Solheim was elected president of FEPA and was asked to write a constitution-up to this time, the organization had been without a constitution or bylaws. At each meeting, Solheim would propose incorporation, and Duff would counterpropose a vote of confidence in Solheim and that the organization should continue informally with Solheim doing all of the work. Duff always won. In 1972, Solheim started editing *The Far-Eastern Prehistory Association Newsletter* and continued to do so until 1975 when R.J. Lampert of Australia took over. The newsletter was replaced by the *Bulletin of the Indo-Pacific Prehistory Association* in 1980, edited by Peter Bellwood, who continues as editor.

A major congress was held in Nice, france, in 1975 in conjunction with the Eleventh Congress of the International Union of Prehistoric and Protohistoric Sciences. At this congress, a constitution was accepted, and it resulted in a reorganization and the change of the name to the Indo-Pacific Prehistory Association (Solheim 1977, 172-175). Solheim was elected president, and jack golson became vice-president, to assume the office of president in 1980. Rajendra Misra took over as president of IPPA in 1985 at the group's first independent congress, the twelfth, held at Penablanca, Cagayan Province, Philippines. Proceedings of a portion of this congress appeared in *Asian Perspectives* (Bellwood and Solheim 1984-1985). The second independent congress, the thirteenth, was held in Osaka and Tokyo in 1987, and the fourteenth congress took place in Yokyakarta, Indonesia, in 1990, with roger green assuming the office of president. The fifteenth congress was held in Chiang Mai, Thailand, in January 1994 where R.P. Soejono took over as president and the sixteenth conference was held in Malacca, Malaysia, in 1999.

Indonesia

The growth of archaeology in Indonesia from an amateur activity to a science can be divided into five phases of development. The first phase comprises the intensive registration of ancient remains without the coordination and supervision of any authorized archaeological organization and occurred during the eighteenth and nineteenth centuries. The second phase, from 1900 to 1950, saw the institutionalization of archaeological activities, the consolidation of archaeological work, the emergence of new data, and the

formulation of hypotheses across many different fields of archaeology. During the third phase, from 1950 to 1956, little archaeology was undertaken due to disruption by the struggle for political independence from Holland. Between 1956 and 1975 the study of archaeology of Indonesia by Indonesians was consolidated. From 1975 until the present archaeology in Indonesia has come of age.

Prior to the eighteenth century, knowledge of ancient objects and monuments was acquired through local and descriptive exploration, sometimes accompanied by classification based on their historical background but more often partly mythological and based on the beliefs of the local people. This kind of descriptive activity

was carried out during the peak of the Majapahit kingdom in the middle of the fourteenth century by Npu Prapanca, as affirmed by several cantos of the Nagara Krtagama [Book of Royal Ode/Hymn] (Krom 1920, 1926, 1, 2, 47; Pigeaud 1960-1963, vol. 3).

The Eighteenth and Nineteenth Centuries

Descriptions of ancient objects and remains increased with the arrival of European powers in Indonesia. Many merchants, scholars, soldiers, civil servants, naturalists, travelers, priests, etc. (Koentjaraningrat 1958, 15-48) wrote about their experiences and Indonesia's curiosities as they explored the Indonesian archipelago (Rumphius 1705). Their descriptions included not only local traditions, history, and the economic situation but also prehistoric remains. Some descriptions, particularly during the eighteenth century, were in the form of reports and were later supplemented with more accurate observations of archaeological objects, such as the measurement of the Prambanan Temple by F. van Boeckholtz in 1790. The foundation of the Bataviaasch Genootschap van Kunsten en Wetenschappen (Batavian Society of Arts and Sciences) in 1778 had a great impact on research into the history, traditions, and archaeological remains of Indonesia.

During the nineteenth century, there was an increase in activity in several archaeological domains. Apart from more extensive observations, particularly of Hindu Buddhist temples (or *candis*), methods of dealing with the problems posed by ancient remains became more advanced. Archaeological activities were primarily of a documentary nature, with particular emphasis on *candis,* and they took the form of drawings (by H. Cornelius, H.N. Sieburgh, C.J. van der Vlis, F.C. Wilsen), photographs (by J. van Kinsbergen), inventories (by F. Junghuhn), restorations (e.g., of Mendut), and excavations (such as the temples on the Dieng Plateau). Systematic surveys and documentation (by J.F.G. Bramund, C. Leemans, W.P. Groeneveldt, R.D.M. Verbeek, J. Crawfurd, T.S. Raffles, etc.) are still important sources of information about Indonesia's past. Other European methods of site recording, such as the making of glass negatives of the Borobudur monument by A. Shaefer in 1845, were used with little success in Indonesia.

Other activities in prehistory undertaken during this century (Soejono 1969) included the grouping or classification of rectangular axes (C. N. Pleyte and others), a great interest in megalithic remains (H. E. Steinmetz and others), and the provenance of bronze kettledrums (jens jacob worsaae, A.B. Meyer, and others). By far the most significant achievement in prehistory during the nineteenth century was the discovery of *Pithecanthropus erectus* (Java Man) by eugene dubois at Trinil, on the island of Java, in 1891.

Interest in Indonesia's Islamic past and observations and recordings of Islamic remains were minimal during this period. However, some fieldwork in this area included reports on the discovery of ancient gravestones in Aceh (1884) and a plan for the documentation (drawings, photographs, rubbings) and restoration of Islamic remains (Tjandrasasmita 1977). Many observers of ancient remains such as *candis,* megaliths, and bronze artifacts concluded that they were Hindu in origin. This observation was often the consequence of British archaeological activity in India and the structural resemblance between temple complexes and statues of deities or gods in Indonesia and those in India.

The increase of interest in ancient relics led to some attempts to establish a specific organization concerned with field archaeology, such as the Commissie tot het Opsporen, Verzamelen, en Bewaren van Oudheidkundige Voorwerpen (Commission for the Discovery, Collection, and Conservation of Ancient Objects) in 1822, but such attempts were unsuccessful. The private sector attempted to assist in archaeological research by founding the Archaeologische Vereeniging (Archaeological Society) in 1885, chaired by the engineer J.W. Ijzerman. He succeeded in exposing the basement of the Borobudur

Temple decorated with Karmawibangga reliefs, which is, at present, covered by the lower terrace.

The foundations for the development of archaeology as a discipline in Indonesia were created by the Dutch in the fields of documentation, restoration, excavation, and interpretation.

These activities paralleled similar developments in Europe (Daniel 1950), as did all advances in archaeology in Indonesia during this period. By the middle of the nineteenth century, European principles of archaeology, such as the application of the three-age system to ancient objects, diffusion, homotaxis, typology, the comparative method, synchronization techniques, and stratigraphic excavation, were being applied to sites and data in Indonesia. However, only a few of these, such as diffusion, typology, and homotaxis, were successfully applied. The reason may be that the archaeological practitioners in Indonesia were primarily amateurs and unable to fully grasp the development of the European methods of research, which had turned archaeologists there into professionals (such as christian j. thomsen, austen h. layard, heinrich schliemann, and others).

