again be mentioned, as its decorated paddle blades are perhaps the finest Mesolithic designs known from Europe (S. H. Andersen 1987a and 1987b, fig. 165). Artistic work did, therefore, clearly continue in the Mesolithic, although not on cave walls-except in eastern spain, where parietal art persisted into the postglacial period (e.g., Sieveking 1979, 193-195).

Ecological Anthropology

In European hunter-gatherer studies there is little effective contact between archaeologists and anthropologists. As a result concepts derived from ecological anthropology have tended to reach Europe via the works of North American scholars. Early influential examples include Meiklejohn (1978) and Price (1981). Such work made use of concepts such as the mating network of about 500 people (Wobst 1976). Price (1981) noted that the areas occupied by stylistically defined archaeological entities are frequently 100 to 200 kilometers in diameter, thus measuring about 8,000 to 31,000 square kilometers. If these represent mating networks of 500 people, they imply population densities of 0.064 to 0.016 people per square kilometer (Price 1981, table 4). This is within the expected range and therefore supports the identification of these stylistic units as closed mating networks. Late-glacial stylistic units covered far larger areas; J.G.D. Clark (1975, 72-73) mentioned a range of 70,000 to 120,000 square kilometers. An area of 100,000 square kilometers would, if occupied by 500 people, imply a population density of 0.005 people per square kilometer-similar to that of some inland groups of caribou hunters in North America.

These concepts, derived from ecological anthropology and listed above, were rapidly adopted in Britain (Jacobi 1979), but it is perhaps accurate to say that they have made less impact in mainland Europe. Although these ideas are clearly very useful, some scholars have argued that more flexibility needs to be employed when applying them to coastal regions (Rowley-Conwy 1986). Price (1981, 227) stated that at normal population densities, Denmark might have contained three mating networks. Coastal productivity very much exceeded that of inland regions, however, and hunter-gatherer populations in favorable regions would have been much larger (Rowley-Conwy 1983; Zvelebil and Rowley-Conwy 1986). Some of the smallest stylistic entities in the European Mesolithic are in Denmark-those identified by Vang Petersen (1984, fig. 15). These are only some 50 kilometers across and are, furthermore, not circular because they are on the coast, so they are far smaller than others in the continental interior. *If* these are interpreted as semicircular mating networks, population density would have been in the order of 0.5 people per square kilometer. Territorial behavior was likely. In any event, favorable coastal regions were likely to have seen higher population densities and group sizes, arguably in conjunction with more complex social organizations (Renouf 1991; Rowley-Conwy 1983; Rowley-Conwy and Zvelebil 1989). This may be why agriculture was relatively slow to penetrate some of these coastal regions (Zvelebil and Rowley-Conwy 1986).

Anthropological concepts have been important in other areas, such as technology. Robin

Torrence demonstrated that technological complexity varied with latitude (1983, figs. 3.1, 3.2). She suggested that economic activities in higher latitudes were more likely to be "time stressed" because resource availability was concentrated into ever more limited periods as latitude and seasonality increased. The shorter the period a resource is available, the more specialized the technology must be to maximize procurement in the brief time available (Torrence 1983). When the Mesolithic is considered in this light, it is evident that a technology *less specialized* than that of the Upper Paleolithic would be expected because conditions changed from arctic to temperate. Arguably, this is what the microlith represents: an unspecialized blank capable of use in a wide variety of tools. Thus, anthropology provides an alternative to the view that the Mesolithic was a period of cultural retrogression: a less specialized technology can be seen as an adaptation to less time-stressed activities.

This section has sought to demonstrate the transition from a cultural to a behavioral perspective by European Mesolithic studies, and recent syntheses do indeed combine archaeology with anthropologically derived concepts (for a good example in the British context, see Smith 1992). The study of hunter-gatherers is perhaps the area of archaeology in which the behavioral perspective is most developed, and the Mesolithic certainly used to be regarded as the most retrogressive period in European prehistory. The changes described earlier therefore amount to probably the biggest shift in views anywhere in European prehistory.

Regional Perspectives

This section will present a discussion of work in various areas of Europe. In no sense can the presentations that follow be considered reviews; space permits the inclusion of only a few aspects of work and a small number of publications. The coverage is intended to emphasize variability.

The Mesolithic is sometimes thought of as a temperate forest phenomenon, but, although southern Scandinavia is indeed in the temperate zone, Iberia is mostly Mediterranean in climate, and the upper reaches of Norway lie far north of the Arctic Circle.

Southern Scandinavia

It is appropriate to begin with the region that has both the earliest work and the most complete record of any in Europe. Good reviews of the Danish and southern Swedish Mesolithic can be found in Brinch Petersen (1973), J.G.D. Clark (1975), and Price (1985).

The earliest phase of the Mesolithic is represented by only a few sites, such as Klosterlund. The second phase, characterized by lanceolate and triangular microliths (see the previous discussion), is the period of the Maglemose culture, falling in the eighth millennium b.p. Most sites lie on the banks of former lakes that have since filled with peat, creating excellent conditions for organic preservation. Many sites were discovered during peat cutting in the early years of the twentieth century, and some of these have been published, including Ulkestrup (K. Andersen, Jørgensen, and Richter 1982), Sværdborg I (Henriksen 1976), and Lundby (Henriksen 1980). The sites are all small, and sometimes they include the preserved bark floors of small dwellings (e.g., at Ulkestrup); the sites might have been occupied only once or multiple times over a certain period and involve material being dumped in the former lakes alongside the huts (Blankholm 1987, 1996; Grøn 1995).

Faunal remains consist of the "big five" land mammals of postglacial Europe, namely, red deer, elk (or moose), roe deer, aurochs, and wild boar. In addition, many fish bones, mainly of pike, are found on some settlements (see the earlier description of the Mosegården III fishing area), and hazelnut shells hint at the wide range of plant foods that must have been exploited. Most of the settlements are believed to have been occupied in summer (as was the similar site of Star Carr in Britain-see Legge and

Rowley-Conwy 1988). The case has been made that a minority were occupied in winter (Grøn 1987), although the faunal evidence argues against this conclusion (Rowley-Conwy 1993; Blankholm 1996). At the time of occupation the sea level was appreciably lower than it is today; it may be that some winter settlements lie below the present sea level, for Maglemosian artifacts have been found by divers at depths of 10 to 15 meters in the now submerged

Rowley-Conwy 1988). The case has been made that a minority were occupied in winter (Grøn 1987), although the faunal evidence argues against this conclusion (Rowley-Conwy 1993; Blankholm 1996). At the time of occupation the sea level was appreciably lower than it is today; it may be that some winter settlements lie below the present sea level, for Maglemosian artifacts have been found by divers at depths of 10 to 15 meters in the now submerged

PREV NEXT

area between Denmark and Sweden (Larsson 1983b).

In the earlier part of the third (blade and trapeze) phase of the Mesolithic, the sea was rising rapidly. The Kongemose culture belonging to this period (ca. 6800 to 6300 b.p.) is little known, but the succeeding Ertebølle culture (ca. 6300 to 5200 b.p.) has provided many settlements. In the north and east of Denmark, Ertebølle coasts are above present sea levels; on these raised beaches are the many shell middens for which this culture is renowned (Europe's first recognized Mesolithic settlement, Havelse Mølle, is one of these). Oysters usually predominate among the shellfish, but bones of land and sea mammals, birds, and fish are numerous, and these taxa probably provided most of the diet-the importance of plant foods again being unquantifiable. Analysis of C-13 content in human skeletons indicates that the Ertebølle diet was dominated by marine foods, probably to a greater extent than would be suspected from other lines of evidence, and that this changed abruptly to a terrestrially based diet at the start of the Neolithic period (Tauber 1982).

Many excavations have been published; in Jutland the eponymous site of Ertebølle has been the scene of renewed work (S. H. Andersen and Johansen 1986), and smaller shell middens such as Norsminde (S. H. Andersen 1989) and the inland site at Ringkloster (S. H. Andersen 1975) have also been recently excavated. Farther east oysters played a lesser part in the diet as salinity decreased, but sites were still large; examples include those around Vedbæk Fjord in Denmark (Price and Brinch Petersen 1987) and Segebro in Sweden (Larsson 1982). In southern Denmark the raised beaches run below present sea levels; the site of Tybrind Vig, excavated by divers, testifies to the continuation of the Ertebølle in this region (S. H. Andersen 1987a and 1987b).

Some of the larger shell middens were occupied year-round (Rowley-Conwy 1983). Other sites were seasonally occupied; Ringkloster, in the interior, was a winter-spring site. The sedentism suggested by evidence in the sites has given rise to discussions of possible social complexity (Rowley-Conwy 1983), although it has been stressed that the data are vague (Price 1985). The remarkable early Ertebølle cemeteries at Vedbæk in Denmark (Albrethsen and Brinch Petersen 1976) and Skateholm in Sweden (Larsson 1988) may indicate territorial behavior.

Iberia

Iberia is a large and diverse landmass, ranging from a cool, temperate north to a warm, oceanic southwest and a hot, Mediterranean south and east. Research has inevitably been somewhat patchy in so large an area, but enough has been done to identify Iberia as an area of key interest in the European Mesolithic.

The later Mesolithic of portugal was characterized by groups of substantial shell middens (for recent reviews, see Arnaud 1989, 1990; Lubell and Jackes 1988; Zilhão 1993). These date to around 7000 to 5500 b.p. and lie some way inland from the present seacoast, overlooking post-Mesolithic alluvial deposits. Those on the Muge River (a tributary of the Tagus) are comparatively well known. Moita do Sebastião is a major midden with traces of one or more structures and a large cemetery (Roche 1972a), and Arruda and Amoreira also both have cemeteries (Roche 1972b). Other shell middens lie farther south on the Sado River. Cabeço do Pez and Poças de São Bento are the two largest; these and several others have cemeteries (Arnaud 1989). Finally, a third group lies on or close to the Mira River (Arnaud 1990).

Although these shell middens do not consist of tightly packed oysters like the ones in Denmark, they have a more diffuse content of smaller marine and brackish-water shells and are sometimes a short distance from the contemporary shore. Animal bones are present in quantity in some middens, with those

of red deer and wild boar being the most common. Fish bones tend to be less visible, although many were recovered at Arapouco at the seaward end of the Sado group. The species of fish in question indicate a summer occupation of this site, whereas Cabeço do Pez at the inland end may have been a winter site. This supports the suggestion that there was short-distance seasonal movement within at least the Sado middens, with groups spending summers near the seacoast

PREV NEXT

and winters further inland (Arnaud 1989). The role of plant foods is difficult to determine; Arnaud (1989) stressed the potential importance of acorns and pine nuts, both available locally. Unusually for the European Mesolithic, the middens contain grindstones, which could have been used to prepare plant foods. Stable-isotope analysis indicates that Mesolithic populations had more marine foods in their diets than did Neolithic populations, but the break between the two is less abrupt in Iberia than in Denmark (Lubell and Jackes 1988).

The Asturian culture of the northern Spanish coasts has been relatively thoroughly researched (see, e.g., G.A. Clark 1983a; González Morales 1989). Many of the sites are shell middens with limpets as the main component, and some of these are found in caves-a major example being La Riera, where the Asturian midden overlies substantial Paleolithic deposits (Straus and Clark 1986). Among the animal bones those of the red deer predominate (G. A. Clark and Yi 1983). Less is understood of seasonality and settlement patterns in this area. It has been suggested that the Asturian sites may be seasonally complementary to Azilian sites inland, at least during the relatively short period of chronological overlap between the two-but longer-term coast-inland complementarity was likely (G. A. Clark 1983b, 1989).

Other areas of Iberia have received less scrutiny. One particular problem in this connection is the possible appearance of domestic sheep and/or goats and pigs in Mesolithic sites in eastern and southern Spain (Boessneck and von den Driesch 1980; Bernabeu, Aura, and Badal 1993; Ribé, Cruells, and Molist 1997; Zilhão 1993). The appearance of the bones of sheep, goats, and pigs in the data have recently come under criticism from two directions. First, the stratigraphic problems in the caves in question may have been underestimated, with the relevent bones ascribed to the wrong layers (Zilhão 1993); second, the distinction between wild and domestic pigs is problematic and may have been too rigidly applied (Rowley-Conwy 1995a). There are currently no compelling reasons to assume that domestic livestock were present in the Mesolithic of southeastern Spain.

Norway

The sheer size of the Scandinavian peninsula is not always appreciated: the distance from Copenhagen to the most northern cape of Norway equals the distance from Copenhagen to Naples, and most of this span is Norway, which extends to beyond 71° north latitude. In addition, the coastline is deeply indented, giving Norway a total coastal length of over 26,000 kilometers. Much of the country's terrain is steep and difficult, and organic materials usually do not survive in Norway's climate. Given such difficulties, it is a testimony to Norwegian colleagues that so much is known of the Norwegian Mesolithic period, one of the most interesting in Europe.

The central parts of the country are less well researched than the Arctic or southern parts (for a good review, see Nygaard 1989). A consensus is growing that agriculture did not appear at the start of the artifactual Neolithic. The first evidence in southeastern Norway may date to the middle Neolithic (mid-fifth millennium b.p.). Elsewhere it occurred substantially later: in southwestern Norway there is no agricultural evidence until the late Neolithic (Bjørgo, Kristoffersen, and Prescott 1992; Prescott 1991), and near the Arctic Circle stratigraphically early cereal grains from Stiurhelleren have been directly dated to as late as around 3200 b.p. (Johansen 1990). For more recent reviews, see Prescott (1996) and Peter Rowley-Conwy (1995b).

Early-Mesolithic groups are known as the Fosna culture in southern Norway and the Komsa culture in the Arctic (Nygaard 1989). Organic material is rare, and later periods are better known. In the south there was extensive late-Mesolithic/early-Neolithic hunter-gatherer settlement in the deeply dissected coastal zone (see, e.g., Mikkelsen 1978; Bang-Andersen 1996). The major settlement of Kotedalen lay on a strait rich in fish and was probably occupied all year (A. B. Olsen 1992). The large faunal sample

showed a strongly marine orientation, dominated by fish (primarily from the cod family). The most common mammals were seals and otters, followed by red deer and pigs (Hufthammer 1992). Farther inland, in the inner fjord zone, remains at the cave site of Skipshelleren

also contain many fish and seals, but there is a much larger proportion of land mammals (H. Olsen 1976). Whether Skipshelleren was utilized by groups from the outer coast on a seasonal basis remains unclear. Small sites in the Hardanger massif in the interior were probably seasonal reindeer-hunting stands (Bang-Andersen 1996).

Arctic Norway also presents a picture of maritime adaptations. Substantial house structures are known (Engelstad 1989). The best-surveyed area is Varanger Fiord, in the most northeastern part of the country. Substantial faunal remains have been recovered from some settlements there. Earlier models of long-range mobility based on recent ethnography have given way to models of restricted movement or sedentism based on the archaeological material: individual middens on the same site may indicate different seasons, but in all, they suggest year-round occupation (Renouf 1988, 1989).

Eastern Europe

The Mesolithic of eastern Europe is little known in the west, although recent years have seen an upsurge in contacts between east and west, and the coming years will surely see this increase still further. The best review of the whole region is Dolukhanov (1979). Various areas are of major interest.

The northeast Baltic contains many large settlements with excellent organic preservation. Archaeologists with command of the relevant languages have provided information about these (e.g., Zvelebil 1979), and some information about individual settlements, such as Sventoji in Lithuania (Rimantiené 1992), is becoming available. Claims are made for a small number of domestic cattle and pigs in some sites (see Dolukhanov 1979), but detailed zooarchaeological data are not available.

The Iron Gates Gorge, containing the Danube, separates romania from the former Yugoslavia. The gorge contains a number of major Mesolithic sites. The most famous is lepinski vir, which has substantial house remains and monumental sculptures (Sjrejovic 1972), but other sites are also substantial (see, e.g., Prinz 1987; Voytek and Tringham 1989). Fish, mainly catfish and members of the carp family, apparently were a very important resource, accounting for over half the bones recovered from Lepinski Vir (Bökönyi 1970), Padina III (Clason 1980), and Icoana (Bolomey 1973). Faunal reports all conclude that these three settlements were occupied all year.

Continuity from the Later Upper Paleolithic

Historically, the Mesolithic has been described as a separate entity. However, much new work is now being done to bridge the gap between the Upper Paleolithic and the Mesolithic, and not surprisingly, there is substantial continuity. The two periods are now being studied largely by the same researchers, whereas in earlier years the division between Pleistocene and Holocene also formed a research division. This is particularly the case in the North European Plain, where human occupation ceased during the maximum extent of the last glacial period: the later Upper Paleolithic reoccupation is treated together with the Mesolithic as a single unit of study, albeit with recognition of rapid change through time. This renders irrelevant any question of whether we should actually call the postglacial period “Mesolithic” or “Epipaleolithic.”

Climatic warming at the Pleistocene-Holocene boundary appears to have been extremely rapid. As a result, it took some centuries for plant communities to begin to adjust. There is a substantial similarity between the flint technology of this period and the immediately preceding later Upper Paleolithic, both on the mainland (Gob 1991) and in Britain (Barton 1991). Similarity in bone and antler artifacts is also attested (Smith and Bonsall 1991). One interesting recent development is the accelerator dating of a point recovered from the bed of the North Sea at a depth of 39 meters; the date is 11,740±150 b.p. (OxA 1950), which places the point firmly in the later Upper Paleolithic and emphasizes the large areas

that have been submerged since the last glacial.

It was mentioned earlier that microliths may reflect a less specialized technology, as would be expected when climatic amelioration takes place. Can microlithization therefore be considered

also contain many fish and seals, but there is a much larger proportion of land mammals (H. Olsen 1976). Whether Skipshelleren was utilized by groups from the outer coast on a seasonal basis remains unclear. that have been submerged since the last glacial.

It was mentioned earlier that microliths may reflect a less specialized technology, as would be expected when climatic amelioration takes place. Can microlithization therefore be considered

an adaptation to prevailing conditions? Much more work needs to be done on the late-glacial industries before this question can be answered, but some observations can be made at this point. Late-glacial environments are becoming better understood. The last millennium or so was characterized by very cold conditions (the so-called Dryas III, ca. 11,000-10,000 b.p.). Preceding this was a warmer interstadial period (the late-glacial interstadial, sometimes divided into the Bølling and Allerød interstadials, ca. 13,000-11,000 b.p.) in the North European Plain. Before 13,000 b.p. came the major period of last-glacial cold (Barton, Roberts, and Roe 1991, xii).

Microlithization varies with this in what is potentially a most interesting way. Later Upper Paleolithic industries in southern Europe showed a trend toward microliths (Gamble 1986, 220-221), which increased in the Azilian around the Pleistocene-Holocene boundary (Straus 1985). Remarkably, southern france for a time saw a chronological overlap between (1) groups hunting reindeer with Magdalenian technology and (2) groups hunting red deer with Azilian technology (Straus 1996). In northern Europe, the Hamburgian dates to the earlier part of the late-glacial interstadial period and is typified by the heavy, tanged points that were used to kill reindeer (Fischer 1991, 1996; Holm and Rieck 1992). Microlithization began in the second part of the late-glacial interstadial period (Rozoy 1989, 25). Cultural entities of this period in the North European Plain are variously termed Federmesser, Tjongerian, Arch Backed Piece, and so forth (Fischer 1991; Gob 1991; Schild 1976; Houtsma et al. 1996; Newell and Constandse-Westermann 1996). Large, tanged points continued in the northern edge of occupation, in the Brommian of Denmark (Fischer 1991), although some Federmesser elements are also known (Holm 1996). Ahrensburgian tanged points from the final cold spell in the Younger Dryas have been found across much of the North European Plain, again associated with reindeer hunting (Schild 1976; Fischer 1991). At the end of the Younger Dryas final Paleolithic industries continued until 9600 b.p. in poland, by which time the site of Friesack in Germany had already "gone Mesolithic," although this phenomenon cannot yet be linked to ecological factors because no faunal remains survive (Schild 1996). This pattern could be consistent with (1) specialized reindeer hunting using tanged points and (2) more generalized hunting using smaller armatures, moving north and south as climate and resources fluctuated. More work is, however, needed on late-glacial industries and resources before this supposition can be substantiated.

Final Remarks

This essay has tried to show why the Mesolithic period in Europe is no longer regarded as a cultural hiatus or a retrogressive backwater. Variability has been stressed; in some areas hunter-gatherer economies were apparently a viable alternative to farming for centuries or longer. Thus, when farming spread across Europe, groups of people who lived at the Portuguese shell middens and the Iron Gates hunter-fisher sites continued to occupy them for centuries although surrounded by farmers; by contrast, the boundary between hunter-gatherers and farmers in southern Scandinavia and northern Germany was more or less stable for over a millennium.

It is heartening that many of the changes in views discussed here have come about not as theoretical changes divorced from the archaeological material but as the direct consequence of methodological and interpretational advances on the part of Mesolithic scholars all across Europe. An optimistic view of the future of Mesolithic studies thus stresses the importance of continued work: excavation, interpretation, reinterpretation, synthesis. It is from this process that a greater understanding will come in the years ahead.

Evans, Sir Arthur

(1851-1941)

Arthur Evans was the eldest son of the famous geologist and antiquary sir john evans. The father's friendship with many notable archaeologists such as Sir John Lubbock (lord avebury), hugh falconer, augustus pitt rivers, and gustaf montelius must have had an impact on his son Arthur, and the death of his mother when he was six resulted in a close relationship between father and son. Arthur Evans attended Harrow School and Oxford University and graduated in history in 1874. Independently wealthy, Evans traveled to Germany to study for a year, and he then went to Bosnia, Herzegovina, finland, and Lapland. He pursued independent research on the history and antiquities of the southern Slavic peoples and became an advocate of Illyrian independence from the Austro-Hungarian Empire. He returned to England in 1878 and married Margaret Freeman.

In 1883, Evans and his wife left for an extended tour of greece, meeting heinrich schliemann in Athens and visiting his sites. Seeing preclassical Mycenean civilization captured and kept Evans's interest for the rest of his life. He returned to England to become keeper of the ashmolean museum in Oxford, restoring its collections and rehousing them in a new building. In 1894, a year after the death of his wife, Evans traveled to Crete for the first time.

His subsequent passion for Cretan archaeology was the result of his interest in the nature and extent of oriental influences on the cultures of early Europe. He returned to Crete in 1895 and 1896 and successfully negotiated the purchase of one-quarter of Kephala Hill at Knossos from its Turkish owner. He was able to purchase the rest in 1899 after the Turks had been driven from Crete as a reward for his public support of Greek independence.

Evans and his colleage david hogarth established a Cretan Exploration Fund, with links to the British School in Athens, and with Evans's private resources began to excavate. In the first year, the general plan of the Bronze Age palace of knossos was uncovered, and the “throne room” and “magazines” were revealed. Other finds included the first of the marvelous frescoes, traded items from Egypt and babylon, and tablets covered with linear script. Intensive excavation of the site continued for the next eight years and was largely financed by Evans, whose success at Knossos encouraged more excavations on Crete and in Greece proper.

Of equal importance to his excavations were Evans's self-funded efforts to restore the palace of Minos. Although Evans's motivations were to make the site comprehensible to others and to stabilize it, he was greatly criticized for compromising conservation in favor of restoration and worked at the site to that end until 1931. Between 1921 and 1936, Evans's most enduring legacy, the book *The Palace of Minos at Knossos,* was published.

Evans resigned from the Ashmolean in 1908 and worked for the Hellenic Society and the British Schools in Athens and Rome. He transferred all of his property on Crete to the British School in Athens, and during the Versailles Peace Conference after World War I, he tirelessly lobbied the British government to support an independent Yugoslavia. He was an accomplished draftsman, numismatist, collector, and excavator, and his artistic tastes were matched by his deductive flair. His development of the chronology of Knossos was a tour de force.

Evans, Sir John

(1823-1908)

Born in Buckinghamshire, England, and educated at his headmaster father's school, John Evans intended to go to Oxford but instead traveled to Germany. On his return in 1840, he joined his uncle's paper-manufacturing business, John Dickinson and Company, of which he became a partner in 1850. Although he was an excellent businessman, and did not retire from the company until 1885, he also pursued many interests that lay outside the field of his employment. These included geology and palaeontology, which led him to accompany geologist sir joseph prestwich to France, as an assistant, to visit French palaeontogist jacques boucher de perthes and examine chipped flints from the Somme gravels.

Evans and Prestwich were convinced that the stone tools were indeed proof of human antiquity in western Europe, and Evans began to collect stone and bronze implements, to visit cave sites, and to publish his findings. Evans also collected and published on fossil remains of extinct animals and the provenance, typology, and distribution of medieval antiquities, Anglo-Saxon and Lombardic jewelry, posy-rings, bronze weapons, and ornaments. His real area of expertise was in numismatics, and his collections of ancient British money, Roman emperor gold coins, and Anglo-Saxon and English coins were unique. He also contributed more than a hundred items to the *Numismatic Chronicle* and the standard works on British coins.

Evans was elected a fellow of the Royal Society in 1864 and was the society's vice-president from 1876

to 1878 and then its treasurer from 1878 to 1898. He was president of the Geological Society from 1874 to 1876, and in 1880, he received the Lyell Medal for his services to geology, particularly post-tertiary geology, and for developing the relationship between archaeology and geology. At various times in his busy life, he was a member and president of the society of antiquaries of london, the Numismatic Society of London, the Anthropological Institute, the egypt exploration society, the Society of Arts, the Paper-makers Association, and the British Association. He was also a trustee of the british museum and was awarded many academic honors in England and abroad, as well as being on one occasion high sheriff of Hertfordshire. He left his collections to his son sir arthur evans, who in turn presented portions of them to the ashmolean museum in Oxford.

Falconer, Hugh

(1808-1865)

Born in Scotland, Hugh Falconer graduated from Aberdeen University in 1826. Despite his interests in botany, geology, and paleontology, he went to Edinburgh University to study medicine. After graduating, and before taking up a position as surgeon with the East India Company, he spent a year in London working with the botanist Nathanial Wallich and with William Lonsdale, curator for the Geological Society of London. It was through these contacts that he finally traveled to India as a botanist rather than as a doctor.

Falconer eventually became superintendent of the East India Company's botanical gardens at Saharanpur in northern India, which allowed him to also pursue his interests in natural history in the nearby Siwalik Hills, which he dated to the Tertiary period. With the help of a military engineer, Falconer recovered a series of wonderful fossil mammals and reptiles from sites in the hills, for which he and the engineer were awarded the Geological Society of London's Wollaston Medal in 1837. Falconer's work in northern India stimulated his interest in the issue of human antiquity.

Because of illness, Falconer spent the years between 1838 and 1847 in London working on his collections at the British Museum. He returned to India and served as the superintendent of the Royal Botanic Gardens in Calcutta until 1855 when he retired from colonial service. Back in London, Falconer took up full-time paleontological research, examining fossil faunal assemblages from caves across Europe. In 1858 he met the Cornish archaeologist william pengelly, and together they excavated brixham cave in Devon.

The results of these excavations had consequences for the extension of human antiquity, as they provided evidence for the coexistence of human beings with extinct mammals. It was with Falconer's support that geologist sir joseph prestwich and the archaeologist sir john evans demonstrated the similarity of evidence from Brixham Cave with evidence from open sites in the Somme River valley found by the French paleontologist jacques boucher de perthes. In 1860, Falconer provided even more evidence for human antiquity through his discoveries of material at the Grotta di Maccagnone near Palermo, Sicily.

Falconer was also deeply involved in resolving the moulin quignon controversy concerning the authenticity of human remains found France in 1863 and with the first description of the Gibraltar skull and site in 1864. He received the Royal Society's Copley Medal in 1864, was elected to the Royal Society in 1845, and was its vice-president when he died in London.

Florida and the Caribbean Basin, Historical Archaeology in

The post-1492 history of the Caribbean Basin has been largely defined by colonialism. It has the longest colonial history in the Americas, with the first European colony in the region established in 1493 and the last European colonies and American commonwealths remaining there until 1995. This time depth is accompanied by a cultural diversity unparalleled elsewhere in the post-Columbian Americas. The Caribbean Basin is the only region in the hemisphere in which American Indian, Spanish, French,

English, Danish, Dutch, African, and Euro-American people established societies and claimed political dominion during the colonial era. At least partly because of this complexity, relatively few historians and even fewer archaeologists have treated the circum-Caribbean area as a coherent unit (for one of a number of exceptions see Williams 1970). Instead, its written history-to which historical archaeology is inextricably linked-has been largely defined and organized by discrete episodes of European and North American intervention and involvement in the region.

Historical archaeology as used here refers to the archaeological investigation of sites occupied after 1492 for which both written documents and European technology are pertinent to interpretation. This endeavor has been largely a twentieth-century phenomenon not only in the Caribbean region but throughout the Americas as well. Both avocational and professional historical archaeologists in the Caribbean Basin and Florida have addressed questions related to an exceptionally diverse array of cultural and ethnic groups, time periods, site types, historical

Florida and the Caribbean Basin, Historical Archaeology in

The post-1492 history of the Caribbean Basin has been largely defined by colonialism. It has the longest colonial history in the Americas, with the first European colony in the region established in 1493 and the last European colonies and American commonwealths remaining there until 1995. This time depth is accompanied by a cultural diversity unparalleled elsewhere in the post-Columbian Americas. The Caribbean Basin is the only region in the hemisphere in which American Indian, Spanish, French,

English, Danish, Dutch, African, and Euro-American people established societies and claimed political dominion during the colonial era. At least partly because of this complexity, relatively few historians and even fewer archaeologists have treated the circum-Caribbean area as a coherent unit (for one of a number of exceptions see Williams 1970). Instead, its written history-to which historical archaeology is inextricably linked-has been largely defined and organized by discrete episodes of European and North American intervention and involvement in the region.

Historical archaeology as used here refers to the archaeological investigation of sites occupied after 1492 for which both written documents and European technology are pertinent to interpretation. This endeavor has been largely a twentieth-century phenomenon not only in the Caribbean region but throughout the Americas as well. Both avocational and professional historical archaeologists in the Caribbean Basin and Florida have addressed questions related to an exceptionally diverse array of cultural and ethnic groups, time periods, site types, historical

questions, and anthropological problems over the past century, during which changing social philosophies, national interests, and technologies have additionally affected the orientations and outcomes of archaeology (*see* Patterson 1991; Sued Badillo 1996). Despite recent criticism that historical archaeology in the region has been unfruitful and dominated by concerns defined by European hegemony (Sued Badillo 1992), twentieth-century historical archaeological research in Florida and the Caribbean has, in fact, addressed questions of internal development, indigenous American identity and colonialism for several decades.

The following discussion of the history of that work in the Caribbean and Florida is ordered in a general way by the chronology of archaeological research in the region; however, it should be emphasized that equally important organizational distinctions for historical archaeology in the Caribbean are provided by the dominant postcontact cultural distinctions of the region-that is, American Indian, African, Spanish, French, English, and Dutch-as well as by the traditional geographic distinctions-that is, the Lesser Antilles, the Greater Antilles, the Bahamas, Florida, and the mainland Caribbean coasts. These will be incorporated as necessary.

The chronology of circum-Caribbean historical archaeology is organized here for convenience by four somewhat artificial and overlapping periods, which nevertheless correspond roughly to paradigmatic and political developments in the region. These include: (1) the period before 1935 and the formalization of professional archaeology, (2) the years of ca. 1935-1970, (3) the period between ca. 1970 and 1990, and (4) the Quincentennial-dominated post-1985 period.

Historical Archaeology before 1935

A few essentially archaeological studies of post-Columbian sites took place in Florida and the Caribbean before 1930; however these were generally undertaken by historians or other nonspecialists to commemorate the anniversary of a historic event or a famous European person. In 1767 for example, the French geographer Moreau de St. Mery attempted through survey and collection to locate and identify the site of La Navidad, the first fort that Columbus was forced to establish in Haiti after the wreck of the *Santa Maria* in 1492. In the process, he inadvertently identified the site of Puerto Real, a sixteenth-century Spanish town, as La Navidad (Moreau de St. Mery 1958; Hodges 1995). Another early archaeological effort to study Columbus was that commissioned by the North American Commission for the Observance of the Columbian Quadricentennial in 1891. The U.S. Navy vessel *Enterprise* was sent to the site of La Isabela in the Dominican Republic, which was the first settlement intentionally established by Christopher Columbus in the Americas. The site was surveyed, mapped, and described by Navy Lt. Colvocorresses (Thatcher 1903).

Little historical archaeology was attempted in Florida or the Caribbean Basin during the early twentieth century, and most information about postcontact archaeological sites was buried as footnotes or ancillary observation in studies of pre-Columbian sites (e.g., Hatt 1932). One notable exception to this was the work of William Goodwin in Jamaica. A businessman who went to the West Indies in 1915 to recover from nervous prostration, Goodwin began a long-term study of the early Spanish and English ruins of Jamaica, occasionally studying presumed Spanish ruins in Florida as a comparison (Goodwin 1946). Between 1911 and 1937 he mapped and excavated a series of colonial sites on the island, including what was probably the first underwater search for Columbus's caravel ships (Goodwin 1946, 46-55), and collaborated with local collectors and antiquarians to document many of Jamaica's historic colonial remains. It was not until after 1935, however, that the largely idiosyncratic interest in monumental sites and highly visible historical events manifested by nineteenth- and early-twentieth-century investigators coalesced into the discipline of archaeology in Florida and the Caribbean. From this time onward, historical archaeology was practiced consistently, if eclectically, in the region.

questions, and anthropological problems over the past century, during which changing social philosophies, national interests, and technologies have additionally affected the orientations and outcomes of archaeology (*see* Patterson 1991; Sued Badillo 1996). Despite recent criticism that historical archaeology in the region has been unfruitful and dominated by concerns defined by European hegemony (Sued Badillo 1992), twentieth-century historical archaeological research in Florida and the Caribbean has, in fact, addressed questions of internal development, indigenous American identity and colonialism for several decades.

The following discussion of the history of that work in the Caribbean and Florida is ordered in a general way by the chronology of archaeological research in the region; however, it should be emphasized that equally important organizational distinctions for historical archaeology in the Caribbean are provided by the dominant postcontact cultural distinctions of the region-that is, American Indian, African, Spanish, French, English, and Dutch-as well as by the traditional geographic distinctions-that is, the Lesser Antilles, the Greater Antilles, the Bahamas, Florida, and the mainland Caribbean coasts. These will be incorporated as necessary.

The chronology of circum-Caribbean historical archaeology is organized here for convenience by four somewhat artificial and overlapping periods, which nevertheless correspond roughly to paradigmatic and political developments in the region. These include: (1) the period before 1935 and the formalization of professional archaeology, (2) the years of ca. 1935-1970, (3) the period between ca. 1970 and 1990, and (4) the Quincentennial-dominated post-1985 period.

Historical Archaeology before 1935

A few essentially archaeological studies of post-Columbian sites took place in Florida and the Caribbean before 1930; however these were generally undertaken by historians or other nonspecialists to commemorate the anniversary of a historic event or a famous European person. In 1767 for example, the French geographer Moreau de St. Mery attempted through survey and collection to locate and identify the site of La Navidad, the first fort that Columbus was forced to establish in Haiti after the wreck of the *Santa Maria* in 1492. In the process, he inadvertently identified the site of Puerto Real, a sixteenth-century Spanish town, as La Navidad (Moreau de St. Mery 1958; Hodges 1995). Another early archaeological effort to study Columbus was that commissioned by the North American Commission for the Observance of the Columbian Quadricentennial in 1891. The U.S. Navy vessel *Enterprise* was sent to the site of La Isabela in the Dominican Republic, which was the first settlement intentionally established by Christopher Columbus in the Americas. The site was surveyed, mapped, and described by Navy Lt. Colvocorresses (Thatcher 1903).

Little historical archaeology was attempted in Florida or the Caribbean Basin during the early twentieth century, and most information about postcontact archaeological sites was buried as footnotes or ancillary observation in studies of pre-Columbian sites (e.g., Hatt 1932). One notable exception to this was the work of William Goodwin in Jamaica. A businessman who went to the West Indies in 1915 to recover from nervous prostration, Goodwin began a long-term study of the early Spanish and English ruins of Jamaica, occasionally studying presumed Spanish ruins in Florida as a comparison (Goodwin 1946). Between 1911 and 1937 he mapped and excavated a series of colonial sites on the island, including what was probably the first underwater search for Columbus's caravel ships (Goodwin 1946, 46-55), and collaborated with local collectors and antiquarians to document many of Jamaica's historic colonial remains. It was not until after 1935, however, that the largely idiosyncratic interest in monumental sites and highly visible historical events manifested by nineteenth- and early-twentieth-century investigators coalesced into the discipline of archaeology in Florida and the Caribbean. From this time onward, historical archaeology was practiced consistently, if eclectically, in the region.

out in Florida and the Caribbean during the 1930s and 1940s, most of it devoted to the Spanish colonial presence in the region, and much of it dominated by North American concerns. These projects reflect the diffuse nature of American historical archaeology at that time, both in the reasons for doing archaeology and in the people who did it. Avocational archaeologists, for example, played a central role during this period in the development of historical archaeology in the region.

A major emphasis was the study of monumental sites for purposes of historical interpretation, not only by archaeologists but often by historians or architects. Other concerns of the period addressed primarily by archaeologists were questions of artifact classification and chronology and of Spanish influence on, and the acculturation of, the American Indians of the region. All of these themes have endured as important emphases in the historical archaeology of Florida and the Caribbean to the present day.

Three developments in the United States at this time shaped the direction of historical (and pre-Columbian) archaeology. The establishment of the society for american archaeology in 1935 marked the formalization of professional archaeology in the Americas. Although prehistory was the primary concern of the Society, its establishment focused professional consensus on appropriate archaeological questions and methodologies, which in 1935 were predominantly those of classification and chronology (*see* Dunnell 1986; Willey and Sabloff 1980, 73-74). This coincided with the establishment of the United States Works Progress Administration Program of the 1930s, which provided some of the first opportunities to develop and implement these archaeological methodologies on historic sites.

The end of this period was marked by the emergence of historical archaeology as a recognized discipline, signaled by the establishment of the Conference on Historic Sites Archaeology. This annual conference was first organized by Stanley South in 1960, and was held in conjunction with the Southeastern Archaeological Conference (*see* South 1994). Florida historical archaeologists John Goggin, John Griffin, Hale Smith and Charles Fairbanks were particularly active in the conference, and the first four conference proceedings were published in the *Florida Anthropologist.* During the 1960s the conference was largely devoted to what Goggin called the “brass tacks” of historical archaeology, “to the kind of details that archaeologists deal with. In other words my feeling is that as archaeologists we deal with artifacts, and with few exceptions colonial artifacts have not been analyzed or classified by a method suitable for the archaeologists to handle” (South 1964, 34). Resolving this problem was to be one of the enduring themes of historical archaeology after 1960.