1900-1950

The focus on Hindu-Buddhist monuments continued into the twentieth century, indeed, until World War II. The Commissie in Nederlandsch Indie voor Oudheidkundig Onderzoek op Java en Madura (Commission in the Dutch East Indies for Archaeological Research in Java and Madura) was established in 1901, and its name reveals its limited powers and limited research scope. Behind its establishment was concern for the neglected state of Javanese antiquities, which had received little careful, detailed, or systematic examination, and the political necessity of creating a specialist archaeological organization similar to such organizations already in existence in Indochina and India. The commission survived until 1913 when the chairman of its board, J.L.A. Brandes, died. Then the Oudheidkundige Dienst (or OD, Archaeological Service) was created by the government of the Dutch East Indies, and N.J. Krom was appointed as its director. The OD's tasks, authority, and staff were extended in order to ensure better results.

The establishment of those two organizations was an important step in the development of archaeology in Indonesia. For the first time, a variety of archaeological activities was undertaken, and there was a center for the planning and direction of archaeology, which led to many improvements in archaeological practice in Indonesia (Soekmono et al. 1977). For the first time the results of archaeological research were published in the *Rapporten van de Oudheidkundige Commissie* (or *ROC* [Report of the Archaeological Commission]), which later continued as *Oudheidkundig Verslag van de Oudheidkundige Dienst in Nederlandsch Indie* (*OV;* Archaeological Report of the Dutch East Indies Archaeological Service). Archaeological schedules were proposed for every part of Indonesia, not just Java and Madura, and the technical support for the implementation of these plans was increased. H.L. Leydie Melville, P.J. Perquin, and J.J. de Vink were employed in the areas of inventory and documentation.

The restoration of Javanese temples received special attention, but it was not without controversy. There were arguments for a limited restoration of the remains of extant monuments, arguments for reconstructions of them on paper only (Krom), and arguments for the restoration of monuments, as far and as much as possible, by reconstruction. While F.D.R. Bosch was in charge of the OD, in 1916, there was conspicuous progress in temple restoration in Java. These restoration activities resulted in the formation of a permanent technical staff for this specialist restoration work located at Prambanan.

As the OD matured, there was more interest in other fields of archaeology such as Islamic remains (P. J. Moquette), prehistoric remains (P. V. van Stein Callenfels), and the more recent historic remains of the Portuguese and the Dutch East India Company (V. I. van de Wall). The investigation of inscriptions, pioneered in the previous century by R.M. Th. Friederich, Cohen Stuart, H. Kern, and others, increased, and archaeological investigations took place in Sumatra, Kalimantan, Sulawesi, Bali, the Lesser Sunda Islands, and the Moluccas.

Archaeological activities were also supported financially by prominent people outside the OD, such as civil servants, experts from other government institutions, and private individuals. The position of archaeology in Indonesia became even more stable after the Dutch East Indies government promulgated the Monumenten Ordonnantie (Ancient Monuments

Conservation Act) in 1931, which protected ancient remains and sites against damage, removal, and destruction.

The improvement in research, restoration, and recording led to the development of theories and hypotheses regarding the creation; distribution; styles; cultural, social, and religious significance; and history of Indonesia's antiquities. Bosch argued for the Indonesian people's greater involvement in the construction of their temples (Bosch 1919), counter to some opinions that Indians were the architects of these buildings and Indonesians only the laborers. These Indonesia-centric theories were supplemented more and more by the views of other scholars (Krom, W.F. Stutterheim, etc.). Other archaeological landmarks of this period include the publication of basic books on the Jago, Singasari, and Penataran monuments by Brandes (1904, 1909); Borobudur by Krom (1920) and Krom and van Erp (1920-1931); and Krom's work on Hindu-Javanese history (1926; Krom and van Erp 1920-1931) and Hindu-Javanese architecture. There was also growth in scientific archaeological activities when the OD was led by W.F. Stutterheim in 1936, but fieldwork declined owing to a shortage of staff and the economic crisis of the 1930s.

Although institutional and scientific archaeology was productive in Indonesia until the outbreak of World War II in East Asia, only a cadre of Dutch professionals were active in it. The OD was not large, and it was staffed by a core of Dutch archaeologists who worked across extensive regions. Archaeology stagnated in Indonesia during the Japanese occupation and the fight for independence from the netherlands after 1945. Only the technical staff at Prambanan was able to keep on with restoration and excavation during the Japanese occupation.

In 1945, during civil dissidence against the Dutch army, many documents that had been collected in Jakarta since the beginning of archaeological activities in Indonesia (such as archives of photographs, drawings, and books and a collection of research objects) were destroyed or disappeared. In 1947, the Dutch army, which had reoccupied Jakarta, set up and reorganized the OD.

This time the organization had technical branches in Ujung Pandang (South Sulawesi) and Gianyar (Bali). During the period of the struggle for independence, between 1947 and 1949, the prehistorian H.R. van Heekeren excavated in South Sulawesi, particularly at Maros, the cave-painting area, and at Kalumpang, a Neolithic settlement site. During this same period, J.C. Krijgsman was actively involved in the restoration of the ancient Hindu-Buddhist monuments of Bali.

1950-1956

In 1950, the Dinas Purbakala R.I. (Archaeological Service of the Republic of Indonesia) was established, with headquarters in Jakarta and A.J. Bernet Kempers as its head. Technical staff from Ujung Pandang were recalled to reinforce the staff at headquarters, and district offices called Seksi Bangunan Dinas Purbakala R.I. (Building Section of the Archaeological Service of the R.I.) were established. It was clear that the Republic of Indonesia urgently needed more support to become effective archaeologically as its scientific and technical staffs were inadequate.

In 1953, the Dinas Purbakala R.I. was placed under the charge of R. Soekmono, which meant that for the first time in the history of archaeology in Indonesia, the responsibility for Indonesia-wide archaeological work was under the supervision of an Indonesian archaeologist. Dutch archaeologists such as V.R. van Romondt, H.R. van Heekeren, J.G. de Casparis, M.J. van den End-Blom, and J.C. Krijgsman continued to work in Indonesia until 1960. Important work was accomplished in prehistory (Heekeren 1957), the Hindu-Buddhist or classical period (Bernet Kempers 1959), the Islamic period, and epigraphy (Casparis, 1950; Goris,1954).

The last issues of *OV* (1941-1947, 1948, 1949) were published, and the journal was replaced by *Laporan Tahunan Dinas Purbakala* [Annual Reports of the Archaeological Service], which was published from 1950 to 1955. These publications contained general descriptions of the activities of the various branches of archaeology. The archaeological journal *Amerta,* a popular analysis of archaeological research in Indonesia, was also published at this time, and a more scientific

PREV NEXT

analysis of data could be found in the series *Berita Dinas Purbakala* [Newsletter of the Archaeological Service]. More Indonesian scholars became involved in prehistoric, classical, and Islamic archaeology, and staff in the building sections were supplemented with Indonesian personnel and placed under Indonesian management. Professional courses for Indonesian archaeologists began at the Universities of Jakarta, Yogyakarta, and Denpasar, ensuring an ongoing Indonesian participation in the discipline.

When Dutch archaeologists returned to Holland after Indonesia's political independence, archaeological activities slowed down because of a shortage of appropriate Indonesian personnel. Although the operating budget for archaeology was minimal, Indonesian archaeologists, charged with the task of continuing the work of the OD, remained committed to the importance of Indonesian archaeology. Ironically, just at the time when more Indonesian archaeologists were beginning fieldwork and the science of archaeology was advancing rapidly, political circumstances in Indonesia made their lives and work difficult. Much effort was expended to fill gaps in the archaeological record and, with limited resources, to try to keep up with the many changes in archaeology and within the archaeological profession at an international level. Contact with international circles was maintained by means of regional and international conferences, publications in international media, and participation in joint archaeological programs with foreign teams.

Dutch archaeologists made significant contributions to the archaeology of Indonesia, and they were responsible for the establishment of Indonesia as an important area of archaeological research in Southeast Asia. In spite of many shortcomings, Dutch archaeologists laid the foundations for the further development of archaeology in Indonesia. Their most significant oversight was their failure to educate a cadre of Indonesian archaeologists to succeed them. (This was the case in many other ex-colonies in Southeast and south asia as well.) At independence, there was no leadership and little expertise in archaeology among the Indonesian people. Dutch archaeologists had concentrated on developing technical staff to support their interests and fieldwork, and it was only these staff members who had received any education or training. Consequently, the archaeological infrastructure and focus bequeathed by the Dutch to Indonesia was outside the capabilities and interests of the Indonesian people.

It is important to note that prior to World War II, the Dutch discovery of Indonesian archaeological evidence contributed to the development of an Indonesian identity and to Indonesian nationalism, and Dutch archaeological literature and research remain important parts of Indonesia's archaeology. In 1956, the small number of Indonesian archaeologists left to shoulder the archaeological burden of the country found it almost impossible to carry out administrative and organizational tasks and also to conduct field and scientific research. Funding, facilities, and resources for archaeology declined to levels below those provided for it before World War II.

1956-1975

During this period, although archaeology in Indonesia remained complex and vast, and despite a lack of resources, the discipline matured and produced professional and high quality results. The Lembaga Purbakala dan Peninggalan Nasional (National Institutes of Archaeology and Antiquities, the former Archaeological Service) was set up with four field or branch offices. The provision of minimal facilities and funding, for both the central and the branch offices, meant that planned archaeological fieldwork, such as surveys, excavations, and restorations, was difficult to accomplish. Between 1956 and 1975, little fieldwork took place, and documentation, registration, reports, and scientific article writing all stagnated. Factors such as the system of government, politics, and socioeconomics, and the small higher-education system, meant that archaeology in Indonesia continued to develop slowly.

But there were some achievements, including the designation and restoration of the Borobudur Temple

as a national project supported with special funds, the implementation

of joint programs with teams of foreign archaeologists, and the sending of Indonesian archaeologists abroad to further their education in both the technical and the theoretical fields. The last two achievements have increased Indonesia's ability to carry out restorations with the support of laboratories, technology, and the appropriate surveys and excavations.

One of the ornate temples at Borobudur, Indonesia

(Corel)

1975-

A military coup of 1975 and the rule of the Suharto regime until 1999 drastically affected the organization of archaeology in Indonesia. The state organization for archaeology was divided into two special units, each with its own function and tasks (Soejono 1987). Archaeological activities were divided into two categories, administrative and scientific. The organization in charge of the administrative functions became the Direktorat Sejarah dan Purbakala (Directorate of Archaeology and History), and the organization in charge of the scientific activities was the Pusat Penelitian Purbakala dan Peninggalan Nasional (Center of Archaeological Research and National Monuments). These names have been changed and are now the Direktorat Perlindungan dan Pembinaan Peninggalan Sejarah dan Purbakala (Directorate for Protection and Development of Historical and Archaeological Remains) and the Pusat Penelitian Arkeologi Nasional (National Research Center of Archaeology).

This division is significant for two reasons. First, each division concentrates on its respective area and tackles problems separately. There had been too many and complex administrative and organizational problems for a joint organization to resolve. Second, the division has created more opportunities for scientific work. The division of archaeology has been unified and coordinated with a large and qualified staff, a broad organizational structure, and a sufficiently large infrastructure. It is possible to avoid overlapping activities, and the two official divisions work to develop a national plan of priorities for monuments and archaeology.

National short- and long-term development programs now support a wide range of archaeological projects. These programs have improved conditions for archaeology, and their

Indus Civilization

First Phase (1924-1946)

On the basis of excavations in what is now Pakistan by D.R. Sahni at harappa in 1920-1921 and by rakal das banerji at Mohenjo Daro in 1921-1922, john marshall, the then-director general of the Archaeological Survey of India, made the first formal announcement of the discovery of this civilization in 1924 (Marshall 1924). Both of these sites were known earlier, however. In 1911-1912, D.R. Bhandarkar had visited Mohenjo Daro to report on a Buddhist stupa there; in 1876, alexander cunningham had published some seals and antiquities from Harappa; and "Indus" material from the site of Sutkagendor along the western part of the Makran coast in Baluchistan, much to the west of the Indus Valley, had been illustrated by W.T. Blandford in 1877. However, the Bronze Age character of these sites was not understood earlier (Chakrabarti 1988, 156-164; Deva 1982; Pande 1982; Possehl 1982).

Before mortimer wheeler (1947), a successor of John Marshall, reexcavated the citadel mound at Harappa in 1946 and began a new phase of Indus studies, the work on that civilization had proceeded in the following directions. Mohenjo Daro in the lower Indus Valley, or the province of Sind, was excavated until 1927 under Marshall's supervision. It was further excavated in 1927-1931 by E. Mackay who, although an outsider to the survey, was engaged for the purpose because of his experience at the large and more or less contemporary Mesopotamian site of Kish. In 1935, Mackay excavated Chanhudaro, another Indus site in Sind. In both north and south Baluchistan, some Indus sites were reported by aurel stein (1929, 1931) after exploring the region in 1927. Information about more of the sites in Sind were published by N.G. Majumdar (1934) and M.S. Vats (1938). In Gujarat in western India, an Indus site was identified by Vats (1937) at Rangpur. Sahni excavated Harappa in the upper Indus Valley, or Punjab, in 1920-1921 and 1923-1925, but between 1926 and 1934, the site

was excavated by Vats (1940) who reported another site near Harappa in addition to pointing out the Indus character of Kotla Nihang Khan in the Simla foothills of northern India. In 1942, Stein (1942) reported Indus sites in Bahawalpur in what is now Pakistan.