The Development of Enduring Themes: Spanish Towns and Monuments

St. Augustine, Florida-the United States' oldest European settlement-was an early beneficiary of the U.S. Works Progress Administration program. A program of survey, excavation, and study of historical resources was undertaken jointly from 1935 to 1937 by the Federal Works Project Administration, the Carnegie Institution of Washington, D.C., and the St. Augustine Historical Society. The work was explicitly multidisciplinary, involving archaeologists, historians, and architects, and it emphasized monumental sites in its attempt to archaeologically study and partially reconstruct the Spanish defensive systems in the colony (Chatelaine 1941). The archaeological program initiated in St. Augustine during this period has continued to the present day, evolving to incorporate questions of Spanish acculturation and the development and recognition of colonial identity (see Cusick 1994; Deagan 1983; Deagan 1991).

Interest in monumental sites associated with early Spanish presence was sustained throughout the period, often in support of restoration and public interpretation of sites. The historical archaeology of the sites of forts and towns in Florida during this period was continued in St. Augustine at the Castillo de San

Marcos in 1947 and 1953 and at several domestic sites in the town by Smith and Griffin (*see* Deagan 1991, xvi-xvii; xxv-xxiv). Elsewhere in Florida, investigation was initiated at other seventeenth- and

began in Santo Domingo, in support of restoration and interpretation efforts of the sixteenth-century section of the city. Excavations during this time contributed primarily to the mitigation of threatened sites, the interpretation of Spanish colonial presence to the tourist public, and the beginnings of the systematization of Spanish colonial material culture. The results of much of this work are summarized in a large and varied literature (*see* Nieves Sicart 1980; Ortega 1982; Pérez Montás 1984). Archaeology in Santo Domingo continued into the 1990s with much the same objectives, and was greatly stimulated in the 1980s by the observation of the Columbian Quincentenary (Veloz Maggiolo and Ortega 1992).

Spanish-Indian Interaction and Transculturation

Not all of the historical archaeology in Florida and the Caribbean was oriented toward descriptive or restoration goals during this period. Several pioneers of American historical archaeology, including Griffin, Smith, Goggin, José Cruxent, Francisco Prat Puig and Fairbanks developed active programs in Florida and the Caribbean between 1940 and 1960. They were explicitly interested in the mechanisms and consequences of European-American Indian contact, primarily from the perspective of the American Indians (see Smith 1956).

Among the most important elements of these programs were the Florida missions, which provided the focus for some of the first anthropologically oriented historical archaeology in the United States. In 1934, a historic-period Indian burial ground was discovered on the grounds of the Fountain of Youth Park tourist attraction in St. Augustine by archaeologist J. Ray Dickson, and the site was identified by smithsonian institution archaeologist Matthew Stirling as a probable Spanish mission. Archaeological and physical anthropological research at the mission site and surrounding areas has been carried out at the site intermittently since then for more than sixty years, not only focusing on the Timucua village associated with the mission, but also locating the original site of St Augustine (Chaney and Deagan 1989).

The focus of mission archaeology was explicitly defined by Griffin and Smith during the 1940s when they undertook the study of several seventeenth-century Spanish missions in order to better understand the responses of the Florida Indians to Spanish colonization and evangelization (Boyd, Smith, and Griffin 1951; Smith 1956). Recent assessments of this work, as well as syntheses of mission archaeology into the 1990s can be found in Thomas 1990, among others.

Questions of interaction and transculturation between Spaniards and American Indians in settings other than missions were the focus of considerable archaeological attention during the 1930s and 1940s, and were centered on Cuba, due largely to the influence of anthropologist Fernando Ortíz. Not only were a number of contact period Indian sites located and recorded, but some of the first explicit theoretical attention was paid to the processes of transculturation in the contact period (Ortíz 1983). This was largely owing to the activities of the Grupo Guamá, an organization of archaeologists committed to the archaeological investigation of Caribbean history, prehistory, and art. Organized and based in Cuba, the group also included archaeologists from the Dominican Republic, Venezuela, and North America, and sponsored projects and expeditions throughout the Caribbean Basin. The Grupo Guamá was active during the 1940s and 1950s, and during that time laid the groundwork for much subsequent Spanish colonial and contact-period Taino archaeology in the West Indies. This emphasis, too, has continued in Cuba to the present time (*see* Dominguez and Pantoja 1992; Fariñas Gutierrez 1992).

Tools of Chronology and Classification

A significant amount of pre-1970 historical archaeology in Florida and the Caribbean was undertaken specifically to develop classificatory and chronological tools. The most notable and broadly based of these efforts were Goggin's comprehensive studies of Spanish majolica (a tin-enameled earthenware

pottery) and Spanish Olive Jars (storage containers) (Goggin 1960a, and 1958, respectively). Goggin not only drew from existing collections but also initiated surveys,

began in Santo Domingo, in support of restoration and interpretation efforts of the sixteenth-century section of the city. Excavations during this time contributed primarily to the mitigation of threatened sites, the interpretation of Spanish colonial presence to the tourist public, and the beginnings of the systematization of Spanish colonial material culture. The results of much of this work are summarized in a large and varied literature (*see* Nieves Sicart 1980; Ortega 1982; Pérez Montás 1984). Archaeology in Santo Domingo continued into the 1990s with much the same objectives, and was greatly stimulated in the 1980s by the observation of the Columbian Quincentenary (Veloz Maggiolo and Ortega 1992).

This emphasis, too, has continued in Cuba to the present time (*see* Dominguez and Pantoja 1992; Fariñas Gutierrez 1992).

Tools of Chronology and Classification

A significant amount of pre-1970 historical archaeology in Florida and the Caribbean was undertaken specifically to develop classificatory and chronological tools. The most notable and broadly based of these efforts were Goggin's comprehensive studies of Spanish majolica (a tin-enameled earthenware

pottery) and Spanish Olive Jars (storage containers) (Goggin 1960a, and 1958, respectively). Goggin not only drew from existing collections but also initiated surveys,

surface collections, and excavations throughout Florida and the Caribbean between 1949 and 1957 in order to recover well-dated samples of majolica to use in a dated typological seriation (Goggin 1968). The result was a detailed classification of majolica using the then-standard North American Midwestern Taxonomic system. Despite criticism of his typological system, Goggin's majolica study has remained a reliable classificatory and dating system since its publication, with only minor revision (Deagan 1987).

Sunken Towns and Ships

Systematic underwater historical archaeology in Florida and the Caribbean began during the 1950s with a series of investigations loosely coordinated by Mendel Peterson of the Smithsonian Institution (see Peterson 1965, 5-17). Various shipwrecks, including those of the Spanish treasure fleets and British privateers sunk in Florida were studied; however the most important project of this period was at the sunken city of Port Royal, Jamaica. The British colonial city was plunged into the sea by an earthquake in 1692 and remained submerged as a seventeenth-century time capsule. Edwin and Marion Link, avocational archaeologists working with Peterson and a team of U.S. Navy divers, began investigation of the site in 1956 to identify sunken structures and recover evidence of life in seventeenth-century Port Royal (Link 1960).

Archaeological research at the site has continued to the present day under the auspices of the Jamaican government, carried out from 1965 to 1968 by Robert Marx (Marx 1973), and during the 1980s and 1990s by the Institute for Nautical Archaeology at Texas A&M University under the direction of Donald Hamilton (Hamilton 1992). Through Texas A&M's involvement, Port Royal became the site of one of the few academic field training programs in underwater archaeology in the Americas. Port Royal is also one of the few colonial sites in the hemisphere at which underwater and terrestrial excavations have been conducted simultaneously, in order to coordinate the study of submerged remains with those buried remains not drowned by the 1692 earthquake.

Meanwhile in Florida, developments in shipwreck excavation shaped a very different kind of trajectory for underwater archaeology in the state, which until recently was defined by the search for sunken treasure. The first organized treasure hunting consortium in Florida, Real Eight, was formed during 1959 and 1960 through the efforts of Kip Wagner and Mel Fischer. Real Eight received permits from the State of Florida to salvage several wrecks off the east coast, with 25 percent of the recovered value going back to the State of Florida. Archaeologists Goggin and William Sears provided oversight for both the projects and the division of remains, but by 1964 fiscal and contractual problems resulted in the appointment of Florida's first State Underwater Archaeologist, Carl Clausen (*see* Burgess and Clausen 1982; Wagner and Taylor 1972). The State Underwater Archaeologist was assigned to manage and oversee the study and salvage of Florida's marine resources, and the position as well as the permitting partnerships have been maintained since that time.

One consequence of these early developments in Florida's marine archaeology program was the sustained interest of Goggin in underwater archaeology. Goggin and Fairbanks encouraged the incorporation of submerged archaeological data with terrestrial research in a way that has rarely been seen since that time. Goggin's early interest in underwater historical archaeology was focused on a variety of sites and materials submerged in rivers and springs, including isolated finds, mission refuse, Seminole materials, and abandoned settlements (Goggin 1960b; Fairbanks 1964).

Despite the level of activity and the diversity of interests in the historical archaeology of Florida and the Caribbean during the period from 1935 to 1970, the field was not formally recognized as a coherent school, specialty, or subdiscipline within the wider archaeological community until the 1960s. The Conference on Historic Sites Archaeology was organized by Stanley South and many of the Florida

historical archaeologists (*see* South 1994), publishing its first several proceedings in the *Florida Anthropologist.* The primary professional organ for

Caribbean archaeology was not established until 1965 with the name "The International Congress for the Study of pre-Columbian Man in the Lesser Antilles," and the first congress paper with an explicitly historical-archaeological theme was not included in the Congress Proceedings until 1977 (Garcia Arévalo1978b). In 1979 the archaeologists in the region decided to change the name of the congress to "The International Congress for Caribbean Archaeology" to reflect the broader temporal and geographical interests of archaeology in the Caribbean that developed after 1970.

Historical Archaeology, 1970-1990

Historical archaeology in both Florida and the Caribbean region expanded considerably in scope and in intensity after 1970 as a consequence of political and professional developments at both the international and regional levels. The decade of the 1960s was one of widespread political change in the Caribbean, with seven British colonial nations gaining independence between 1962 and 1974 and the communist revolution in Cuba in 1959. These events ultimately directed historical archaeology toward questions of colonialism and American cultural identity near the end of the period.

One of the most influential professional developments was the gradual formalization through the 1960s of American historical archaeology as a distinct discipline, with the expansion of the Conference on Historic Sites Archaeology, and the formal establishment of the society for historical archaeology in 1967 (*see* South 1994). The latter event marked the advent of a conscious self-identification of historical archaeology as a social science distinct from both prehistoric archaeology and from history, with its own set of theoretical and methodological principles, and therefore a distinct set of guiding questions. One of the most important of these for historical archaeology in the circum-Caribbean was the explicit general recognition that the encounter between Europe and America-which first took place in this region-was one between literate and nonliterate people, and that systematic investigation of that world-changing process required both archaeological and documentary information. Historical archaeology was the only field that developed and articulated such an approach.

Archaeologists working in Cuba had been among the first to explicitly address these issues, as well as others that focussed on colonialism. The Cuban revolution of 1958 promoted active attention among Cuban historians and archaeologists toward questions of cultural origins and national identity. For much of the subsequent three decades, during which cold war politics dominated the globe, Cuban historical archaeology was relatively isolated from the rest of the Caribbean. Cuban archaeologists during this period continued to work on the questions of transculturation and social dynamics posed during the previous period by the Grupo Guamá, but their inquiries came to be informed by Marxist theory and a concern with the dialectics of property and class considerably before these paradigms emerged in mainstream American archaeology.

The formalization of historical archaeology coincided with the emergence and general acceptance of what came to be known as the new archaeology, which called for attention to dynamic cultural processes rather than to the structural culture histories that had dominated earlier periods (*see* Dunnell 1986). These concerns had a profound effect on the kinds of questions asked by historical as well as pre-Columbian archaeologists in Florida and in the Caribbean, and in the methods used to answer them. Subsistence strategies and environmental adaptations, for example, figured prominently in frameworks for investigation, and required the incorporation of multidisciplinary specialists in the natural sciences in addition to those in history and architecture. Although some interdisciplinary research, such as Elizabeth Wing's pioneering study of food remains from Nueva Cádiz (1961), had been carried out in the Caribbean and Florida before 1970 the involvement of multidisciplinary scholars did not become standard in the historical archaeology of the region until after about 1975.

A third important influence on historical archaeology throughout the Americas during this period was the increased consciousness of and

PREV NEXT

legal attention to cultural resources management issues. This was particularly influential in those areas under formal U.S. government jurisdiction after the passage of the Moss-Bennett Bill in 1974, as well as in Cuba after the establishment of the Castro government. Although legislation mandating survey and mitigation of archaeological sites was not universal throughout the Caribbean, the management of cultural resources for the preservation of cultural patrimony and the potential for tourism was nearly so.

Serious attention was given to the definition of national identities and the management of historic sites, and this encouraged the development of programs throughout the region that were designed to recover information relevant to public interpretation.

Developments in marine archaeology during this period were closely tied to the management of historical archaeological resources on land. Research-oriented archaeology of shipwrecks evolved into an important, if controversial, emphasis in the historical archaeology of Florida and the Caribbean during the period from 1970 to 1990, paralleled by an even greater growth in treasure hunting and salvaging of shipwrecks for commercial reasons.

These developments directed the course of historical archaeology in Florida and the Caribbean after 1970 in several ways. One was by encouraging explicitly historical archaeological research unrelated to the specific concerns of prehistoric archaeology or of historic monument restoration, and by placing stronger emphasis on systemic questions of encounter and acculturation, colonialism, capitalism, and slavery, and less emphasis on chronology and classification. Archaeologists in general became more interested in cross-cultural studies as a way to address some of these questions, and increasingly turned archaeological attention to non-Spanish and postcolonial historic sites for the first time. This broadening of focus was also encouraged by the requirements of cultural resources management programs aimed at cultural patrimony in newly independent nations, which brought attention to bear on both non-Spanish and post colonial sites. This trend has been perhaps most notable in the initiation and rapid growth of effort devoted to African-American archaeology since 1970.

It should be noted that a number of programs continued research after 1970 to refine and enhance the understanding of historic material culture classification, chronology, and interpretation. Such efforts built upon and extended the work begun in the previous period (*see* Cruxent and Vaz 1975; Deagan 1987; Marken 1994).

The formalization of historical archaeology as an entity was reflected in both Florida and the Caribbean during this period in the training of archaeologists. Formal training in historical archaeology was provided at the state universities of Florida by Fairbanks, Smith, and Griffin and led to many of the historical archaeological programs ongoing in the Caribbean and Florida. Another training program with far-reaching influence on Caribbean historical archaeology was the *Curso de restauracion de bienes muebles especializado en ceramologia historica.* This program was established in Panamá in 1974 under the auspices of the Organization of American States and the Instituto de Cultura de Panamá, and continued for a decade under the direction of José M. Cruxent (Cruxent 1976, 1980).

Basic methods for excavation methodology and artifact classification-including those of historical archaeology-were taught in the program, which trained archaeological technicians from throughout Latin America and the Caribbean.

Cultural Resources Management

In some areas, such as San Juan, Santo Domingo, and St. Augustine, management programs built upon the studies of monumental sites that dominated the pre-1970 period, and were intensified by formal programs of cultural resources management. In other areas, programs of urban cultural resources

management archaeology began during this period, including in Havana (Cuba), Pensacola (Florida), and Spanish Town (Jamaica). In all of these areas historical archaeologists are still attempting to accompany the rapid growth and development in these cities, to salvage sites, and to trace the cities' architectural and economic evolution.

PREV NEXT

The 1970s also marked the initiation of programs that concentrated on rural sites and regional landscapes in areas occupied by English, Dutch, African, and French colonists. The impetus for these efforts was often provided initially by historical architects in the region, working with international and national historic preservation organizations such as the International Council of Monuments and Sites (ICOMOS), the Organization of American States (OAS) and the United Nations Educational, Scientific and Cultural Organization (UNESCO). Between 1978 and 1982 historic preservation architects and archaeologists from throughout the Caribbean, coordinated by Eugenio Pérez Montás of the Dominican Republic, worked on the development of a region-wide plan for historic preservation. Plan CARIMOS (Plan for Monuments and Sites in the Wider Caribbean) was formalized at the University of Florida in 1982, with its seat established in Santo Domingo. Since that time, CARIMOS, working with the OAS, UNESCO,ICOMOS, and the University of Florida's Preservation Institute-Caribbean (PIC) has been an important force in the intensification and diversification of historical archaeology throughout the Caribbean. (For summaries of CARIMOS activities *see* Pérez Montás 1991.)

Underwater Archaeology

Much of the marine archaeology during the period from 1970 to 1990 also developed in the context of the management of resources for public interpretation and, with the exception of Port Royal, was dominated by shipwrecks of the Spanish treasure fleets and explorers (see Burgess and Clausen 1982; Borrell 1983; Marx and Marx 1993; Smith 1993). The necessity for protecting underwater resources and developing a broad base of public support for noncommercial marine archaeology led to programs of site protection and public interpretation throughout the region. In some areas, such as the Dominican Republic and Florida, a significant part of underwater archaeology was carried out through joint efforts between private salvers, recreational sport divers, and government archaeological agencies. The Comisión de Rescate Arqueólogico Submarino was established in the Dominican Republic in 1979 to oversee the management and study of the submerged historic resources of the Dominican Republic. The Comisión, coordinated by Pedro Borrell, worked closely with the Grupo de Investigaciones Submarinas, Inc., a group of professional and avocational divers and archaeologists, and the commercial firm of Caribe Salvage, Inc. to study and interpret many of the vast number of shipwrecks along the country's north coast (see Borrell 1983). This ongoing effort is still under way.

Florida during this period was the location of some of the earliest underwater historical archaeological parks in the region. The U.S. National Park Service established Fort Jefferson National Monument (today known as Dry Tortugas National Park) near Key West in 1935, and Biscayne National Park in southeast Florida in 1968. Underwater surveys were first undertaken at these sites in 1970 and 1975 by George Fischer of the National Park Service, and continue.

Shipwrecks in Florida were both studied and salvaged (often simultaneously) during this period. Although most of the shipwrecks were investigated by private salvage companies operating under permits issued by the state, academic and governmental research programs increased toward the end of the period. Unlike the initial days of public-private partnerships, the projects of the 1970s and 1980s, such as the excavation of the controversial *Atocha,* were often conducted by professional marine archaeologists working for private companies (Matthewson 1986). A heated debate over the conduct and ethics of underwater archaeology for commercial purposes was born during the 1970s, centering on the issues of professional methods and the ethics of selling artifacts. The debate remains vigorously unresolved.

The Institute of Nautical Archaeology (INA) at Texas A&M University, through the efforts of George Bass, Donald Keith, and Donny Hamilton, was also an important influence on the development marine archaeology in the Caribbean and in Florida during this period. Through the 1980s INA initiated a series

of academic marine survey and study projects in the Caribbean that were intended to illuminate the evolution of ship architecture and maritime economy in the region.

Late-fifteenth and early-sixteenth-century ships of discovery and exploration provided a primary focus for the INA efforts, at least partly in anticipation of the 1992 Quincentenary of Columbus's voyages of exploration. Survey and testing were carried out in the Dominican Republic, Jamaica, the Bahamas, and Panamá.

Crewmen on a commercial salvage expedition lift a bronze cannon, believed to be from the galleon Atocha. The Atocha, which sank in a hurricane in 1622, was believed to be carrying $100 million in gold and silver.

(© Bettmann/Corbis)

Programs of marine archaeology were begun in several non-Spanish areas of the Caribbean toward the end of the period between 1970 and 1990 (*see* Bequette 1991), offering a systematic basis for international comparisons of circum-Caribbean maritime technology and economy.

Transculturation, Adaptation, and the Euro-American Experience

The emphasis on culture contact and interaction exhibited by archaeologists during the period from 1970 to 1990 had strong roots in the previous period, particularly in the research of the Grupo Guamá and the work in the Florida missions. Unlike historical archaeology in the earlier period, however, research on European-American contact and interaction after 1970 was concerned with adaptations in Euro-American as well as in Native American society. This interest corresponded in the Caribbean to the increasing influence of nationalism that pervaded the Caribbean after World War II and particularly through the 1960s (see Sued Badillo 1996; Williams 1970, 463-478).

Long-term multidisciplinary programs of historical archaeology were undertaken in several Spanish-American town sites, building on work begun in the previous period. While the pre-1970 projects had been devoted primarily to the excavation and reconstruction of monumental remains, the later projects were intended to better understanding of the adaptive processes and resulting Creole cultural forms of post-Columbian America (*see* Deagan 1988), and were often carried out by interdisciplinary teams of researchers. These have included Santo Domingo (1502-present) and Concepción de la Vega (1498-1562) in the Dominican Republic, Puerto Real in Haiti (1503-1578), Havana, Cuba (1511-present), St. Augustine, Florida (1565-1763), and Sevilla Nueva, Jamaica (1510-1535).

Research in these towns has concentrated on cultural interaction among Spanish, American Indian, and African residents and the resulting syncretic and newly developed *criollo* forms. In all of the excavations that have been so far reported from these sites, a pattern of differential adoption and incorporation of Amerindian and/or African traits along gender lines has been documented in Spanish households. The archaeological record suggests that this admixture included the incorporation of Amerindian elements in non-socially visible, infrastructural areas, such as diet and food preparation, while visible symbols of social identification remained rigidly Spanish. Even after the extinction of the native Taino and related Amerindian people in the Caribbean, Spanish colonists continued to incorporate non-European traits into their households, replacing Indian contributions with African.

Subsistence studies have been central to these interpretations. Faunal analysis in historical archaeology was pioneered during the 1970s by Elizabeth Wing (1961, 1989) and her students working in Florida and the Caribbean, notably Elizabeth Reitz (1979, 1990). Zooarchaeological analysis is now a standard part of historical archaeology throughout the region. The use of floral remains has been an even more recent development.

The Non-Spanish Caribbean

The attention to multicultural transculturation and integration that has pervaded the post-1970 historical archaeology of Spanish-occupied areas has not been as pronounced in the English, French, or Dutch colonial sites of the region. This is at least partly owing to the developmental histories of both Euro-American societies in these areas and the historical archaeology that occurred there. By the time many of the seventeenth-century English, French, and Dutch colonies were established, the resident Amerindian populations had been severely decimated, thereby reducing the opportunities for cultural exchange. The populations of these areas came quickly to be dominated by people of African origin, brought for the most part unwillingly to the Caribbean and Florida as slaves (see Dunn 1972). The non-Spanish colonial occupations of the Caribbean and Florida Basin were furthermore dominated by dispersed plantation systems, in contrast to the more centralized towns that characterized the Spanish colonies, and this led to different approaches to the archaeological database.

Systematic historical archaeology first took place in these areas during the 1970s and 1980s and was informed by the methodological advances of cultural resources management that pervaded American archaeology in general. These advances emphasized regional settlement patterns and broad-scale surveys and were particularly appropriate for the problems related to plantation economies. Much of the initial work in these areas was thus devoted to survey and inventory, such as that done in Barbuda and Antigua (Clement 1995); St. Eustatius (Barka 1985); Montserrat (Goodwin 1982); Jamaica (Higman 1991); the Virgin Islands (Righter 1990) and Curacao (Haviser and Simmons-Brito 1991).

Although some archaeological attention has been devoted to European towns-most notably Spanish Towne and Port Royal, Jamaica, Oranjestad, St. Eustatius (Barka 1985), and more recently in the Guyanas to contact period Amerindian sites (Petitjean Roget 1991)-historical archaeology in the non-Spanish Caribbean has for the most part concentrated on plantations rather than on towns, with particular attention paid to slave settlements and to agricultural industrial systems.

Some of the earliest explicit archaeological attention to sugar production remains took place in Florida, with the study and excavation of the eighteenth-century Bulow sugar plantation. Intermittent projects in industrial archaeology took place at sugar installations in the Caribbean after that time; however, it was the advent of resource management surveys and historic preservation in the region after about 1980 that focused attention on industrial aspects of the Caribbean sugar plantations (*see* Eubanks 1993).

African Heritage

Intermittent projects in industrial archaeology took place at sugar installations in the Caribbean after that time; however, it was the advent of resource management surveys and historic preservation in the region after about 1980 that focused attention on industrial aspects of the Caribbean sugar plantations (*see* Eubanks 1993).

African Heritage

Some of the earliest historical archaeology in the hemisphere to explicitly address issues of African

towns in British-dominated areas to vacant lands in Florida (Fairbanks 1978, 171). The Seminoles furthermore formed close alliances and lived together with African runaways.

The archaeological study of Seminole sites was actually initiated before 1970 by Goggin, who incorporated Seminole archaeology into his overall schemes of cultural evolution and chronology in Florida and defined archaeological manifestations of Seminole culture for the eighteenth and nineteenth centuries (Goggin 1958). His colleagues and students subsequently became interested in aspects of Seminole-European interaction (Gluckman and Peebles 1974), and by the 1990s there was increased archaeological interest in Black Seminoles (Harron 1994). Archaeological work that took place between 1970 and 1990 to better understand Seminole cultural formation and development has been synthesized by Weisman (1989).

Much of the archaeological attention to African influence in the colonial Caribbean has focused on Afro-American ceramic traditions. One of the earliest inquiries into this question was that of Duncan Matthewson, who correlated locally made folk pottery in Jamaica with West African ceramic traditions. Since that time, African-Caribbean ceramic traditions have been studied in a number of areas, including Cuba (Dominguez 1980), Haiti (Smith 1986), Jamaica (Eubanks 1993), and the lesser Antilles (Heath 1988; Peterson and Watters 1988). Like those of Ferguson and others in the southeastern United States, these investigations concluded not only that African influence was considerably more pronounced in the material world of post-Columbian American society than has traditionally been acknowledged, but also that African contributions are most accurately understood through historical archaeology (rather than through history or archaeology alone). This has been especially relevant in the Caribbean region, where African influence in the Americas persists most visibly in the syncretic societies of the twentieth century.

Historical Archaeology in the 1990s

The 1990s in Florida and the Caribbean were marked by the convergence of nationalist ideology in the Caribbean and by postmodernist thought (“postprocessualism”) in historical archaeology. A focus for this convergence was provided by the 1992 Quincentenary of Columbus's first voyage, which marked the beginning of European colonialism in the Americas and provoked not only an enormous increase in attention to the Caribbean past but also a great deal of support for historical archaeology in the region.

Postprocessualism gained ascendancy as a major paradigmatic addition to historical archaeology in the 1980s, and in fact, much of the Quincentenary-related archaeological research informed by postprocessual thought was initiated and largely carried out in the 1980s. Postprocessualism of the 1980s objected to “reductionist” approaches designed to provide a generalized expression or description of cultural behavior (such as statistical correlations reflecting group characteristics), and especially to efforts to arrive at general statements or lawlike generalizations about past behavior. These activities were perceived essentially as masking the true internal diversity of a society as represented by the individuals who constituted it, and as inevitably communicating the prevailing dominant perspective while burying the roles of resistance and individual variation. Individual actions and decisions were seen as more important and influential than group norms or environmental variables in shaping societies and the archaeological records they leave. The postprocessualist approach is concerned with individual decisions and acts-rather than systemic processes or environmental factors-that reflect, mitigate, or enforce the unending cycle in societies of efforts by both individuals and groups to assert social dominance in some cases and to resist it in others (*see* Little 1994; Paynter and McGuire 1991; Schmidt and Patterson 1996).

Despite claims to the contrary by at least one Caribbean ethnohistorian (Sued Badillo 1992), the

coincidence of the Quincentenary with the entry into the mainstream of postprocessual thought provoked many historical archaeologists throughout the Caribbean to turn attention toward questions of modern Caribbean cultural identity, the historical roles of non-European

Flowerdew Hundred Plantation, Virginia

Flowerdew Hundred Plantation is a working plantation and an archaeological park on the James River near Hopewell, Virginia. A 1,000-acre grant in 1617 to Governor George Yeardley was named for his wife, Lady Yeardley, née Temperance Flowerdew, and occupation has been continuous since 1619 despite numerous changes in ownership.

Excavations in the late 1960s by N.F. Barka of the College of William and Mary exposed a compound enclosing a large house of post construction, a stone foundation for a dwelling, its outbuildings, and other early- and later-seventeenth-century structures. William and Mary field schools in the 1970s explored both prehistoric and historical sites, and in the 1980s, j. f. deetz, with students from the University of California at Berkeley, initiated long-term research into the succession of plantation and settlement types from the early-seventeenth century through the mid-nineteenth century. Deetz synthesized the results in *Flowerdew Hundred* (1993).

Dates derived from measuring bore diameters of pipe stems recovered from eighteen sites indicated three groups: seven early-seventeenth-century sites, six late-seventeenth-century ones, and five mid- to late-eighteenth century sites. Deetz interpreted the evidence from each grouping in light of local, regional, and global factors influencing changes on the Chesapeake frontier of the British Empire, offering comparisons with British colonial sites in South Africa and elsewhere and assessing findings in light of contemporary debates in historical archaeology.

Evidence from Flowerdew indicates slave manufacture both of pottery and decorated clay pipes, products formerly assumed to be of Native American manufacture. Deetz saw Flowerdew as a microcosm for examining the emergence of a distinct American culture from a British colony.

Fontana, Bernard L.

(1931-)

Bernard L. Fontana was born on 7 January 1931 in Oakland, California, where he spent his formative years. In 1948, he entered the anthropology program at the University of California, Berkeley, and graduated with a B.A. in

1953. After serving two years in the U.S. Army, he continued his education at the University of Arizona, where he entered the Ph.D. program in anthropology. He received his degree in 1960 and took a position as field historian with the University of Arizona Library. Two years later, he became an ethnologist at the Arizona State Museum. In 1977, Fontana once again became the library's field historian, a post he held until he retired in 1992. He continues to be active despite his official retirement.

Primarily as a result of a graduate archaeology seminar, Fontana became interested in historic sites. In 1958, while still a student, he and others began excavations at the eighteenth-century mission of San Xavier de Bac, outside Tucson, Arizona. This work was followed in 1962 with the publication of a book on Papago Indian pottery, a study that has achieved status as a regional classic and remains the only reliable source on this historic pottery. Also published in 1962 was the johnny ward's ranch report on the 1960-1961 excavations at a nineteenth-century site in southern Arizona. The ranch was the first non-Spanish period historic site to be excavated in Arizona, and the pioneering report received national recognition because it was the first to treat late-nineteenth-century interchangeable parts type artifacts seriously. The report remains a widely used classic.

Additionally, Fontana taught the first-ever regular historic sites archaeology course in the American Southwest from 1966 to 1972. This stimulating and innovative course served to encourage many students to pursue a career in the field.

Fontana's professional career, which has spanned thirty-five years, has been punctuated by contributions to historic sites archaeology in addition to those in ethnography, history, and related subjects. Despite the fact that archaeology was not his major field, Fontana undoubtedly will be best remembered for his contributions to historic sites archaeology at a time when historic sites were neither popular nor valued.

James Ayres

Foote, Robert Bruce

(1834-1912)

Robert Bruce Foote was an officer of the Geological Survey of India employed mainly in the southern part of the country. He was deeply influenced by the Royal Society's acceptance of the geological antiquity of man in 1859. Both Neolithic stone tools and microlithic flakes and tools had been found in various parts of India, but it was Foote who discovered Paleolithic evidence in a gravel pit near Madras in 1863. He pursued his prehistoric interests for the rest of his working life, publishing a two-volume catalog of his collection in the Madras Museum (Foote 1914, 1916). He worked all over southern India and in Gujarat in western India. Many of the premises he developed, based on his study of the prehistory and protohistory of the areas where he worked, have been found to be substantially correct by modern researchers (see Chakrabarti 1979).

Foote's work symbolizes a vigorous phase of prehistoric discoveries in India during the second half of the nineteenth century. It was during this time that the basic significance and the general distribution and stratigraphy of prehistoric artifacts, and their association with extinct fauna in some cases, came to be well understood. Among his contemporary workers were Valentine Ball in east India, William King in south India, and A.C.L. Carlleyle and William Cockburn in central India. However, it must be emphasized that investigators during this period were concerned not only with stone tools but also with a wide ranges of “prehistoric” finds from southern Indian Iron Age megaliths to Neolithic sites. Rock paintings were discovered throughout central India.

Ford, James Alfred

(1911-1968)

James Alfred Ford was an outstanding American archaeologist from the 1930s to the late 1960s. He was born in Water Valley, Mississippi, on 12

February 1911, and perhaps because of that birth date took on a Lincolnesque appearance with dark black hair and a lean six-foot, four-inch height. He excavated and reported his results on sites from Point Barrow, Alaska, to the viru valley in Peru, but he is best known for his work in the southeastern United States.

Ford received his B.A. degree from Louisiana State University in 1936, his M.A. degree in anthropology from the University of Michigan in 1938, and his doctoral degree from Columbia University in 1949. His passage through the formal requirements of academia was slowed by World War II and the pull of opportunities for fieldwork. His all-around skills in excavating and interpreting what he had found had created a market for his talents by the late 1930s. Later his position at the American Museum of Natural History enabled him to direct his own field program.

Ford and a high school associate, Moreau Chambers, worked for three summers, 1927-1929, doing survey work for the Mississippi Department of Archives and History, and they became closely associated with Henry B. Collins of the Smithsonian Institution at the excavation of sites in Yazoo County in 1929. Collins introduced them to northern Alaskan archaeology in 1930-1931, and he also sponsored Ford as assistant to Frank M. Setzler, also of the Smithsonian, who initiated the first labor relief program during the Great Depression at Marksville, Louisiana.

Ford is best known in the southeast United States for his excavations at Oculgee National Monument near Macon, Georgia; a group of Hopewellian mounds near Helena, Arkansas; and the Jaketown multicomponent site near Belzoni, Mississippi, in association with Philip Phillips and William G. Haag. He also coauthored reports on the early Marksville period Crooks site in LaSalle Parish, Louisiana, with gordon r. willey and on the Tchefuncte early Woodland period of southern Louisiana with George I. Quimby. A survey report in 1951 on the lower Mississippi Valley was coauthored with Phillips and james b. griffin.

The 1951 landmark survey report was a major presentation of Ford's seriation of the pottery collections with the percentage computation of individual types per site, or site unit arranged stylistic inception, popularity, decline, and extinction. This methodology confirmed his concept of a uniform gradualistic ceramic change, and he became a convert to cultural determinism. He wanted to introduce quantitative and empirical methods to make archaeology a science, and he also employed the direct historical approach, diffusion, migration, and interareal relationships.

Ford was president of the society for american archaeology in 1963-1964, received the Spinden Award in 1966 for outstanding accomplishments in theory, methodology, and chronology, and chaired a number of southeastern archaeological conferences. He did not like large gatherings or formal social events, and he was unhappy living in or large cities. He was very effective espousing his ideas to small groups of archaeologists, and he was a versatile and ingenious innovator and a probing theoretician. He was a living refutation of his belief that an individual does not make a difference in the pattern of cultural change, for he was a leader in changing the tenor of archaeological work in the southeastern part of the United States and in South America.

France

The study of prehistory began in France. In the nineteenth century the worked stone tools that the customs officer jacques boucher de perthes collected in northern France were the oldest tools known anywhere in the world, even older than their discoverer had thought, since they dated back 700,000 years (Demoule 1990).

One hundred and fifty years later, in one of the two issues of *World Archaeology* devoted to "regional traditions of archaeological research,"

Françoise Audouze and andré leroi-gourhan (1981) called their contribution "France: A Continental Insularity," emphasizing how separate French research had been from that of other countries. Yet there was nothing original about the work done in France after the time of Boucher de Perthes. French archaeology has been unique only in that more than half of its professional archaeologists have excavated abroad. Most of the excavations within France were conducted by amateurs, and archaeology in France suffered as the result of a severe economic crisis (Chapelot et al. 1979; Querrien and Schnapp 1984). At the end of the 1970s French archaeology received only about one-tenth of the funding that its counterparts in equally affluent European countries did.

In fact, for a very long time in France, prehistoric and historic remains were given no protection whatsoever if they were not monumental (well known and associated with known historical events); the public authorities were not even interested in them. Archaeological research was entirely free from any government control or protection until 1941, when the Vichy government issued the first law relating to archaeology (endorsed in 1945), at a time when part of France was occupied by the Germans. Under the law, excavations required authorization, chance finds had to be declared to the authorities, and the land on which they were found was "frozen." This law was the first recognition of archaeology as a part of French heritage. However regional organizations, later established around a few "directors of antiquities," were given virtually no resources to protect or conserve archaeological sites. Nothing in dreams or reality gave any indication of the radical changes that were to occur in the last quarter of the twentieth century.

The Upheavals at the End of the Twentieth Century

The first signs of change in the French government's approach to archaeology came at the end of the 1960s, when two scandals, caused by clashes between archaeological authorities and powerful commercial interests, caused a considerable stir in Paris and Marseilles. These arguments reached the highest levels of government and the scandals had such an impact that a report was commissioned from Jacques Soustelle in 1974. On Soustelle's advice, the Fonds d'Intervention pour l'Archéologie de Sauvetage (Intervention Fund for Rescue Archaeology) was established. In 1977, an article was added to the urban planning regulations stipulating that a building permit could be refused or issued subject to restrictions if the project threatened the conservation or enhancement of archaeological remains. But nothing was stipulated about how and by whom the costs of excavation or conservation were to be met.

In 1981, a "Department of Archaeology" was finally created to study, protect, conserve, and promote archaeological sites. Then, in 1996, France ratified a European Union convention (the Malta Convention) intended to "protect the archaeological heritage as a source of the European collective memory and as an instrument of historical and scientific study." In ways that no one had foreseen, the number of excavations in France rose-from 720 in 1964 to 3,410 in 1995. France made up for lost time, and whole areas of national heritage were preserved.

The number of staff employed by the state to supervise excavations multiplied by 25 in 25 years (increasing from 10 in 1964 to 255 in 1988). Local authorities, who had not hired an archaeologist before 1971, employed 120 archaeologists in 1988. In 1989 there were 160 researchers working on French archaeological topics employed either by the national funding body for academic research, the Centre National de la Recherche Scientifique (CNRS), or by the universities. During the 1980s, significantly, major politicians began claiming a personal interest in archaeology. Heritage issues, often rather ambiguous ones-tied up with the effects of globalization on the national consciousness-came to play a key role in the budgets allocated by state and private enterprise to rescuing the archaeological remains that they were destroying. French president François Mitterrand, like the emperor Napoleon III and Marshal Pétain before him, started making references to the mythical ancestors of the French, the

Gauls. In September 1985, he made a speech

on this theme at the top of Mont Beuvray-where Vercingetorix had been proclaimed “leader” of the uprising against Julius Caesar. At the same time, he granted the site, which had been dug in the nineteenth century by joseph déchelette, more generous funds for excavation and improvement than ever before in French research. The complete refurbishment of the louvre Museum, including the building of a glass pyramid in the center of the main courtyard, was another of the principal cultural endeavors of the Mitterrand presidency.

However, public authorities had to operate in a total legal vacuum as they attempted to force developers to contribute to the costs of rescue archaeology, amounting to 400 million francs per year nationally. This contribution was exacted on each occasion in return for the release of the land in question, following bargaining (which might be described as racketeering) based on the extent of the threat that the plans posed to the national heritage, and the legal obligation of the developers to preserve it. The funds were collected from the developers, with the backing of the Ministry of Finance, by a voluntary organization: the Association pour les Fouilles Archéologiques Nationales (Association for National Archaeological Excavations), better known by its acronym, AFAN. Between 1985 and 1989, AFAN's budget increased from 30 million francs to 130 million. In 1990, it had more than 1,300 archaeologists working under contract, that is, many more than in all French research institutions put together.

Thus, in a country that had for so long refused to recognize that remains under the ground constituted part of its heritage, rescue archaeology made steady progress at the end of the twentieth century. It is estimated that, in the last twenty-five years of the century, it was the source of 90 percent of the data produced by French archaeology.

Archaeologists Resort to Public Demonstrations

By the end of the 1990s, in the absence of any law on funding rescue digs and of resources allocated by the state to its own services, developers were becoming less and less inclined to pay for excavations. Furthermore, since developers' contributions were limited to releasing the land, analysis studies and publications of the archaeological material could not keep up. It looked as if there would be an inevitable division into two opposing types of archaeology. On the one side, field archaeology (*de terrain*) with abundant material and means but with little time to think about their findings, and on the other side, laboratory archaeology with little material and few facilities but with plenty of research time. This split deeply affected a professional community with a short institutional past. The archaeologists working on French sites-who had acquired their status only twenty years earlier-were still full of the utopian dreams and dynamism that drives any first generation of conquerors. It was at this point, in 1998, that the Ministry of Finance recommended that rescue archaeology be privatized and subject to financial competition. Archaeologists went on strike, occupied government buildings, opened museums and invaded television studios. In the end, more than a thousand archaeologists (over two-thirds of the archaeological community) demonstrated noisily in the streets of Paris against the government's policy.

To deal with this crisis, an emergency committee with three members, including archaeologist Jean-Paul Demoule, was set up by the Ministry of Culture. A parliamentary bill on the funding of rescue archaeology and the creation of a new public agency were proposed, and the bill was passed into law and the agency created in 2001. At the start of the second millennium, French archaeology-both scheduled archaeology and rescue archaeology-is still united, employs 2,000 people, and at long last has the modern resources that it requires.

Nevertheless some questions remain: Why was there so little hurry to professionalize archaeology in France, and why has the country never felt a lasting need to investigate its origins? The answer lies in the vision that France has always had of its citizenship and culture, having for years looked for its past in the

Parthenon or the Capitol rather than in the huts

of “our ancestors the Gauls.” In any case, in a country with a large immigrant population, it was thought absurd to wish to show all the nation's children that their ancestors were Gauls.

Why Has France Never Felt a Lasting Need to Investigate Its Origins?

France is the source of the modern concept of the nation-state, based on the ideals of the French Revolution. It is also the most complete example of a nation-state in that, for longer and more strongly than elsewhere, the central government in France has asserted its supremacy over all other democratic institutions. The continuity of the structures of the state is indeed usually taken-now, as for several centuries past-to be identical with the unity of the country.

Nevertheless, the Revolution and the upheavals of the eighteenth century that affected Europe's sense of space, identity, time, and history led in France to the profound questioning of the concepts of society and nation. During that period the medieval myth of the Germanic and Trojan origins of the aristocracy was replaced by a different social and national model, in which the history of the nation was driven by historical, ethnic, and social forces that pitted the winners-the Franks-against the losers-the Gauls (Olivier 1999). Given the attitude toward social emancipation propounded by the Revolution and following in the philosophical tradition of the Enlightenment, the Frankish racial ancestry claimed by the aristocracy became socially indefensible. The nation henceforth was to be made up of the whole of society, meaning all those-whatever their origins-who had chosen to live together, and anyone who supported the values of the Republic was deemed to be a citizen.

However, conjuring away the racial ancestry allegedly bequeathed by the Franks to the minority of their noble descendants in favor of the cultural inheritance from the Gauls and Romans (supposedly the prerogative of the majority) gave rise to a pernicious notion of the French nation and its citizenship. As French archaeologist Laurent Olivier argues, these notions are both political (all those who support the values of the Republic are citizens) and ethnic (all those who live within the national frontiers are French). This ambiguity was to reemerge every time that the structural legitimacy of the state or the country's frontiers were challenged: in the reign of Napoleon III, after the defeat of 1870, and during the Second World War under the Vichy régime. Appeals were made to archaeology on each occasion because, on each occasion, the myth of “our ancestors the Gauls” was revived. This myth, by supporting the idea of the continuous existence of the nation ever since the very beginning (and France or the Republic being taken as its expression), made it possible-very briefly-to give legitimacy to the coincidence of the state, the frontiers, and the nation.

It is therefore logical that in 1996, at a time of increasing Americanization and when socially productive relationships were being affected by globalization, France did not hesitate to sign the Malta Convention, which advocated the protection of archaeological heritage as a source of European collective consciousness. It is also easy to understand why the French archaeological community shifted in a couple of decades from “universal” interests to curiosity about questions of identity, unconsciously based on a return to the values of a “national” past.

Low Priorities: Theoretical Models and Epistemological Curiosity

For many years the second feature peculiar to French archaeology was its rejection of theoretical models and its lack of epistemological curiosity. During the 1970s and 1980s, this trend was contradictory to those in the rest of society because French philosophy was emerging from one of its most productive periods, with figures like Sartre, Merleau-Ponty, Lévi-Strauss, Ricœur, Lacan, Goldmann, Lefèvre, Braudel, Althusser, Foucault, Barthes, Piaget, and later Vernant, Godelier, Bourdieu, Baudrillard, Derrida, and others making contributions. The paradox was even odder in that

Anglo-American postmodern (or “postprocessual”) archaeology borrowed most of the terms for its concepts from French.

It must be borne in mind, however, that French archaeologists were still few in number,

of “our ancestors the Gauls.” In any case, in a country with a large immigrant population, it was thought absurd to wish to show all the nation's children that their ancestors were Gauls.

This myth, by supporting the idea of the continuous existence of the nation ever since the very beginning (and France or the Republic being taken as its expression), made it possible-very briefly-to give legitimacy to the coincidence of the state, the frontiers, and the nation.

It is therefore logical that in 1996, at a time of increasing Americanization and when socially productive relationships were being affected by globalization, France did not hesitate to sign the Malta Convention, which advocated the protection of archaeological heritage as a source of European collective consciousness. It is also easy to understand why the French archaeological community shifted in a couple of decades from “universal” interests to curiosity about questions of identity, unconsciously based on a return to the values of a “national” past.

Low Priorities: Theoretical Models and Epistemological Curiosity

For many years the second feature peculiar to French archaeology was its rejection of theoretical models and its lack of epistemological curiosity. During the 1970s and 1980s, this trend was contradictory to those in the rest of society because French philosophy was emerging from one of its most productive periods, with figures like Sartre, Merleau-Ponty, Lévi-Strauss, Ricœur, Lacan, Goldmann, Lefèvre, Braudel, Althusser, Foucault, Barthes, Piaget, and later Vernant, Godelier, Bourdieu, Baudrillard, Derrida, and others making contributions. The paradox was even odder in that

Anglo-American postmodern (or “postprocessual”) archaeology borrowed most of the terms for its concepts from French.

It must be borne in mind, however, that French archaeologists were still few in number,

and their institutions lacked, to put it mildly, coherence and policies. They had ludicrously tiny resources, and as a result theoretical models were not among their top priorities. Furthermore, at the time when French metropolitan archaeology was at last becoming established, modernity and grand explanatory paradigms were no longer in fashion. Besides, the individuality and proliferation of "post-modernist" ideas, which have continued to spring up ever since, were unable to gain widespread acceptance. French intellectuals grow up in a Cartesian deductive tradition, captured in the famous phrase *cogito, ergo sum.* In other words, their ability to think is their prime certainty. Their "reason" is not a faculty for epistemological questioning but a means of acquiring a direct grasp of the way things are. By following the logic of *cogito, ergo sum,* the intellectual can come to know and understand this reality purely through deduction.

Consequently, unlike their British or North American counterparts (who grow up in a system of empiricism), French researchers are not tempted to throw out the old paradigms and replace them with new ones that appear better suited to the problems of the moment. Instead, old and new concepts are combined as necessary into a general intellectual approach that cannot easily be labeled. This is why, for instance, structuralism in France has never been considered to be a theory or a school of thought, but simply a working method. Moreover, although nowadays young French archaeologists are familiar with epistemological concepts and ideas, they have difficulty in believing that there could be archaeological theories. The French indeed observe that archaeological data have never been used directly as the basis of a theory, when theory is defined as an explanatory system that works for data *other than* those used originally to generate the theory.

Archaeology, French Style

We have seen that, despite several crises of national legitimacy, French archaeology developed without the impetus of necessity. Local archaeology from the northern shores of the Mediterranean was never very interesting or contentious in France because of its inability to ever match up with the vision of excellence of Greco-Roman "civilization." This notion of archaeology as distinct from any idea of civilization is extremely important for an understanding of the situation of archaeological research in a country where the intelligentsia has always held a dominant position.

Yet everything began well. The fifteen volumes of *L'Antiquité expliquée en figures* by the Benedictine scholar bernard de montfaucon (published 1719-1724), which brought to public notice the antiquities attributed to the Gauls, and the *Recueil d'antiquités égyptiennes, étrusques, grecques, romaines et gauloises* by the comte de caylus (1752-1757), which emphasized the new notion of a typology, are evidence of the birth and growth of archaeological knowledge well able to take its place among the other humanities (Schnapp 1993). Admittedly, Montfaucon and Caylus were antiquaries, representatives of a style of archaeology that was mainly object-based and concerned only with monuments. But Caylus was not content merely with using antiquities for "illustrative" purposes. He wanted the study of antiquities to be one particular means of learning about the past, to interpret them using ethnographic comparisons, and to establish stylistic rules that would make it possible to assign a date and a place of origin to every object. Hence the care taken to collect the objects, describe them, and publish them formed the basis of a technical knowledge that, in the hands of men like Auguste Millin (1826) and later Solomon Reinach, was extremely important for French classical archaeology.

However, this prestigious tradition was eclipsed in the first half of the nineteenth century by the rise of German archaeology. In Germany, the *Altertumswissenschaft* revolution was under way, in which philology was given pride of place. It carried along with it German classical archaeology, which acquired a position in academe well before archaeology elsewhere in Europe was accorded similar status. Admittedly, the discoveries in France and the immense prestige of j.-f. champollion and, later, p. e. botta

contributed to the creation of outstanding schools of Egyptology and Assyriology. But Orientalism

developed in Europe more as a cultural phenomenon than as a branch of archaeology. The philological research of scholars like Champollion or sir henry rawlinson mattered more at that time than did the work of explorers like Botta or austen layard. But the years 1830 to 1850 were decisive for the French study of prehistory quite independently of these other developments (Laming-Emperaire 1964). Prehistory in France grew out of anthropology, which had utterly different philosophical roots.

Despite his literary interests and his general culture, which were influenced by the Enlightenment, Boucher de Perthes helped create a type of prehistoric archaeology that owed little to the antiquaries of the eighteenth century. The natural history of mankind-as it developed in the second half of the nineteenth century, and to which the anthropological school of physical anthropologist Paul Broca made a substantial contribution-was very much a branch of natural science that devised its methods by analyzing remains directly in the field. It turned to experimentation and ethnological comparison for the same assistance that classical archaeology derived from aesthetics. This major difference still divides the field of archaeology and explains why prehistory and classical archaeology have had such dissimilar fates in France. Men like Jacques Boucher De Perthes, édouard lartet, and gabriel de mortillet never had positions in the French academic system. And although Lartet was appointed late in life to the Museum of Natural History (where he did not have time to take up his chair) and de Mortillet was given a curatorship at the Museum of National Antiquities, French prehistorians were doubly excluded from academe until the 1950s, barred from both arts and science faculties. At the very time that French prehistory was making an impact on the study of archaeology worldwide, thanks to the wealth of finds in France and to de Mortillet's abilities as an organizer and theoretician, it was completely lacking in resources for action. Within France, nevertheless, de Mortillet's nomenclature and his typological definition of lithic industries were adopted as the frame of reference for the study of prehistory. But although the discipline was magnificently equipped to investigate Paleolithic periods, it had to look elsewhere-to Scandinavia, Britain, Germany, and Central Europe-for the elements it needed in order for the study of French protohistory to develop beyond its earliest stages. Despite the work of Déchelette, prematurely ended by his death in the First World War, French protohistorical archaeology never raised itself to the same standard as archaeology in Scandinavia or Central Europe. Excavations were few in number and depended entirely on private funding, and although oscar montelius's methods were acknowledged and adopted, they never generated original extensions.

A Long Period in the Wilderness

After the First World War, the Durkheim “school” of sociology, under its director, anthropologist Marcel Mauss, resumed its work. Faithful to the universalist traditions of the Enlightenment, it broadened its approach to include linguistics, comparative studies (*comparatisme*), and Orientalism. However, the archaeology of France itself did not seem able to develop, or to raise much interest. The state continued to exist, in conjunction with national unity, and in contrast to what happened in Germany nationalist claims were still not sufficiently intense to generate the idea of a foundation myth and a national archaeology. There had never needed to be any appeals to the origins, prehistory, and protohistory of France in order to legitimize anything. Consequently, while the human and social sciences started to grow around the journal *Année sociologique* and as Lucien Febvre and Marc Bloch launched *Les Annales,* the most influential French historical journal, French prehistorians and archaeologists were nowhere in sight.

Henri Hubert, curator at the Museum of National Antiquities, and Marcel Mauss worked together to initiate some fascinating studies of the expansion of Celtic culture. Classical archaeology, based on the French Schools in Athens and Rome, continued to develop slowly, and the abbé henri breuil offered a first synthesis of the cultural prehistory of Europe. But the only courses of study available to anyone

interested in prehistory were those of the Institute of Human

Paleontology, where men like Raymond Vaufrey and Henri Vallois maintained the tradition, rather than helping to train the key professionals in an expanding discipline. From that time onward the choice was straightforward: between orthodoxy (superbly represented by the abbé breuil and françois bordes) or heterodoxy, inevitably shaped by the ideas of people who were self-taught. The institutional marginality and creativity of someone like André Leroi-Gourhan reaped their own reward in this setting.

Standing stones in Carnac, France

André Leroi-Gourhan and Prehistoric Ethnology

After Gabriel de Mortillet, André Leroi-Gourhan was undoubtedly the person who made the greatest contribution to shaping French prehistory. Like de Mortillet, he was self-taught and he brought the same passionate interest to understanding technical systems as the former did to defining the laws of evolution (Leroi-Gourhan 1943, 1945). By laying the foundations of comparative ethnography and drawing on anthropology and Orientalism, he established prehistory as a field in its own right. His approach to prehistory was completely different from the typologies of Breuil, which François Bordes later brilliantly developed and transformed (Bordes 1973). Whether with regard to the techniques of human labor, hominization, the interpretation of wall paintings, or excavation finds, the work of Leroi-Gourhan provided a frame of reference, an area of debate as vital for prehistoric archaeology as the work of Gordon Childe for protohistory. Against the disciplinary approach of traditional archaeology, which was primarily concerned with culture and classification, Leroi-Gourhan argued in favor of synthesis, combining anthropology and semiology in “prehistoric ethnology.”

Leroi-Gourhan's approach-which had similarities with oriental archaeology-seemed well placed to win the day. But because it stayed deliberately marginal to both traditional prehistory and established ethnology, the work of Leroi-Gourhan was for a long time a matter of disappointment rather than development. It is important to realize that the questions raised by Leroi-Gourhan were discussed, then accepted or rejected. But the repercussions for archaeology

were patchy rather than fully assimilated, and details, rather than the whole approach, were adopted. Excavation techniques were used when necessary, as was the criticism of ethnographic analogy when trying to establish a different analogy (Leroi-Gourhan 1985). Nevertheless by the end of the 1990s and at the beginning of the third millennium, his overall view of the process of hominid development-which raises the question of what it is to be human-was at last put into perspective, and his analysis of post-Neanderthal epiphylogenesis became part of the cognitive sciences. The visionary postulate of his book *Le Geste et la parole* (1964, 1965) and the logic underlying *Mécanique vivante* (1983), written in 1954, appear now to be remarkably relevant and epistemologically inspiring, compared with the debates on the origins of modern humans that stir up and cause futile clashes between researchers from all parts of the world.

Stumbling Blocks on the Way Out of the Wilderness

Etudes archéologiques, the wide-ranging volume by several authors edited by Paul Courbin in 1963, was uninspiring and made no impact outside professional circles. But some of the papers (such as the one by Courbin himself on stratigraphy) were critical of French archaeology abroad, which had long been accustomed to clearing the most renowned sites around the Mediterranean in a somewhat cavalier fashion. Other papers, such as those of André Leroi-Gourhan and Jean-Claude Gardin, set out the program of work for the future. For this reason, these two authors were to be among the few French role models for a whole generation.

Almost all archaeological attention in the 1960s and 1970s concentrated on the technical aspects of observation and recording. As prehistoric archaeology emerged from the wilderness of a lack of public and government support, essential improvements in excavation methods quickly became an ideological stumbling block: for classical archaeologists, stratigraphic excavation was an end in itself, whereas prehistoric archaeologists always and everywhere excavated using the delicate tools of dentist's spatula and fine brush. Consequently, when in 1971 Bohumil Soudsky started excavating at Cuiry-les-Chaudardes and other sites in the Aisne valley by machine-stripping, which he had perfected twenty years earlier in Bohemia, this use of this innovation-which was generally accepted everywhere else in Europe-caused outrage. And when, also in the Aisne valley, the first report appeared in 1973 listing all the sites threatened with destruction and suggested the idea of "selecting" which should be given priority on the basis of urgency, available funding, and scientific interest, the same violent reaction was unleashed. At that time in France there was no middle way between excavating inch by inch and total destruction. Methods based on physics and chemistry ("archaeometry") that had begun to be used by archaeologists were another stumbling block. The ability to obtain data and generate results using scientific apparatus and statistical techniques opened up the possibility of dispensing with philosophy, or the under-picture, which gave physicists-themselves just as much novices in this new collaboration-an unwarranted feeling of absolute power. Disillusionment was, however, painful when the first assessments were made in the early 1980s and these substitutes for clear thinking were found lacking. Documentation, data-processing, and interpretation encountered the same problems. Leroi-Gourhan's seminar at the Collège de France was devoted to developing a "temporary terminology" that was not just descriptive but also provisional. The creation of archaeological databases and expert systems as proposed by Gardin (1970) suffered from the same generalizing and self-defeating tendencies. In fact, the difficulty of creating a list of standardized generally applicable terms, required in order to computerize data, was an obstacle to creating a completely formal scientific discipline in the manner prophesied by Gardin (1979). Instead, two disparate kinds of study developed: nonspecialist documentary studies using a highly simplified descriptive vocabulary and individual, narrowly specialized research projects using incompatible complex descriptive terms. In studies of prehistory, the "analytical typology" of Laplace was unlikely to be adopted because its

PREV NEXT

formal approach was much more difficult to put into practice than François Bordes's synthetic lists, and its criteria were not relevant to the questions that could now be addressed by analyzing the technologies of prehistoric tools.

For most people, the problems were intellectual, institutional, and financial; for others, the stumbling block was conceptual. Those who tried to echo the discussions about the "new archaeology" (Cleuziou et al. 1980; Schnapp 1980) were obliged to begin with the fundamentals, which meant becoming directly involved in the reform of institutions. This commitment was all the more necessary because archaeology was disastrously lacking in resources. The journal *Nouvelles de l'Archéologie,* launched in 1979, was a particularly effective weapon in this regard. A similar strategy, though less political, if not actually apolitical, was adopted by Gardin, who was the main architect of what he saw as a general reorganization of archaeology in France with the creation of a national archaeological institute, the Centre de Recherches Archéologiques. Thus it was that some members of the younger generation of the time, imbued with the utopian visions of 1968 and exceptionally united, tried-first via a systematic survey of the resources of French archaeology-to make the decision-makers fully aware of the discipline's chronic lack of funding (Normand and Richard 1974; Chapelot et al. 1979). This group worked tirelessly for more than twenty years to reshape university teaching, to create a unified discipline, to define policies for research, and to get funds earmarked, but also to adapt the techniques and strategies of excavation to the realities on the ground and the academic issues involved.

Consequently contacts with the inspiring new ideas of the "new archaeology" were real but anecdotal and personal. A notable exception was the debate between François Bordes and lewis binford on the meaning of the different Mousterian *faciès,* which the former interpreted in terms of different cultures whereas the latter saw them as reflecting different functions. Ironically, the more "conservative" position (that of Bordes) was probably the more relevant. Thanks to the interest of American scholars in the Perigord, Bordes's work was soon translated and became popular in the United States, as he did himself. By contrast, the studies of Leroi-Gourhan (which should have generated even more interest) remained unknown to the English-speaking public until the1990s.

The Special Characteristics of French Archaeology in Its Early Phases

It is noteworthy that archaeology played only a tiny role in the *Annales* school of history, in spite of the efforts of Lucien Febvre and Marc Bloch and Fernand Braudel's interest in "material civilization." Prehistory and "new history" came into contact only rarely (Brun 1987), and then with regard to material culture (Coudart and Pion 1986). It is true that *Annales* was the victim of its own success. Swept along by the growth of publishing and the media and affected by the European disenchantment with the models of economism and Marxism, the journal ultimately switched its focus to the history of *mentalités,* of cultural areas and "micro-history" rather than history over long periods (*de la longue durée*). Nevertheless, the studies undertaken by the Center for Historical Research at the École des Hautes Études en Sciences Sociales (EHESS) helped to develop the history of deserted villages and the social investigation of the rural world in the Middle Ages. It was a medieval historian and an archaeologist, then teaching at the EHESS, who produced the fullest survey of the medieval village (Chapelot and Fossier 1980). Today, other fields are proving equally fruitful. Excavations and work on the Bronze and Iron Ages are shedding new light on the role and situation of the Bronze Age and Celtic inhabitants of the temperate regions of Europe. The archaeology of Western Europe now faces vast ethnic and historical questions that so far have barely been addressed.

As for the school of Jean-Pierre Vernant and Pierre Vidal-Naquet, which brings together history, the history of religions, and anthropology, the focus there has been on framing questions of social and economic history and examining the role of images in ancient Greece (Vernant and Bérard 1984; Durand

1986; Schnapp 1993). This approach-the result of combining a

structuralist analysis of the Greek tradition with an analysis of iconography-has been highly revealing and has helped to demonstrate the need for an hermeneutics of archaeology. This kind of history should now be deriving new material from the excavations in urban areas that have been under way in France since the 1980s. These major sites (the most famous is at the Louvre) are totally transforming the knowledge of daily life in medieval and postmedieval cities.

The French have also developed particular expertise in the specialized field of technological culture. This tradition arose from the conjunction of three things. The first is ethnology proper, starting with the work of pioneers such as André-Georges Haudricourt and André Leroi-Gourhan, who were followed by Charles Parain, Bertrand Gille, Robert Cresswell, François Sigaut, and most recently Pierre Lemonnier. Second is Leroi-Gourhan's ethnological approach to the study of prehistory. Last are the experiments in the technology of stone tools conducted by Jacques Tixier and the team he established. The anthropological study of technologies and technical systems, which has been particularly strong and is well illustrated by the group producing the journal *Techniques et culture,* is at present of greater interest to archaeologists than to ethnologists. The former are hoping that it will yield theories about the relationship between artifact and cognition, between material culture and society. But it is above all in the field of stone tools that archaeological experimentation in France has developed a wide range of resources-instruments for observing and monitoring movements of lithic raw materials (Tixier et al. 1980, 1984), "*chaînes opératoires*" (operating sequences) for producing tools, theories on the technical and cognitive capacities of *Homo erectus,* etc. Technology was therefore the direction taken by what may be called the "ethno-archaeological strategy" in the 1980s (Pétrequin 1984; Pétrequin and Pétrequin 1984). But the use made of ethnology has been both prudent and highly empirical, whether with regard to vernacular architecture in the Middle East, pottery-making in India, the dynamics of lake-settlements in Bénin, processing skins in western North America, the lifestyles of Arctic peoples, or tool-making in New Guinea. This research taken as a whole has, however, yielded a substantial quantity of data and fresh ideas.

At the Beginning of the Twenty-first Century: Every Reason for Optimism

Only with the creation in 1979 by Fernand Braudel's Maison des Sciences de l'Homme of the journal *Les Nouvelles de l'Archéologie,* an academic journal also concerned with policies and information, did conceptual thinking about archaeology acquire coherence in France. At the same time, as we saw earlier, rescue archaeology was radically overhauled-a development that the editors of the journal were to follow and sustain with interest. The idea of an excavation plan became indispensable in the context of the large-scale rescue operations, and at the same time it led to the development of practical thinking about prospecting, sampling, and quantitative methods. Salvage excavations and regional programs to support them and bring together all available methods were put into place, and proved effective in the Aisne valley in Picardy and on Lakes Clairvaux and Chalain in the Jura. Nevertheless it took the revolt of the archaeologists in 1998 (the third of its kind since 1989) and the appointment of Catherine Trautmann as minister of culture for this growth at last to be restructured through reform, law, and the creation of a public body responsible for excavation and research that would look after rescue archaeology, and indeed archaeology in general (*Les Nouvelles de l'Archéologie* 1999-2000, 73-79).

As is clear from the catalogue for the 1989 Paris exhibition (Mohen 1989), and in spite of the work of people like Jacques Cauvin (1994) or the 30- and 40-year-olds who received less media coverage, French archaeology in the 1990s was still committing the same sins as before. Thus most archaeologists continued to be skeptical about building social and cultural models, following in the tradition of people like Bordes, Leroi-Gourhan (his position in the 1970s and 1980s, at least), Courbin, Gardin, and some others. This skepticism led them to deal in notions that are all the more dangerous because they are not

stated explicitly. For instance, the arsenal of techniques drawn from the natural sciences has often given rise to oversimplified determinist environmental models. At the same time, the appearance from time to time of British or North American scholars in France has encouraged the development of antidiffusionist approaches-frequently based on an excessive use of radiocarbon dating, with its imprecise measurements that can give a false impression that objects are contemporary-that do not always appear to fit the facts. Similarly, certain postprocessual works have been read by people without enough background and this has led to ahistorical interpretations at variance with the facts or lacking in any determinism. By contrast, in a completely different field, diffusionism has been much used in France by a group of extreme right-wing intellectuals, "the New Right," in order to account for the Indo-Europeans and to demonstrate the superiority of European civilization. In passing, it should be pointed out that archaeology alone certainly would not provide a simple answer to this intriguing question; rather, the solution would require the close collaboration of archaeologists, linguists, and experts on ethnology and myth to produce new theoretical models (Demoule 1980, 1999).

Frankfort, Henri

(1897-1954)

Born in Amsterdam, Henri Frankfort served in the army of the netherlands during World War I and later studied history at the University of Amsterdam before transferring to University College, London, to

work on his M.A. with sir william matthew flinders petrie. From 1925 until 1929, Frankfort directed excavations for the egypt exploration society at Tell el amarna, abydos, and Armant. He received a Ph.D. from the University of Leiden in 1927.

In 1929, Frankfort was invited by the great American ancient historian Henry Breasted to be field director of the University of Chicago's oriental institute's Iraq Expedition at Diyala, a position he held until 1937. In 1932, he was appointed Research Professor of Oriental Archaeology at the Oriental Institute of the University of Chicago and concurrently held the position of extraordinary professor in the history and archaeology of the ancient Near East at the University of Amsterdam. During World War II, Frankfort lived in Chicago and concentrated on research, publications, and teaching, and during the war and afterward he influenced a generation of U.S. student archaeologists and anthropologists.

Frankfort published fifteen books, among which are the seminal *Studies in Early Pottery of the Near East* (1924-1927), *Cylinder Seals* (1939), *Ancient Egyptian Religion: An Interpretation* (1948), *Kingship and the Gods* (1948), and *The Art and Architecture of the Ancient Orient* (1954). He also wrote over seventy-three journal articles and as many book reviews.

In 1949, he accepted the directorship of the Warburg Institute in London and a professorship in the history of preclassical antiquity at the University of London. He last visited the Near East in 1952 as a Guggenheim fellow to research and write *The Art and Architecture of the Ancient Orient.*

French Archaeology in the Americas

As might be expected, French archaeological research in the New World began only at the start of the nineteenth century, when the independence of the United States put an end to Spanish colonial rule. The same is, of course, mostly true for other European countries, if one does not take into account the early years of archaeological investigation in the United States and the Moundbuilders controversy. In their *History of American Archaeology* (1974), gordon willey and Jeremy Sabloff called the period from discovery until 1840 the time of witnesses and armchair historians. ignacio bernal garcia, in his *History of Mexican Archaeology* (1980) differed somewhat, considering the discovery of the Calendar Stone in mexico in 1792 and its study by Alzate and Leon y Gama as the starting point for the next period of early study. In fact, the first four decades of the nineteenth century were a period of intense activity-but mainly due to local, French, or English investigators. The publication of john stephens and frederick catherwood's *Incidents of Travel in Central America, Chiapas and Yucatán* in 1840 was the culmination of this early interest.

From 1840 to 1914 the explorations and descriptions of archaeological sites in the Americas were intensive, but by the end of the nineteenth century there was more of a tendency toward institutional and scientific research. During this period French explorers were quite active, but 1914 marked the end of an era, and this date has a deep significance for the whole of Americanist research. Specific events, such as the Mexican Revolution and its consequences and World War I in Europe, generated a rare strain of European field research that was to last for several decades and, therefore, an Americanization of archaeological investigation that would continue until the end of World War II. The year 1914 also brought strong changes in archaeological theories and methods. The development of new techniques, such as the stratigraphic revolution, and the establishment of new institutions in Mexico and the United States, such as the Carnegie Institution, accompanied a complete transformation in the ideological background of archaeology, under American anthropologist Franz Boas's influence.

The aftermath of World War I resulted in a nearly total absence of French investigators the Americas for many years. French anthropological research fared slightly better in the 1930s, but the political situation prevented the acceleration of this trend, and it is not possible to discern French involvement in the Americanization process until the 1950s. By the time French investigators and archaeologists once again became active in this field, American archaeology had undergone a complete and autonomous growth, to which the Europeans had to adapt themselves. In the 1950s those working in the field of archaeology experienced turmoil and dissatisfaction, partly because of their own results but also because of the introduction of new techniques (aerial photography, radiocarbon dating). This occasioned a change in theoretical approaches toward functional and contextual preoccupations, which in turn paved the way for the “New Archaeology.” Many Latin American countries began to organize archaeological research on an institutional basis and to promote the legal protection of sites and their national patrimony. Renewed French archaeological research had to adapt to these many changes: ultimately, it took several years to put together the scientific and institutional basis that gave birth to the new French Americanism, which is still very active today.

Thus, the history of French Americanism does not fit within either Willey and Sabloff's or Bernal's proposed chronological frameworks, as exemplified in the accompanying table (see page 536). If 1492 is taken as a starting point, the first period-the period of discovery and history-would last until 1824-1834, ending

with the publication of *Antiquités Mexicaines.* The next decades, up to 1860, continued this early start, and from 1860 until 1914 France took an active role in the exploration and registration of archaeological sites in the Americas. The first half of the twentieth century saw a collapse of French archaeological research in the Americas, and it is only after 1960 that this complex history resulted in actual scientific and systematic studies of the American past.

From Discovery to Antiquités Mexicaines

It took France some time to become interested in the discovery of the Americas. Like Great Britain, France was deeply entangled in its struggle against the Spanish king Charles V in Europe, and the existence of a new continent aroused only slight interest in intellectual circles, mostly among writers and artists. Writers such as Michel Eyquem de Montaigne or François Rabelais sometimes referred to the inhabitants of the New World; this interest did not amount to more than a mere curiosity for exotics and new artifacts.

As its political situation improved, France slowly paid more attention to the American continent. While corsairs plundered colonies and attacked Spanish fleets in the south, the arrival of Jacques Cartier in canada in 1534 marked the beginning of French colonial enterprises in that part of the world. Canada quickly became a French stronghold and would remain so for several centuries, but French settlements in Florida and Brazil did not succeed, and only a few scattered settlements in the West Indies were permanently occupied. These territories proved themselves, in many respects, much less attractive than Mesoamerica or Peru, and France quite naturally turned its attention toward the exploitation of economic resources, rather than Indian civilizations. Very few artifacts were taken away to be featured in the Wunderkammer, or Cabinets de Curiosités (collections of strange objects and precursors of museum collections), in France. Those that were featured there, as Pascal Riviale (1993) demonstrated, were usually classified as “naturalia” or “artificialia,” rather than works of art. From the very beginning

American artifacts in France were assigned to the realm of natural history.

This does not mean that French Cabinets de Curiosités were entirely devoid of American objects. Their presence was acknowledged, the most important instance being the *Codex Telleriano-Remensis,* the collection of artifacts given to the Royal Library by Archbishop Le Tellier at the beginning of the eighteenth century. A few Peruvian ceramics were also taken back to France by smugglers from Saint Malo, with the help of French residents in Lima, such as Dr. Leblond. In addition, there was a great desire to acquire larger collections, as was made obvious in documents such as the instructions issued to the Jussieu-La Condamine and Dombey expeditions to peru, which directed the teams to try to collect artifacts from Chancay and Pachacamac. But the whole collection amounted to little more than a few items, and the American past was more likely to be the subject of speculative or literary activity.

As Keen amply demonstrated (1971), from the end of the sixteenth century until 1820, the Americas and the Amerindian civilizations became the focus of a growing interest. The pioneering books of De Belleforest in 1572 and Thevet, a geographer in the court of King Henri II, were quickly translated into many languages. Discussions of the Americas became contentious as time went by, and most well-known eighteenth-century philosophers, such as Buffon, Voltaire, and Prevost, took sides in these controversies. The Americas even provided a source of inspiration for poetry, theater, and opera. This general interest for American civilizations was part of an increasing tendency to dwell on humankind's past. As Schnapp recently demonstrated, archaeology-or at least scholarly activity in archaeology-was establishing itself as a scientific discipline, and discoveries in southern Italy quickly led to the systematic study of ruins. The kings of spain promoted this research and sent explorers to the Mayan ruins of palenque (Baudez 1987). In Mexico the chance discovery of aztec sculptures in 1792 prompted national investigations by scholars such as Alzate and Leon y Gama. The Bonaparte expedition to Egypt stands out as the most famous example of early French studies in archaeology. The American continent was not entirely neglected, as evidenced by the travels of Humboldt and Bonpland in South and Central America in 1810. The French concept of the American past was anthropological in nature, expressing a natural historical approach rather than an interest in American art, and French research focused mainly on human diversity, not just upon archaeological remains. The end of Spanish rule in Latin America provided opportunities that France and other countries seized immediately.

The breakthrough for French Americanism came in 1834, six years before Stephens and Catherwood's book, with the appearance of *Antiquités Mexicaines.* This book included the manuscripts of Galindom Del Rio and Juarros, as well as articles by Humboldt, Warden, Jomard Baraère, and even Chateaubriand, but it failed to attract much attention. The French public had to wait 150 years to be able to read Stephens and Catherwood's book in translation. This situation symbolizes perfectly the original inadequacy of French Americanism in the nineteenth century-too little and too late.

A Century of Exploration

For the whole of the nineteenth century (or, more precisely, from 1824 to 1914), American archaeology in France remained restricted to a small circle of explorers and scholars, who succeeded in obtaining the backing of official institutions but failed to raise public interest. French explorers and adventurers, though few in number, *were* able to organize associations and committees to raise funds for their travels. The French Ministry for Public Instruction was the most prominent sponsor, especially after the creation of the Mission Service, but the Natural History Museum and the Navy also played useful roles. For example, in 1836, the ship *La Venus,* commanded by Dupetit-Thouars, was instructed by Brongniart to collect Peruvian ceramics for the Musée de Sèvres. Societies such as the Geographical Society in Paris created prizes and medals, published reports, and organized conferences, and they succeeded in attracting investigators from other countries, such as the American antiquarian Ephraim Squier and naturalist Alexander von Humboldt, as corresponding members.

PREV NEXT

In North America explorers were less numerous, but some of them made important contributions to archaeology. In the Mississippi Valley Lesueur excavated some mounds, and Pinart's research on the northwest Pacific Coast is still significant. The most important contribution was made by Cessac, whose lithic collections in the Chumash area still form the basis of the history of California.

mesoamerica attracted most investigators. There, Charnay used photographs for the first time to register monuments. He also identified the mythical Tollan as Tula, and he conducted the first excavations of that site. Diguet's contribution to the archaeology of northwestern Mexico still awaits proper evaluation, and in the Mayan areas, Périgny discovered the Rio Bec site and style. The Swiss investigator De Saussure published a unique article on the site of Cantona, now for the first time the subject of a vast archaeological project. But his main contribution lay in the study of glyphs, with his publication of *Codex Becker*.

The study of Mesoamerican writing systems constituted a special branch of archaeology in which French scholars participated during the nineteenth century. Brasseur's discovery of Landa's Relacion de las Cosas de Yucatan and of the Popol Vuh and then the Codex Tro-Cortesianus were essential landmarks in the field of epigraphy. Despite the intervention of scholars such as Charencey and Rosny later on, epigraphical studies were quickly left to German or American specialists (Seler, Förstemann, Scwellhas, Maler, Maudslay, and Goodman).

South American civilizations were somewhat neglected but not ignored by French archaeologists: Wiener is known for having brought back 2,500 artifacts from his two-year stay in Peru, many of them characteristic of previously unknown styles such as Recuay. The Créqui-Montfort expedition to the South Andes benefited from the help of specialists such as gabriel de mortillet and Boman, and it brought into focus little-known aspects of South American civilizations, including the Diaguites. A special mention must be made of Ber, who, though still neglected, insisted for the first time upon the need for a contextual approach to collecting Peruvian remains. This list of researchers is far from exhaustive: one could add many other names, among them Nadiallac, Crevaux, and Colpaert in Peru and Pector in Central America.