Thus, in the first phase of its study, the distribution of the Indus civilization was known to have extended from the Makran coast to the Simla foothills and from northern Baluchistan to Gujarat. Its extensive distribution in Sind and in the dried-up Ghaggar-Hakra drainage system of Bahawalpur was also understood during this period. More significantly, the classical excavation reports on Mohenjo Daro (Mackay 1938; Marshall, ed. 1931), Harappa (Vats 1940), and Chanhudaro (Mackay 1943) were published.

Indus Civilization

First Phase (1924-1946)

On the basis of excavations in what is now Pakistan by D.R. Sahni at harappa in 1920-1921 and by rakal das banerji at Mohenjo Daro in 1921-1922, john marshall, the then-director general of the Archaeological Survey of India, made the first formal announcement of the discovery of this civilization in 1924 (Marshall 1924). Both of these sites were known earlier, however. In 1911-1912, D.R. Bhandarkar had visited Mohenjo Daro to report on a Buddhist stupa there; in 1876, alexander cunningham had published some seals and antiquities from Harappa; and "Indus" material from the site of Sutkagendor along the western part of the Makran coast in Baluchistan, much to the west of the Indus Valley, had been illustrated by W.T. Blandford in 1877. However, the Bronze Age character of these sites was not understood earlier (Chakrabarti 1988, 156-164; Deva 1982; Pande 1982; Possehl 1982).

Before mortimer wheeler (1947), a successor of John Marshall, reexcavated the citadel mound at Harappa in 1946 and began a new phase of Indus studies, the work on that civilization had proceeded in the following directions. Mohenjo Daro in the lower Indus Valley, or the province of Sind, was excavated until 1927 under Marshall's supervision. It was further excavated in 1927-1931 by E. Mackay who, although an outsider to the survey, was engaged for the purpose because of his experience at the large and more or less contemporary Mesopotamian site of Kish. In 1935, Mackay excavated Chanhudaro, another Indus site in Sind. In both north and south Baluchistan, some Indus sites were reported by aurel stein (1929, 1931) after exploring the region in 1927. Information about more of the sites in Sind were published by N.G. Majumdar (1934) and M.S. Vats (1938). In Gujarat in western India, an Indus site was identified by Vats (1937) at Rangpur. Sahni excavated Harappa in the upper Indus Valley, or Punjab, in 1920-1921 and 1923-1925, but between 1926 and 1934, the site

was excavated by Vats (1940) who reported another site near Harappa in addition to pointing out the Indus character of Kotla Nihang Khan in the Simla foothills of northern India. In 1942, Stein (1942) reported Indus sites in Bahawalpur in what is now Pakistan.

Thus, in the first phase of its study, the distribution of the Indus civilization was known to have extended from the Makran coast to the Simla foothills and from northern Baluchistan to Gujarat. Its extensive distribution in Sind and in the dried-up Ghaggar-Hakra drainage system of Bahawalpur was also understood during this period. More significantly, the classical excavation reports on Mohenjo Daro (Mackay 1938; Marshall, ed. 1931), Harappa (Vats 1940), and Chanhudaro (Mackay 1943) were published.

Second Phase (1947-1963)

The second phase of Indus studies began in 1947 when Wheeler published the results of his excavations at the western mound of Harappa in 1946. The main achievement of this work was that a major Indus civilization site came to be bracketed between earlier and later occupations. Wheeler also argued that the Indus civilization was ruled by “priest-kings,” had a military character in the form of defense walls, and eventually fell to the Aryan invaders whose archaeological evidence he claimed to have found in Cemetery H ware at the site. In 1950, in his new capacity as the archaeological adviser to the government of Pakistan, Wheeler outlined the fortification wall of the western mound of the site and argued for the presence of a granary among its building complexes.

Seals of the Indus Valley culture

(Image Select)

In 1953, Wheeler published the first edition of *The Indus Civilization,* a work that in two major ways marked a significant departure from the earlier analysis of the civilization by Marshall. First, its chronology was brought down to 2500-1500 b.c. Assuming that evidence of its contact with Mesopotamia went back only to the Sargonic period (c. 2300 b.c.) and that its end coincided with the assumed date of Aryan invasions to India around 1500 b.c., the Indus civilization, instead of being roughly a contemporary of the Sumerian antiquities of Mesopotamia, as in Marshall's analysis, became one of its late contemporaries. Second, Wheeler argued that the idea of civilization in the Indus Valley was derived from Mesopotamia. This idea was a complete turnaround from those of Marshall's days and marked the beginning of a trend that has only been reinforced by the writings of a large number of Western scholars who have recently worked between iran, the Gulf, and the Indus.

In India, this phase was marked by a great number of discoveries in the Ghaggar-Drishadvati system in Rajasthan-Haryana and Gujarat. This was also the time when the easternmost point in the distribution of Indus sites was traced at Alamgirpur in Uttar Pradesh near

Delhi. Among the excavations in India undertaken or begun during this period were those at Rupar in Punjab, Alamgirpur in the Doab, Rangpur and Lothal in Gujarat, and Kalibangan in the dried-up Ghaggar Valley in Rajasthan (Pande 1982, 397-398). In Pakistan, the major breakthrough at Kot Diji led to the premise of a continuity between the earlier Kot Diji culture and the later Indus civilization level at the site, and at Amri, there were further elaborations of Majumdar's work during the preceding phase. Some miscellaneous work in Baluchistan highlighted the early character of village farming communities in the region. Along the Makran coast, the "port" character of the Indus site of Sutkagendor was highlighted, especially in the context of new discoveries in the Gulf area throwing light on its contact with the Indus civilization (annual volumes of *Pakistan Archaeology,* a government publication from 1964 onward).

Third Phase (1964-1984)

Beginning in about 1964, the third phase lasted up to the mid-1980s. This phase perhaps began with G.F. Dales's publication on the mythical massacre at Mohenjo Daro (Dales 1964), in which the improbability that the city fell to Aryan invaders was argued graphically. The excavations at Kalibangan in Rajasthan (Lal 1979) continued through the 1960s, and excavations began during this period at Surkotada in Kutch in northwestern India (Joshi 1990) and at Banawali (Bisht 1982, 1987) in Haryana. In Pakistan, this phase witnessed the beginning of a massive structural and other documentation project at Mohenjo Daro, including an intensive surface survey to locate craft-activity areas (Jansen and Urban 1984, 1987). A late level of the civilization was identified at Daimabad (Sali 1986) in the Godavari Valley of Maharashtra, and a mature form of the civilization was located at Shortughai, around the Indus River in India (Francfort 1989).

In Pakistan, the discovery of a large number of sites from the presumably fifth millennium b.c. Hakra ware phase to the late "Harappan/Indus" horizon of the second millennium b.c. in the dried-up Hakra drainage system in Bahawalpur (Mughal 1982) was a major event. In India, it was found that the entire area between the Ghaggar course in Rajasthan (known as the Hakra in Pakistan) and Saharanpur in the Doab was dotted with early, mature, and late sites. Another major discovery was that of the Ganeshwar-Jodhpura culture in the Sikar district of Rajasthan, a culture contemporary with the early phase of the civilization. The northernmost extension of the Indus sites in India was found at Manda in Jammu, and in Gujarat, too, there were major discoveries during this phase, notably in Kutch (Joshi, Bala, and Ram 1984).

Ideas regarding the origin and decline of the civilization took some specific forms during this period. On the basis of earlier work at Amri and Kot Diji and the ongoing work at Kalibangan, a. ghosh (1965) argued in favor of a homogeneous pre-Harappan substratum in the entire Harappan distribution area. Other scholars also favored such a hypothesis, which was put on a more solidly documented basis by R. Mughal (1971). However, the reason for the transformation from the early to the mature Harappan was not explained, which left scope for factors such as long-distance trade and proto-Elamite influence to be invoked as catalytic factors in the genesis of the Indus civilization. Radiocarbon chronology was applied to this civilization in the early 1960s (Agrawal 1964), but so far it has not been able to dislodge the Wheeler bracket of 2500-1500 b.c., an attempt at calibration (Brunswig 1975) and evidence of pre-Sargonic contact with Mesopotamia (Chakrabarti 1982) notwithstanding. The quest for Aryans is not yet over (cf. Hiebert and Lamberg-Karlovsky 1992).

On the whole, however, there was no difficulty at all in visualizing the late phase of the Indus civilization as transformation into an essentially nonurban form that developed regional characters in all the relevant areas. Subsistence (Vishnu-Mittre and Savithri 1982; Weber 1991), trade (Chakrabarti 1990; Lahiri 1992, 67-144; Ratnagar 1981; Shaffer 1982), metallurgy (Agrawal 1971), script (Mahadevan 1977),

miscellaneous craft behavior such as the manufacturing of shell bangles and beads (Hegde, Karanth, and Sychanthavong 1982; Kenoyer 1984), etc., began to be subjected to detailed study. In the early 1980s, the “Neolithic” discovery at Mehrgarh in the Bolan Valley

alluvium of Baluchistan provided a very long rural antecedent to the development of civilization in the Indus region.

(AAA)

Current Phase (1985-)

Since the mid-1980s, the study of the Indus civilization has been in its fourth and current phase. In India, this phase is likely to be dominated by the ongoing excavations at Dholavira in Kutch (Bisht 1991), which have already added new features to Harappan planning, water management, stonemason's work, etc. The discovery of a few large script signs, made of carefully cut crystalline material and presumably set on a wooden board, has also led to a fresh appreciation of the extent of Harappan literacy. This site has also shown the entire archaeological sequence of this civilization in Kutch, including its early and later phases. In Pakistan, this is the phase of prolonged excavations at Harappa, especially in its eastern sector, and the stratigraphic and cultural details that have already emerged (Dales 1992) help us to understand this civilization, as at Dholavira, as an integral part of a deep-rooted cultural development and its subsequent transformation.

On the theoretical side there is now a marked contrast between an approach centered on western Asia and an approach that favors an indigenous framework of development and transformation. The first approach favors a short chronology for the civilization and restricts it, by implication, to the status of being a mere episode in the history of south asia. Second, this approach puts an inordinate amount of emphasis on external trade with various areas in western and central Asia. For instance, western archaeologists who work in Oman argue that Oman was the main supplier of copper to the Indus civilization, despite the very large presence of copper on the subcontinent. In contrast, the indigenous approach argues for a long chronology, cites ethnographic data to argue that the civilization's external trade was not characteristically different from the trade that continued well into the twentieth century in this region overall, and provides a scheme that helps to understand the civilization as an integral part of the total process of Indian history and culture.

Basically, there were apparently two major variables in the emergence of the Indus civilization. First, the sites in the Indus Valley shift to

Industrial Archaeology

A systematized means of utilizing artifacts, images, structures, sites, and landscapes in the investigation of the industrial past, industrial archaeological studies are making significant contributions to historical understanding. There are learned societies, journals, and publications on the subject in most western European countries, in North America, in japan, and in Australia. Industrial heritage is receiving increasing attention in russia and in Latin America and is beginning to be recognized in most other countries.

An international organization, the International Committee for the Conservation of the Industrial Heritage (TICCIH), was formally constituted at a conference at Grangärde, Sweden, in 1977 after preliminary meetings at Ironbridge, England, in 1973 and Bochum, Germany, in 1975. TICCIH holds conferences, usually at three-year intervals, and each result in a volume of reports on developments in the industrial heritage of particular countries in addition to the conference proceedings (CEHOPU 1992; CILAC 1981, 1985; Cossons 1975; Georgeacopol-Winischhofer, Swittalek, and Wehdorm 1987, 1990; Kroker 1978; Nisser 1978, 1981; Nisser and Bedoire 1978; Vanderhulst 1992; Victor and Wright 1984; Wright and Vogel 1986). TICCIH also encourages the establishment of national organizations for promoting the study of the industrial heritage, and its council and officers are elected by the accredited representatives of such bodies.

In England, the expression *industrial archaeology* is sometimes used to imply that it is a social activity, and, in other European countries, terms meaning industrial heritage-*patrimoine industriel* or *industrieel erfgoed,* for example-are similarly comprehensive, encompassing such activities as the conservation and operation of railways and canals, the collection of steam road vehicles, and the adaptive reuse of industrial buildings. The term *industrial archaeology* is best used in a more narrow academic sense to describe research into past industrial societies based on the scientific analysis of physical remains, whether these are artifacts, images, structures, sites, or landscapes, and industrial archaeology is a subsector of the broader field of investigation defined as archaeology.

The Portuguese polymath Francisco de Sousa Viterbo (1845-1910) first used the term *arqueologia industrial* in 1896 in a study in which he argued that much could be learned from study of the physical remains of past manufacturing activities and from the memories of people who had been involved in the production process (Sousa Viterbo 1896/1986). The value of artifacts in the study of industrial history was acknowledged by the founders of the great national museums of technology like the Musée National des Techniques, Paris; the Science Museum, London; and the Technisches Museum für Industrie und Gewerbe, Vienna. Historians of industry in the first half of the twentieth century nevertheless made sparse use of archaeological evidence, and some standard works on the British Industrial Revolution show a remarkable ignorance of the most basic technological processes and scarcely any awareness of the most important manufacturing complexes. The only outstanding archaeological study of industry in England in this period was by an amateur scholar (Straker 1931).

Industrial archaeology was reborn in the 1950s. The Belgian scholar René Evrard (1907- 1963), founder of the Museum of Iron and Coal in Liège, was using the term *archéologie industrielle* by 1950. The first recorded use of the English term in print was by Michael Rix (1913-1981) of the University of Birmingham in an article published in 1955 (Rix 1955), although supposedly it was used by scholars in the Department of Economic History at the University of Manchester before that date. Kenneth Hudson (1916-), journalist, broadcaster, and subsequently museum critic, was the author of

Instituto Hondureño de Antropología e Historia

Founded in 1952, the Instituto Hondureño de Antropología e Historia (IHAH, Honduran Institute of Anthropology and History) is the legal guardian of the archaeological patrimony of Honduras and publishes the journal of Honduran anthropology and history entitled *Yaxkin*. Through its function in approving research proposals, it shapes the course of Honduran archaeology. The institute has sponsored significant programs of research, trained Hondurans in archaeological methods, and fostered the development of archaeology as a career in the country.