This intense activity rested, as already mentioned, on a fragile theoretical basis, but it led to some outstanding results, including the organization of the first International Congress of Americanists in Nancy, France, in 1875. This meeting proved to be such a success that three more congresses were held in Paris before 1900. The Société des Américanistes recruited old hands such as Rosny, Hamy, Lejéal, and Nadaillac, as well as newcomers such as Cordier, Capitan, Rivet, and even Maspéro, and the duke of Loubat. The duke sponsored field research, either by French or foreign scholars (Seler, Holmes, and Saville), and he created the first academic position, at the Collège de France, where Lejéal and Beuchat had a chance to teach. Unfortunately, these changes came too late, and in the field, French explorers were confronted with trained archaeologists from other countries such as max uhle, Alfred Tozzer, and manuel gamio. Exploration gave way to scientific research, and at the creation of the first school of archaeology in Mexico in 1910, only one Frenchman was involved-Enguerrand, who stands as the perfect symbol of this new situation. French explorers lost touch with current trends and the study of the Americas was no longer deemed fashionable. When World War I exploded in 1914, most French scholars in archaeology were either dead or retired, and the Americanization of American studies was on its way.

1914-1960: A Collapse?

If we follow Willey and Sabloff's chronological scheme, the period between 1914 and 1960 was characterized by the stratigraphic revolution. Everywhere in America, chronologies were sought after,

excavations were conducted by huge teams, and at the end of the period, the use of new techniques such as aerial photography and radiocarbon dating allowed for the elaboration of secure aereal chronological charts. Although similar progress occurred in France itself, with some influence on this evolution,

PREV NEXT

French archaeologists were not in the field in the Americas. French research was limited to a short-lived grant allowance that enabled young students in anthropology to spend some time in the field (such as Soustelle Ricard, Gessain, Stresser-Péan), and to the field intervention of a few trained investigators such as d'Harcourt, Beuchat, and Rivet. Their most important achievement lay in the creation of the Musée de l'Homme, in Paris, the third stronghold of French American studies.

The public perception of American Indian art, at the same time, went through a significant change under the influence of both artists (e.g., the surrealists) and antiquarians. Along with African and Far Eastern civilizations, the peoples of Mesoamerica and the Andes were at last recognized as art producers. Several exhibitions and numerous articles and catalogs were devoted to the popularization of native art from the Americas, which had finally found a place in French art history.

World War II suppressed this renewed interest. The turmoil of war and political instability caused many European anthropologists, among them Armillas Palerm and Wittfogel, to emigrate to the American continent. But only Rivet in colombia contributed to the establishment of scientific research. French-trained archaeologist Reichel-Dolmatoff migrated as well, and his synthesis of Colombian archaeology stands out among the few general publications of the 1950s. In chile Emperaire conducted field research on the Alakaluf, a neglected area, and some other archaeologists kept working, including Flornoy in Peru and Lehmann in guatemala. But ethnology and general anthropology were the dominant interests, and the French contribution to the archaeology of the Americas remained small. One must nonetheless mention Soustelle's books on the Aztecs, which, though closer to ethnohistory, showed that French American studies were not to be underestimated.

By the end of the 1950s the economic situation in France had improved, and French research, which was supported by the firmly established structures of the Société des Américanistes, the Musée de l'Homme, and the International Congresses, could begin again.

Institutional Research: The Flowering of French Activity

French Americanists sought official backing from the French government's secretary for foreign affairs, who was called on to create the equivalent of the Athens or Rome schools of archaeology in the Americas. This caused the birth of the Institut Français d'Etudes Andines (IFEA) in Lima and the Mission Archéologique et Ethnologique Française (MAEFM, now known as CEMCA) in Mexico, both of which were devoted to anthropological investigation in the Andes and Mesoamerica. The MAEFM was established in 1961, and the IFEA in Peru was part of a general cooperational governmental agreement in 1970 between Mexico and France, on a permanent basis. There is some justification for the existence of such centers, despite their being characteristic of a French state-oriented mentality. They provide stability and financial or technical help to French investigators, and they encourage an interdisciplinary approach that suits the present needs of scientific research.

It is too early to judge recent research in the Americas, but this history of French Americanist archaeology would be incomplete if it did not include the results of the IFEA and MAEFM. French archaeology in the Americas has grown steadily. In 1971 these institutions directed three archaeological projects; by 1990 fifteen projects were under way in nine different countries.

Thanks to the help and efficiency of P. Guillemin, director of the department who manages IFEA and MAEFM at the secretary for foreign affairs,the IFEA and the MAEFM consolidated their local position, and simultaneously in France, specialized sections at the Centre National de la Recherche Scientifique (CNRS) and at various universities were organized. Archaeological research also started up in French territories-that is, in Guyana and some islands in the West Indies, an area that had previously been

neglected.

These institutional and governmental structures were also strengthened by French investigators living in the Americas, and French-trained archaeologists and French Canadians began to get involved: Paul Tolstoy and Louise Paradis in Canada, A. Nelken Terner, C. Niedergerger, and P. Gendrop in Mexico, and A. Ruz Lhuillier, who helped create a teaching department for archaeology in Paris, are only a few examples. Meanwhile, the European Community has generated cooperative archaeological projects in Spain, Germany, England, belgium, and Holland (with whom France shares some interest in the West Indies) and in northwestern Mexico (research by Hers and Daneels, for instance).

French Archaeology in the Classical World

France was not in the forefront as a founder of archaeological science. In the fifteenth and sixteenth centuries, it was the Italians, such as cyriac of ancona and Pirro Ligorio, who were the pioneers in the field, which was only to be expected given the abundance of antiquities on Italian soil. Meanwhile in France, as elsewhere in the western world, the climate of the Renaissance and the spread of humanism sparked an interest in antiquity. The humanists were concerned primarily with the writings of earlier authors and the discovery of new manuscripts; archaeology took second place to philology. Mention should be made of the collections of King Francis I (1494-1547) of France and the casts he commissioned of Roman remains.

In the seventeenth century, however, the presence of the French was very significant in the field of classical archaeology. Nicolas-Claude de Fabri, seigneur of Peiresc, was typical of the new breed of French antiquarian. He was a councilor at the parliament of Aix-en-Provence and was interested in law and sciences as well as archaeology. His cabinet of curios, one of the most famous in Europe, testified to his eclectic tastes: antiques were displayed alongside works of art and natural curiosities. For him, an artifact was not merely a sign of prestige but also an object of study that led to knowledge of antiquity. Although he never published any of his research, he had a considerable influence on scholars through the network of connections he established in Europe. Yet his influence had its limitations; even though he had done the grand tour of Italy, he remained more interested in collectable objects than in historical

monuments, more interested in written works than in sites to be explored.

In the second half of the seventeenth century, a new spirit of inquiry appeared as the result of voyages by both scholars and ambassadors accompanied by artists and men of letters. In 1674, the marquis of Nointel, the French ambassador at the Turkish court, visited Athens and had drawings made of the sculpted marble of the Parthenon-pediments, frieze, and metopes-thus preserving a record of the state of the temple before it was badly damaged by the Venetians in 1687. One sign of the new way of thinking was that antiquarians began to concede a greater importance to material sources, which they saw as being more reliable records than the printed word. They were particularly interested in inscriptions and coins found at the sites where they had been made.

Jacques Spon may be seen as the best example of this new type of antiquarian. He was a doctor

French Archaeology in Egypt and the Middle East

By the end of the eighteenth century, France began a political extension toward the Oriental world. Simultaneously, far from its national borders, it entered into archaeological research, first in Egypt, then in the Near East (i.e., the Asiatic possessions of the Ottoman Empire that came into existence as nations after World War I), and lastly in Persia (modern iran). Considering the importance of the archaeology undertaken by France in those countries, it is not feasible to catalogue or sum up nearly two hundred years of its archaeological work in this article. However it should be understood that the prestige of French archaeology lies less in the great width of its activities than in the simple fact that, more than once, these stand as landmarks in the history of the archaeological studies of the Ancient Near East.

The first contact between France and Eastern civilization happened in a rather striking way. In 1798, for intricate political, scientific, and ideological reasons, Napoleon Bonaparte decided to have scholars and engineers join his army in a military expedition to Egypt. His science crew's mission was to obtain and collect all the information they could about Egypt, both ancient and modern.

Although the works and facts recorded about Coptic and Islamic monuments proved to be the most remarkable achievements of this expedition, the greatest immediate influence was the investigation of Pharaonic relics from antiquity. For instance, the knowledge of Upper Egyptian sites, so far virtually unknown, increased considerably. Vivant Denon was the first author to publish accounts of the expedition, in his *Voyage dans la Basse et la Haute-Egypte, Pendant les Campagnes du Géneral Bonaparte en Egypte.* This very successful work was the result of the first investigations of Upper Egypt in 1798, when Denon followed General Desaix, who was pursuing Mourad-Bey and his followers on their retreat south.

Edouard de Villiers and Prosper Jollois, two young engineers, made important additions to Denon's accounts. Both men were members of a commission departing for Upper Egypt in early 1799 with numerous tasks, one of which was to draw the outlines of the Nile Valley. Fascinated by the monuments they encountered, of their own accord they made thousands of drawings and notes of them. With the full cooperation of the other members of the expedition, who had concentrated on the monuments of Lower Egypt, this vast collection of data was published in the monumental multivolume work *Description de l'Égypte* in late 1799. This exceptional work not only comprises the largest and most comprehensive collection of documents ever to have been published on Egypt in those days, but it is still referred to, and is seen as all the more precious as many of the sites it recorded no longer exist. The scientific achievements of the different expeditions constitute the most lasting and least questionable gain of Napoleon Bonaparte's adventures in Egypt.

During a military expedition, on the eve of the land battle of Aboukir (1799), Captain Bouchard, as a consequence of prebattle trenching at Rosette, came across the famous “Rosetta” stone bearing inscriptions in two languages and three kinds of writing: hieroglyphic, demotic, and Greek. The importance of this find was immediately understood by scholars. England confiscated the stone after the Eastern Army surrendered to them, and however unfortunate this loss was for French scholars, it was no hindrance to jean-francois champollion. Working from a copy of the stone, in 1822 he established the foundations for deciphering hieroglyphic writing.

The exciting years at the close of the Age of Enlightenment at the end of the eighteenth century and those at the beginning of the nineteenth century mark the beginning of scientific Egyptology. France became involved in the protection of monuments and laid the foundations for its future research at these sites.

auguste mariette, the excavator of Memphis Serapeum, was prominent in the creation of the “Service des Antiquités,” an organization that policed and protected archaeological sites, and the first museum in Egypt. A few years prior to this, between

and results of excavations undertaken in Susiana, as well as control over the whole archaeology of Persia. The Délégation lasted fifteen years, from 1897 to 1912, and its prestige was due to the character of Jacques De Morgan. A prehistorian by training, De Morgan's great knowledge of Iran was the result of extensive travel between 1889 and 1891, from the Caucasus into and around Northern Persia, then over the whole country, and finally to Susa. When the French government appointed him to a position in Persia, he had already successfully managed the Service des Antiquités in Egypt.

De Morgan's plans were initially very ambitious, with the whole of the archaeological wealth of Persia under his control. But De Morgan believed that the urgent work at Susa had to come first before all other projects and should never be sacrificed for the sake of hazardous ventures. So, facing a financial situation that did not allow him to diversify his research unless he jeopardized the studies at Susa, his efforts and those of the Délégation were essentially devoted to the Susa site. His important work at Susa greatly benefited both the louvre Museum and other scholars, and in the long term it seems that Jacques De Morgan was right about his priorities. However, he was criticized about his research choice and attacked by fellow workers, and by then his long, hard-working years in the Middle East had exhausted him. In 1912, De Morgan resigned, and with this the Délégation Scientifique Française en Perse came to an end.

The agreement that founded the Délégation was not repealed until 1927, and France's archaeological interests were maintained by the Direction des Antiquités under command of André Godard until 1960 and the Institut Français de Recherche en Iran (IFRI). But while the Délégation ceased to exist after De Morgan's departure, the excavations at Susa continued. After World War I, when France diversified its archaeological research into the Iranian plateau and along its borders, Susa and Susania remained the center of its activity. Roland de Mecquenem until 1946, then Roman Ghirshman, and finally Jean Perrot from 1968 have been successively responsible for the work in this area. Nothing less than two world wars and, in 1979, the Islamic Revolution in Iran, could interrupt nearly a century of French research in Susania.

The archaeological activity of France in most of the Near East goes back to the nineteenth century. Due to scientific concerns, politics, and economics other areas have been opened to research more recently. In Arabia France is presently engaged in numerous archaeological projects. Twice interrupted by world wars, and then, occasionally, by the repercussions of political events, the archaeological activity of France in the Near East and Egypt has carried on for two centuries and, as much as circumstances will allow it, it continues.

Frere, John

(1740-1807)

John Frere was born in Norfolk, England, and graduated from Caius College, Cambridge. An antiquary and a member of the local upper-middle class, Frere was also high sheriff of Suffolk in 1766, was elected to Parliament for Norwich in 1799, and became a fellow of the Royal Society in 1771.

In 1797, Frere reported to the society of antiquaries of london that he had found stone tools (what are now described as Acheulean hand axes) in the same levels as the bones of long-extinct animals-four

meters down-in undisturbed Pleistocene deposits in a brickpit at Hoxne, Suffolk. He argued that the overlying strata, which included evidence of a rise in sea level and half a meter of deposit, could only have been laid down over a very long period and that the stone tools and animal deposits had to be over 6,000 years old. *Archaeologia* in 1800 included a description of the find, a stratigraphic description, and a section of the deposit. Frere and his publication were politely ignored by the scientific establishment mainly because the conclusions seriously challenged the accepted date for the creation of human beings, which had been established in 1650 by Bishop james ussher, based on biblical calculations, as occurring on the evening of 22 October 4004 b.c. G

Gabrovec, Stane (1920-)

Stane Gabrovec is a Slovenian archaeologist and a specialist in the Bronze and Iron Ages of central and southwestern Europe. He graduated in archaeology and classical philology from Ljubljana University in 1948, specialized in prehistoric archaeology at the University of Tübingen in Germany, and received his Ph.D. from the University of Zadar in Croatia. He was curator of prehistory at the National Museum in Ljubljana after World War II (1948) and after 1956, head of the Prehistory Department at the same institution. From 1969 to 1989, he taught prehistory at the University of Ljubljana. Gabrovec became a member of the Slovenian Academy of Arts and Sciences and a correspondent member of the Bavarian Academy of Sciences in Munich.

Gabrovec has dedicated most of his scientific work to solving problems of chronology and cultural definition in the Bronze and Iron Age cultures of the southeastern Alps and Caput Adriae, the area comprising slovenia, austria, northeastern italy, western Hungary, and northern Croatia. His most important and highly influential work on Slovenian prehistoric archaeology and beyond, i.e., on the establishment of the chronology for the late-Bronze and early-Iron Ages in Slovenia, was published in *Halstatska kultura v Sloveniji* [Hallstatt Culture in Slovenia], *Arheoloski vestnik* (Ljubljana) 15-16 [1964- 1965]: 21-63. In those studies, he defined five regional groups within the Slovenian Hallstatt culture: the Dolenjska (lower Carniola) group in central Slovenia, the Sveta Lucija (St. Lucia) group in western Slovenia, the Notranjska (inner Carniola) group in southwestern Slovenia, the Gorenjska (upper Carniola) group in northwestern Slovenia, and the Stajerska (Styria) group in northeastem Slovenia and southeastem Austria. Gabrovec incorporated these groups into the cultural and chronological schemes of southeastern and central Europe, and he also demonstrated that the process of transition from the late Bronze Age to the early Iron Age is characterized to a great extent by cultural and ethnic continuity from the "Urnfield culture" and by the presence of the early Iron Age elements originating from the Balkans. He demonstrated a similar phenomena of ethnic and cultural continuity in the la tène period in Slovenia, when several cultural groups continued their development from the early Iron Age while celts populated only parts of central and eastern Slovenia in the middle La Tène period.

Gabrovec also published an extensive and updated synthesis of the late Bronze Age and early Iron Age in Slovenia. Among the numerous sites excavated by Gabrovec, the most important is the famous princely hill fort at stična. This large barrow was excavated between 1960 and 1964, and part of the settlement was excavated between 1967 and 1974. Besides studies of the Bronze and Iron Ages, his work includes the history of Slovenian archaeology, prehistoric topography, and prehistoric art.

Methodologically, Gabrovec's approach can be described as part of the so-called Gero von Merhart historical school, developed in the 1940s and 1950s at the University of Marburg in Germany. This approach is based on a detailed analysis of material culture, its chronological sequence and development, and its geographical distribution, and such analysis is applied to the definition of the different cultural regions, the

Gallatin, Albert

(1761-1849)

Albert Gallatin was born in Geneva, switzerland, into an aristocratic family. He studied classical and modern languages, geography, and mathematics and became a follower of the French philosopher Jean-Jacques Rousseau and European Romanticism. He left Geneva for the United States in 1789, where he briefly taught French at Harvard College before purchasing land on the then-frontier in western Pennsylvania. He was not a successful farmer or frontiersman and soon became involved in politics. He was elected to the state legislature between 1790 and 1791 and then served as a senator in the federal government, becoming a friend of thomas jefferson, Henry Adams, James Madison, and Alexander Hamilton. He married into New York society, served in Congress, and was secretary of the Treasury from 1801 to 1814. He then served as a diplomat, traveling to Russia and Belgium, and was a representative for the government of the United States in Paris from 1816 to 1823 and in London from 1826 to 1827.

Gallatin left government service and returned to New York City, where he and John Jacob Astor founded a bank and he became one of the founders, and the first president of the council, of the University of the City of New York in 1831. During his years in france, Gallatin had shared his long-term interest in philology with Alexander and Wilhelm von Humboldt and in 1823 had contributed an essay to their book on American Indian languages. It was this latter interest that now absorbed most of his time and earned him the title "father of American ethnology."

In 1826, Gallatin's book *A Table of Indian Languages in the United States* was published, and it included the first map of tribal languages and the first attempt at designating language groups through the comparative method. This work was followed in 1836 by "A Synopsis of Indian Tribes… in North

America," an extended version of the Humboldt essay. In 1843, Gallatin was instrumental in the founding of the American Ethnological Society and became its first president. His "Notes on the Semi-Civilized Nations of Mexico, Yucatan, and Central America" and "Introduction to Hale's Indians of North-West America and Vocabularies of North America" were published in volumes one and two of the *Transactions of the American Ethnological Society.* Although he was most proud of these publications, and judged them to be the most important he wrote, Gallatin is far more widely known for all of the annual and special reports he wrote as secretary of the Treasury, for his diplomatic notes and correspondence, and for his numerous pamphlets on finance, public lands, the Oregon question, and the Mexican War written during his years in government.

Tim Murray

Gamio, Manuel

(1883-1960)

Manuel Gamio was born in Mexico City and studied mining until 1903, when his father sent him to administer a family plantation. While engaged in that work, he had contact with the indigenous Nahua people, learned their language, and was appalled by their poverty. Returning to Mexico City in 1906, Gamio studied anthropology and archaeology at the National Museum for two years. His first archaeological excavations were of the site of Chalchihuites, Zacatecas,

identification of cultural groups, and their social structure, historical, and ethnic adherence.

Gamio, Manuel

(1883-1960)

Manuel Gamio was born in Mexico City and studied mining until 1903, when his father sent him to administer a family plantation. While engaged in that work, he had contact with the indigenous Nahua people, learned their language, and was appalled by their poverty. Returning to Mexico City in 1906, Gamio studied anthropology and archaeology at the National Museum for two years. His first archaeological excavations were of the site of Chalchihuites, Zacatecas,

In 1917, Gamio founded and was the first director of a federal department of anthropology and, despite political upheavals, received sufficient resources to set up several research programs. One of these was the first multidisciplinary anthropological program in the Americas- work on the population of the Teotihuacán Valley. This program lasted five years (1917-1922), involved investigations by over twenty scholars, and combined ethnographic and archaeological studies. The five-volume report that resulted is still an indispensable reference source for central Mexican anthropology and history. Gamio also wrote a doctoral dissertation for Colombia University based on this research.

Other projects initiated by Gamio during the 1920s included investigations into the early sedentary archaic (formative) cultures in the basin of Mexico, the excavation of Copilco and other sites, and supporting a project by Byron Cummings at an early urban center of Cuicuilco. Gamio also founded and edited the journal *Ethnos* (1920-1925), which published influential reports and essays by Gamio and others concerning the archaeology, ethnology, and contemporary problems of the indigenous peoples of Mexico.

Between 1924 and 1925 Gamio had a brief political career as undersecretary of public education, but after denouncing government corruption in Mexico City newspapers, he had to flee the country. He spent over two years in exile in the United States and guatemala, during which time he began his famous studies of Mexican immigrant laborers in the United States, which became classic in sociology and applied anthropology. After his return to Mexico and for the rest of his life, Gamio was primarily concerned with the direction of several key government and international institutes devoted to improving the living conditions of indigenous groups. He founded and then directed (1942- 1960) the Inter-American Indian Institute, and his work still exercises a profound influence on contemporary Mexican anthropology.

Garbology: The Archaeology of Fresh Garbage

Gold cups, jade beads, mummies, temples lost in rainforests-to me, these were the essence of archaeology. Oh, how I longed to become an archaeologist and journey back to the days of our ancient ancestors by following the breadcrumb trails of the artifacts they left behind. In 1954, when I was nine, that was the archaeology I dreamed about as I drifted to sleep beside my dog-eared copy of *The Wonderful World of Archaeology* (Jessup 1956).

Fourteen years later I found myself in graduate school immersed in the stifling smell of dusky potsherds punctuated every so often by the thunderous explosions of 200-300 broken pieces of pottery being poured out of linen bags onto masonite laboratory tables. These potsherds had become my path to ancient lives. By this time, I had learned enough of archaeology's arcane secrets that I fully appreciated the stories that could be told by potsherds and other commonplace discards about a society's rise and fall and its day-to-day existence. I was, in fact, literally excited to be systematically and scientifically analyzing the vast expanse of discards to discover replicated patterns of human behavior that we can still recognize today. At the time, I believed I was about to add my own small piece to understanding the puzzle of the classic Maya collapse (Rathje 1971, 1973). In 1968, that was the archaeology I dreamed about when I dozed off late at night on top of my well-worn copy of *Uaxactun, Guatemala:*

Excavations of 1931-1937 (Smith 1950).

Today, more than three decades years later, I look back on my past dreams of archaeology with a bemused smile on my face, my hands full of fresh garbage, and my mind dancing with thoughts of the calories from fat in our diet or of the recyclables mixed into garbage instead of separated for curbside collection. And instead of

estimates of the refuse that goes to MSW (municipal solid waste, or standard community refuse) landfills. Nevertheless, C/D accounted for 20 percent or more of excavated refuse by volume and was the second-largest category of discarded materials recovered by the Garbage Project from MSW landfills.

The largest category occupying MSW landfill space was paper. This was true for refuse buried in the 1980s as well as for refuse dating as far back as the 1950s, because in most landfills, paper seemed to biodegrade very slowly. As a result, by volume, nearly half of all of the refuse excavated by the Garbage Project consisted of newspapers, magazines, packaging paper, and nonpackaging paper such as computer printouts and phonebooks.

Not long after the Garbage Project's first reports following its landfill digs, the energy directed at passing bans was largely redirected toward curbside recycling. A number of communities began placing emphasis on reuse and recycling programs for C/D, and paper recycling promotions started stressing the need to keep paper out of landfills because it did not biodegrade as quickly as most people had once hoped. An association of state attorneys general determined from dig data that several products that claimed to be “biodegradable,” including some brands of disposable diapers and plastic garbage bags, did not biodegrade in landfills, and the false advertising of these products was eradicated. All of this was evidence that some crucial views of garbage held by policy planners, the media, and the public had changed-and that garbology had been validated as a new kind of archaeology, one that could make an immediate public contribution.

The Rationale for Garbage Archaeology

For as long as there have been archaeologists there have been jokes, cartoons, and stories that guess what it would be like for an archaeologist to dig through our own refuse (Macaulay 1979). Although often humorous, such speculations are, in fact, based on a serious rationale: if archaeologists can learn important information about *extinct* societies from patterns in ancient garbage, then archaeologists should be able to learn important information about *contemporary* societies from patterns in fresh garbage. The pieces of pottery, broken stone tools, and cut animal bones that traditional archaeologists dig out of old refuse middens provide a surprisingly detailed view of past ways of life, just as all the precisely labeled packages, food debris, and discarded clothing and batteries in modern middens reveal the intimate details of our lives today.

During the summer of 1921, the great American archaeologist alfred v. kidder seemed to understand this fact when he took the trouble to observe the artifacts that were coming out of a trench being cut for a sewer line through a “fresh” garbage dump in Andover, Massachusetts. From at least this point on, archaeologists have studied contemporary urban refuse informally and sporadically as class exercises and methodological experiments. A variety of subspecialties-ethnoarchaeology, historic sites archaeology, industrial archaeology, and experimental archaeology-have been edging ever closer to analyzing what citizens of the industrialized world discarded last year, last month, and even yesterday. In fact, all archaeologists are aware that it is inevitable that contemporary rubbish will be studied by traditional archaeologists in the same manner they now study the middens of ancient Troy and Tikal-that is, in a hundred or so years from now.

If there are useful things to learn from an archaeological study of our garbage-things that can enrich human lives and minimize the undesirable environmental consequences of the industrialized world-why wait until we (and I literally mean you and I)are all dead and buried to find them out? At least, that is what a group of students and I thought when we founded the Garbage Project at the University of Arizona in the spring of 1973. Today, all of us who are a part of the project, including codirector Wilson

Hughes who was one of the founding students, are still thinking along these same lines (Rathje 1996).

After nearly two and a half decades of sorting, recording, and interpreting MSW, garbology, or the archaeological study of contemporary urban refuse, has become a recognizable subspecialty within archaeology and other behavioral

(such as three or four half-full cans of paint or several full containers of pesticide in just one pickup). The Garbage Project's interpretation was that the media surrounding the collection day made people aware of the potentially hazardous commodities in their homes, but for those who missed the collection day, no other appropriate avenue of discard had been identified. As a result, some residents disposed of their hazardous wastes in the only avenue available to them-their normal refuse pickup. The same pattern was verified in subsequent studies in Phoenix and Tucson (Rathje and Wilson 1987). The lesson learned: communities that initiate hazardous waste collection days should inform residents of future collection times or of other avenues for appropriate discard.

Such counterintuitive interview/refuse patterns indicate that consumers may not be aware of how much their reported behaviors differ from their actual behaviors and that the Garbage Project is beginning to document a previously unmeasurable phenomenon between what people think is happening and what is really going on. Such studies have already led to some general principles of the differences between people's awareness of their behavior and their actual behavior (Rathje 1996).

The Garbage Project's contribution to a better understanding of the relationship between what people report they do and what they actually do (Rathje 1996; Rathje and Murphy 1992a) relies heavily on the use of archaeological methods and theory to quantitatively document actual behaviors from refuse. This is the grist of any archaeologist's mill, and the validity of the Garbage Project's data records and interpretations is based upon 100 years of previous archaeological studies that have analyzed refuse to reconstruct behavior.

For the same period of time, archaeologists have also been studying refuse in an attempt to count the number of people who lived within particular sites or regions at particular times. The Garbage Project has now done the same thing at the request of the U.S. federal government. The U.S. Census Bureau has long been aware of the criticism that its interview-survey methods lead to a significant undercounting of ethnic minorities, especially young adult males who may be undercounted by 40 percent. In 1986, the Quality Assurance Branch of the Census Bureau funded a study to answer the question, Could the Garbage Project count people based on the types and quantities of residential refuse they generate? The answer was yes (Rathje and Tani 1987). For any unit of time in any given neighborhood, the overall weight of total refuse discarded (minus yard wastes, which vary markedly between suburbs and inner cities) varies directly according to the number of resident discarders. The Garbage Project converted quantities of refuse thrown out per week to numbers of people by using “per person” generation rates documented in test areas. Overall, a series of garbage-based estimates of population were within 5 percent of the actual number of residents. The Garbage Project now stands ready to cross-verify census counts with a method that does not violate the subjects' anonymity.

Ongoing Research

Since 1980, the Garbage Project has worked on a large number of specialized topics similar to the census study, and all of them are the focus of continuing inquiry. Landfill excavations, for example, are gauging the impact of recycling programs on the volume of wastes that reach landfills. The first reported results estimated that metropolitan Toronto's “blue box” curbside recycling program has conserved some 20 percent of landfill space in the metropolitan area since 1982 (Tani, Rathje, Hughes, Wilson, and Coupland 1992).

The recovery of 2,425 datable, readable newspapers from the project's excavations dramatically changed the view that biodegradation is commonplace in landfills. To better understand why biodegradation does and does not occur in landfill environments, the Garbage Project has so far conducted four cooperative digs that have involved microbiologists and environmental engineers from the

University of Arizona, University of Oklahoma, University of Wisconsin-Madison, Argonne National Laboratories, and Proctor and Gamble's Environmental Laboratory (Suflita et al. 1993). In this same

mode, the Garbage Project excavated and examined samples of refuse from a ten-year-old “bioreactor” landfill in Sandtown, Delaware, one designed to enhance biodegradation. According to the project's evaluation, after ten years of burial, the Sandtown refuse exhibits some indications of increased biodegradation but nothing conclusive (Rathje 1999). The next Sandtown dig is scheduled for 2008.

The Garbage Project has also initiated several studies that integrate its fresh and landfill data on hazardous wastes in MSW. The heavy-metal assays of finds are being compared with detailed item-by-item lists (such as two lightbulbs, one drain opener can, two newspapers, etc.) of the refuse identified within each 150 pounds of landfill sampled. The goal is to determine the rate of movement of heavy metals in commodities and inks and other hazardous wastes from refuse into the landfill matrix (Rathje, Hughes, et al. 1992).

Garbage Project Students and Staff

The Garbage Project does not consist of only systematic records compiled by a hands-on sorting of household garbage; it also consists of the sorters and project staff attached to the hands. Although many people find the results of project data studies interesting, most of them also find the sorting process itself revolting. In fact, a few market researchers realized in the 1950s that household refuse contained useful information but after repeated experiments they found they could not pay people to sort refuse. Those hired either quit quickly or kept sloppy records. Who would possibly be willing to rummage through someone else's smelly trash and keep accurate records of its contents?

The answer is a matter of public record. *Rubbish!* (Rathje and Murphy 1992b, paperback 1993) contains a list of more than 900 university students and others who sorted refuse for the Garbage Project between 1973 and 1991. The intimate archaeological view these and subsequent sorters have had of the materials that are discarded from households much like their own has provided them with a unique perspective, and while they do not preach to others, they are enthusiastically dedicated to providing everyone possible with the same insights they have drawn from their own hands-on sorting of residential refuse.

In attempting to share results, the Garbage Project has focused most directly on schools, museums, and other avenues of access to students. The rationale is that the archaeology of our own society will mean the most to the young people who can do the most with archaeological insights. Currently, the project is especially proud of two endeavors. The first is the compilation of *WRAP (Waste Reduction Alternatives Program) Resource Manual* (Dobyns and Hughes 1994), which has been distributed to schools throughout Arizona and the United States. The manual is designed to help both students and teachers learn how their individual behavior can produce significant quantities of garbage and how they can each make changes that will greatly decrease that amount of garbage. The second endeavor resulted in “The Garbage Dilemma,” an interactive video on permanent display in the Hall of Science in American Life at the Smithsonian's National Museum of American History. The video was the product of cooperation among the Garbage Project staff, the Smithsonian's design staff, and the Chedd-Angier Production Company. Schools and museums-not landfills-provide the kinds of environments where the Garbage Project hopes all of its results will eventually come to reside.

Garbology in the Twenty-first Century

What has set the archaeologists of the Garbage Project apart from other behavioral science researchers is that all of their studies have been grounded in the hands-on sorting of quantifiable bits and pieces of garbage instead of collecting data through interview surveys, government documents, or industry records. In other words, the Garbage Project is studying consumer behavior directly from the material

realities that are left behind rather than from self-conscious self-reporting.

The exhaustive level of detail Garbage Project student sorters use to record data has also set the project's studies apart from other data sources. Many local plans by engineering consultant firms and even by solid waste managers

mode, the Garbage Project excavated and examined samples of refuse from a ten-year-old “bioreactor” landfill in Sandtown, Delaware, one designed to enhance biodegradation. According to the project's evaluation, after ten years of burial, the Sandtown refuse exhibits some indications of increased biodegradation but nothing conclusive (Rathje 1999). The next Sandtown dig is scheduled for 2008.

The Garbage Project has also initiated several studies that integrate its fresh and landfill data on hazardous wastes in MSW. The heavy-metal assays of finds are being compared with detailed item-by-item lists (such as two lightbulbs, one drain opener can, two newspapers, etc.) of the refuse identified within each 150 pounds of landfill sampled. The goal is to determine the rate of movement of heavy metals in commodities and inks and other hazardous wastes from refuse into the landfill matrix (Rathje, Hughes, et al. 1992).

Garbage Project Students and Staff

The Garbage Project does not consist of only systematic records compiled by a hands-on sorting of household garbage; it also consists of the sorters and project staff attached to the hands. Although many people find the results of project data studies interesting, most of them also find the sorting process itself revolting. In fact, a few market researchers realized in the 1950s that household refuse contained useful information but after repeated experiments they found they could not pay people to sort refuse. Those hired either quit quickly or kept sloppy records. Who would possibly be willing to rummage through someone else's smelly trash and keep accurate records of its contents?

The answer is a matter of public record. *Rubbish!* (Rathje and Murphy 1992b, paperback 1993) contains a list of more than 900 university students and others who sorted refuse for the Garbage Project between 1973 and 1991. The intimate archaeological view these and subsequent sorters have had of the materials that are discarded from households much like their own has provided them with a unique perspective, and while they do not preach to others, they are enthusiastically dedicated to providing everyone possible with the same insights they have drawn from their own hands-on sorting of residential refuse.

In attempting to share results, the Garbage Project has focused most directly on schools, museums, and other avenues of access to students. The rationale is that the archaeology of our own society will mean the most to the young people who can do the most with archaeological insights. Currently, the project is especially proud of two endeavors. The first is the compilation of *WRAP (Waste Reduction Alternatives Program) Resource Manual* (Dobyns and Hughes 1994), which has been distributed to schools throughout Arizona and the United States. The manual is designed to help both students and teachers learn how their individual behavior can produce significant quantities of garbage and how they can each make changes that will greatly decrease that amount of garbage. The second endeavor resulted in “The Garbage Dilemma,” an interactive video on permanent display in the Hall of Science in American Life at the Smithsonian's National Museum of American History. The video was the product of cooperation among the Garbage Project staff, the Smithsonian's design staff, and the Chedd-Angier Production Company. Garrod, Dorothy

(1892-1968)

Born in London the daughter of Sir Archibald Garrod (who became Regius Professor of Medicine at Oxford University), Dorothy Garrod studied history at Newnham College, Cambridge. During World War I, in which all three of her brothers were killed, she worked for the Ministry of Munitions and then for the Catholic Women's League in france. Convalescing in Malta toward the end of the war, where her father was director of war hospitals, she first became interested in archaeology.

After the war, Dorothy Garrod began to study anthropology at Oxford under R. R. Marret, one of the excavators of the Paleolithic site of La Cotte de St. Brelade on the Channel island of Jersey. By the time she graduated, Garrod had become fascinated by Paleolithic archaeology, and Marret sent her to study in Paris under the great French paleontologist henri breuil. There she gained valuable practical experience, excavating Upper Paleolithic cave sites at La

Garstang, John

(1876-1956)

Born in England, John Garstang was educated at Blackburn Grammar School and owing to his excellence in mathematics, won a scholarship to Jesus College, Oxford, in 1895. He became interested in archaeology while he was still at school and after excavating the Roman camp of Bremetennacum at Ribchester, he published his findings in 1898. Garstang spent his undergraduate vacations excavating, and after he graduating with third-class honors in mathematics, he took up archaeology full time, joining sir william matthew flinders petrie at abydos in Egypt and discovering and excavating the tomb of Beyt Khallaf.

Garstang was appointed reader in Egyptian archaeology at Liverpool University in 1902 and led expeditions to Negadah, Hierakonpolis, Esneh, and Beni Hassan in Egypt over the next two years. By then his interests in the Hittites had been aroused, and in 1904, he traveled to Asia Minor and received permission to excavate the Hittite capital of bogazköy, turkey. In 1907, at the personal request of the Kaiser of Germany, this site was instead given to German archaeologists to excavate.

From 1907 until 1941, Garstang was professor of the methods and practice of archaeology at Liverpool University where he contributed to the establishment of the Institute of Archaeology and the journal *Annals of Archaeology and Anthropology*. In 1908, he returned to Asia Minor, excavating the late Hittite site of Sakje-Geuzi in Turkey; in the winter, he returned to Abydos in Egypt to continue excavating there. His topographic study of Hittite monuments, *The Land of the Hittites*, was published in 1910.

From 1909 to 1914, Garstang excavated at Meroe in the Sudan, the site of the capital of Meriotic civilization from early third century b.c. to the early fourth century a.d. He served with the Red Cross in France during World War I, and in 1919, he became head of the newly created School of Archaeology in Jerusalem (serving in that post until 1926) and working as director of the Department of Antiquities in Palestine (1920-1926). Among his many achievements during this time was the discovery of the site of Hazor in israel, an important Canaanite town. He published *Joshua Judges* in 1931 and *The Heritage of Solomon* in 1934, and from 1930 until 1936, he excavated Jericho until the political situation made it impossible to continue.

In 1936, Garstang returned to Turkey to survey the Cilician plain, and he excavated the site of Yumuk Tepe near Mersin until the outbreak of World War II. He returned to complete this work in 1946, published in *Prehistoric Mersin* (1953), and to help establish the British Institute of Archaeology at Ankara in 1948, becoming its first director. He received honorary degrees from Aberdeen University, received the Legion of Honour in 1920, and became a Commander of the British Empire in 1949.

Tim Murray

Geoffrey of Monmouth

(ca. 1100-1154)

It is thought that Geoffrey of Monmouth was born in Monmouth, Wales, at the beginning of the twelfth century. The son of the family priest of William, earl of Gloucester, an influential aristocrat of the time, Geoffrey was brought up by his paternal uncle Uchtryd, archdeacon and later archbishop of Llandaff, Wales. Geoffrey attended Oxford University where he met another archdeacon, Walter Calenius, from whom he was supposed to have obtained the material for his monumental book *Historia Regum*

Britannia. This book was widely available in some form by 1139, because it was reported on and examined by Henry of Huntingdon in Normandy on his way to Rome with Theobald, the archbishop of Canterbury. Geoffrey of Monmouth became a Benedictine priest at the age of fifty in 1152, was consecrated as a bishop by Theobold that same year, and was buried in Llandaff two years later.