According to Honduran archaeologist Ricardo Agurcia, the earliest Honduran government action directed toward preservation of the archaeological record was legislation passed in 1845 to control exploration of the ruins of classic Mayan Copán and place the responsibility for their protection in the hands of local authorities. Nonetheless, Agurcia notes that in the 1890s, legally approved expeditions from Harvard University's peabody museum and the british museum removed large quantities of archaeological remains from the site. These actions led to new legislation in 1900 prohibiting the exportation of material from Copán and also from other ruins in the country. The legislation explicitly allowed exploration, including excavation, with prior permission by the executive branch of the government. In 1946, the first legislation authorizing a governmental body charged with exploration and protection of the archaeology, ethnography, and history of the country was produced, laying the groundwork for IHAH.

The founding of IHAH in 1952, according to Honduran archaeologist Vito Veliz, owed much of its

impetus to Jesus Nuñez Chinchilla, an archaeologist trained in mexico in the 1940s. Nuñez Chinchilla conducted excavations at Copán, and during its early years, IHAH emphasized this site. New legislation in 1968 legally established IHAH as an autonomous institution, and this legal status gave IHAH control over its personnel and facilities and effectively allowed it to function as an investigative unit. According to Agurcia, this new status reached fruition in 1975 when IHAH began its modern history of aggressively fostering archaeological research.

All archaeology conducted in Honduras since the last date has taken place under permits issued by IHAH. Even in the 1960s and 1970s, the scope of projects proposed by outside researchers extended far beyond Copán to encompass a broad corridor extending south from the Ulua Valley through Lake Yojoa, Comayagua, and the Gulf of Fonseca and extending east along the north coast. In addition to reopening research in these areas by its approval of outside projects, beginning in the 1970s IHAH initiated its own programs of archaeological inventory

and periodic conferences, IHAH has begun the development of standards crucial to coordinating research, which in recent decades has involved archaeologists from france, Germany, Great Britain, japan, Australia, canada, the United States, and Mexico and Hondurans trained in European, North American, and Latin American traditions.

International Union of Prehistoric and Protohistoric Sciences

The creation in La Spezia, Italy, in September 1864 of the Congres Paleoethnologique International (CPI) during a meeting of the Societa Italiana di Scienze Naturali marks the de facto beginnings of the International Union of Prehistoric and Protohistoric Sciences. In 1867, the CPI changed its name to Congres International d'Anthropologie et d'Archéologie Prehistoriques (CIAAP), and that organization can be described as the direct ancestor of the contemporary union. The origins of the present organization therefore go back some 130 years. The prime movers in this international initiative were Giovanni Capellini (president of Societa Italiana di Scienze Naturali) and the French archaeologist gabriel de mortillet.

Between 1866 and 1912, fourteen international congresses were organized (a Permanent Council was created during the Lisbon session of the CIAAP in 1880), but World War I put a stop to these fruitful and constructive meetings. The Institut International d'Anthropologie (IIA), founded in 1921 after the war, tried to bring archaeologists and anthropologists together again, but this group was almost totally French inspired and dominated (all five members of the executive committee were French). It was also totally different from the CIAAP in two essential ways: its main emphasis was on “anthropology” in its widest sense (as the study of living human communities, comparative religion, folklore, etc.), with prehistoric archaeology forming a smaller section than had previously been the case; and scholars belonging to the “vanquished nations” were excluded from the activities of the IIA. For both of these reasons, numerous prehistorians and anthropologists did not choose to join or belong to the IIA, and several (such as marcellin boule, R. Verneau, hugo obermaier, and P. Bosch-Gimpera) tried to continue the real international tradition of the prewar CIAAP.

After several efforts at collaboration between members of the Permanent Council of the CIAAP and the Executive Committee of the IIA, it was finally decided that the fifteenth session of the CIAAP and the fourth session of the

Seventh, members of the National Organizing Committee serve for five years and are responsible for organizing the next international congress. The Permanent Council elects the secretary of the National Organizing Committee, and its members are the Permanent Council members of the country hosting the next congress.

Over the years, a number of special committees have been created to organize projects of international importance, and many of them still continue. Several of these special committees have built up an imposing group of specialists and are responsible for a long list of publications. In addition, some twenty scientific commissions have been incorporated into the organization of the U.I.S.P.P. to coordinate research in specific areas of pre- and proto-history, which can be thematic, regional or interregional, chronological, interdisciplinary, etc. Finally, several international associations have become affiliated with the UISPP, through which they have access to the CIPSH. All of the special committees, scientific commissions, and other organizations meet regularly during congresses and in symposia, colloquiums, and conferences, and the results of their work are generally published, sometimes in multivolume proceedings, sometimes in less ambitious collections of papers.

To conclude, I quote part of the Preamble to statutes of the UISPP, in which the international union clearly proclaims its scientific aims and philosophical convictions:

The U.I.S.P.P. is an international association of scholars; the universality of Science is the philosophical basis of its activities. Its aim being the collaboration of the scholars from all countries to help advance prehistoric and protohistoric studies, it proclaims its total attachment to academic freedom.

Knowledge of Humanity concerns all present-day societies. For this reason, the U.I.S.P.P. is in total opposition to any form of discrimination based upon the concepts of race, ethnic group, geographical unit, philosophical conviction, nationality, sex, language or any other; such discrimination being, by its intolerance and its very definition, the negation itself of any form of co-operation. The U.I.S.P.P. excludes no bona fide scholar from its scientific activities.

(Bulletin of the XIII Congress of the International Union of the Prehistoric and Protohistoric Sciences, Forli, Italy, 1996, 34-38).

Jacques Nenquin

Iran

No comprehensive history of archaeology in Iran exists though there are a few summaries about specific aspects (e.g., Amiet, Chevalier, and Carter 1992; Dyson 1968; Moorey 1972; Young 1986) and a few autobiographies (Dieulafoy 1888, 1890; Ghirshman 1970; Goff 1980). There are also important recent syntheses and collections of articles (Hole 1987; Olszewski and Dibble 1993; Smith 1986; Voigt and Dyson 1992), a basic bibliography for the prehistoric periods (Voigt and Dyson 1992), virtually exhaustive bibliographies for all periods (Van den Berghe 1966, 1979; Van den Berghe and Haerinck 1981), and an archaeological tour of Iran (Matheson 1972).

Historical Overview

Archaeology in Iran has developed unevenly in terms of periods and regions studied. The earliest archaeological investigations, from the late nineteenth century onward, concentrated on western and southwestern Iran, and this pattern has largely persisted. This emphasis is primarily owing to the facts that these areas had the strongest interaction with mesopotamia; they were the homeland of historically important civilizations such as Elam and Achaemenid Persia, which were of greatest interest to western

scholars; and access to them was relatively easier. In addition, the discipline has been compartmentalized chronologically, and with some exceptions, researchers fall into one of three groups: those few who have studied the relatively neglected Paleolithic period, the majority who have focused on the Neolithic to the Achaemenid periods, and another smaller group of people who have concerned themselves with the post-Achaemenid and Islamic periods.

Late-nineteenth- and early-twentieth-century archaeology in Iran can be reasonably characterized

Historical Overview

Archaeology in Iran has developed unevenly in terms of periods and regions studied. The earliest archaeological investigations, from the late nineteenth century onward, concentrated on western and southwestern Iran, and this pattern has largely persisted. This emphasis is primarily owing to the facts that these areas had the strongest interaction with mesopotamia; they were the homeland of historically important civilizations such as Elam and Achaemenid Persia, which were of greatest interest to western

scholars; and access to them was relatively easier. In addition, the discipline has been compartmentalized chronologically, and with some exceptions, researchers fall into one of three groups: those few who have studied the relatively neglected Paleolithic period, the majority who have focused on the Neolithic to the Achaemenid periods, and another smaller group of people who have concerned themselves with the post-Achaemenid and Islamic periods.

Late-nineteenth- and early-twentieth-century archaeology in Iran can be reasonably characterized

as museum-driven, object-oriented research. Throughout this period, france had a monopoly on archaeological research in the country, and they concentrated almost entirely on the great Elamite and Achaemenid site of Susa in Khuzistan. There was no expansion of archaeological research in Iran immediately after the hiatus caused by World War I because the French retained their monopoly for several more years and western archaeologists had much easier access to Iraq, Syria, Lebanon, and Palestine, which had all become foreign mandates. In 1927, Reza Shah's government radically revised the antiquities regulations, and the French monopoly was finally broken. The scope of archaeological research widened greatly thereafter as other international expeditions finally gained access, and there was also some general improvement in field methods, which, hitherto, had been primitive. Because of the pronounced geographical and environmental regionalization of the country, the main thrust of Iranian archaeology from then on has been the establishment of regional sequences.

World War II brought another hiatus in fieldwork, but after it, the discipline continued to improve, especially from the late 1950s onward with the launching of many major new projects and the first impact of "the new archaeology." In addition to elaborating regional sequences, there was a strong focus on sophisticated regional surveys and on achieving a more comprehensive investigation of the entire country. All work came to an abrupt halt as a result of the 1979 revolution, and it is only recently that fieldwork, conducted by the Iranians themselves, has resumed in a very limited manner.

Knowledge of Iran's Past Prior to the Late Nineteenth Century

By the end of the Sassanian period (a.d. 651), knowledge of the preceding Achaemenid (550-331 b.c.), Hellenistic/Seleucid (331-175 b.c.), Parthian (175 b.c.-a.d. 224), and Sassanian (a.d. 224-651) periods was virtually lost within Iran itself. Alexander the Great was (and still is) remembered in oral tradition and the Iranian national epic, the *Shahnameh* [Book of Kings]-but as the half-brother of Darius III. The advent of Islam in the mid-seventh century a.d. effectively discouraged any scholarly or popular interest in a pagan past. Only under the Qajar shahs in the nineteenth century did Iran experience a revival of concern with the Achaemenids and their successors. Although there was no systematic research, it became fashionable to copy Achaemenid reliefs for architectural decoration and to carve new reliefs in an archaic style. Indirect knowledge of Achaemenid Iran was preserved in Europe through the Old Testament and classical Greek sources, especially Herodotus (though he never visited the country) and Xenophon. Reports from other ancient Greek travelers and mercenaries and the testimony of expatriate Persian refugees in greece provided additional detail.

From the fourteenth century onward, European travelers brought back descriptions of the great ruined cities of persepolis and Pasargadae, though their true identity remained unknown until the beginning of the seventeenth century. From the seventeenth to the nineteenth centuries, an increasing number of European travelers, diplomats, and scholars-mostly French, British, and Dutch-reported in greater and greater detail about the standing monuments of Iran (Sancisi-Weerdenburg and Drijvers 1991; Wright 1977).

The first excavations occurred in 1825 when Colonel Stannus, the East India Company resident at Bushire, dug at Persepolis and made the first set of molds of sculptures along the north facade of the Apadana. Colonel Macdonald, head of a mission to Iran, also excavated at the site shortly afterward. In 1835, henry creswicke rawlinson, a former officer in the Indian army who had studied Persian, Arabic, and Hindustani, was posted to Kermanshah as a military adviser, and by 1837, he had produced fairly accurate copies of the trilingual (Old Persian, Akkadian, and Elamite) cuneiform relief carved by Darius I in about 520 b.c. on a rock face at Bisitun (Behistun). In the subsequent decade, Rawlinson unraveled the Old Persian and Akkadian texts. In 1840-1841, austen henry layard, later distinguished by his work at the great Neo-Assyrian capitals of nineveh and nimrud, traveled throughout western Iran and visited

Beginnings of Sustained Archaeological Research in Iran

The first scholarly excavations in Iran were those of the British geologist, William Kennett Loftus, a member of a commission formed by the British and Russian governments to arbitrate the delineation of the frontier between Persia and Turkey. In 1850, Loftus and another member of the commission, Henry A. Churchill, visited Susa intending to excavate. Because of local resentment, the visit was brief. The two returned in 1851 along with Colonel W.F. Williams, the commandant of the frontier commission, and they planned the site, identified it through inscriptions as the Susa of the Old Testament, and established the presence of Sassanian, Achaemenid, and earlier (Elamite) levels.

The French at Susa

During a trip across Persia in 1881-1882, Marcel-Auguste Dieulafoy, a French engineer, soldier, and architectural historian, visited Susa with his wife, Jane, and upon their return to France, Dieulafoy persuaded the national museums to provide modest financing for excavations. Unlike most of his contemporaries, Dieulafoy was more interested in architecture than museum-quality objects. Thus, from 1884 to 1886, the Dieulafoys worked exclusively on the columned Apadana (Audience Hall), previously identified by Loftus, from which they retrieved spectacular Achaemenid remains. These antiquities became the core of the louvre's extensive Susa collection.

In 1886, Nasir el-Din Shah (1848-1896), who was aware that the local population was still discontented with the excavations, shut them down, and almost a decade passed before the French legation in Tehran felt it could reopen the matter. In 1895, the French ambassador, Rene de Balloy, finally persuaded the shah to sign a treaty that granted the French an exclusive concession for archaeological research throughout Persia. In Mesopotamia, then under Ottoman control, considerable rivalry between

Beginnings of Sustained Archaeological Research in Iran

The first scholarly excavations in Iran were those of the British geologist, William Kennett Loftus, a member of a commission formed by the British and Russian governments to arbitrate the delineation of the frontier between Persia and Turkey. In 1850, Loftus and another member of the commission, Henry A. Churchill, visited Susa intending to excavate. Because of local resentment, the visit was brief. The two returned in 1851 along with Colonel W.F. Williams, the commandant of the frontier commission, and they planned the site, identified it through inscriptions as the Susa of the Old Testament, and established the presence of Sassanian, Achaemenid, and earlier (Elamite) levels.