Geoffrey of Monmouth was a significant medieval scholar and historian whose great knowledge of both older and contemporary writers was evident from the acknowledged sources in his book, although he was criticized in his day for his bad Cymric (Welsh) and vulgar Latin. Victorian scholars dated the surviving edition of the *Historia Regum Britanniae* as the last 1147

Geoffrey of Monmouth

(ca. 1100-1154)

It is thought that Geoffrey of Monmouth was born in Monmouth, Wales, at the beginning of the twelfth century. The son of the family priest of William, earl of Gloucester, an influential aristocrat of the time, Geoffrey was brought up by his paternal uncle Uchtryd, archdeacon and later archbishop of Llandaff, Wales. Geoffrey attended Oxford University where he met another archdeacon, Walter Calenius, from whom he was supposed to have obtained the material for his monumental book *Historia Regum*

Britannia. This book was widely available in some form by 1139, because it was reported on and examined by Henry of Huntingdon in Normandy on his way to Rome with Theobald, the archbishop of Canterbury. Geoffrey of Monmouth became a Benedictine priest at the age of fifty in 1152, was consecrated as a bishop by Theobold that same year, and was buried in Llandaff two years later.

Geoffrey of Monmouth was a significant medieval scholar and historian whose great knowledge of both older and contemporary writers was evident from the acknowledged sources in his book, although he was criticized in his day for his bad Cymric (Welsh) and vulgar Latin. Victorian scholars dated the surviving edition of the *Historia Regum Britanniae* as the last 1147

edition, which comprises Geoffrey of Monmouth's translations and retelling of ancient British legends from written Cymric and Breton sources into medieval Latin. The Breton language, used by the inhabitants of Brittany in france, and Cymric, or Welsh, were almost identical at the time that Geoffrey of Monmouth was working on his book and up until the reign of Henry I, when substantial differences between the two languages occurred.

Geoffrey's sources for his work included manuscripts from the tenth century, such as the Latin "Nennius," which is extant, and a book of Breton legends, which has since vanished. The latter was the source of the story of the descent of British princes from the fugitives of Troy, a legend that is also common in stories about the origins of the Franks in Gaul; the story seems to have become popular in both countries after the invasion of the Teutonic tribes in the sixth century. Although the legends were not recorded by the historian Bede in his eighth-century chronicle, they were part of written history by the ninth century.

The publication of *Historia Regum Britanniae* marks a milestone in the literary history of Europe. Within fifty years of its completion, stories about the Holy Grail, Lancelot, Tristan, Perceval, and the Round Table had appeared, and Merlin and Arthur had become as popular in Germany and Italy as they were in England and France. The book was later translated into Anglo-Norman, and 100 years later into English. The material was then used by a long line of famous British storytellers and historians such as Robert of Gloucester, Roger of Wendover, Holinshed, Shakespeare, Milton, Dryden, Pope, Sir Thomas Malory, Wordsworth, and Tennyson.

As important as its long-term impact on European civilization was the book's short-term influence on the people of England, which included a large part of France at the time. The popularity of the work's legends and stories helped to defuse racial animosities among Welsh, Breton, British, French, and Teuton, and the various groups became more politically unified through their mutual belief in a shared origin.

Tim Murray

Geographic Information Systems

Historical Background

Archaeologists, like geographers, think spatially, and both make sense of their data by referring to its spatial dimension. Archaeology-particularly European archaeology-has been closely linked to geography and has borrowed from it methodological principles to develop its own theoretical tenets. This close association with geography dates from the formal mapping methods of attributes and artifacts developed by the Austro-German school of "anthropogeographers" of the 1880s and 1890s. However it is with the Cambridge School of New Geography, and in particular with Peter Haggett's *Locational Analysis in Human Geography* (1965), Richard Chorley and Peter Haggett's *Models in Geography* (1967), and Michael Chisholm's *Rural Settlement and Land Use* (1968) that the otherwise implied sway of geography toward archaeology was formalized. This influence is best reflected in the archaeologists Claudio Vita-Finzi's and eric higgs's 1970 site catchment analysis of Mount Carmel, Ian Hodder and Clive Orton's *Spatial Models in Archaeology (*1976), and david clarke's *Spatial Archaeology* (1977).

More recently, geography is once more leaving its mark on the theoretical development of archaeology. The emergence of landscape archaeology, a derivation of geography's landscape theory, has re-ignited interest in the spatial associations between archaeological sites and their physical environment on both sides of the Atlantic. Within this context, the application of geographic information systems (GIS) has been hailed as the new paradigm. But just how much can the application of GIS assist in the

interpretation of the archaeological data? Before attempting to answer this question a brief review on the development of gis is necessary.

Development of GIS

Reflecting about the complexity of archaeological data, David Clarke declared in 1977 that the analysis of the spatial relationships of artifact and site distribution could no longer be done by intuitive methods such as simple visual inspection, or "eyeballing." The challenge, then, was to develop the methodological tools that would

More recently, geography is once more leaving its mark on the theoretical development of archaeology. The emergence of landscape archaeology, a derivation of geography's landscape theory, has re-ignited interest in the spatial associations between archaeological sites and their physical environment on both sides of the Atlantic. Within this context, the application of geographic information systems (GIS) has been hailed as the new paradigm. But just how much can the application of GIS assist in the

interpretation of the archaeological data? Before attempting to answer this question a brief review on the development of gis is necessary.

Development of GIS

Reflecting about the complexity of archaeological data, David Clarke declared in 1977 that the analysis of the spatial relationships of artifact and site distribution could no longer be done by intuitive methods such as simple visual inspection, or "eyeballing." The challenge, then, was to develop the methodological tools that would

make the analysis of enormous amounts of data feasible. With the advent of the personal computer as an affordable, fast, and user-friendly analytical tool, it is now possible to process in a very short period of time amounts of data that otherwise would have taken days or even weeks to process.

The sheer size of the databases that archaeologists have to work with, which include archaeological and environmental data, made it extremely difficult, if not virtually impossible, to integrate all the material into a spatial-temporal framework. The best archaeologists could hope for was that through the production of accurate maps of site or artifact distribution, a meticulous visual inspection would reveal any spatial pattern.

Traditionally, maps have been an indispensable tool for archaeology and related disciplines. The basic geographic features are displayed using various visual artifices, such as diverse symbols or colors or text codes, which are explained in the legends. Naturally, the most important limitation these maps have is the amount of information they can effectively communicate, if more information is needed, it would have to be included in another form.

Map production, however, is a very expensive and time-consuming activity. As our scientific knowledge of the earth advances, new information needs to be charted almost immediately, but the effective and prompt assessment of natural resources, meteorological phenomena, and urban growth requires that maps be produced expediently and at low cost.

The demand for detailed map information has put pressure on for the development of better mapping techniques, and naturally, computer applications such as computer assisted design (CAD) and computer assisted mapping (CAM) have been instrumental in meeting this demand. Still, these advantages in map production and the ability of computer applications like CAM or CAD to identify spatial patterns between the mapped features-points, lines, and polygons-are very limited, because they are not linked to a relational database. It is only with the advent of GIS that we are able, for the first time, to link the geographic position of the mapped features with the qualitative and quantitative information that describes them and make queries about them.

In essence, GIS is a spatially referenced database that allow us to store great amounts of data, retrieve it with ease, manipulate it mathematically, and visualize the results within its spatial context. Hence, the core of the analytic power of GIS lies in its ability to handle digital maps to create new information from the preexisting data.

To fully understand this advantage we need to take a closer look at the conceptual changes in maps as a result of the insertion of GIS. Prior to this insertion, the study of the spatial distribution of natural resources and human and plant populations was approached in a qualitative way. The principal aim was to produce inventories of these data, and the enormous amount of information produced forced the cartographer to rely on qualitative methods of classification and mapping.

Consequently, quantitative descriptions were hindered mainly because of a lack of the appropriate mathematical tools needed to describe the spatial variations. With GIS, however, maps underwent a critical transformation because spatial variations could now be rendered as digits. Therefore, maps are no longer conceived as simplified pictorial depictions of the real world but as numbers. This is a major conceptual leap since throughout the approximately 8,000 years of mapmaking, maps have been primarily *descriptive,* which has limited their application to showing the exact location of things. Increasingly, however, maps are becoming *prescriptive,* containing the data necessary to assist us in making decisions.

Applications of GIS in Archaeology

GIS technology is relatively recent as the first operational GIS was developed in Canada in 1972, around the same time that the first text on GIS was published. It was not until the 1980s, however, that archaeologists begin applying GIS to their field of study. In 1982, the study of the settlement patterns in relation to the seasonal availability of natural resources in western Arizona was approached using GIS.

Database management and cultural resource management (CRM) applications began in the mid-1980s, and toward the latter part of the decade, GIS was being used in site prediction models.

By enabling the management of extensive spatially related databases, GIS has provided archaeologists with a powerful analytical tool, one that can lead to the discovery of the various levels of spatial patterns in the archaeological record. This in turn can lead to a more in-depth analysis of the underlying principles of those spatial patterns. There are three broad categories into which all spatial modeling done using GIS fall: data mining, predictive modeling, and dynamic simulation. The first two are perhaps the more common forms applied in archaeology.

Data mining consists of the retrieval of specific data items or a combination of items in relation to their spatial/temporal location. The settlement pattern studies in western Arizona mentioned above, and the study of the potential impact on known archaeological sites owing to works of infrastructure, e.g., the construction of a dam or a road, constitute good examples of this type of model.

Predictive modeling in GIS differs from simple mathematical models in the sense that it interpolates the field data into mapped variables, thus providing us, in addition to a hard figure, with the spatial location of the relevant variables. Predictive modeling is frequently used in CRM when dealing with the potential effects to unknown archaeological sites from the aforementioned infrastructure works. There are also various examples in the American Southwest where site prediction has been used in the study of settlement patterns, and its potential in assisting in the design of the archaeological survey strategies has just been tapped.

Only recently has the third category begun to be explored in connection with archaeological problems. Its most promising feature is that it enables the user to interact with the spatial model by allowing for change in the variables in order to track alternative behavioral patterns. A fine example of this type of modeling is Kohler and Carr's swarm-based modeling of prehistoric settlement systems in the American Southwest. Swarm is an object-oriented model designed to ease the process of simulating large numbers of interacting agents, and traditional GIS modeling was combined with this object-oriented model to explore and refine models of settlement behavior in the Mesa Verde region of Colorado. The initial GIS approach was limited to the data mining and prediction models mentioned above, which resulted in statistical measures of strength and significance of association of sites with the relevant environmental variables. In the case of Mesa Verde, the agents were represented by the prehistoric households, which were “released” onto the paleoproductivity landscapes generated with the GIS, and the Swarm model was run to observe their locational solutions to making a living on those landscapes.

It has become apparent that the application of GIS to archaeological issues has assisted archaeologists in addressing more complicated questions on the nature of the interaction between human societies and their landscapes and that it can ultimately help in obtaining a better understanding as to how the factors involved in the formation of the archaeological record interact. More and more, through the application of GIS, archaeologists are enable to address not only questions such as, Where is? or How many? but also questions such as, What if?

German Classical Archaeology

The first scientific approaches to classical archaeology in Germany date back to the so-called antiquaries, who were active from the sixteenth century on and who-due to their systematic classification of the material estate of Antiquity-were often and rather unjustly called ignorant. The *Thesaurus Brandenburgicus selectus,* written by Lorenz Beger (1653-1705) and published in three volumes between 1696 and 1701, may be regarded as the most significant opus of an antiquary in Germany. The intensity of the antiquaries' influence, especially that which they exerted on following generations of classical scholars, characterized particularly in Germany by the factual and substantial organization of manuals and, above all, of corpora.

Even johann joachim winckelmann (1717- 1768), who vehemently opposed the antiquaries, followed an antiquarian pattern in the draft of his *Monumenti antichi inediti,* published in 1772. Winckelmann's hermeneutic method (i.e., his explanation of antique monuments mainly by means of Greek mythology) and his aesthetic approach built on the achievements of the antiquaries. A significant difference, however, can be noted in his observation that the art of antiquity, until that time regarded as an absolute entity, could be given a chronology. In this observation he was partially influenced by concepts taken from the late-Hellenistic period, although Winckelmann's judgment was predominantly influenced by the aesthetic criteria of his time. His discovery of the possibility of differentiating the various stages of the development of antique art by means of stylistic analyses enabled him to subdivide that art into several periods, a classification that is more or less still valid today. In his *Geschichte der Kunst des Altertums* (1764) he distinguished between the *Alterer Stil* (Older Style) of the first half of the fifth century b.c., the *Hoher Stil* (Grand Style) of the period of Phidias, the *Schoner Stil* (Beautiful Style) of Praxiteles, Lysipp, and Hellenistic works of art, and the *Stil der Nachahmer* (Style of the Imitators) of the classicist period. The time of the Roman Empire was defined as an era of decay and the complete decline of art.

Winckelmann's aim was to discover the Wesen der Kunst (nature of art) and define the use of beauty and verity, distinctive to a particular work of art. Both of these values he regarded as fulfilled in the Hoher Stil and the Schoner Stil. He also wanted to develop a model of general (as in a universal) validity: “The history of art should teach the origin, the growth, the change, and the decline of art, as well as the different styles of peoples, periods, and artists and to prove this to the greatest possible extent by means of those works of Antiquity left over” (Winckelmann 1764).

In this way Winckelmann prepared the basis for a developmental approach to art, which is still influential today. This model of development of a comparative art history almost necessarily implied a concentration on each and every work of art, as well as an understanding of its contents and its value (despite this being often determined subjectively). Winckelmann's influence on successive generations of scholars was considerable and his passionate and refined language, used to describe such monuments as the outstanding statutes Laocoon and the Apollo of Belvedere, was also influential. Both the study of art, according to his model, and his literary attainments can be regarded as strange contrasts to the intended delineation of art-historical contexts. Winckelmann's subjective idealization and, above all, mystification of Greek art and his intention to deduce aesthetic rules and standards from it was inherently contradictory to an interpretation striving for historical facts.

Christian Gottlob Heyne (1729-1812), the realistic, dispassionate archaeologist who was also enthusiastic about Greek beauty, was Winckelmann's counterpart. Heyne was greatly important to the development of archaeology as an academic discipline, primarily because of his “Academic Lectures on the Archaeology of the Art of Antiquity,” which he had given since 1767 at the University of Gottingen. His work “Introduction into the Study of Antiquity, or Draft of a Guide to the Knowledge of Ancient Works of Art,” published in 1772, was also very significant and pioneering because he was a

philologically determined classical scholar. On the one hand he proceeded methodically according to

perspective, that is, when different approaches are used for a reciprocal control.

This limitation on the role of monuments is echoed in Adolf Heinrich Borbein's recent request for a model of interpretation that comprises the artistic form as an upholder of significance, those external circumstances by which the latter is influenced, different kinds of contemporary artistic expressions, political, social, and cultural phenomena, and the question of the relation of each of these factors to the other and for their mutuality in substance. In this view, visual art provides the concrete idea of the "spirit of time" or of its contemporary and intellectual tendencies, even more so than historical facts. By extension, artistic farsightedness may influence or anticipate future developments in other social fields.

This concept, which integrates historical context and aims to describe the historical position of monuments, allows new access to the comprehension of Roman art, an area to which German archaeology has recently been devoted. Tonio Holscher's 1960 treatise *Roman Picture Language as a Semantic System* must be understood in this way. Proceeding on the assumption of a pluralism of styles in Roman art, formulated earlier, Holscher demanded that monuments must begin to be observed within an overall cultural-historical context, before a single aspect of Roman visual art and its significance can be commented on. Furthermore, he propounded the substantial thesis that in Roman art for different allied subjects and different patterns from different epochs of Greek art were selected. These established patterns were reused throughout Roman art, unaffected by contemporary stylistic tendencies. On the basis of examples he succeeded in demonstrating that the choice of Greek stylistic forms followed a system, or semanticization of styles. Holscher argued that by Augustan times there was an established canon of representational modes and picture types, that is, a more or less constant picture language, and this semantic system did not undergo serious changes during the first and second centuries a.d. With regard to the relation of picture language and style, he made clear that style "as an expression of general taste and habit" represents a variable factor, in contrast to the more likely static character of the picture language. This picture language submitted to the semantic system does not exclude stylistic changes, that is, different modes and types of representation. In the historical dimension of his examinations Holscher showed that a systematic, static picture language was advantageous for the conveyance of messages and general communication in the Roman Empire. He also pointed out that the tendency to set up norms, observed in a section of art, was generally characteristic of Roman imperial culture. Holscher's theoretical analyses of Roman art characterized the position of German classical archaeology today: to practice archaeology as both a science of art and a historical discipline.

German Prehistoric Archaeology

Germany, like other European nation states, has a long tradition of prehistoric research, but prehistoric archaeology was first taught in the universities

is further complicated by significant differences within the archaeological record itself. Roman and Celtic antiquities are concentrated in the south and west of Germany and in Switzerland and Austria, but in the eastern and northern parts of Germany, Germanic (and partly Slavic) antiquities dominate. In the past this was a permanent source of conflict for the discipline. Nevertheless, it is possible to uncover some common themes in its development.

The name traditionally used by institutions that deal with research on human prehistory in Germany, Austria, and Switzerland is *Vor- und Frühgeschichte* (or *Ur- und Frühgeschichte*). This is most aptly translated as "pre- and proto-history" and refers to those periods from which written sources are unknown or, at best, rare. The German term *Archäologie* (archaeology) has long been virtually reserved for the archaeology of classical antiquity (*Klassische* archaeology). Only in the last few years has it become customary among prehistorians to use the term *Archäologie* or, more accurately, *Ur- und Frühgeschichtliche Archäologie* (pre- and proto-historic archaeology).

Toward a History of Prehistoric Archaeology in Germany

The history of prehistoric archaeology has been a topic of interest within the discipline of archaeology in Germany for a long time. In 1938 Hans Gummel published a thick volume on the history of German prehistoric archaeology from the seventeenth century until the 1930s. In retrospect the early date chosen for the beginning of this synthesis seems somewhat surprising. The first ordinary chair for prehistoric archaeology at a German university was established only in 1927, at the University of Marburg. Before that time prehistory at German universities was taught by extraordinary professors or by lecturers and scholars from other disciplines. The first extraordinary chairs were established at the turn of the twentieth century at the Universities of Vienna (assumed by Moritz Hoernes in 1900) and Berlin (occupied by gustaf kossinna in 1902), and as early as 1874 rudolf virchow had expressed doubts as to whether prehistory would ever become an independent discipline. Under these circumstances, why was such an early date given for the history of archaeology in Gummel's work? From the historical context it is clear that Gummel's synthesis must be seen in relation to contemporary attempts to transform prehistoric archaeology into what could be regarded as a mature discipline. Due to political circumstances the success of this initiative remained limited.

Gummel's efforts to promote the necessity of a continued reflection on the history of prehistory were not very successful. Despite his own early monograph and other early contributions to this topic, especially by Ernst Wahle (1951), research on the history of prehistoric archaeology even today remains underdeveloped in central Europe, and critical assessments of the history of prehistoric archaeology have only become available since the mid-1990s (Härke 2000). Many of the more recent attempts focus on the role of prehistoric archaeology during the Third Reich (Leube 2000), a topic that was dealt with earlier by historians (Bollmus 1970; Kater 1974). Older periods of the history of prehistoric archaeology are still only seldom written about, and apart from publications that deal with single aspects of the subject in Germany, only one recent overview is available today (Kossack 1999; also see Kossack 1992 and Kühn 1976). In that overview author Georg Kossack drew on his own long experience within German prehistoric archaeology and not only gave valuable information on important scholars, excavations, methods, and ideas but also described the political background of twentieth-century prehistoric archaeology.

A Short Outline of the Development of Prehistoric Archaeology in Germany

The history of prehistoric archaeology in central Europe is closely linked with the political history of the relevant countries. This is especially true in Germany. The main crises and resolutions in German history during the nineteenth

the Viking age settlement of Haithabu, also joined the party and shared the new ideology; he became head of the prehistory section of the SS-Ahnenerbe, an association founded in 1935 by members of the Nazi secret police (Schutzstaffel, or SS) with the aim of studying the German past.

The situation for Gerhard Bersu (1899- 1964) and Gero von Merhart (1886-1959) was very different. In 1935 Bersu was removed from his post as first director of the RGK because of his Jewish background. He left Germany in 1937 and spent the war years in England, where his excavations at Little Woodbury contributed to the development of British field archaeology. Gero von Merhart, a professor at Marburg University, was accused of not complying with the demands of the new regime by party members (including Reinerth) and was forced to retire.

Despite such cases of open discrimination, however, the Nazi influence on prehistoric archaeology was probably not as effective as it could have been. From the beginning there were conflicts between leading opponents of the new ideology, especially between scholars working in the Rosenberg office and those in the SS-Ahnenerbe. Both sections struggled for influence within Germany and, after the beginning of the war, within the countries that Germany occupied, where they confiscated whole museum collections and transported them back to their homeland. In the end Jankuhn's SS-Ahnenerbe proved to be more successful, and Reinerth and his adherents came under pressure during the war.

Looking at these developments, it comes as no surprise that after Germany lost the war in 1945, the reputation of its prehistoric archaeology was diminished. As a consequence of the misuse of archaeological knowledge for political reasons, the discipline's central paradigm was suspect, and the prospect of Germans writing a prehistory of European peoples seemed illusory. No alternative paradigms had been developed over the Nazi period. From an organizational point of view, however, the structure of the discipline was kept intact despite changes in personnel.

When Bersu returned to office and reorganized the work of the RGK in Frankfurt, Reinerth was banned from holding a publicly funded post in West Germany. He became director of the Lake Village Museum (Pfahlbaumuseum) at Unteruhldingen on Lake Constance, a private institution. But Reinerth was the only person eliminated from public service. Despite their membership in the SS many other prehistorians eventually held high positions within the discipline. Jankuhn, for example, ultimately became the director of the University Institute at Göttingen, continuing his research on the social and economic problems of pre- and proto-historic communities of northern Germany and directing large archaeological projects on the coastal region of northwest Germany.

With the partition of Germany into two opposing political systems-the capitalist Federal Republic of Germany (FRG) and the socialist German Democratic Republic (GDR)-cold war prehistoric archaeology also became paradigmatically divided into two camps. In West Germany a traditional culture-historical approach still dominated, but in East Germany a small group of archaeologists lead by Karl-Heinz Otto (and later Joachim Herrmann) tried to develop a specific Marxist approach to prehistory. Although a large number of publications were produced, this project ultimately proved unsuccessful. In practice most East German archaeologists continued to adhere to the traditionalist, culture-historical outlook.

Apart from these ideological battles, the post-World War II period, especially the decades between 1960 and 1990, was characterized by the major development of state archaeological services, in both the FRG and the GDR. In the short time since German reunification in 1990, there has been a reorganization of institutions, and some attempts have been made to achieve a paradigmatic renewal of German archaeology. Because it is too early to speculate about the outcome of these efforts, the main contributions of the German tradition to the development of prehistoric archaeology will be summarized

in the following section.

Main Contributions of the German Tradition of Prehistoric Research

From a long-term perspective at least four central aspects characterize the archaeology of German-speaking

Today German prehistoric archaeology is appreciated worldwide for its solid and meticulous work on primary evidence, for its careful source criticism, and for its prolific publications. It would be unfair, however, to limit the acknowledgment of German scholarship to these points alone. In the past more abstract ideas played an important role, especially with regard to the concept of writing history by archaeological means and, even more concretely, writing the history of prehistoric peoples.

Getty Museum

The J. Paul Getty Museum was established in 1953 to make Getty's personal collections of Greek and Roman antiquities, French decorative arts, and European paintings available to the public. Located first in one wing of a ranch house in a Malibu Canyon in California, the museum moved in 1974 into a Roman-style villa built on the same site. Designed with the assistance of Norman Neuerburg, the plans for the building were adapted from the ground plans of the original Villa dei Papirii in herculaneum in italy, which has not yet been fully excavated; various other Roman villas in pompeii and Herculaneum provided the inspiration for the building's elevations and interior and exterior architectural details and wall paintings.

Although the museum as an institution has never participated in archaeological excavations, it has served as a resource and sponsor for archaeological and archaeometric research. Its collections now include over 25,000 ancient objects in various media; most represent the cultures of greece and Rome, though some examples of the arts of cyprus, Persia, and Egypt are also included. The primary collections include Cycladic sculpture and terracottas, Greek and Roman sculptures in stone and bronze, Greek and southern Italian vases, Greek and

Ghosh, Amalananda

(1910-)

Along with Indian archaeologist hasmukh d. sankalia, Amalananda Ghosh was the most important archaeologist of postindependence India. From 1953 to 1965 he was the director general of the Archaeological Survey of India, which he had joined in the 1930s, and a tremendous surge of work that was initiated all over the country, covering virtually all phases of cultural development, occurred as a result of his leadership and guidance.

Ghosh's early work was in Bihar in eastern India, where he surveyed early historic Asur sites on the Ranchi plateau and the Buddhist city site of Rajgir. English archaeologist mortimer wheeler supervised Ghosh's fieldwork at Taxila, India, and earlier Ghosh had been involved in the Archaeological Survey of India's excavations at Ahichchhatra in India. Soon after independence in 1948, Ghosh surveyed the Ghaggar Valley in the former Bikaner state of Rajasthan, which resulted in the discovery of a large number of Indus sites in that part of India. On the assumption of the office of the director-general of the survey, which greatly expanded in size under him, Ghosh had little time to be in the field for prolonged periods, but it was he who finally recommended sites for excavation and edited the reports of the survey's officers.

After retirement in 1965, Ghosh worked briefly in Indonesia and elsewhere and wrote a thoughtful volume, *The City in Early Historical India* (1973). The two volumes of the *Encyclopaedia of Indian Archaeology* (Ghosh 1989), which he painstakingly edited, carry, for those who knew him, the unmistakable stamp of his intimate familiarity with all the ways and byways of ancient Indian historical and archaeological scholarship. These include entries on Sanskrit and epigraphy, which were the foundations of his academic career. He established a school of archaeology in the survey to train staff, and it has served its purpose well.

Gjerstad, Einar and the Swedish Cyprus Expedition

(1897-1979)

Einar Gjerstad first traveled to cyprus in 1924 to undertake postgraduate research. His *Studies on Prehistoric Cyprus* (1926) presented a summary of all known Bronze Age sites, and a critical evaluation of past research was presented alongside the results of his pioneering excavations of settlement sites. The typological and chronological systems he developed at this time and later remain fundamental to Cypriot research. After completing his doctoral work, Gjerstad conceived and organized the Swedish Cyprus Expedition.

There are few projects in the history of archaeology that match the scale and professionalism of the Swedish Cyprus Expedition. Together with the other three members of the expedition (Alfred Westholm, John Lindros, and Erik Sjoqvist-and their families), Gjerstad spent the years 1927-1931 surveying and excavating a series of twenty-five sites of all periods across the island. The expedition's

professional approach to excavation, recording, analysis, and publication resulted in the efficient production of the first three volumes of very substantial detailed site reports in 1934, 1935, and 1937 (*The Swedish Cyprus Expedition*). Six further volumes, containing syntheses and overviews, were published over the next thirty-five years. One of these, volume four, published in 1948, was Gjerstad's own study of the Cypro-geometric and Cypro-archaic periods. The Swedes set new, and very high, standards of efficiency, quality, and thoroughness for Cypriot archaeology, and the data they collected and the frameworks they developed continue to structure approaches to research on the island.

In 1935, Gjerstad turned his attention to the archaeology of early Rome following his appointment as director of the Swedish Institute there, but he maintained a continuing involvement in Cypriot archaeology.

(1897-1979)

Einar Gjerstad first traveled to cyprus in 1924 to undertake postgraduate research. His *Studies on Prehistoric Cyprus* (1926) presented a summary of all known Bronze Age sites, and a critical evaluation of past research was presented alongside the results of his pioneering excavations of settlement sites. The typological and chronological systems he developed at this time and later remain fundamental to Cypriot research. After completing his doctoral work, Gjerstad conceived and organized the Swedish Cyprus Expedition.

There are few projects in the history of archaeology that match the scale and professionalism of the Swedish Cyprus Expedition. Together with the other three members of the expedition (Alfred Westholm, John Lindros, and Erik Sjoqvist-and their families), Gjerstad spent the years 1927-1931 surveying and excavating a series of twenty-five sites of all periods across the island. The expedition's

professional approach to excavation, recording, analysis, and publication resulted in the efficient production of the first three volumes of very substantial detailed site reports in 1934, 1935, and 1937 (*The Swedish Cyprus Expedition*). Six further volumes, containing syntheses and overviews, were published over the next thirty-five years. One of these, volume four, published in 1948, was Gjerstad's own study of the Cypro-geometric and Cypro-archaic periods. The Swedes set new, and very high, standards of efficiency, quality, and thoroughness for Cypriot archaeology, and the data they collected and the frameworks they developed continue to structure approaches to research on the island.

In 1935, Gjerstad turned his attention to the archaeology of early Rome following his appointment as director of the Swedish Institute there, but he maintained a continuing involvement in Cypriot archaeology.

Gladwin, Harold Sterling

(1883-1983)

Harold Sterling Gladwin was born in New York City and educated in England. After returning to the United States in 1901, he became a stockbroker until 1922 when he moved to California and became associated with the Santa Barbara Museum of Natural History. Although his first scientific interest was with butterfly mutations, Gladwin also developed an interest in the prehistory of California, and that interest soon excluded any other and expanded to include the archaeology of the Americas with a particular interest in theories of migrations from Asia.

By 1924, Gladwin had become a friend of the great American archaeologist alfred v. kidder and a research fellow in archaeology of the Southwest Museum in Los Angeles. Gladwin began to excavate the ruins of the casa grande in Arizona, where he used occupation refuse to develop a chronology and identify the prehistoric Hohokam culture. His work revived archaeological interest in southern Arizona, which had been neglected since Frank Cushing's work twenty years earlier. In 1928, Gladwin and his wife-to-be, Winifred MacCurdy, established the Gila Pueblo Archaeological Foundation outside Globe, Arizona, and that foundation became the research center for Southwestern prehistory for the next thirty years. In 1951, Gila Pueblo was given to the University of Arizona, and its collections were transferred to the Arizona State Museum.

Gladwin created a number of new field methods, such as a method of archaeological surveying that allowed for extensive but economic data collection. The result was the establishment of records of 10,000 ruins and habitation sites across a huge area of the United States-from Montana to mexico and from California to the Mississippi River-and these records were the basis for ongoing research. His greatest contribution was in the area of cultural reconstruction, mapping large data sets over long time periods, and he was an early convert to the use of dendrochronology in archaeology. Gladwin's best known publications were *Men out of Asia* (1947) and his popular synthesis, *A History of the Ancient Southwest* (1957).

Tim Murray

Godwin, Sir Harry (A. J. H.)

(1901-1985)

A. J. H. (Harry) Godwin was born the son of a grocer, attended a local grammar school, and won a scholarship to Clare College, Cambridge, in 1918. Godwin studied both botany and geology, and he was influenced by the ecological work of the botanist Sir A. G. Tansley. Godwin obtained first-class honors at Cambridge and went on to study for a Ph.D. in plant physiology. He began teaching at Cambridge in 1923, moving from junior university demonstrator in botany to research fellow at Clare College in 1925, college fellow from 1934 to 1968, and professor of botany from 1960 to 1968, when he retired.

In 1923, Godwin began the systematic study of Wicken Fen, in Cambridgeshire, applying methods of pollen analysis to the deep deposits of peat in this fen (or swampland) to establish a long history of changes in its vegetation. Godwin proved the relationship between pollen zones and peat stratigraphy based on the identification and relative abundance of pollen grains of different trees in different strata-which helped define the ecology of the area during prehistoric times, i.e., its climate, forest composition, and agricultural practices. These data and their interpretation were published in *The History of British Flora* (Godwin 1950).

Godwin became a global leader in ecological thought and practice. He was president of the British Ecological Society in 1942-1943 and joint editor of the *New Phytologist* from 1931 to 1961. In 1948, he was founding director of the subdepartment of quaternary research within the School of Botany at Cambridge University.

Holding this position until 1966, he contributed to the uses of radiocarbon dating, to the geological history of changes in land and sea levels, and to the archaeological implications of this work. He was elected fellow of the Royal Society in 1945, received the Prestwich Medal from the Geological Society of London in 1951, the gold medal of the Linnean Society in 1966, and was knighted in 1970.

Tim Murray

Golson, Jack

(1926-)

A native of Yorkshire, England, famed as a cricketer as well as an archaeologist of great skill and wisdom, Jack Golson studied archaeology at the University of Cambridge in the late 1940s and early 1950s. Originally intending to pursue research in medieval archaeology (he had embarked on graduate fieldwork at the abandoned English village of Wharram Percy in 1953), Golson soon emigrated to New Zealand to take up a position as the first prehistoric archaeologist appointed to the University of Auckland. His relocation to New Zealand lent great impetus to the development of prehistoric archaeology in that country and in the developing field of Pacific archaeology. Moving to the Australian National University (ANU) in 1961 to assume a founding position in prehistory, Golson set about conducting fieldwork in tropical northern Australia and encouraging the earliest of the thirty-nine graduate students who would earn Ph.D. degrees under his supervision.

Golson's role at the ANU (which concluded with his retirement in 1991) has marked him as one of the most significant archaeologists in Australia. However, it was his excavations in the western highlands of Papua New Guinea, particularly at the site of Kuk, that brought him considerable international fame due to the site's association with evidence of early agriculture in the region. A past president of the world archaeological congress, Golson is an inspiring educator and scientist whose strong political and ethical principles have done much to establish the special character of Australian and Oceanic archaeology.

Gorodcov, Vasiliy Alekeyevich

(1860-1945)

Vasiliy Alekeyevich Gorodcov was born in the Russian province of Riazan. The son of a village sexton, he initially studied to become an Orthodox priest but instead joined the army, serving as an officer from 1880 until 1906. Gorodcov's interest in archaeology was inspired by his reading of Anuchin's Russian translation of John Lubbock's (lord avebury's) *Prehistoric Times,* and he began to undertake field surveys in the areas where his military unit was stationed.

In 1887, Gorodcov attended the Seventh Archaeological Congress and reported on some Neolithic sites he had found, but it was not until the following congress in Moscow that prehistoric archaeology, with the support of the geographer and anthropologist Anuchin and the geologist Inostrantsev, became part of the congress agenda. In response to the interest in prehistoric sites and the need for archaeological mapping, Gorodcov mapped the Neolithic settlements of the Oka River and began to excavate the dunes. In 1901, when he was transferred to the southern part of the Russian Empire, he

excavated burial mounds in the Donets River basin and organized excavations in the Izium district of Kharkov; in 1903, there were more excavations in the Bakhmut district of Yekaterinoslav Province. In 1905 and 1907, in the monumental transactions of the Twelfth and Thirteenth Archaeological Congresses, Gorodcov published the full reports of all of these excavations, including summary tables for the distribution of grave materials and photographs that were a model of archaeological reporting for their time.

The scope of Gorodcov's fieldwork was extraordinarily wide, but he also became interested in the theoretical and methodological analysis of archaeological material. In a paper of 1902 entitled “Russian Prehistoric Ceramics,” he attempted to create a universal classification system for pottery that was even more rigorous

The scope of Gorodcov's fieldwork was extraordinarily wide, but he also became interested in the theoretical and methodological analysis of archaeological material. In a paper of 1902 entitled “Russian Prehistoric Ceramics,” he attempted to create a universal classification system for pottery that was even more rigorous

PREV NEXT

than the Linnaean system for biology. He based it on his classification for fragmentary Neolithic ceramics, from which he could define territorial and chronological boundaries of groups as well as contacts and influences, a system more useful for diffusionists than for evolutionists. Between 1908 and 1916, Gorodcov published his analyses of pre-Scythian burial mounds-a quantum leap for prehistoric archaeology in russia, taking it from antiquarianism to twentieth-century science through his delineation of pit, catacomb, and timber graves and the Indo-European origins of their occupants.

In 1907, after his retirement from the army, Gorodcov began to teach archaeology at the Moscow Archaeological Institute. In 1908 he published the first part of his lectures as *Prehistoric Archaeology,* and in 1910 the second part, *Everyday Archaeology,* appeared. Both served as basic manuals and reference books for decades in russia. In 1919, Gorodcov became professor at Moscow University and in 1923 head of the Archaeological Department of the Russian Association of Scientific Research Institute of Social Sciences (RANIION).

An active school of archaeology formed around Gorodcov, and many Russian archaeologists of the second half of the twentieth century were taught and influenced by him. In 1933, some of his work on classification was translated into English and influenced the North American archaeologists Clyde Kluckhohn and irving rouse. He survived the Stalinist political upheavals of the early 1930s, and the radicalism of Marxist archaeology, and received an honorary doctoral degree in 1934.

Graebner, Fritz

(1877-1934)

Fritz Graebner was born and studied history in Berlin, where by chance he became a research assistant in the Royal Museum of Ethnography in 1899. By the time he graduated from Berlin University a year later, Graebner had become fascinated by ethnographic problems and had begun working with the museum ethnographer Bernard Ankermann. In 1904, Graebner and Ankermann founded *Kulturkreislehre* ("study of culture circles," or "cultural-historical ethnology") within the Berlin Society for Anthropology, Ethnology, and Prehistory. Stimulated by the work of anthropologist Leo Frobenius and the geographer friedrich ratzel, Graebner and Ankermann lectured on *Kulturkreise* ("culture circles") and *Kulturschichten* ("culture strata") in Oceania and Africa, rejecting the then-dominant biological-evolutionary concepts of ethnography.

In 1907, Graebner moved to Cologne to work at the new Rautenstrauch-Joest-Museum where he was able to research the museum's collections and continue his work on theoretical issues. The result of was his book *Die Methode de Ethnologie* [The Method of Ethnology] in which he argued for an epistemology of "culture-historical" research, emphasizing the importance of culture-historic connections for the interpretation of data and the understanding of development sequences. With the museum's director, Willy Foy, Graebner founded the museum's publication *Ethnologica*.

Graebner's area of fieldwork was the South Pacific, and he published wide culture-historical-based work concerning that area. In 1914, while trying to leave Australia after a conference, he was arrested and interned for the duration of World War I.

After his return to Germany, he studied for his Ph.D. at the University of Bonn and became a professor there in 1921. He succeeded Foy at the museum in Cologne in 1925 and became a professor at the University of Cologne in 1926. Ill health caused his early retirement in 1928, and he moved back to Berlin. Graebner's studies of Oceania are still relevant today, but his culture-historical theories, which greatly influenced researchers in Vienna, central Europe, and Scandinavia until the middle of the twentieth century, are today regarded as crudely reducing cultural variation to a few key geographic influences.

Great Zimbabwe

Great Zimbabwe stands at the top of a granite hill in the modern nation of Zimbabwe, in the center of the Victoria District. The site consists of a stone-walled settlement composed of enclosures, towers, portals, and staircases, occupying both the hilltop and the valley below. Great Zimbabwe existed for over 500 years as a bustling center of trade and commerce, and it politically dominated the surrounding valley and plateaus. At its peak, around a.d. 1200, it was probably the largest settlement in sub-Saharan Africa (Ndoro 1994). Built by ancestors of the present Shona people, Zimbabwe derived its name from the Shona word for "houses of stone." In 1980 Rhodesia was renamed Zimbabwe in recognition of the country's cultural heritage.

First documented by Portuguese explorers in the sixteenth century, the site was noted for its carvings and sophisticated architecture. From the beginning of colonial contact in the nineteenth century, the city's origins were a focus of controversy. Europeans were unwilling to recognize a connection between the impressive ruins and the indigenous Shona people of the area. Instead, explorers and excavators proposed a range of sources for Great Zimbabwe, suggesting, for example, that it was a palace of the Queen of Sheba or King Solomon or a monument built by the Phoenicians, south Indians, or Arabs. These attempts to strip the local African people of their archaeological past persisted well into the twentieth century and served as a tool in the recession efforts of the white Rhodesia Front government in the 1960s (Mahachi and Ndoro 1997).

The ruins were looted repeatedly beginning in the late 1800s in an effort to find the legendary gold of King Solomon and to carry away ornamental stonework and artifacts. Richard Hall was appointed curator of the site in 1902 and conducted large-scale, unscientific excavations that resulted in the destruction of almost all culture-bearing deposits in the stone enclosures. Later archaeologists, such as gertrude caton-thompson who excavated in the 1930s, argued that the site showed evidence of local African development and had clearly been built by indigenous inhabitants. Such views were largely ignored, however, in favor of sensationalist foreign-origin theories. Recent research supports the African Iron Age provenance of the site, and current investigations are being conducted by Zimbabwean archaeologists such as Kundishora Tungamirai Chipunza and students eager to reclaim their history.

Inhabited from a.d. 900 to 1450, Great Zimbabwe occupied an important trade position between the Zimbabwean plateau and the Indian Ocean coastline. Its wealth was derived from control of local gold and ivory production and trade of the resulting goods with Arab and Swahili merchants. The city functioned as a marketplace and trade emporium, importing such exotic items as cotton cloth, Persian glass beads, and Chinese porcelain. The political influence of the Great Zimbabwe complex extended as far as Mozambique, Botswana, and South Africa; other important contemporary sites of this Zimbabwe Tradition include Khami, Nalatale, Danamombe, and Tsindi (Chipunza 1997).

Inhabitants raised cattle, cultivated sorghum and millet (Callahan 1998), and depended on food tribute from surrounding farming communities. The center declined with the degradation of the local environment (including depletion of the soil and exhaustion of firewood sources), due to the demands of a dense urban population. The Shona inhabitants had largely abandoned the area by 1500, only to be forced back by European settlement of the more fertile and productive high plains areas during the colonial period. The widespread distribution of the Shona language over this area today gives support to the idea that a powerful trading empire was based at Great Zimbabwe in the past (Callahan 1998).

The stone walls of the hilltop complex delineate a classic African village design, containing groups of wattle-and-daub huts within each stone-walled enclosure. These would have been occupied by elite family groups associated with the settlement's leader (Callahan 1998). The ruler lived in the uppermost

enclosure, removed from the common people and proclaiming his or her power through the visible manifestation of stone walls and towers (Pwiti 1996). Architectural similarities found in other ruins on the Zimbabwe plateau indicate that Great Zimbabwe had established hegemony over a network of trading centers and gold and ivory production sources. This dominance may have been achieved by installing members of the royal family as local leaders in the outlying sites.

PREV NEXT

The permanent population in the surrounding valley numbered between 3,000 and 6,000 people; at its height, Great Zimbabwe itself may have had a population between 12,000 and 15,000 people (Ndoro 1997). The site occupies about 1,800 acres and consists of three main parts-the Hill Complex, the Great Enclosure, and the Valley Ruins (Ndoro 1997). The stone walls, rising up to 11 meters, were not constructed according to a preconceived plan. Instead, workers built and expanded walls as the need arose, creating an organic settlement plan.

The Hill Complex occupies the top of the granite hill that dominates the site. This area was inhabited dating to the early Iron Age, before the use of dry stone walling. Sophisticated engineering techniques were employed to stabilize the walls in the complex on the uneven granite boulders that were incorporated into the architecture. The Great Enclosure is located in the valley and includes a 178-meter-long outer wall and an interior conical tower, decorated with stones in a chevron-and-checker pattern. The Valley Ruins are located between the Hill Complex and Great Enclosure and consist of several individual enclosures with parallel passages connecting them (Ndoro 1997).

Erosion has been a problem at the site since Hall's excavations in 1902, when large soil deposits were removed without backfilling, and it has been made worse by reconstruction efforts that entailed the removal of earthen structures and archaeological deposits surrounding the stone walls. In the 1950s all wooden structural elements were removed for carbon dating, resulting in further damage. Future efforts at the site include the preservation of fragile stone architecture, a more accurate restoration of material remains, and the integration of the Shona's historical beliefs into the official literature interpreting the site for visitors (Ndoro 1994).

Greece

The astonishing wealth of archaeological material found in Greece over the last 300 years has provided something of interest to virtually everyone that has seen it, and the precise nature of that interest has varied greatly according to the culture and personality of the viewer. Art historians from Enlightenment Europe, intellectuals from a newly independent Greece, U.S. university professors between the two world wars, and the local schoolchildren and foreign tourists of today have all looked for different archaeologies of Greece, and so far, Greece has always been able to provide them.

The history of archaeology in Greece has often been told from the point of view of the

PREV NEXT

perfection to revive western European art, and a convenient location to house a military garrison. To understand the history of archaeology in Greece, we need to investigate a wide range of participants and place them within their social and political contexts.

Art, Enlightenment, and Statue Smuggling

During the eighteenth century, the aristocrats of western Europe were educated in the classics, and part of a young man's education was to go on “the grand tour” of classical sites. They first went mainly to Italy, the home of western Christianity and the Renaissance and thus more relevant to European culture. Gradually their destination changed, as the Enlightenment encouraged reason, logic, and a belief in human progress as opposed to an unquestioning acceptance of a universal order imposed by God. The relics of Christianity became irrelevant, and the search for the origins of Europe led to the art and architecture of ancient Greece.

As the new values became prevalent, painters and architects were dispatched to Greece to record this first flowering of European civilization and thereby rejuvenate the art of their own more decadent times. In 1751, for example, a prestigious London dining club called the society of dilettanti sent the painter James Stuart and the architect Nicholas Revett to Athens to paint and record the ruins there. Their meticulous work was marred only by minor inaccuracies in recording the higher parts of the temples, owing mainly to a chronic shortage of ladders. The four volumes of *The Antiquities of Athens* published between 1762 and 1816 were intended entirely for a British audience and provided models for the then-current craze for Greek architecture and ornament. The Ottoman governors of Greece, when it suited them, were happy to gain credibility with the European powers by allowing their painters and architects to record apparently valueless ruins. As for the local inhabitants, they only appeared as small and stereotypical figures in the paintings to provide local color and a scale for the architecture of their ancestors.

By 1800 the shift in European intellectual fashion from Italy and Christian origins to Greece and European origins was complete and was further heightened by the Napoleonic Wars, which prevented easy travel to Italy. There was yet another intellectual change. Eighteenth-century art historians, particularly the Prussian johann joachim winckelmann, had used ancient texts to elucidate the Greek spirit that lay at the origins of European civilization. Thanks partly to the efforts of Stuart and Revett and their successors, there was, by the early nineteenth century, a firm interest in the monuments and masterpieces themselves.

When lord elgin was appointed British ambassador to Constantinople in 1799, he originally intended only to make casts of the Parthenon sculptures for the inspiration of British artists. Ottoman gratitude for British help in removing the French from their province of Egypt gave him the opportunity to go further, however, and between 1801 and 1804 he was able to remove and export the actual pieces. The removal was not without criticism. The British architect Robert Smirke, watching Elgin's men extracting the sculptures, commented on his feelings: “a strong regret” as they were being taken “as a sort of signal of the annihilation of such interesting monuments.”

Smirke's reservations were amply confirmed by the activities of European architects and agents in Greece during the first two decades of the nineteenth century. Not content with painting and measuring, they competed with each other in finding and removing statuary and even whole buildings for their various collections and national museums. If they could not gain permission, then perhaps the local governor could be bribed; if not, they could smuggle the statues out of the country by night. In 1811, for example, the English architect Charles Cockerell managed to send his newly discovered statues from the Temple of Aphaea on the island of Aegina to Athens with the help of a bribe to the pasha of the islands.

From there they were smuggled out from a small fishing village to the island of Zante (now Zákinthos or Zacynthos), which was then under British occupation. At an international auction for the pieces the next year, the british museum representative was misdirected to Malta, and the statues were snapped up by the

agent of Prince Ludwig of Bavaria for £6,000. Like the scramble for colonies in the later part of the century, western powers scrambled for Greek statuary to inspire their artists and bring prestige to their museums and their countries.

Archaeology and Hellenism in Independent Greece

Five years before the auction of the Aegina Marbles, the leading intellectual of the Enlightenment in Greece, Adamantios Koraïs, had called for the protection and preservation of Greek antiquities. The year after the auction, in 1813, a group of Greek intellectuals formed the Philomousos Eteria, or Society of Lovers of the Arts. Their aim was to discover antiquities and display them in a museum, originally intended to be the Erechtheum in Athens, for the benefit of the people of Greece in general and the country's youth in particular. Under Ottoman rule little progress could be made, but a revolution in 1821 and the eventual independence of the southern part of Greece under a Bavarian monarch in 1832 changed the situation. Even in 1825 the temporary government had protested the looting of antiquities and proposed setting up a museum in every school to teach future generations the importance of their ancestors.

One of the earliest laws that the new government passed concerned the archaeological heritage of the Greek nation. This law, passed in May 1834, declared that all antiquities were “national heritage” and “state property” and could not therefore be exported. Excavations could be carried out only with a permit. The foundation of the Greek Archaeological Service the next year provided the personnel and infrastructure to carry out excavations in the new state and marked a major shift toward Greek-run projects.

The reason for the major emphasis on archaeology lay in the ideology of the new kingdom and its need to create a new and widely accepted identity. Previously the inhabitants of this relatively unimportant Ottoman province had called themselves *Romei* (“Romans”) and Orthodox Christians; they were ruled by Ottoman governors and by local chiefs and aristocrats who had attained some measure of autonomy-all of which hardly made them members of a modern European nation. Thanks to the European Enlightenment, however, they could appropriate their own classical past and identify themselves with “the Hellenes,” the originators of European civilization. To do so required knowledge and control of the classical past, discovery of the tangible monuments of that past, and appropriate education of the people now to be called Hellenes.

The most famous symbol of the Hellenic past was the Acropolis, but the four classical structures that can be seen there today-the Parthenon, the Erechtheum, the Propylaea, and the Temple of Athena Nike-had been converted, respectively, into a mosque, an armory, a fortress, and a bastion. Visually, they were dominated by a tall Frankish defensive tower beside what had been the Propylaea and were surrounded by a warren of small houses and alleys. The task of the new Archaeological Service was to purify this morass of different periods and peoples. Under the directorship of Kyriakos Pittakis, conservator of antiquities from 1836, the mosque and minaret within the Parthenon were demolished, the Venetian and Turkish defenses were removed, the various houses and streets were destroyed, the blocks of the Temple of Athena Nike were discovered and reconstructed, and the Erechtheum porches were restored. This work of cleaning and restoring continued into the 1860s when the Acropolis Museum was built, and finally, in 1874, the Archaeological Society of Athens, with financial help from the archaeologist Heinrich Schliemann, demolished the Frankish tower. The Acropolis was thus returned to its original “pure” classical form with all its barbarian accretions removed.

There were dissenting voices. Not everyone, including some Greek intellectuals, agreed with the removal of all traces of later periods. King Otto, the son of the same Ludwig of Bavaria who had so eagerly

acquired the Aegina Marbles, was wholeheartedly in favor of Greek classicism, but he and his advisers also favored the Byzantine period, which was a better symbol of stable autocracy than the warring democracies and oligarchies of the classical city-states. In

1837, Otto passed a royal decree protecting Byzantine monuments as Greek archaeologists were happily destroying them in their enthusiasm for the classical antiquities that lay beneath. Greek archaeology, however, was firmly launched on a classicist agenda, and that agenda culminated in 1889 with the completion of the National Museum, an imposing Greek Revival structure designed to display the national heritage in suitable classical grandeur.

The western end of the Acropolis in Athens as seen from the pediment of the Parthenon ca. 1801. The Frankish tower stands in the center. Drawing by Sir William Gell.

The Foreign Missions

The Greek state and the growth of the Greek Archaeological Service did not, of course, mean an end to foreign participation in archaeology in Greece. As archaeological methods improved during the nineteenth century, teams from Germany, Great Britain, the United States, France, and elsewhere were keen to excavate major classical and prehistoric sites. The difference was that foreign projects were now carefully controlled and they were entirely at the mercy of the Greek government, which often gained considerable prestige and power from the situation.

A good example of the need for control was Heinrich Schliemann's work at Mycenae in 1874. He brought with him from his excavations at Troy in northwestern Anatolia a reputation for smuggling gold artifacts out of the country without the knowledge of the Ottoman authorities and generally for trying to get round his permit in any way possible. The Greek government had actually given the permit to excavate at Mycenae to the Greek Archaeological Society, but as often happened, it was short of funds and asked Schliemann to excavate on its behalf and at his expense.

The government was decidedly wary of Schliemann but finally agreed to his excavation on condition that he was supervised by Panayiotis Stamatakis, on behalf of both the society and the government, and that all the finds would belong to Greece. The gold masks and jewelry that Schliemann's excavations uncovered in the sixteenth-century b.c. shaft graves are well known. Less well known are the briefness of Schliemann's visits to the site, his impatience with the classical and Roman material that interfered with his search for Agamemnon, and the constant difficulties of Stamatakis, who was actually running the excavation but with every obstruction put in his way by Schliemann and his Greek wife, Sophia.

It was clearly easier for the Greek government to deal with respected foreign institutions such as universities and museums. It was also easier for the foreigners to have representatives of their countries permanently in Athens to carry on the often complex negotiations with the government. The first foreign school of

new law in 1928 limited the foreign schools to three excavation permits each. But with the economic problems of the late 1920s and early 1930s, the Greek Archaeological Service was almost bankrupt. For this reason, one of the potentially most exciting sites in Athens, the Athenian Agora, had to be given to the Americans. Between 1927 and 1940, they lavished on the site $1 million donated by John D. Rockefeller alone, quite apart from other sources. Much of the money went for expropriating the land from the several thousand refugees from Asia Minor who had inhabited it since 1922. In spite of gaining independence and control over its own archaeology, Greece could not quite escape the influence of the western archaeological powers.

The Advance of Method and Chronology

As early as 1852 the German archaeologist ernst curtius began raising money for a new type of excavation at Olympia, one that would not remove archaeological material to other countries but one that would systematically record and analyze this important site. It was only after Schliemann's more dramatic, if less systematic, work at Mycenae and elsewhere that the Germans (and others) began to appreciate the need for large-scale, well-funded projects. Curtius finally won his funding in 1875, and a treaty was signed between Germany and Greece allowing the German Archaeological Institute (deutsches archäologisches institut--dai) to undertake systematic exploration at Olympia, on condition, of course, that all finds remained in Greece. Stratigraphy and particular find spots were carefully recorded, structures underwent architectural analysis, and the Olympia excavations became a model of the new systematic, scientific excavation methods.

Another result of Schliemann's massive self-publicity was a sudden interest in the prehistoric period. The key figure here is Christos Tsountas, who followed Schliemann at Mycenae and worked there over a period of more than two decades as well as at numerous other Bronze Age and earlier sites all over the mainland and islands of Greece. Unlike his predecessor, Tsountas set out, not to prove a myth, but to investigate material culture and the development of human society. He achieved his aims partly by remarkable finds, such as an undisturbed fifteenth-century b.c. princely tomb at Vapheio in Laconia, which he excavated in 1889, complete with weapons, jewelry, and gold cups. More pertinently, through the meticulous excavation of a broad range of sites, particularly cemeteries, and the careful comparison of their materials, he was able to put together a broad picture of the development

of prehistoric Greece. *The Mycenaean Age*, written by Tsountas and J. Irving Manatt and published in 1897, was the first great synthetic work of Aegean prehistory, and the book made the subject the major branch of Mediterranean archaeology that it has been ever since.

Improvements in excavation techniques were accompanied by a general systematizing of the analysis of artifacts, particularly pottery, the basis of most archaeological dating. Before and after World War I, the Englishman Alan Wace and the American Carl Blegen complemented Tsountas's work by producing a coherent and precise chronology of pre-Mycenaean pottery. In the field of classical archaeology, the first half of the twentieth century was characterized by connoisseurship. Archaeological knowledge was ordered and classified, with artifacts being sorted and pigeonholed into vast corpora of inscriptions, coins, potsherds, figurines, lamps, and so on. The ultimate analysis was that of Greek vases by the Oxford art historian john beazley. By identifying characteristic stylistic traits and mannerisms, as well as using the occasional signatures, he managed to detect the “hands” and “workshops” of individual ancient painters. Classical archaeology remained subservient either to art history, with statues, vases, and buildings being taken out of context as works of art, or to textual history, where the objects merely illustrated the accounts of Thucydides, Euripides, and the other classical writers.

Further changes came to archaeological methods and interpretations in the 1960s with the advent of scientific techniques and processual archaeology. Prehistorians such as Colin Renfrew led the way in modeling the influences and processes that had caused social change in the past. Most classical archaeologists remained firmly entrenched within their empiricist and descriptive traditions until the 1970s and 1980s when scholars such as Anthony Snodgrass began using the contextual analysis and theories of social change that are more normally associated with prehistory to question the rich range of data from the Iron Age and classical period.

Another striking change in archaeological methodology in Greece during the last two decades of the twentieth century was a rapid growth in the popularity of archaeological survey and landscape archaeology. These involved the use of a very different technique than that used in the exploration and site-hunting by earlier archaeologists. Teams of field-walkers covered large areas of landscape systematically and intensively, recording and sampling the surface material they found. This allowed an examination of small rural sites such as farmsteads and hamlets and when combined with geomorphological mapping and other disciplinary studies, enabled investigators to study the development of agriculture, ancient soil management, and a host of other off-site activities.

Because such survey projects found material of all periods, especially the late post-Roman period, they sparked an important interest in the archaeology of medieval and Ottoman Greece, in striking contrast to the classical purists of the nineteenth century. In 1988, the Greek government amended the antiquities law to allow each school to run three surveys and three excavations each year, and Greece now leads the eastern half of the Mediterranean in the field of archaeological survey.

The Archaeology of the Greek Nation

“Hellenic archaeology, gentlemen, is not a profession but a sacred mission.” So spoke Georgios Oikonomos, secretary of the Archaeological Society of Athens, during preparations for the society's centenary in 1937. Ever since the War of Independence, in the first third of the nineteenth century, archaeology had been something greater than a job or an interest. Classical antiquities were considered to be almost sacred relics that expressed the innermost spirit of the Hellenic nation, which, above all, was the reason why the Greek state was determined to keep control over all artifacts and excavations and why it worked so hard from as early as the 1820s to educate future generations about the importance of the classical past.

The precise nature of this belief, of course, varied according to occasion and individual and developed in accordance with changing ideological and political conditions. Christos Tsountas, for example, was interested in the Mycenaeans for their own sake as they had an important and

fascinating culture. But he also felt it was important to refute the views of his foreign colleagues who declared that the Mycenaean civilization was non-European and certainly non-Greek. To Tsountas, the Hellenic spirit could appear at different times in different forms, and the rich culture of late Bronze Age Mycenae was one of those manifestations. He was proved right in a very literal sense in 1952 when the British architect Michael Ventris deciphered the Linear B tablets from the palace archives of the late Bronze Age and discovered that they were written in an early form of Greek.

In 1833, newly independent Greece encompassed only a fraction of its current area, and as new areas were gradually acquired, they had to be incorporated into the state. Archaeology played a vital role in this process of nation building. When Macedonia (that is, the current Greek province of Macedonia) became part of Greece after the Balkan wars of 1912-1913, a Greek Archaeological Service of Macedonia was immediately set up, and numerous excavation projects were organized. It was initially rather awkward that the area lacked much of the classical architecture and artwork of southern Greece, and as a result, there was a strong focus on the much richer Byzantine culture of the region. In the mid-nineteenth century, the Byzantine period had been considered unimportant or even shameful, a time when Greece was ruled by an outside empire. Now it was incorporated into the Hellenic heritage, and the Byzantine churches of Thessaloníki that had been converted into mosques were restored to their original “pure” form.

Archaeology in Macedonia, and its role within the Hellenic nation, received a major boost in 1977 when Manolis Andronikos discovered a rich fourth-century-b.c. tomb at Vergina in Macedonia. Quite apart from the elaborate wall paintings, armor, and silver vessels, a gold ossuary within a marble sarcophagus contained bones wrapped in gold and purple cloth that were identified as those of Philip of Macedon, father of Alexander the Great. The outer chamber of the tomb also contained a gold box holding cremated ashes and was embossed with a star burst, or “star of Vergina,” a symbol of the Macedonian kings. This archaeological discovery was widely believed to be a direct link with the Hellenic past. Macedonia was suddenly flooded with up to forty archaeological projects a year, and a wealth of publications appeared, both academic and popular. The star of Vergina became the national symbol of Greece in 1993, and when Andronikos died in 1992, he was given a state funeral and the honor of being the first Greek archaeologist to be depicted on a postage stamp.

The importance of archaeology to Greek national identity has, of course, led to disputes with other groups making rival claims to the past. One was with the former Yugoslav Republic of Macedonia, which also claimed the star of Vergina as a state symbol. Most well known is the dispute over the Parthenon (or Elgin) Marbles, which became a major national issue in the 1980s owing to the hugely popular ex-actress and minister of culture, Melina Mercouri. The campaign for the restitution of the sculptures by the British Museum is inspired above all by an almost religious belief in their centrality to Hellenic culture and identity. Manolis Andronikos, in a 1983 newspaper article, declared that “these sculptures belong to the most sacred monument of this country, the temple of Athena, which expresses the essence of the Greek spirit and incorporates the deepest nature of the Athenian democracy.”

Conclusions

Greek archaeology has never been static or monolithic. Nor is its history a mere list of discoveries and acquired facts. The antiquities of Greece and the societies that produced them were major players in the European Enlightenment, the development of western art, the new academic discipline of archaeology, and above all in the formation of the identity and character of an independent Greek nation. Such is Greece's archaeological wealth and variety that there is still material to satisfy all new trends in archaeology, from scientific techniques of dating and analysis to an interest in the entire landscape of a region to the recent growth in underwater archaeology. New trends will arise, but Greece will always

have the material to satisfy their pursuits.

PREV NEXT

Although there has been great variety in the last 300 years of archaeology in Greece, some general themes are common to much of the period. The wealth of material has not always been beneficial, attracting treasure hunters and allowing academics to slide into mere description rather than the questioning and analysis of material. The balance between local and foreign participation has swung to and fro depending on the international relations of the time, but cooperation has always been to the benefit of all parties. Even the Cockerells and Schliemanns inspired important developments in the history of archaeology in Greece.

The most striking aspect of Greek archaeology is its unique double association with a national identity and an international culture. The antiquities of Greece do indeed lie at the heart of western culture, through the artistic and intellectual revolutions of classical Athens, their rebirth in the Renaissance, and the craze for neoclassicism in the eighteenth and nineteenth centuries, but they are also the inspiration and symbol of one of the proudest national identities in Europe. The history of archaeology in Greece reflects the tension between the two sides of this paradox, as locals and foreigners alike focus on a heritage that is both universal and uniquely Greek.

Green, Roger Curtis

(1932-)

Born in New Jersey, from an early age Green was interested in archaeology, and first studied anthropology at the University of New Mexico. He moved to Harvard to study for his doctorate in 1955, and was deeply influenced by Professor gordon willey's settlement pattern approach to archaeology. Green was also influenced by julian steward and Clyde Kluckhohn, but it was Douglas Oliver who steered him firmly away from the archaeology of the Southwest and Central America and toward the archaeology of the Pacific.

In 1958 Green took up a Fulbright Fellowship in New Zealand, based in the anthropology department at the University of Auckland. Here he worked with social anthropologist Ralph Piddington and British archaeologist jack golson. Green excavated a coastal midden at Tairua on the Coromandel Peninsula that was a landmark for its careful interpretation of all the material recovered, and for Green's use of what Golson has characterized as the “ecological approach.”

Green then undertook major fieldwork projects in French Polynesia, Samoa, and the Solomon Islands based on settlement pattern study and ethno-historic approaches, which established him as a major figure in the relatively new field of Polynesian archaeology. From 1961 to 1967 Green taught at the University of Auckland and carried out a number of small excavations and surveys to provide training and opportunities for students. He served a term as president of the New Zealand Archaeological

Association and played an important role in the early effort to establish protection for archaeological sites. He produced a major synthesis of the prehistory of the Auckland province and a revision of the Fijian sequence. Green also taught at the University of Hawaii.

Despite his activity in New Zealand, Green's major interest lay in tropical polynesia, and with support of the Bishop Museum in Honolulu, the U.S. National Science Foundation, and other institutions in New Zealand and Fiji, he returned to Western Samoa between 1963 and 1967 as part of the Polynesian Prehistory Program. From 1968 until 1970 Green undertook the Makaha Valley Historical Project in Hawaii, a major contract investigation funded entirely by private sources, which also made major contributions to the professional literature. Green also began his long collaboration with New Zealand ethnobotanist Douglas Yen at this time.

Green returned to New Zealand as the first Captain James Cook Fellow at the Auckland Institute and Museum and began a major fieldwork project in the southeast Solomons, co-directed by Yen and involving participants from New Zealand, Hawaii, and Australia. The major outcome of the project was the discovery of a number of sites containing Lapita pottery on the Santa Cruz and Reef Islands. This became the focus of his subsequent work. Green had been an important contributor to the definition of Lapita and other pottery in the central Pacific; now he was to become influential in defining the Lapita cultural complex in the western Pacific as well. The second phase of the southeast Solomons project during the late 1970s, again directed by Green and Yen, was concerned with Lapita sites on the Santa Cruz group.

During the 1970s Green wrote influential papers on the chronology of Oceanic languages, reviewed what was known about the Lapita cultural complex, and developed his ideas about Near and Remote Oceania. In the 1980s Green, along with archaeologist Dimitry Anson, undertook the reinvestigation of Lapita sites on Watom Island as part of the multi-institutional Lapita Homeland Project organized by Jim Allen, then of the Australian National University. The ongoing analysis of Lapita material from this project and from the Santa Cruz and Reef Islands absorbed Green over more than a decade.

In 1973 Green was appointed to a personal chair in the anthropology department at Auckland University, which he held until his retirement in 1992, and he then became professor emeritus. He has continued to exert an influence through his teaching and the supervision of numerous theses. He has played a major role in the growth of Pacific archaeology, and his culture historical approach has been influential. He has served on the council of the Royal Society of New Zealand and he was elected a Fellow of the Royal Society of New Zealand in 1975 and a member of the American Academy of Sciences in 1984.

Griffin, James Bennett

(1905-1997)

Griffin was born in Kansas, the son of a railway worker who eventually settled his family in Illinois. Griffin originally studied law and business at the University of Chicago but changed to anthropology. In 1930 he received his M.A. and began his long-term association with the Hopewell culture, digging the Morton site near Lewiston, Illinois. In 1931 he excavated late Algonkian and historic Delaware sites in Pennsylvania. In 1932 Griffin began a doctorate in American archaeology at the University of Michigan and became one of the founding members of the National Society for American Archaeology. In 1936 he received his doctorate for his dissertation that focused on the ceramics from the Norris basin in Tennessee.

From 1936 to 1941 Griffin was a research associate and associate curator in charge of the Ceramic Repository in the Museum of Anthropology at the University of Michigan. With this responsibility he began his lifelong investigation of eastern archaeology, characterized by specimen study and frequent travels to conferences

PREV NEXT

and museums. In 1937 he helped to found the Southeastern Archaeological Conference in conjunction with James A. Ford, then a graduate student at Michigan. He also formulated the preliminary synthesis that became the intellectual background for his seminal paper on “Cultural Continuity and Change,” delivered at the American Anthropological Association meeting in 1941. Griffin's goals were always larger than mere cultural-historical integrations, although his forays into that realm were very influential. He was interested in cultural process. From early on he also repeatedly examined the connection of prehistoric remains to the historically recorded tribal units-*ethno-historic* concerns, as they are now termed. The cardinal rule of his investigations was to obtain as much firsthand knowledge of the sites and artifacts as he could, and in his search for broad expertise he traveled extensively. He was also open-minded about new methods of analysis. He helped to pioneer the use of Carbon 14 dating in North America and to establish the radiocarbon-dating laboratory in Ann Arbor, which would serve as a major source of New World dates for nearly twenty years.

During the war he taught economic and political geography to soldiers. In 1945 he was finally made an associate professor of anthropology with regular teaching responsibilities, and his title at the museum was upgraded to director in 1946. In 1941 Griffin had teamed up with James Ford at Louisiana State University and Philip Phillips of Harvard's peabody museum to undertake extensive field survey and archaeological testing in the Lower Mississippi Valley that continued during the war, resulted in a major and influential monograph, and was representative of his interest in spatial expanses and interareal interactions.

Over the next twenty-five years, until he retired in 1975, Griffin continued to build his record of accomplishments from his base in Ann Arbor. He became a full professor in 1949, and his teaching and extensive involvement with graduate students increased as the Museum of Anthropology and the department became one of the principal training grounds for North American archaeologists in the country. Griffin was president of the society for american archaeology from 1951 to 1952, and in 1957 the society awarded him the Viking Fund Medal for Archaeology for his achievements. He was made a member of the National Academy of Science in 1968.

Griffin's legacy to American archaeology was significant. His strong published record of basic research totaled more than 260 items. He affected the personal and intellectual lives of scores of students and scholars-by 1975 he had guided more Ph.D. candidates through their degrees than anyone else in the department. He had a fine-tuned ability to evaluate new data and new ideas critically. All serious students of the archaeology of eastern North America must acknowledge Griffin's contribution, whether their area is woodland influences on the western plains or on the mid-Atlantic coast or the question of Iroquoian origins in the Great Lakes region. Griffin covered an unequaled range of subjects in space and time.

Guatemala

Guatemala is one of the five independent republics of Central America and comprises a major part of what is defined in archaeology as the Mesoamerican region. The population today is approximately 12 million, over half of whom are Indians of Maya ancestry. Some twenty-two Maya dialects have been identified since the Spanish conquest, as well as Pipil (Nahuat) and Xinca, which are currently nearing extinction. Today the predominant Maya language groups in Guatemala are the Quiche, Cakchiquel, Tzutujil, Kekchi, Pokomam, and Mam.

Two major geographic-ecological regions have affected cultural evolution through time: the tropical lowlands and the temperate highlands. The lowlands area includes the Pacific coast and piedmont zone and the entire northern

part of the country known as Petén. The highlands area is the mountainous and volcanic region that lies between the Pacific piedmont and Petén.

The history of Guatemala begins with its conquest in 1524 by Pedro de Alvarado, a trusted captain under Hernán Cortés in the conquest of Mexico. However, the area of Peten, occupied by groups such as the Maya Itzá, was not subdued until 1697. The country remained a Spanish colony until it gained independence, along with the rest of Central America, in 1821.

Precursors to Archaeological Exploration

Various letters and reports of the Spanish conquerors (e.g., Pedro de Alvarado and Bernal Diaz del Castillo) and early chroniclers described the Cakchiquel capital of Iximche and the Quiche capital of Utatlan in the highlands. Cortés wrote of various villages, such as Tayasal in Petén and Nito around Lake Izabal, on his march through the lowlands en route to Honduras in 1524 and 1525. All of these centers were abandoned by the inhabitants shortly thereafter. A few documents written by the Quiches and Cakchiquels in the early colonial period survive, including the *Popol Vuh* and the *Memorial de Tecpan Atitlan,* and these provide important information regarding these peoples' pre-Columbian history, their early migrations to Guatemala, and their worldview in general. Early land titles also contained references to events prior to the conquest. Reports by the clergy often provided valuable descriptions of native life, among them those by Bartolome de Las Casas in the 1550s, Bartolome de Fuensalida, and Juan de Orbita (1618-1619), and Andres de Avendaño y Loyola (1695-1696), as well as reports by the clergy to the various religious orders, such as those by Francisco Ximenez at the end of the seventeenth century.

The native population declined rapidly after the Spanish conquest, largely due to exposure to European diseases and the harsh conditions imposed by heavy labor in construction and agriculture. Christianization was achieved rapidly, and the influence of Christianity was seen in the native writings. These often reflected the biblical notions of the Spanish regarding the origins of the Americans, including the idea that they were descendants of one of the Lost Tribes of Israel. One exception was the work of Francisco Antonio Fuentes y Guzman who, writing in the 1700s, used the native documents and maps of the ancient centers to highlight the achievements and illustrious past of the former inhabitants and to show that the Guatemalan Indians of his day were descendants of those people (Fuentes y Guzman 1933, 2: 211, 3: 199).

The Enlightenment of the eighteenth century was reflected in Guatemala by a new interest in archaeological remains. The inclusion of Naples, Italy, in the Spanish domain during the reign of Carlos III awakened this interest and inspired the colonial authorities in Guatemala to carry out the first archaeological explorations on record. Between 1784 and 1789 three investigations were carried out in palenque and Chiapas, which today are part of mexico but at that time were still part of Guatemala. The reports, maps, and drawings from the third expedition were published in London in 1822 and circulated among the intellectuals of the era. The first museum in Guatemala, exhibiting both natural and archaeological specimens, was established by the Sociedad Economica in 1797. It functioned until 1801, when it was closed by the Spanish government on the pretext that it was involved in political movements toward independence from Spain (Lujan 1972, 354, 360).

Guatemala succeeded in obtaining its independence in 1821, along with the rest of Central America. In 1832, after a period of turbulence and civil wars, the government of Guatemala under Mariano Galvez organized an investigation of the archaeological sites of Utatlan and Iximche in order to put together an atlas and recapitulation of the history of the country. Galvez also reinstalled the Sociedad Economica and ordered that a new archaeological museum be established under its aegis (Lujan 1972, 364).

With independence from Spain, Guatemala experienced heightened interaction with the outside world, including the United States, England, France, and other European countries. During the time of the Federal Republic of Central

America, organized in 1823 and lasting until 1839, numerous archaeological explorations were carried out by Europeans and others. In 1839 and again in 1841 john l. stephens, a New Yorker, and the Englishman frederick catherwood traveled to Mexico and Central America and visited Maya sites such as Tonina, Palenque, and Uxmal in Mexico, Quirigua, Utatlan, and Iximche in Guatemala, and Copan in Honduras. Subsequently Stephens published his account of the trips, along with drawings by Catherwood, and this helped to call the attention of the world to the subject of Maya archaeology.

The Beginnings of Archaeological Investigation in the Nineteenth Century

The second half of the nineteenth century witnessed increasing archaeological explorations in the Peten both by Guatemalans and by foreigners. In 1848 Ambrosio Tut, a Guatemalan, discovered the ruins of tikal. He reported these to the governor of Petén, Modesto Mendez, who published information on the find in the local newspapers and in the journal of the Academia de Geografía e Historia de Guatemala. In the next few years he found more sites in the general area of Petén (Lujan 1972, 364). Toward the end of the century further exploration was encouraged by the interest of U.S. companies in obtaining chicle from the forest for the manufacture of chewing gum.

Between 1881 and 1894 the Englishman Alfred P. Maudslay discovered and systematically issued reports on archaeological sites and monuments, all accompanied by excellent photographs and maps, which stimulated the first studies of Maya hieroglyphs. Slightly later the Austrian Tobert Maler discovered and photographed a number of sites along the Usumacinta River, and the results of his work were published by the peabody museum of Archaeology and Ethnology of Harvard University. The inception of coffee cultivation in Guatemala brought a number of Germans and other Europeans to the country to establish plantations, especially in the highlands. Karl Sapper, Otto Stoll, and Erwin Dieseldorff made important studies on the local ethnography and archaeology, especially in the region of Alta Verapaz.

The organization of liberal governments at the end of the nineteenth century promoted interest in pre-Columbian archaeology as a way of reconstructing national history. For this purpose Manuel García Elgueta, considered by some to have been the first Guatemalan archaeologist, carried out excavations in the highland sites of Xolchun and Chalchitan (Lujan 1972, 368). In celebration of the fourth centennial of the discovery of America in 1892, President José Maria Reyna Barrios ordered molds of monuments to be made and presented, along with archaeological objects, at the Columbian Exposition in Chicago and at another exhibition in Seville, Spain. During this endeavor the site of Ceibal in Peten was discovered by Federico Artes (Morley 1937-1938, 80). President Reina Barrios was the first government official to design laws to protect archaeological goods in the country, prohibiting the illegal excavation and exportation of these materials to other countries. The laws, however, were ignored during the following decades (Rubin de la Borbolla and Cerezo 1953, 13).

Professionalizaion of Archaeological Investigation in the First Half of the Twentieth Century

With the twentieth century came a new era in archaeological investigation in Guatemala, carried out by professional, trained archaeologists

America, organized in 1823 and lasting until 1839, numerous archaeological explorations were carried out by Europeans and others. In 1839 and again in 1841 john l. stephens, a New Yorker, and the Englishman frederick catherwood traveled to Mexico and Central America and visited Maya sites such as Tonina, Palenque, and Uxmal in Mexico, Quirigua, Utatlan, and Iximche in Guatemala, and Copan in Honduras. Subsequently Stephens published his account of the trips, along with drawings by Catherwood, and this helped to call the attention of the world to the subject of Maya archaeology.

The Beginnings of Archaeological Investigation in the Nineteenth Century

The second half of the nineteenth century witnessed increasing archaeological explorations in the Peten both by Guatemalans and by foreigners. In 1848 Ambrosio Tut, a Guatemalan, discovered the ruins of tikal. He reported these to the governor of Petén, Modesto Mendez, who published information on the find in the local newspapers and in the journal of the Academia de Geografía e Historia de Guatemala. In the next few years he found more sites in the general area of Petén (Lujan 1972, 364). Toward the end of the century further exploration was encouraged by the interest of U.S. companies in obtaining chicle from the forest for the manufacture of chewing gum.

The laws, however, were ignored during the following decades (Rubin de la Borbolla and Cerezo 1953, 13).

Professionalizaion of Archaeological Investigation in the First Half of the Twentieth Century

With the twentieth century came a new era in archaeological investigation in Guatemala, carried out by professional, trained archaeologists

New Trends in Archaeological Investigations

Beginning in the late 1940s and continuing into the present, the Guatemalan government has focused on using archaeological sites to attract tourists. The first of such project was the restoration of the site of Zaculeu, the ancient Mam capital in the northwest highlands, financed from 1946 to 1949 by the United Fruit Company. The French Archaeological Mission carried out a similar project (1959-1974) at Iximche, the Cakchiquel capital in the central highlands at the time of the Spanish conquest, and another at Jilotepeque Viejo (formerly known as Mixco Viejo). The Tikal Project (1956-1969) was undertaken with the idea of developing it as a national park in the Peten, sponsored by the Museum of the University of Pennsylvania; with the cooperation of the Guatemalan government, almost $1 million was obtained for this project from various foundations in the United States (Rainey 1970, 3). In 1970 the project was taken over by the Instituto de Antropologia e Historia, and the investigations continue under Guatemalan direction at the present time, more recently with cooperation from Spain.

In the 1950s the Rockefeller Foundation funded an educational program in archaeology at the Universidad de San Carlos, the national university in Guatemala City, to train professionals in the field. The program was short-lived, but some of the students were able to continue their field training by participating in the Tikal Project. By 1967 the university established a formal program in archaeology in the form of a regular curriculum to obtain a professional degree. From this time forward archaeological field projects increased significantly in all regions in Guatemala. In 1981 the Universidad del Valle initiated its Department of Archaeology, where the Madeleine and Alfred V. Kidder Chair was inaugurated in 1986, providing the funds for student training.

The guerrilla warfare that disrupted Guatemala beginning in the 1960s and continued for the next thirty years seriously interfered with archaeological investigation. The conflicts causing this unrest were settled by the Peace Accords of 1998, which included new regulations concerning rights and public access to "sacred places," often synonymous with pre-Columbian sites. Another public concern in Guatemala is the issue of national identity, and for this theme archaeological, historical, and ethnohistorical information is essential and is receiving more attention. The ethnohistorical studies of the Quiche by Robert Carmack in the 1970s are a good example of the type of work being done in this area. The recently published *Historia General de Guatemala* is helping to incorporate the archaeological, historical, and ethnohistorical information into the educational system at all levels.

A law issued in Guatemala in the early 1980s requires construction companies to finance at least a year of excavation on the land on which they wish to build, especially if it is suspected that archaeological remains are present. The law has facilitated archaeological research in many areas, especially on the south coast and at Kaminaljuyu, located on the southwestern fringe of the modern capital of Guatemala City. Nevertheless, although more public attention is being drawn to archaeological information through education and the media, investigation is being seriously hampered by urban expansion and rampant looting.

The accompanying table presents a summary of some of the archaeological projects carried out in Guatemala since the 1970s.

Guo Moruo

(1892-1978)

President of the Chinese Academy of Sciences from 1950 until his death in 1978 and Chinese Minister for Culture, Guo Moruo (or Kuo Mo-jo) was a famous writer, a poet, a cofounder of the literary Creation Society, and a radical who had communist leanings. In 1927 he escaped from china and Chiang Kai-shek's anticommunism to Japan, where he lived in exile for ten years. During his exile he wrote several influential books, *A Study of Ancient Chinese Society* (1930), *A General Outline of Bronze Inscriptions of the Western and Eastern Chou Dynasties* (1932), *A General Study of Oracle Inscriptions* (1933), and *An Illustrated Catalogue of Bronze Inscriptions of the Western and Eastern Chou Dynasties* (1934), which established him as an important scholar of ancient China and some of which remain indispensable reading. Guo was not a field archaeologist, but his first book *A Study of Ancient Chinese Society* (1930) was the first attempt to write a Marxist history of China and was influential in archaeological circles. Both Guo's periodization of ancient Chinese history and production as the basis of society became fundamental to the writing of history and archaeology after 1949, when Marxism became the national and party doctrine.

Hamilton, Sir William

(1730-1803)

Hamilton was born into the British aristocracy, becoming an equerry to his foster-brother, the Prince of Wales, later King George III. After serving in the army in Holland, he married a wealthy wife and was briefly a member of Parliament until 1764. At that time he was appointed the British envoy extraordinary and plenipotentiary at the court of Naples in southern italy. He was popular at the court, and with little diplomatic work spent most of his time pursuing his interests in volcanoes and antiquities.

Hamilton was elected a fellow of the Royal Society in 1766. He published his observations on volcanoes and presented a collection of volcanic earths and minerals to the british museum. Nonetheless, his interest in geology gradually gave way to his passion for the Greek and Roman antiquities of southern Italy. He purchased the outstanding Porchinari family collection in Naples, which he sold to the British Museum in 1772, founding the museum's department of Greek and Roman antiquities. Hamilton also published inventories and pictures of other collections of artifacts, helping to create the fashion for collecting the antiquities of greece and Rome among the English and European aristocracy and wealthy middle classes during the late eighteenth and early nineteenth centuries.

Hamilton spent almost forty years in Naples assembling collections and then selling them. He never saw himself as an antiquarian or an archaeologist. Instead, he valued antiquities as models for modern artists, which also justified his funding of the excavation and plunder of cemeteries, and of Roman sites such as pompeii and herculaneum. His second collection was sent to England in 1798, and a third was partially lost when the ship carrying it went down. These collections greatly influenced the styles and fashions of the day-from architecture and furniture to fashion and fine arts, with Josiah Wedgwood reproducing elements from them

Harappa

The type site of the Harappan (indus) civilization, Harappa is a major city located in the Punjab, south asia, and is thought to have been at its height between 2500 and 2000 b.c. Harappa was recognized as an archaeological site in 1826, but research had to wait for nearly a century when, between 1920 and 1921, Rai Bahadur Daya Ram Sahni of the Archaeological Survey of India began to explore the site. M.S. Vats continued the work during the time before the beginning of World War II, and after the war, sir mortimer wheeler, during his time at the Archaeological Survey of India, dug for a season in 1946. Another long hiatus in activity was broken in 1986 when George Dales began excavations here.

River, he gave equal attention to historic artifacts and assemblages. His "Dating Stem Fragments of Seventeenth and Eighteenth Century Clay Tobacco Pipes" (Harrington 1954) created a new absolute dating technique with global application.

Outside the laboratory and away from the field Harrington was equally a pioneer. He wrote the first survey of North American historical archaeology in 1952, and the article "Archaeology as an Auxiliary Science to American History" (Harrington 1955) initially defined the field and its relationship to history and the social sciences. He also carried the message of this new area of scholarship to the public in a number of popular articles. He was the first historical archaeologist named in the *National Geographic Magazine* (1942), and his well-written booklet *Archaeology and the Historical Society* (Harrington 1965) was widely distributed.

By January 1967, Harrington was fully retired from his thirty-year career in the National Park Service, but he was still a key player in the founding of the society for historical archaeology at its organizational meeting that year in Dallas, Texas. That society, in turn, honored Harrington in 1981 when it established the j. c. harrington medal in historical archaeology, the highest and most prestigious award given worldwide within the discipline.

Hassuna

Tell Hassuna is a prehistoric site found on the Tigris River in northern Iraq. It was first excavated by Seton Lloyd and Fuad Safar during World War II, when Lloyd was an adviser to the Iraq Department of Antiquities. The site is late Neolithic in age (about the sixth millennium b.c.) and is the type site of the Hassuna cultural complex, which features Hassuna, Samarran, and Halaf styles.

That same year Hawes began to excavate Gournia, a Bronze-Age town that is still the only well-preserved urban Minoan site on Crete. This time, however, she

was sponsored by the American Exploration Society of Philadelphia for a number of seasons-1901, 1903, 1904-and the results of her work were published in 1908. Harriet Hawes was not only the first woman to direct an excavation, she was also the first woman to publish her results.

Between 1900 and 1906 Hawes taught archaeology, epigraphy, and modern Greek at Smith College. She married and had two children and continued to publish and teach, first at the University of Wisconsin and then at Dartmouth College (1910-1917). After World War I she became assistant director (from 1919 to 1924) and then associate director (from 1924 to 1934) of the Museum of Fine Arts in Boston. She taught at Wellesley College until 1936. In her later years she was more involved with international and U.S. politics than with archaeology, becoming an active New Dealer in Boston in the 1930s.

Tim Murray

Hawkes, Christopher

(1905-1992)

Hawkes was educated at Winchester and New College, Oxford. In 1928 he began working with the Department of British and Medieval Antiquities at the british museum as an assistant keeper. This position allowed him to develop an extensive overview of, and familiarity with, a wide range of material and artifacts. Hawkes was one of the national secretaries for the first International Congress for Pre- and Protohistoric Sciences (a forerunner of the International Union of Prehistoric and Protohistoric Sciences) held in London in 1932, publishing, with archaeologist thomas d. kendrick, *Archaeology in England and Wales 1914-31* and annual summaries of prehistoric research in Britain for the *Archaeological Journal.*

Hawkes came to archaeology through fieldwork, starting with sir mortimer wheeler in Wales, and then from 1924 to 1928 at St. Catherine's Hill, Winchester, both excavating the chapel and establishing the Iron-Age date of the fortifications. He also worked at Wroxeter, and directed the excavations at Alchester, a small Roman town north of Oxford. From 1930 to 1931 he participated in the excavation of the Iron Age *oppidia* (or fortified town) of Camulodunum at Sheepen Hill, Colchester. Hawkes's publication of this work firmly established his expertise in late Iron Age studies. In 1932 Hawkes joined the Fenland Research Committee, the first truly modern prehistoric project in terms of its interdisciplinary scope. He later endorsed gerhard bersu's principles of excavation as practiced at Little Woodbury, and rejected Wheeler's overreliance on section/sequence evidence, allying himself with the sociological school of open-area plan-recovery excavations.

Primarily concerned with the problems of protohistoric Europe, Hawkes's archaeology was removed from the pure prehistory practiced by contemporaries grahame clark, stuart piggott, vere gordon childe, and glyn daniel. Situated at the cusp of history/prehistory, it was formulated with an awareness of the impact of past migrations, ethnic pluralities, comparative philology, and social stratification. For many, it was the weight given to the historic that ultimately limited Hawkes's prehistory. His book *The Prehistoric Foundations of Europe, to the Mycenean Age* (1940) was both influential on, and comparable to, Childe's *Dawn of European Civilization,* but he was entirely overshadowed by Childe. By the 1960s his advocacy of invasion theory and diffusionism was considered dated.

During World War II Hawkes worked in the Ministry of Aircraft Production. In 1946 he was appointed Oxford University's first professor of European Prehistory. He was elected to the British Academy of Science in 1948. Hawkes established the Oxford Department of Archaeology and, in 1955, its

Research Laboratory for Archaeology and the History of Art. Fluent in both French and German, along with Childe, Hawkes was one of the most "continentally" influential British prehistorians and was responsible for the integration of much British material with core European sequences. He retired in 1972.

Hensel, Witold

(1917-)

One of the most eminent Polish archaeologists after World War II, Hensel studied prehistory at the University of Poznan under archaeologist józef kostrzewski, historian Kazimierz Tymieniecki, and ethnographer Eugeniusz Frankowski. While still a student, Hensel took part in excavations conducted by Kóstrzewski at biskupin, and he also participated in research on early Polish medieval sites in Gniezno, Klecko, and Poznan.

Hensel was one of the most important initiators of a huge archaeological and historical research project realized in connection with the commemoration of the anniversary of the millennium of the Polish state and the baptism of Prince Mesco I in a.d. 966. In a 1946 article entitled *Potrzeba przygotowania wielkiej rocznicy* (Need for Preparation of a Great Anniversary), Hensel outlined the main objectives of this research project. He actively participated in the activities of the Management of Studies of the Beginnings of the Polish State, which was changed in 1949 into the Institute of the History of Material Culture, Polish Academy of Sciences. His main scientific interests were focused on the problems of early medieval period, especially issues related to settlement studies, technology, contact, trade and exchange, and the process of creating the proto-classic societies and their transformation into the classic societies of early Piasts. These were western Slavic tribes who united to form small states between a.d. 800 and 960, and came to be ruled by the Piast dynasty, whose descendents ruled greater poland from a.d. 1047 until 1386.

Hensel was one of the founders of Slavonic archaeology, as he created the background that was fundamental for the development of the modern discipline in relation to the previous traditions of Polish archaeology. Additionally, that field of interest was one of the most important areas of contact between archaeologists from the former Soviet Union and the Slavonic former socialist countries. He contributed to the origin of a new journal, *Slavia Antiqua,* founded chiefly for the sake of these problems, and became its first and longstanding editor. Hensel also was the first director of the Department of Slavonic Archaeology at the University of Warsaw, and he contributed very effectively to the dynamic development of Slavonic archaeology in other Slavonic countries. He was one of the main initiators and organizers of the International Congress of Slavic Archaeology, held in 1965 in Warsaw, and he was elected the first president of an International Union of Slavic Archaeology.

After World War II, Hensel advocated the introduction of Marxist methodology into Polish archaeology. This methodology was to serve as a platform for an integrated archaeology of Poland, including classical archaeology and ethnography within the history of material culture. Hensel was also interested in the periodization of Polish prehistory as he wished to reconcile traditional archaeological chronological divisions with the general divisions of history originated by Friedrich Engels and lewis henry morgan. He devoted a great deal of time to the history of archaeology, and to the methodology of archaeological enquiry, and in the latter area he was to initiate microregional analysis.

Hensel was an active supporter of international cooperation in historical archaeology, and he was an active organizer. In 1953, he became a member of as organizational committee to establish the Institute of the History of Material Culture at the Polish Academy of Sciences. From 1954 to 1989 he was director of the institute, which was the central, largest, and the most important archaeological institution in poland, and under his supervision, the institute became the center for Polish archaeology. His other duties included working at and then becoming director of the Department of Archaeology at the University of Poznan (1945-1954). He was director of the Department of Slavonic Archaeology from 1956 to 1965 and director of the Department of Prehistoric and Early Mediaeval Archaeology at the

University of Warsaw from 1965 to 1970.

He is a full member of the Polish Academy of Sciences; editor of the archaeological journals *Slavia Antiaqua, Archaeologia Polona, Polskie Badania Archeologiczne* (Polish Archaeological Research), and *Swiatowit;* and a member of editorial committees for other Polish and foreign journals. Hensel remains an active member of

PREV NEXT

many societies and institutions both scientific and social, for example, the International Union of Pre- and Protohistorical Sciences and the International Committee of Slavists, and he was a president of Archeologia Urbium.

Hensel has been one of the most productive Polish archaeologists of the postwar period, and has excavated in Poland (e.g., Czersk, Kruszwica, Poznan) and abroad (e.g., Algiers, Algeria; Styrmen, bulgaria; St. Jean-le-Froid, france; Cappacio Vecchia, and italy).

Arkadiusz Marciniak

Herculaneum

Herculaneum, like pompeii, was a Roman town in the Bay of Naples, destroyed by the eruption of Vesuvius in a.d. 79. The eruption followed a slightly different course at Herculaneum, where a final flow of volcanic mud buried the site much more deeply than Pompeii (over 20 meters deep in places). This has made excavation much more difficult but often more rewarding, since carbonized perishable material is much better preserved at Herculaneum.

Excavation leading to the remains of Herculaneum

(Ann Ronan Picture Library)

The site was discovered during the digging of a well in 1709. But lime burners seeking marble for their kilns displayed more interest in the find than did archaeologists, and systematic excavations only began in 1738, at the command of the Bourbon king Charles III. The theater and basilica were discovered in these early excavations, which were made by tunneling. The most sensational find came in 1750 in the form of the Villa of the Papyri (upon whose design the j. paul getty museum in Malibu, California, is based). The villa was packed with bronze sculptures, including a number of portraits of philosophers. Even more remarkable were the hundreds of papyrus scrolls, found carbonized but largely legible. They are mainly works by the Epicurean philosopher Philodemos. The villa may originally have been owned by the father-in-law of Julius Caesar, L. Calpurnius Piso, a patron of Philodemos.

Karl Weber might be considered the first semiprofessional archaeologist to work on the buried Roman cities around Vesuvius. A Swiss military engineer who had enlisted as a mercenary in Naples in 1743, he was in charge of the excavations at Herculaneum (as well as Pompeii and Stabiae) between 1750 and 1764. He oversaw the excavation of the Villa of the Papyri and produced detailed and accurate plans and other documentation. In this period of treasure hunting

for the royal collections, Weber was unusual for his interest in the archaeological context of his discoveries. The Academia Herculanensis was founded in 1755 for the discussion and publication of the finds. The eight volumes of *Le antichità di Ercolano esposte,* published between 1757 and 1792, had a dramatic effect on contemporary taste in Europe and the United States.

The foul air in the tunnels may have hastened Weber's death, and work was halted on the Villa of the Papyri in 1764 because of the fumes. Herculaneum was at that time beginning to be overshadowed by the finds at Pompeii and other sites buried by Vesuvius. Excavation has been rather fitful since that time, characterized by long breaks-for example, between 1780 and 1828 and 1876 and 1927.

Excavation in open trenches began in 1828 and was carried out on a large scale by Amadeo Maiuri between 1927 and 1958. The picture of Herculaneum that emerged was not of a prosperous commercial and industrial town like Pompeii but rather of a seaside resort. Public buildings were few and large, luxurious houses were restricted to the seafront. Dozens of skeletons (otherwise rare in Herculaneum) have recently been discovered on the ancient shoreline in front of the town, but generally excavation since the 1960s has been conducted on a modest scale. There is enthusiasm in some quarters for continuing the excavation of the Villa of the Papyri after a break of almost 250 years. The recovery of further papyri bearing ancient literature that otherwise has been completely lost is a very strong lure. The cost, however, would be enormous, and the project has been opposed by many who believe that state funds would be better spent on restoration and conservation. The excavation may proceed with private funding from the United States.

Hewett, Edgar Lee

(1865-1946)

A pivotal figure in U.S. archaeology in the early part of the twentieth century, Edgar Lee Hewett is best known for his political influence and dominating personality. Although largely ignored by recent historical syntheses, his influence on the character of archaeology in the American Southwest was far reaching.

Hewett was born in 1865 in Warren County, Illinois, and received a bachelor's degree from Tarkio College in Missouri and a master's degree in pedagogy from the Colorado State Normal School in 1898. His initial experience in archaeology was avocational, acquired while traveling by wagon through the Southwest on summer holidays in the 1890s. His appointment as first president of the New Mexico State Normal School in Las Vegas in 1898 provided an institutional base for fieldwork as well as for the establishment of relationships with a number of prominent important political figures in New Mexico Territory.

While serving in that position, Hewett established a reputation as an advocate for archaeological work, which until that time had largely been conducted by expeditions from eastern universities and museums. His attempts to establish local control over excavations in the region, such as those at chaco canyon, brought him into conflict with those institutions. On a national level, Hewett became allied with cultural

nationalists and nontraditional scholars such as Charles Lummis and Alice Fletcher, heralding splits within the archaeological community along regional and class lines that became more evident following 1900.

Hewett's early field research concentrated on the Pajarito Plateau of northern New Mexico, an area that had been explored earlier by Adolph Bandelier, and some of the important sites in the region were subsequently preserved by the creation of Bandelier National Monument in 1916. Small-scale soundings may have been conducted in the region as early as 1895, and in the subsequent twenty years, excavations were conducted at the major prehistoric pueblos of Puye, Tyounyi, Yapashi, Long House, Tsankawi, and several smaller sites.

PREV NEXT

Resentment over this appointment affected Hewett's relationship with his peers for decades. The school was installed in the Palace of the Governors in Santa Fe, New Mexico, where Hewett maintained a base for the rest of his life. The school's essential function was the training of students in archaeological field methods. The related Frijoles Canyon field school, which functioned between 1908 and 1913, was one of the first of its kind in the United States, and it served as an educational and intellectual center for archaeology in the region. Several future leaders of the discipline, such as alfred vincent kidder, sylvanus morley, Neil Judd, and Jesse Nusbaum, participated in its activities. Hewett subsequently conducted field schools through the University of New Mexico in the Jemez region and in Chaco Canyon in the 1920s and early 1930s.

Throughout his career, Hewett demonstrated a talent for amassing institutional appointments. These included the directorship of the Museum of New Mexico from 1909 until his death; director of exhibits for the Pan-American Exhibition in San Diego, California (1911); and faculty positions at the State Teacher's College in San Diego, California (1922), University of New Mexico (1927), and the University of Southern California (1932). He was also closely involved with popular archaeological journals of the day, such as *Art and Archaeology,* and traveled a strenuous lecture circuit.

With its emphasis on regional, rather than national, institutions and on the importance of building a popular constituency for the conduct of archaeology, Hewett's philosophy ran counter to broader trends within the discipline, which was evolving from a broadly defined community with avocational roots into a smaller, professional cadre based in major universities and museums. Ultimately, Hewett's establishment of the School of American Research, the Museum of New Mexico, and several departments of anthropology created the institutions from which much of the archaeology in the Southwest has subsequently been conducted. It is this work that is his principal legacy.

Higgs, Eric

(1908-1976)

Eric Higgs did not take up archaeology as a full-time career until the age of 47. He had a degree in agricultural economics from London University and had worked as a professional card player, builder, and farmer. In 1954 Higgs began a two-year postgraduate program in prehistory at Cambridge University, studying with grahame clark and charles mcburney, who fostered his interests in the Paleolithic and the economic approach to prehistory.

Higgs participated in the final season of excavations at the cave of haua fteah in Libya with McBurney in 1955, becoming a research assistant in the Department of Archaeology and Anthropology, senior assistant in 1963, and assistant director of research from 1968 until 1972, when he retired. Higgs founded the Cambridge "Bone Room," which was the nearest that the university came to having archaeological laboratory facilities in the 1960s and 1970s. This provided the main focus for undergraduate teaching in practical work for many generations of students.

Between 1962 and 1967 Higgs carried out major fieldwork in the Epirus region of northwest greece that encouraged the development of paleo-geographic and paleo-economic approaches to the archaeological record. From 1967 to 1976 Higgs was director of the "Early History of Agriculture Project," housed in the Department of Archaeology, which consumed most of the funds then available for what was later to become known in Britain as "science-based archaeology." In his role as advocate of a more science-based methodology, he also edited jointly with Don Brothwell *Science in Archaeology,* one of the earliest comprehensive texts on the use of scientific methods in archaeology. Eric Higgs was a provocative and influential colleague and teacher, whose impact, despite only twenty years in archaeology, is still evident.

Hildebrand, Bror Emil

(1806-1884)

Swedish numismatist Bror Emil Hildebrand was a graduate of Lund University, the center for scientific archaeology in sweden during the first half and middle of the nineteenth century. Hildebrand first worked on the collections in the museum at Lund, and then was appointed chief custodian of National Antiquities in Stockholm in 1837. His expansion of the national collection during the 1840s and 1850s was the result not only of both agricultural land reclamations and methodical excavations, but also of his intention to create a national and scientific archaeological collection. As early as 1850 Hildebrand consulted Danish archaeologist christian jürgensen thomsen and reorganized the archaeological collections at Lund and Stockholm based on Thomsen's three-age system.

By the 1860s the Stockholm archaeological collection was remarkable for its quality and breadth-both of which were to influence the research of the next generation of Swedish archaeologists such as oscar montelius and B.E. Hildebrand's son, hans hildebrand. Because Sweden did not have the Roman monuments that absorbed the archaeological interest of much of the rest of Europe, its attitude to, and

care of, prehistoric material were exemplary. The homogeneity of prehistoric cultures in Sweden also meant that its collections provided an overall picture of source material and evidence of local variations. So both general and typical artifact features were easily traced, and were in fact were more accessible than ever before-as greater proportions of collections of artifacts were on exhibition during the nineteenth century than they ever have been since then.

Hildebrand's achievements in museology were more than well matched by his abilities as an outstanding numismatist. In fact he may not have been as effective in his museum role had he not had a numismatic background. In this area, once again Hildebrand was influenced by Thomsen, classifying coins in Copenhagen under Thomsen's personal supervision in 1830 and completing his doctoral thesis *Numismata Anglo-Saxonica* (Anglo Saxon Coins) based on work by one of Thomsen's students. Hildebrand also realized the value of coins for dating native artifacts and ancient remains

Hildebrand, Bror Emil

(1806-1884)

Swedish numismatist Bror Emil Hildebrand was a graduate of Lund University, the center for scientific archaeology in sweden during the first half and middle of the nineteenth century. Hildebrand first worked on the collections in the museum at Lund, and then was appointed chief custodian of National Antiquities in Stockholm in 1837. His expansion of the national collection during the 1840s and 1850s was the result not only of both agricultural land reclamations and methodical excavations, but also of his intention to create a national and scientific archaeological collection. As early as 1850 Hildebrand consulted Danish archaeologist christian jürgensen thomsen and reorganized the archaeological collections at Lund and Stockholm based on Thomsen's three-age system.

By the 1860s the Stockholm archaeological collection was remarkable for its quality and breadth-both of which were to influence the research of the next generation of Swedish archaeologists such as oscar montelius and B.E. Hildebrand's son, hans hildebrand. Because Sweden did not have the Roman monuments that absorbed the archaeological interest of much of the rest of Europe, its attitude to, and

care of, prehistoric material were exemplary. The homogeneity of prehistoric cultures in Sweden also meant that its collections provided an overall picture of source material and evidence of local variations. So both general and typical artifact features were easily traced, and were in fact were more accessible than ever before-as greater proportions of collections of artifacts were on exhibition during the nineteenth century than they ever have been since then.

Hildebrand's achievements in museology were more than well matched by his abilities as an outstanding numismatist. In fact he may not have been as effective in his museum role had he not had a numismatic background. In this area, once again Hildebrand was influenced by Thomsen, classifying coins in Copenhagen under Thomsen's personal supervision in 1830 and completing his doctoral thesis *Numismata Anglo-Saxonica* (Anglo Saxon Coins) based on work by one of Thomsen's students. Hildebrand also realized the value of coins for dating native artifacts and ancient remains

from the Iron Age that were found with them. In his early numismatic works on Roman coins found in Scandinavia, Hildebrand argued that the silver denarii must have been deposited before the third century a.d., and that the coins, like other Roman products, must have reached the north via direct or indirect trade with Roman territories and not by any other means. The grouping of the different flows of imported coins during the Iron Age became an important starting point for determining Iron Age chronology. Hildebrand completed a preliminary classification of the more important groups of coins, and went on to classify Scandinavian coin finds into four main detailed classes-the basis for later Swedish archaeologists' development of a chronology for the Iron Age.

Evans, Sir John

Hildebrand, Hans

(1842-1913)

Archaeologist, numismatist, historian, museum curator, and director, and very much like his father, bror emil hildebrand, Hans Hildebrand graduated from the University of Uppsala in 1865 and received his doctorate in 1866. Hildebrand studied botany, geology, mineralogy, mathematics, and astronomy as well as the humanities at university, and was an early member of the Natural Science Society. He was also interested in geology and paleontology-contentious subjects in Europe at the time of his graduation. In 1862 he accompanied his father and the anthropologist Gustaf Retzius to London and visited henry christy, English banker and partner of the French archaeologist édouard lartet. The three Swedes examined the newest Paleolithic finds of Britain and france and borrowed literature on the subject from Christy. With his father Hans had visited Paris the year before, where they had no doubt heard the debates about jacques boucher de perthes's stone tool finds at Abbeville. He returned to sweden with a strong interest in the earliest history of humanity.

Hans Hildebrand was introduced to numismatics at an early age by his father, and his doctoral thesis *The Swedish People in Heathen Times* (1866) was on Iron Age coins. He was unique in his knowledge of both numismatics and archaeological data from the field and in the museum context. Between 1865 and 1866 Hans and oscar montelius helped B. E. Hildebrand reorganize the Iron Age exhibition in the National Antiquities Museum in Stockholm.

Hans Hildebrand is known as the originator of archaeological “typology.” Unlike his colleague, the great Swedish typologist Oscar Montelius, Hildebrand was not interested in using typology to further chronological research and methodology. He was interested in the methodology of classifying prehistoric material culture. In his essay *The Early Iron Age in Norrland* (1869), Hildebrand used numerous typological descriptions of artifacts and proposed their dating via their find contexts. He also used analogies with other artifacts from coin and bog sites from other parts of Scandinavia to create a descriptive typology. In *Towards a History of the Fibula* (1871) Hans Hildebrand argued, on the basis of descriptive typology, that the Hallstatt and la tène complexes were two successive horizons at the end of the Bronze Age and the beginning of the Iron Age in central and northern Europe. In 1874, as General Secretary of the International Archaeological Congress in Stockholm, he went on to suggest that both the Hallstatt and La Tène complexes were chronological and cultural concepts.

Like his father, Hildebrand was an advocate for the central and national collection of archaeological material in sweden, the subject of *Scientific Archaeology, Its Task, Requirement and Rights* (1873),

written on his return from his second Grand European Tour. In this pamphlet Hildebrand introduced the term *typology* into archaeology and stressed the importance of central museums for the development of scientific archaeology and the typological method. Other European countries such as England, France, and, later, Germany did not have national collections, and Hildebrand understood that they were one of the main reasons that Sweden dominated and led the development of prehistoric archaeology during the nineteenth century.

Hans Hildebrand used the term and concept of archaeological typology in the first section of his great book *The Prehistoric Peoples of Europe* (1873-1880). But it was his great knowledge and synthesis of anthropology, paleontology, geology, and Paleolithic prehistory in this book that was probably more remarkable-it was one of the first examples of a modern European prehistory.

In 1879 Hildebrand succeeded his father as the King's Custodian of Antiquities and director of the National Museum, a position he held until 1906. His book *Medieval Sweden* (1879-1903) remains essential reading today.

Historical Archaeology

Historical archaeology as the archaeology of the modern world involves the excavation of sites and analysis of assemblages dating from approximately the last half millennium of human cultural history. Ironically, two of its distinctive hallmarks, its worldwide scope and the interconnected nature of its subject matter, are shared only with Paleolithic archaeology. This topical unity derives from three overlapping phases of modern world history: the early emergence and spread of major cultural innovations across Europe, Asia, and North Africa between a.d. 1400 and 1600; the subsequent creation of the first truly global world system, primarily a product of European expansion between a.d. 1500 and 1800; and the transformation of this planetary cultural system as a result of the Industrial Revolution (a.d. 1800 to the present).

Because the formation of the modern world spans six centuries and occurred at different times in different places, historical archaeology currently has a number of distinct subfields: postmedieval archaeology in Europe, archaeology of the colonial period in the New World (and by extension elsewhere), industrial archaeology in Europe and North America, and the exploration of post-1400 shipwrecks and submerged sites by underwater archaeologists around the world. Potential new subfields, such as Ottoman archaeology and archaeology of the twentieth century, are on the horizon.

Like its subject matter, historical archaeology arrived late in the sequence, and thus its professional history is limited to the twentieth century. Geographically, it is most developed in North America, with a continuous history extending back to the Great Depression of the 1930s; in western Europe and Oceania (Australia), it appeared only in the 1960s. Outside of Europe, in other regions of ancient Old World civilizations, it is almost nonexistent. With the exception of early work in the West Indies, the field is visible but only now developing in Latin America and parts of sub-Saharan Africa. A discussion of this discipline must therefore concentrate on North America.

Disciplinary Roots

In North America, historical archaeology has two separate but interrelated origins: the excavation of historic contact-Indian sites and the study of the archaeological record left by Europeans and other Old World peoples in the New World. Numerous encounters with both types of sites, and in a few instances excavation of historic sites, occurred in North America during the seventeenth, eighteenth, and nineteenth centuries. After the Pilgrims arrived in 1620, they dug into local burial mounds and found combinations of aboriginal artifacts and European trade goods. After the American Revolution and the closing of the colonial period, a British boundary commission in 1796 excavated the 1604 site of the du-Monts and

Champlain colony in canada on the St. Croix River in an attempt to set the border between the new United States and British Canada. Examples of such work on historic sites increased in the nineteenth century, and in 1856, John Hall, a civil engineer, scientifically excavated the foundation of Myles Standish's house in Duxbury, Massachusetts. Hall not only made a site plan and noted stratigraphy but also plotted the location of individual artifacts.

Hans Hildebrand used the term and concept of archaeological typology in the first section of his great book *The Prehistoric Peoples of Europe* (1873-1880). But it was his great knowledge and synthesis of anthropology, paleontology, geology, and Paleolithic prehistory in this book that was probably more remarkable-it was one of the first examples of a modern European prehistory.

In 1879 Hildebrand succeeded his father as the King's Custodian of Antiquities and director of the National Museum, a position he held until 1906. His book *Medieval Sweden* (1879-1903) remains essential reading today.

Historical Archaeology

Historical archaeology as the archaeology of the modern world involves the excavation of sites and analysis of assemblages dating from approximately the last half millennium of human cultural history. Ironically, two of its distinctive hallmarks, its worldwide scope and the interconnected nature of its subject matter, are shared only with Paleolithic archaeology. This topical unity derives from three overlapping phases of modern world history: the early emergence and spread of major cultural innovations across Europe, Asia, and North Africa between a.d. 1400 and 1600; the subsequent creation of the first truly global world system, primarily a product of European expansion between a.d. 1500 and 1800; and the transformation of this planetary cultural system as a result of the Industrial Revolution (a.d. 1800 to the present).

Because the formation of the modern world spans six centuries and occurred at different times in different places, historical archaeology currently has a number of distinct subfields: postmedieval archaeology in Europe, archaeology of the colonial period in the New World (and by extension elsewhere), industrial archaeology in Europe and North America, and the exploration of post-1400 shipwrecks and submerged sites by underwater archaeologists around the world. Potential new subfields, such as Ottoman archaeology and archaeology of the twentieth century, are on the horizon.

Like its subject matter, historical archaeology arrived late in the sequence, and thus its professional history is limited to the twentieth century. Geographically, it is most developed in North America, with a continuous history extending back to the Great Depression of the 1930s; in western Europe and Oceania (Australia), it appeared only in the 1960s. Outside of Europe, in other regions of ancient Old World civilizations, it is almost nonexistent. With the exception of early work in the West Indies, the field is visible but only now developing in Latin America and parts of sub-Saharan Africa. A discussion of this discipline must therefore concentrate on North America.

Disciplinary Roots

In North America, historical archaeology has two separate but interrelated origins: the excavation of historic contact-Indian sites and the study of the archaeological record left by Europeans and other Old World peoples in the New World. Numerous encounters with both types of sites, and in a few instances excavation of historic sites, occurred in North America during the seventeenth, eighteenth, and nineteenth centuries. After the Pilgrims arrived in 1620, they dug into local burial mounds and found combinations of aboriginal artifacts and European trade goods. After the American Revolution and the closing of the colonial period, a British boundary commission in 1796 excavated the 1604 site of the du-Monts and

Champlain colony in canada on the St. Croix River in an attempt to set the border between the new United States and British Canada. Examples of such work on historic sites increased in the nineteenth century, and in 1856, John Hall, a civil engineer, scientifically excavated the foundation of Myles Standish's house in Duxbury, Massachusetts. Hall not only made a site plan and noted stratigraphy but also plotted the location of individual artifacts.

Such incidents, although numerous and as yet poorly researched, were still isolated and disconnected. One of the two traditions behind the rise of historical archaeology, the excavation of contact sites, began to be carried out continuously in regions like the Southwest in the later nineteenth century, but it was not until the first half of the twentieth century that researchers influenced by the direct historical approach and the rise of ethnohistory were significantly drawn to historic Native American sites and the study of European trade goods. william duncan strong and his colleagues on the Great Plains, James A. Ford in the Southeast and, slightly earlier, alfred v. kidder in New Mexico began to examine historic contact sites in an attempt to link known ethnographic groups with prehistoric sequences. Nevertheless, although there were rare exceptions-like Arthur Woodward, who in 1927 started a lifelong study of historic trade goods and industries-few of these excavators gave primary attention to the historic period. Investigation of contact situations would have likely remained a footnote appended to North American prehistoric studies except that in 1930 a major crisis in world society transformed American archaeology.

The Great Depression of 1930 through 1941 and the following post-World War II years massively expanded the number and, more important, the variety of historic sites being excavated by professional archaeologists in North America, and for the first time, the second origin of the field, work on famous European and Euro-American historic sites, rapidly assumed centrality in the creation of an autonomous discipline. Earlier events helped to set the stage. Passage of the 1906 Antiquities Act, which protected historic as well as prehistoric sites, and the 1916 establishment of the National Park Service (NPS) put key elements in place. A few locally or privately organized projects that included archaeology were already under way, such as John D. Rockefeller's 1927 funding of the restoration of colonial Williamsburg, but it was the 1932 election of the Franklin D. Roosevelt administration, its numerous programs to combat the Great Depression, and the related 1935 Historic Sites Act that opened the door to historical archaeology.

Significant federal funding of some government programs, including the Civilian Conservation Corps, Works Progress Administration, and the Tennessee Valley Authority, and a desire to reemphasize national heritage in the development of national (and some state) parks and monuments meant that a growing number of archaeologists began to work on historic sites across the United States. These researchers shared a set of common traits: they were professionally trained archaeologists, they were specialists in North American prehistory, they had been educated within an anthropological tradition, and they lacked prior knowledge of historic artifacts and architecture. Because of this common background and new institutional sponsorship supplied by the NPS, which was assigned a central role in organizing projects, these archaeologists formed a small but integrated community of professionals.

As prehistorians they spent the two decades before and after World War II inventing American historical archaeology from whole cloth. The excavation of famous and nationally significant Euro-American sites began, such as G. Hubert Smith's 1936 work at Fort Ridgely in the Midwest, A.R. Kelly's 1933 excavation of the Macon Trading Post in the Southeast, Harvey R. Harwood's 1934 exploration of La Purisima Mission on the West Coast, and Preston Holder's 1941 testing at Appomattox Courthouse in Virginia. Some of the archaeologists did one or two projects and then returned to prehistoric research, but a small number made an exclusive commitment to the historic period.

Harrington at Jamestown

One of the converts, jean carl harrington (1911-1998), can be considered the founder of historical archaeology in the United States. He was similar to his colleagues in that he had trained in prehistoric archaeology and anthropology under Fay Cooper Cole at the University of Chicago but dissimilar in that he had a prior background in architectural engineering and one season of undergraduate experience in the restoration and recording of historic missions in the Southwest. When offered an NPS position at

jamestown, where a project started in 1934

PREV NEXT

his fieldwork and material culture studies, for he defined and synthesized historical archaeology as a recognized intellectual endeavor. His article “Archaeology as an Auxiliary Science to American History” (Harrington 1955) established the importance of such research as a contribution to both history and science. Harrington viewed the field as properly centered on Euro-American, not contact-Indian, sites and most naturally tied into the specificity of history although he did recognize its anthropological potential. His suggested name for this new specialization, “historic site archaeology,” highlights his theoretical position.

By the early 1950s, Harrington and his colleagues, including among others Louis Caywood in the Northwest, Arthur Woodward in the Southwest, John W. Griffin and Hale G. Smith working for the Florida Park Service in the Southeast, and Carlyle Smith on the Great Plains, had created historical archaeology as an established area of research. Work on historic Indian sites continued as an important theme, for example, George I. Quimby's study of trade goods in the Great Lakes region and the excavation of sites like the Hopi historic pueblo and mission of Awatovi between 1935 and 1939. kenneth e. kidd's 1941 excavations on a famous Jesuit mission site (1639-1649) in Ontario and his subsequent 1949 publication of *The Excavation of Ste Marie I,* probably the first site report in the field issued in book form, launched historical archaeology in Canada.

1960-1970: A Decade of Transition

By 1960 historical archaeology had been established as a research topic, but it was not yet professionally set off as a specialty. Ten years later it was a successfully organized, separate, publicly visible, and rapidly expanding, if small, discipline within anthropology. Four developments during the 1960s brought about this transformation: new institutional housing for the field, expansion of its subject matter, entrance into the academic world (which allowed formal training and education in the field), and professional autonomy with the founding of several scholarly associations.

After 1960, historical archaeologists found new positions in federal agencies outside the NPS in the United States and the newly active National Historic Sites Service in Canada, and individual states, such as Florida, California, and Texas, entered the field. In Texas, for example, the Office of State Archaeologist was established in 1965, and the Texas Historical Survey (after 1972 the Texas Historical Commission) had started exploring land and underwater sites by the end of the decade. Perhaps more significant, the field was brought into the academic world, as is exemplified by the career of john l. cotter (1911-1999). Like his predecessors, Cotter had a long worked on prehistoric, including Paleo-Indian, sites before he was assigned by the NPS to direct the second major project at Jamestown (1954-1956). By 1960, he was at the NPS office in Philadelphia, and that year, at the request of the Department of American Civilization at the University of Pennsylvania, he taught the first class in the United States to carry the title “Historical Archaeology.” Within the next few years, other courses were introduced at Arizona by Arthur Woodward, Harvard by Stephen Williams, University of Florida by Charles Fairbanks, Illinois State University by Edward B. Jelks, University of California-Santa Barbara by james deetz, and University of Idaho by Roderick Sprague.

The subject matter of historical archaeology began to expand in the same decade. Excavators began to move beyond famous national heritage sites and limiting archaeology to restoration functions at such prominent locations. A telling example of this enlargement is the work of bernard l. fontana and his colleagues at johnny ward's ranch in Arizona. These adobe ruins were originally selected as possibly being one of the oldest Jesuit sites in the area, but when the structure turned out to be a late American ranch house (1858-1903), the project was not abandoned but its purpose and goals were changed. Publication of “Johnny Ward's Ranch: A Study in Historic Archaeology” (1962) marked one of the first reports on a common type of Anglo-American site in the West, and the detailed analysis of the

recovered assemblage became a classic guide for later-nineteenth-century artifacts.

and its domination by prehistorians, served as the crucial organization in nurturing and building the discipline. The SHA was soon joined by the smaller Society for Post-Medieval Archaeology (1966-1967) in Europe, the Society for Australian Historical Archaeology (1970) in Oceania, and more-specialized associations such as the Society for Industrial Archaeology (1972) in America.

1970-2000

American historical archaeology entered the 1970s as an organized and expanding discipline but still clearly secondary to prehistoric studies. The influence of anthropology and various cultural themes initiated in the previous decade now greatly enriched the field and its public appeal, and entirely new topics were added to its subject matter. The study of ethnicity and "peoples without history" began with the work of Charles Fairbanks and his graduate students on mestizo sections of St. Augustine, Florida, and slave plantations of the Old South, and their excavations created a distinct topical specialization on the archaeology of African Americans. Roberta Greenwood and her colleagues started to explore overseas Chinese sites, and urban archaeology, traceable to the early work of Arnold Pilling in Detroit and John Cotter in Philadelphia, now spread to other cities on the East Coast (New York City; Alexandria, Virginia; Paterson, New Jersey; and Lowell, Massachusetts) and in the West (Tucson, Arizona; Ventura and Sacramento, California).

Topical additions to subject matter occurred as the result of a general debate, begun in the late 1960s, concerning the merits of a "historicalist" versus an anthropological framework for the growing discipline; by the end of the 1970s, the debate was clearly decided in favor of anthropology. In 1977, Deetz published *In Small Things Forgotten: The Archaeology of Early American Life,* the first book on the subject to achieve substantial public sales, and in 1978, the first source book for the field, *Historical Archaeology: A Guide to Theoretical and Substantive Contributions,* reprinted thirty-five classic papers and served as a text or supplementary text throughout the 1980s.

During the 1980s and 1990s, new topics-the archaeology of gender, class, race, and labor-were added to continuing work on sites ranging from the contact period to the industrial age. Historical archaeology played a secondary but again quite visible role in the rise of postprocessual archaeology, and many overly speculative interpretations of this countermovement to processual archaeology were at least understandable and sometimes testable in a documented context.

Yet it was not the new research topics, or even the general theoretical debates, that most fundamentally altered historical archaeology after 1970 but the hard realities of politics and economics. In 1966 Congress passed the National Historic Preservation Act, and it was followed by Executive Order 11593 in 1971 and the Archaeological and Historic Conservation Act in 1977. These and related bills created the National Register of Historic Places and State Historic Prevention Office (SHPO) offices on the state level, and soon most large-scale building projects in the United States were required to carry out exploratory archaeology and, if required, mitigation(completely digging the site). Massive public and private funding soon moved both prehistoric and historical archaeology into the maelstrom of the general marketplace, and although universities tried to incorporate these new funding opportunities, they were mostly replaced by private companies practicing cultural resource management (CRM).

On 26 April 1976, the Society of Professional Archaeologists (SOPA) was incorporated to meet the changing environment for archaeology in the United States. Interestingly its first president, Edward B. Jelks, was a leading historical archaeologist, and both anthropologists Charles Cleland and Bert Salwen served on its board. SOPA was only partially successful, drawing just over 700 practicing archaeologists into its membership during its short existence, and in 1998 it was restructured as the larger and growing Registry of Professional Archaeologists (RPA). Again, historical archaeologists took

a leading SOPA-RPA) and Donald L. Hardesty as the first elected RPA president.

Historiography

Historical works dealing with archaeology have been written to entertain the public, commemorate important archaeologists and research projects, instruct students in the basic concepts of the discipline, justify particular programs or ideas, disparage the work of rivals, and, most recently, try to resolve theoretical problems. These studies have taken the form of autobiographies, biographies, accounts of the development of the discipline as a whole, investigations of specific institutions or projects, and examinations of particular theories and approaches. They have used the analytical techniques of intellectual and social history and sought to treat their subject objectively, critically, hermeneutically, and polemically. Over time, historical studies have become more numerous, diversified, and sophisticated. Histories of archaeology are being written for all parts of the world, and in a growing number of countries, a large amount of material is being produced at local as well as national levels. There is no end in sight to the growing interest in this form of research.

The history of archaeology has been written mainly by professional archaeologists, who have no training in history or the history of science, and by popularizers. Only a small number of works have been produced by professional historians. Archaeology has attracted little attention from historians of science, despite its considerable interest to philosophers of science. This lack of interest is hard to understand since the difficulties inherent in inferring human behavior from archaeological evidence make archaeology an ideal discipline for addressing many of the issues of objectivity that are currently of interest to historians of science.

Early Histories of Archaeology

The earliest use of the history of archaeology appears to have been for didactic purposes. In the mid-nineteenth century, the physicist Joseph Henry, the first secretary of the smithsonian institution, sought to purge American archaeology of useless speculation and to encourage an interest in factual research. To do this, he commissioned Samuel F. Haven, the librarian of the American Antiquarian Society, to write a critical historical review of studies of American prehistory titled *Archaeology of the United States* (1856). To improve the quality of American archaeology, Henry also published reports on developments in the discipline in the *Annual Report of the Smithsonian Institution,* which was widely distributed in North America. The most successful of these was "General Views on Archaeology" (1861), the translation of a paper by the Swiss geologist and amateur archaeologist Adolf Morlot, which summarized major developments over the previous fifty years in European prehistoric archaeology, especially in Scandinavia and switzerland. This article did much to encourage the adoption of a

subject, but her thesis has to date only been published in French (Penna 1999).

Histories of archaeology are being written for all parts of the world, and in a growing number of countries, a large amount of material is being produced at local as well as national levels. There is no end in sight to the growing interest in this form of research.

The history of archaeology has been written mainly by professional archaeologists, who have no training in history or the history of science, and by popularizers. Only a small number of works have been produced by professional historians. Archaeology has attracted little attention from historians of science, despite its considerable interest to philosophers of science. This lack of interest is hard to understand since the difficulties inherent in inferring human behavior from archaeological evidence make archaeology an ideal discipline for addressing many of the issues of objectivity that are currently of interest to historians of science.

Early Histories of Archaeology

The earliest use of the history of archaeology appears to have been for didactic purposes. In the mid-nineteenth century, the physicist Joseph Henry, the first secretary of the smithsonian institution, sought to purge American archaeology of useless speculation and to encourage an interest in factual research. To do this, he commissioned Samuel F. Haven, the librarian of the American Antiquarian Society, to write a critical historical review of studies of American prehistory titled *Archaeology of the United States* (1856). To improve the quality of American archaeology, Henry also published reports on developments in the discipline in the *Annual Report of the Smithsonian Institution,* which was widely distributed in North America. The most successful of these was "General Views on Archaeology" (1861), the translation of a paper by the Swiss geologist and amateur archaeologist Adolf Morlot, which summarized major developments over the previous fifty years in European prehistoric archaeology, especially in Scandinavia and switzerland. This article did much to encourage the adoption of a

scientific approach to archaeology in eastern North America.

Popular Histories

For the next century, most histories of archaeology were popular accounts of archaeological discoveries, and they emphasized the romance of exploration and the most spectacular discoveries. As a result, they generally concentrated on the archaeology of ancient civilizations and important Paleolithic finds. One of the most widely read works dealing with the history of archaeology was the rather superficial *Gods, Graves, and Scholars* (1951), written by the Czech journalist C.W. Ceram (pseudonym for Kurt Marek). The continuing demand for works of this type is demonstrated by the success of Brian Fagan's *The Rape of the Nile* (1975).

Some popular histories of archaeology have sought to do more than entertain. Stanley Casson's *Progress of Archaeology* (1934) attempted to provide a balanced survey of the development of archaeology while the Assyriologist Seton Lloyd's *Foundations in the Dust* (1947; 2d ed., 1981) recounted the history of Mesopotamian archaeology in a manner that was of interest to professional archaeologists as well as to the general reader. Both Geoffrey Bibby's *The Testimony of the Spade* (1956), which dealt with European archaeology, and Michael Hoffman's *Egypt before the Pharaohs* (1979) sought not only to provide regional histories of archaeological research but also to explain to readers how archaeology was carried out. The Egyptologist John Wilson's *Signs and Wonders upon Pharaoh* (1964) was a celebration of American contributions to Egyptian archaeology and Egyptology, while Jeremy Sabloff's *The New Archaeology and the Ancient Maya* (1990) sought to explain to nonarchaeologists how processual archaeology has provided more superior insights into the ancient maya civilization than did culture-historical archaeology.

In England, there has long been a receptive audience for popular biographies of archaeologists. These stress personal life and social contacts more than the intellectual context and scholarly contributions of their subjects. One of the earliest and best of these was Joan Evans's *Time and Chance* (1943), which recounted the lives of her father, john evans, and her brother arthur evans. More recent examples include Jacquetta Hawkes's *Mortimer Wheeler, Adventurer in Archaeology* (1982), H.V.F. Winstone's *Woolley of Ur* (1990), and, from the United States, J.J. Thompson's *Sir Gardner Wilkinson and his Circle* (1992). Personal and professional disputes are aired in autobiographies such as w. m. f. petrie's *Seventy Years in Archaeology* (1931) and mary leakey's *Disclosing the Past* (1984). Popular anthologies of archaeological literature include Edward Bacon's *The Great Archaeologists* (1976), a collection of articles from the *Illustrated London News* describing major finds between 1842 and 1970, and Jacquetta Hawkes's two-volume *The World of the Past* (1963), which contains excerpts from the publications of archaeologists who had worked around the world arranged geographically.

A final genre is the history of archaeological institutions pioneered by Joan Evans's *A History of the Society of Antiquaries* (1956) and exemplified more recently at its best by *The Scottish Antiquarian Tradition* (1981), a history of the society of antiquaries of scotland edited by A.S. Bell.

The principal characteristic of popular histories of archaeology is their emphasis on spectacular discoveries. The archaeologists who feature prominently in them include many individuals, such as howard carter, who made celebrated discoveries but contributed little to the intellectual development of archaeology. On the other hand, archaeologists whose ideas played a major role in shaping the discipline, such as oscar montelius, vere gordon childe, and grahame clark, are rarely mentioned in such works. To take account of the contributions of such individuals required the development of a more strictly professional history of archaeology.

Intellectual Histories

The modern scholarly history of archaeology began in England in the late 1930s, as a growing awareness of generational differences among professional archaeologists and the accumulation of a corpus of essential literature revealed changes in the conceptual basis of prehistory. A few far-sighted prehistoric archaeologists became convinced that knowing the reasons for the decline of evolutionary explanations of the

PREV NEXT

scientific approach to archaeology in eastern North America.

Popular Histories

For the next century, most histories of archaeology were popular accounts of archaeological discoveries, and they emphasized the romance of exploration and the most spectacular discoveries. As a result, they generally concentrated on the archaeology of ancient civilizations and important Paleolithic finds. One of the most widely read works dealing with the history of archaeology was the rather superficial *Gods, Graves, and Scholars* (1951), written by the Czech journalist C.W. Ceram (pseudonym for Kurt Marek). The continuing demand for works of this type is demonstrated by the success of Brian Fagan's *The Rape of the Nile* (1975).

Popular anthologies of archaeological literature include Edward Bacon's *The Great Archaeologists* (1976), a collection of articles from the *Illustrated London News* describing major finds between 1842 and 1970, and Jacquetta Hawkes's two-volume *The World of the Past* (1963), which contains excerpts from the publications of archaeologists who had worked around the world arranged geographically.

A final genre is the history of archaeological institutions pioneered by Joan Evans's *A History of the Society of Antiquaries* (1956) and exemplified more recently at its best by *The Scottish Antiquarian Tradition* (1981), a history of the society of antiquaries of scotland edited by A.S. Bell.

The principal characteristic of popular histories of archaeology is their emphasis on spectacular discoveries. The archaeologists who feature prominently in them include many individuals, such as howard carter, who made celebrated discoveries but contributed little to the intellectual development of archaeology. On the other hand, archaeologists whose ideas played a major role in shaping the discipline, such as oscar montelius, vere gordon childe, and grahame clark, are rarely mentioned in such works. To take account of the contributions of such individuals required the development of a more strictly professional history of archaeology.

Intellectual Histories

The modern scholarly history of archaeology began in England in the late 1930s, as a growing awareness of generational differences among professional archaeologists and the accumulation of a corpus of essential literature revealed changes in the conceptual basis of prehistory. A few far-sighted prehistoric archaeologists became convinced that knowing the reasons for the decline of evolutionary explanations of the

PREV NEXT

of inferences based on only a narrow range of excavated material. On the other hand, the historian Gerald Killan's *David Boyle: From Artisan to Archaeologist* (1983) paid considerable attention to the social as well as the intellectual milieu that shaped the career of that nineteenth-century Ontario archaeologist. One encounters in archaeological biographies a similar range of approaches to that found in other studies relating to the history of the discipline.

Despite the influence of relativists such as Collingwood, Australian archaeologistTim Murray has rightly suggested that "much of the history of archaeology reads as an account of the slow journey out of the darkness of subjectivity and speculation towards objectivity, rationality, and science" (1989, 56). One might have expected that such an approach would have appealed to processual archaeologists, yet, in general, processual archaeologists rejected and trivialized the history of archaeology, even though they welcomed Willey and Sabloff's historical charter. In his *Behavioral Archeology* (1976), Michael Schiffer pronounced that "graduate courses should cease being histories of thought" and concentrate instead on communicating the established principles of the discipline and indicating future lines of inquiry (p. 193). If carefully formulated techniques of analysis and an expanding corpus of data can produce increasingly accurate approximations of the past and more accurate theories, the history of archaeology is irrelevant to its past or future practice. If, on the other hand, the relativists are correct, facts constitute the core of archaeology while interpretations amount to little more than a history of personal opinions.

Social Histories

In Britain, the 1970s witnessed the development of the history of archaeology in the direction of social history. Both social and intellectual history share a relativist view of knowledge, but social history is concerned with how economic, political, and social conditions influence the interpretation of archaeological data. Because of this focus on the relationship between archaeological understanding and the sociocultural context in which archaeology is practiced, social history is more broadly externalist than intellectual history, which at most seeks to understand how archaeological interpretations relate to the contemporary intellectual milieu. Thus, social history stands at the opposite extreme from an internalist approach, which aims to delineate only the changing understanding of a problem by archaeologists. The distinction between externalist and internalist approaches is the same one that an older generation of historians drew between intellectual history and the history of ideas.

The social history of archaeology developed as an unforeseen consequence of Daniel's efforts to promote the study of the history of archaeology around the world, for such studies drew archaeologists' attention to the very different conditions under which archaeology was practiced. Ole Klindt-Jensen's *A History of Scandinavian Archaeology* (1975) and ignacio bernal garcia's *A History of Mexican Archaeology* (1980) were both commissioned for Daniel's World of Archaeology series. Each author traced the successive impacts of renaissance, rationalist, romantic, and positivist thought on the development of archaeology in a different part of the world. Klindt-Jensen went further, however, and delineated the political conditions that he believed had promoted the development of antiquarianism and the beginnings of scientific archaeology in Scandinavia. In tracing subsequent developments, he stressed the impact that changing political and economic circumstances had on archaeology in each Scandinavian country.

Partly inspired, although he only grudgingly admitted it, by Benjamin Keen's superb history of *The Aztec Image in Western Thought* (1971), Ignacio Bernal examined in detail the differing attitudes toward the study of pre-Columbian mexico adopted by Spanish officials and Creoles prior to Mexico's independence, liberals, and conservatives during the nineteenth century, and the Mexican government between 1920 and 1950. He also demonstrated how the institutional setting of Mexican archaeology was molded by political events and how it, in turn, influenced the character of Mexican archaeology.

Bernal has perhaps gone further than any other historian of archaeology in delineating the

were responsible for the economic decline of Cyprus and Palestine in recent centuries. In the historical sections of *Black Athena* (1987), Martin Bernal has argued that since the Napoleonic period, as a result of racism and ethnocentrism, European archaeologists have systematically ignored evidence of historical ties between ancient Greece and Egypt.

The Impact of Postmodernism

In the 1980s, externalism was fueled by a growing postmodernist emphasis on subjectivity and relativism, an emphasis that has influenced archaeology no less than it has the other social sciences. Central to this approach is a radical idealism that views understanding as being determined by individual presuppositions rather than by evidence and therefore minimizes the possibility of objective knowledge. This approach has been embraced by many archaeologists who wish to eliminate colonial, gender, and class biases from archaeology or to disempower the discipline as an elite discourse. Basic to this approach is the radical relativist claim that it is impossible to judge any one version of the past as being more right or wrong than any other. Inherent in this nihilistic approach to archaeology is the belief that its main, and perhaps only, legitimate role is to become a vehicle for encouraging political action by calling accepted beliefs into question.

The principal influence of postmodernism on the history of archaeology has been to encourage more radical externalism that seeks to correlate specific changes in archaeological interpretation with particular social movements of varying durations and degrees of specificity. This approach is reflected in stimulating, but highly controversial, papers such as R.R. Wilk's “The Ancient Maya and the Political Present” (Wilk 1985) and Thomas C. Patterson's “The Last Sixty Years: Toward a Social History of Americanist Archeology in the United States” (Patterson 1986).

Although virtually all histories of archaeology agree that every interpretation of archaeological evidence is influenced to some degree by personal or social biases, there is little agreement concerning the distortions produced by bias. The more positivistic see these biases overcome, in either the short or the middle term, by archaeological evidence. At the other extreme are those who are inclined to accept Michael Shank's and Christopher Tilley's denials that it is possible for evidence to contradict presuppositions. Positivists such as Colin Renfrew have countered such claims by demanding to know on what basis any externalists claim to link archaeological interpretations to the social milieu.

Other historians of archaeology have attempted to determine empirically to what extent and under what circumstances archaeologists have been able to achieve insights that are objective in the sense that they have been able to withstand the double test of new evidence and changing social circumstances. This was the main objective of Bruce Trigger's *A History of Archaeological Thought* (1989). Trigger documented the wide range of subjective factors that have influenced the interpretation of archaeological data but at the same time offered evidence that the “resistance” of archaeological evidence had produced certain irreversible changes in the understanding of human history and human nature. Moreover, it appears that in general, as the archaeological increases, the ability of subjective factors to distort the interpretation of archaeological evidence is curtailed. Using the history of archaeology to address such theoretical issues and to understand archaeological practice makes the history of archaeology more of an essential part of the theoretical core of the discipline.

Methodological Developments

Over the years there have been marked improvement in the technical quality of scholarly studies of the history of archaeology. Early histories were based largely on scanning published works and sometimes on secondary sources. This practice continues, especially in large-scale syntheses, but is gradually being

replaced by more varied and sophisticated methods.

The American archaeologist Robert Heizer encouraged the critical reading of archaeological publications by publishing two volumes of original papers that he judged had been crucial for the development of archaeological method and theory: *The Archaeologist at Work* (1959) and

were responsible for the economic decline of Cyprus and Palestine in recent centuries. In the historical sections of *Black Athena* (1987), Martin Bernal has argued that since the Napoleonic period, as a result of racism and ethnocentrism, European archaeologists have systematically ignored evidence of historical ties between ancient Greece and Egypt.

Early histories were based largely on scanning published works and sometimes on secondary sources. This practice continues, especially in large-scale syntheses, but is gradually being

replaced by more varied and sophisticated methods.

The American archaeologist Robert Heizer encouraged the critical reading of archaeological publications by publishing two volumes of original papers that he judged had been crucial for the development of archaeological method and theory: *The Archaeologist at Work* (1959) and

theory and practice, of how archaeology has defined itself as a field, and of other sociological aspects of the production of archaeological knowledge. These debates are raising the self-consciousness of the people who study the history of archaeology and must contribute, in the long run, to improving the standard for such studies.

Conclusions

With a declining adherence to positivism and a lessening belief in a culture-free methodology for explaining human behavior, the history of archaeology has ceased to be regarded as marginal to archaeology and is assuming a more central position in the discipline. Its study provides a matrix for evaluating established theories and is calling current dogmas into question. The field also provides a basis for discussing epistemological questions in terms that are familiar to archaeologists. The history of archaeology is therefore coming to play a major role in both the understanding and the application of archaeological knowledge.

Hogarth, David George

(1862-1927)

Hogarth was born in Lincolnshire and educated at Winchester School and Magdalen College Oxford. He studied classics and won a Craven traveling fellowship to pursue his interests in archaeology. In 1887 and 1890 he traveled with the epigraphist Sir William Mitchell Ramsay in Asia Minor. In 1888 he excavated at the site of paphos on cyprus. Hogarth spent three seasons in Egypt in the early 1890s working for the egypt exploration society at Deir-el-bahri, Alexandria, and the Fayum, where he perfected his excavation techniques, but he preferred classical to Egyptian archaeology. He was as excellent a writer as he was an archaeologist, publishing a number of popular travel books.

In 1897 Hogarth became a correspondent on Crete for *The Times* newspaper to cover its fight for independence from turkey, and later in Thessaly (northern greece) to report on the Greco-Turkish war. At the end of this year he became director of the British School of Archaeology in Athens. During his three years as

theory and practice, of how archaeology has defined itself as a field, and of other sociological aspects of the production of archaeological knowledge. In 1897 Hogarth became a correspondent on Crete for *The Times* newspaper to cover its fight for independence from turkey, and later in Thessaly (northern greece) to report on the Greco-Turkish war. At the end of this year he became director of the British School of Archaeology in Athens. During his three years as

director he excavated at the site of Phylakopi on Melos, and at Naucratis. In 1900 Hogarth left the British School and joined sir arthur evans in his first season on Crete, which saw the beginning of the excavation of knossos.

David George Hogarth

(Image Select)

In 1903 Hogarth spent another season excavating at Naucratis, and in 1904 and 1905 he excavated the temple of Artemis at ephesus on behalf of the british museum. In 1908 he visited the upper Euphrates River surveying the sites of Carchemish and Tell Bashar. In 1908 he became Keeper of the ashmolean museum in Oxford, and to began to excavate Carchemish with the young archaeologists leonard woolley and T.E. Lawrence, both of whom would later become more famous than their mentor.

The Ashmolean Museum prospered under Hogarth-becoming especially important for its Cretan and Hittite archaeological collections, the later of which was Hogarth's primary interest. In 1915 he offered his linguistic, geographic, and historic expertise on Asia Minor and the Eastern Mediterranean to the War Office and was sent first to Athens and then to Cairo where he became director of the Arab Bureau. In this position and with the help of T.E. Lawrence and gertrude bell, Hogarth was able to encourage and support the Arab rebellion against Turkey, which was to be decisive in the war in the Middle East.

In 1917 Hogarth received the gold medal from the Royal Geographic Society and in 1925 he became its president. After the war he was a member of the British delegation at the Peace Conference at Versailles and he returned to the Ashmolean Museum and Oxford. He was awarded a D.Litt. from Oxford in 1918 and a Litt.D. from Cambridge in 1924.

Holmes, William Henry

(1846-1933)

William Henry Holmes was the preeminent figure in American archaeology around the turn of the last century. With the careful eye of an artist, he pioneered material culture studies, particularly the understanding of ceramic form, function, and design, and lithic technology. His analysis of collections at the smithsonian institution (where Holmes was affiliated for nearly sixty years), replicative experiments, and excavations at prehistoric quarries enabled him to reconstruct in unprecedented detail the process and products of ceramic and stone tool manufacturing.

Studying stone tools revealed that what many people thought were primitive, ancient artifacts-indicators of an American Paleolithic period comparable in age to the Paleolithic of Europe-were merely rejects of the manufacturing process. Armed with that realization and the expertise developed in years of geological fieldwork in the western part of the United States, Holmes spearheaded the highly successful rout of the American Paleolithic. For several decades, Holmes, his geologist colleagues, and a protégé, the physical anthropologist ales hrdlicka, critically evaluated all purported claims of Pleistocene humans

in North America. Although they

correctly rejected those claims, the Folsom discovery in 1927 ultimately showed that human antiquity on the North American continent reached back to the late Pleistocene period.

Holmes's work was particularly valued by his peers because of his scientific approach, which entailed the considerable rhetoric on the proper conduct of science that was symptomatic of the growing professionalism of late-nineteenth-century archaeology, and Holmes's own explicit efforts to highlight the stark contrasts he saw between his efforts and the "old archaeology." Science to Holmes meant a commitment to empirical observation and measurement and a strong sense of order and method.

The method of choice, reflecting his geological background, was an archaeological uniformitarianism in which the past was understood in terms of the ethnographic present. Holmes was well aware, in principle, that traces of specific ethnographic groups could only be followed a short distance into the past, but, in practice, he often slighted that principle, attaching ethnographic labels to archaeological phenomena. He did so in the belief-partly rooted in his rejection of the American Paleolithic-that American prehistory was shallow. As a result, when he organized the archaeological record, it was along geographical lines and into cultural areas; temporal units were largely absent.

At the same time, however, Holmes was a confirmed evolutionist who followed anthropologist lewis henry morgan's general cultural evolutionary scheme and envisioned "the pathways of progress" from savagery to barbarism to civilization as being driven by human volition. Progress for Holmes was the axis and measure of evolutionary change, and he embarked on his ambitious effort to show through different classes of material culture "human progress from the point of view of material culture." But he ultimately came to realize that progress was not always evident in the small details, however clear on the larger scale.

Holmes was a key figure in Washington, D.C., museums and research bureaus when those were at the center of science in the United States. But in the twentieth century, that center shifted into the university system, and that caused a change in the theoretical compass of American archaeology. Holmes's brand of evolutionary theory was no longer fashionable, and the next generation of archaeologists-armed with stratigraphy and seriation and needing to fill the chronological gap created by Folsom-moved beyond his geographical archaeology into culture history.

In 1899 he resigned from the institute and became an unsalaried field anthropologist for the American Museum of Natural History in New York City, where he worked under anthropologist frederic ward putnam from Harvard University. From 1899 until 1902 Hrdlicka undertook anthropometric surveys of the Indians of the American Southwest and northern mexico.

In recognition of this field experience and the publication of his results he was appointed head of the new Division of Physical Anthropology at the National Museum of Natural History, smithsonian institution, Washington, D.C., in 1903.

During the next forty years in this position Hrdlicka built his department into a major research center, based on one of the best human osteological collections in the world. He founded the *American Journal of Physical Anthropology* in 1918 and the American Association of Physical Anthropologists in 1930. Hrdlicka's primary research interest focused on the origins and antiquity of Native American Indians. He studied all of the skeletal material claimed to be evidence of early human beings in America, and argued that it did not predate the postglacial period. He also undertook fieldwork in the Kodiak and Aleutian Islands off Alaska in the 1930s as part of a project to test the thesis that indigenous Americans had originally come from Asia. Hrdlicka was also interested in the origin of modern humans and argued that Neanderthals were the direct ancestors of modern humans, presenting the Huxley Memorial Lecture in 1927 on “The Neanderthal Phase of Man.”

Tim Murray

Huaca del Sol

A large platform mound in the Moche Valley of peru, Huaca del Sol (Shrine of the Sun), along with its companion mound Huaca del Luna (Shrine of the Moon), forms the heart of the Moche kingdom. Construction began around the time of Christ, and the site was intensively occupied for a period of 600 years prior to being devastated by floods around a.d. 560. Although the site was rebuilt, it was eventually abandoned owing to the encroachment of sand dunes, which had previously destroyed arable land in the vicinity. Huaca del Sol and its companion pyramid were two of the largest adobe edifices ever constructed in South America. It has been estimated that 143 million bricks were required to construct the stepped pyramid of massive dimensions (2,175,120 cubic meters) and that the rulers of the city employed a system of corvée labor to complete the task.

The Moche Pyramid at Huaca del Sol

Hume, Ivor Noël

(1927-)

Ivor Noël Hume was born in 1927 in London, educated in England, and initially entered the profession as the Guildhall Museum archaeologist (1949-1957) exploring the exposed remains, including postmedieval deposits, of postwar London. However, it was not until he crossed the Atlantic in 1957 to assume command of archaeology at another capital, colonial Williamsburg in Virginia, that he embarked on a career of over forty years that helped to transform historical archaeology.

With the support of his wife and professional colleague, Audrey Noël Hume (1927-1993), he continuously built the field within three spheres: fieldwork, public education, and scholarly publication. As a result of his English archaeological training, he introduced the tradition of tightly controlled stratigraphic excavations to colonial sites within and around Williamsburg. Site reports soon followed, but of equal importance were the articles and monographs reflecting the accumulating knowledge of both of the Humes on recovered archaeological assemblages. In 1970, Noël Hume published *A Guide to Artifacts of Colonial America,* a work that revolutionized understanding of seventeenth- and eighteenth-century archaeology in English North America and, by extension, the world. It stands to this day as the only general source for the field.

Noël Hume was set off from his American colleagues not only because he was not an anthropologist but also because of his ability to handle and appreciate primary archival sources-he produced a fully *historical* archaeology. As early as 1966 he authored *1775: Another Part of the Field,* which made him one of the few archaeologists in the United States to publish straightforward history. His archaeological publications have been equally grounded on documentary as well as belowground data. In 1977, the spectacular discovery and areal excavation of the early-seventeenth-century site at Wolstenholme Town in Martin's Hundred on the James River in Virginia made him equally an expert on the seventeenth as well as the eighteenth century. His 1982 popular *Martin's Hundred* and the full site report have given scholarship one of the best-excavated and most fully explored early-seventeenth-century sites (1620-1622) in the world.

Accomplished as a researcher and scholar, Hume has been an equally important advocate for public education. Numerous lectures, articles (see Hume 1979), and well-received books such as *Here Lies Virginia* (1963) and *Historical Archaeology* (1969) have vividly and invitingly brought the romance of historical archaeology to the general public. Unlike many of his colleagues, Noël Hume can write clear and readable English. Perhaps no single contribution better combines his efforts in field archival research, careful scholarship, and public presentation than *The Virginia Adventure: Roanoke to Jamestown, an Archaeological and Historical Odyssey* (1994), one of the most widely read books in the field. He used a combined archaeological-archival approach in this volume to correctly predict the survival and the location of the original jamestown Fort (1607-1620s), which has since been discovered and is being excavated by William Kelso.

Hume's English training and perspective initially separated him from his U.S. anthropological colleagues, but his productive and insightful scholarship has helped to bridge the Atlantic divide. In January 1967, he was an important participant in the organizational meeting in Dallas, Texas, that created the society for historical archaeology (SHA) and at which he urged an internationalist-global perspective for the new discipline. His membership on the SHA board of directors and vice-presidency of the parallel Society for Post-Medieval Archaeology in Europe helped to link these two organizations in their founding years. Ivor Noël Hume has received many awards, including being made an Officer of the British Empire (1991) for his work in Virginia, and in 1991, the SHA presented him with the highest honor achievable

in historical archaeology, the j. c. harrington medal.

I

Inca

The Inca empire, which controlled much of the Andes of South America, was overthrown as a result of the Spanish conquest in 1532. As they did to the aztec civilization in mesoamerica, the Spanish exploited local political divisions to bring about a swift collapse of imperial authority. The Inca had, themselves, only recently achieved such political and military dominance, with their expansion out of the region of Cuzco beginning only about a century earlier.

In one sense, the Inca were the clear successors of earlier cultures, such as the moche and the chavín, but in terms of political organization, the Inca system of imperial control, which (where possible) allowed for the retention of local religions and power structures, was a unique development. Major sites such as Machu Picchu and Cuzco and their extensive network of roads and bridges, irrigation systems, and terracing demonstrate the Inca's abilities as engineers and builders, but their material culture (particularly in textiles) was also of the finest order.

Indo-Pacific Prehistory Association

The Indo-Pacific Prehistory Association (IPPA) has had several names since its inception in Batavia (at that time the capital of the netherlands Indies) in 1929 and its first congress in Hanoi in 1932. At first it was known only through the names of its congresses. The Hanoi congress was known as the First Congress of Far-Eastern Prehistorians; the second, held in 1935, was titled the Second Congress of Far-Eastern Prehistorians; and the third, held in 1938, was called the Third Congress of Prehistorians of the Far East. At the fourth congress, held after World War II, the name came to be the Far-Eastern Prehistory Association (FEPA). That name continued until 1975 when the organization adopted its final and present name, the Indo-Pacific Prehistory Association.

The beginning came about as a result of the Fourth Pacific Science Congress and the interest of Herbert E. Gregory, founder of the Pacific Science Association. In the preliminary organization of the Batavia Pacific Science Congress (1929), Gregory included a prehistory section and asked P.V. van Stein Callenfels to organize it. Among those taking part in this section, besides van Stein Callenfels, were Davidson Black, sir grafton elliot smith, Sir Richard Winstedt, Victor Goloubew, and henry otley beyer. This group agreed to start an organization to promote research in prehistory in the Far East and settled on Hanoi for its first congress, to be hosted by the government of French Indo-China.

George Coedes was the organizing chairman of the congress, Paul Rivet was president, and Paul Mus acted as secretary. Other local organizers were Victor Goloubew and Madeleine Colani; other members were van Stein Callenfels from Java, Beyer from the philippines, Richard Winstedt of Singapore, Ivor H.N. Evans of Taiping in what was then the Federated Malay States, Prince Rajadabhisek and Luang Boribal Buribhand of Thailand, Joseph Shellshear of Hong Kong, C. Haguenauer from japan, and Henri Parmentier of cambodia. The proceedings of the congress were published as *Praehistorica Asiae Orientalis* in Hanoi in 1932. The second congress was to have been in Bangkok in early 1935, but because of troubled conditions there in 1934, the congress was shifted to Manila. At that congress, there were sixteen delegates and nine associates representing eight different countries. Proceedings of this congress were never published, although a few of the papers presented were published later (Solheim 1957, 8).

The president of the third congress, held in Singapore in 1938, was W. Linehan, and he was assisted by F.N. Chasen and M.W.F. Tweedie. There were twenty-seven delegates and six associates, and in addition to the countries represented before, institutional delegates and associate members came from Australia, New Zealand, and china-from Australia, D.A. Casey and fred d. mccarthy and from China, Lin Huisiang (the founder of the first Anthropology Department in China and a former student of Beyer). Chasen and Tweedie (1940) edited the proceedings.

The fourth congress was to be held in Hong Kong in 1941, but the threatening international situation caused its postponement. It was finally held, jointly with the Eighth Pacific Science Congress, in Manila in 1953, organized by Beyer, in Batavia, with the prompting of H.E. Gregory. This was much larger than the previous congresses and included representatives from many Pacific islands as well as those from countries that had attended previously. Eighteen countries were represented with official delegates, and there were sixty-three members and delegates as well as seventeen associates and observers, with many more Asian participants.

The Far-Eastern Prehistory Association was organized at the final business meeting of the fourth congress. Eleven council members were elected to carry on FEPA business between congresses, and Beyer was elected as honorary chairman. Council members were McCarthy (Australia), li chi (China), Alexander Spoehr (Hawaii and the United States), F.S. Drake (Hong Kong), Bernard P. Groslier (Indochina), H.R. van Heekeren (indonesia), Ichiro Yawata (Japan), C.A. Gibson-Hill (Malaya), roger duff

(New Zealand), E. Arseno Manuel (Philippines), and Prince Dhani Nivat (Thailand). From these members, an executive committee of five was selected: Groslier as permanent president, Duff as permanent secretary, Li, Drake, and van Heekeren. Among other instructions, the executive committee was to sponsor future congresses, encourage the formation of branches in member countries or areas, prepare for member institutions and countries a semiannual report on prehistoric and other anthropological activities, and receive and administer funds.