The French at Susa

During a trip across Persia in 1881-1882, Marcel-Auguste Dieulafoy, a French engineer, soldier, and architectural historian, visited Susa with his wife, Jane, and upon their return to France, Dieulafoy persuaded the national museums to provide modest financing for excavations. Unlike most of his contemporaries, Dieulafoy was more interested in architecture than museum-quality objects. Thus, from 1884 to 1886, the Dieulafoys worked exclusively on the columned Apadana (Audience Hall), previously identified by Loftus, from which they retrieved spectacular Achaemenid remains. These antiquities became the core of the louvre's extensive Susa collection.

In 1886, Nasir el-Din Shah (1848-1896), who was aware that the local population was still discontented with the excavations, shut them down, and almost a decade passed before the French legation in Tehran felt it could reopen the matter. In 1895, the French ambassador, Rene de Balloy, finally persuaded the shah to sign a treaty that granted the French an exclusive concession for archaeological research throughout Persia. In Mesopotamia, then under Ottoman control, considerable rivalry between

Hamadan (the ancient Median capital, Ecbatana) in the late nineteenth century reported that excavation for antiquities in large areas in and around the city was a systematic industry farmed out by the government for revenue. There was also a thriving production of fake antiquities, mostly coins, for the European market.

Griffin-lion shown in tiled relief, from a royal site (probably Persepolis or Susa), fourth century B.C.

The modernizing reforms of Nasir al-Din, the most able of the Qajar shahs, brought about his assassination in 1896. His successors were either ineffectual or despotic, and the period leading up to World War I was one of great internal turmoil that culminated in the invasion of northern and southern Iran by Russia and Britain, respectively. In 1911, members of the first Majlis (National Assembly) introduced a bill designed to cancel the French archaeological monopoly, but by 1913, the French ambassador had successfully arranged for the bill to be shelved. The war brought excavations to an end though sir aurel stein conducted a survey in Seistan in 1915-1916. De Mecquenem remained in Iran until the end of the war to protect French archaeological interests.

The Interwar Period

French control of archaeology continued until 1927 when it was finally abolished by Reza Shah Pahlavi (1925-1941). As a concession, the shah established an archaeological museum and library in Tehran and appointed a French director-general of antiquities responsible for establishing an archaeological service, making an inventory of historic monuments, and carrying out necessary restorations. The position was taken in September 1927 by a French architect, Andre Godard, who held it until 1960. Godard's achievements were considerable: he created the necessary administration, the Iranian Archaeological Service (IAS), and established the Muze Iran Bostan (now the National Museum of Iran) and oversaw its construction in Tehran between 1935 and 1937. He also conducted important work on Islamic architecture and supervised the restoration of historic buildings, especially in Isfahan. In 1931, when the antiquities market was being flooded by Luristan bronzes from illegal excavations in central-west Iran, Godard wrote what became the standard text on the bronzes. He was also vigorous in the

popularization of Iranian art and archaeology on an international level. Laudable as these achievements were, they were largely self-serving, and there was virtually no provision for the training of Iranians who could conduct independent archaeological research, staff museums, or educate the next generation.

Throughout most of Godard's tenure, the only Iranians involved in excavations were those working for antiquities dealers and, up until the 1950s, only three Iranians (Mahdi Bahrami, Issa Behnami, and Mohsen Moqaddam) managed to obtain doctorates in Iranian art and archaeology from French universities. Some excavations initiated by the IAS (e.g., Hasanlu and Khurvin) were, from an Iranian point of view, arbitrarily transferred to foreign projects. There was also a vigorous illegal trade in antiquities, and much material ended up in the british museum, the Louvre, and numerous other museums and private collections. In 1959 alone, the Louvre bought 500 Luristan bronzes from Jacques Coiffard, the French ambassador in Tehran-the question of provenance was never raised.

Other Foreign Projects

In 1931, the oriental institute of the University of Chicago (OIC) began a major archaeological project in Fars with the Achaemenid capital of Persepolis as the main focus and headquarters. Excavations at Persepolis and neighboring sites were directed by Ernst Herzfeld (1931-1934) and Erich Schmidt (1934-1939). The OIC subsequently undertook other projects, including aerial and ground surveys, in the mountains of Luristan and elsewhere in Iran between 1935 and 1937. Brief excavations were made at over a dozen sites. Also in 1931, the university of pennsylvania museum (UM) began two important projects in the little-explored northeastern part of Iran.

During the 1930s, there were few foreign expeditions apart from those of the major players, the French and the Americans. Aurel Stein (Harvard University and the British Museum) made four trips between 1932 and 1936 visiting and testing numerous sites in southeastern (Kerman, Baluchistan, and Fars) and western Iran, and he identified numerous ancient sites, such as Hasanlu, that subsequently became archaeologically famous. A Swedish expedition led by T.J. Arne investigated Shah Tepe in the Gurgan Plain in 1933. Although the situation in the 1930s can be described as considerably improved, there was no coordination of international efforts, excavation methods remained fairly crude, and programs of excavation, while sometimes sustained, were not at all systematic. The decade of research prior to World War II threw isolated and random shafts of light on the development of Iran from the Neolithic to the Achaemenid period, and in no region was there anything approaching a complete sequence.

However, great strides had been made. For example, Herzfeld's 1934 Schweich Lectures on the archaeological history of Iran, over 100 pages in length, devoted only 8 pages to the pre-Median and pre-Achaemenid eras (Herzfeld 1935). Seven years later, D.C. McCown (1942) needed over 60 pages to synthesize the comparative stratigraphy of the prehistoric periods of north-central, western, and southwestern Iran even though some areas were still relatively unexplored. The prehistory of northwestern Iran was disposed of in a single page, and southeastern Iran was not mentioned. World War II and internal conditions in Iran brought a second hiatus in foreign fieldwork.

The Post-World War II Period: 1945-1979

The accidental discovery of the fabulous early-first-millennium-b.c. golden hoard at Ziwiyeh in northern Kurdistan in 1947 gained widespread international interest, but foreign fieldwork still recommenced rather slowly after World War II. The French returned to Susa promptly enough in 1946 under a new director, Roman Ghirshman, who held the post until 1967 when he was succeeded by Jean Perrot (1967-1990), who introduced modern stratigraphic methods there. The British returned to the field in 1948, and the IAS was increasingly active following the completion of work at Persepolis. The IAS

were joined by a Japanese team led by Norio Egami (Tokyo University) in 1956, and in 1957, Robert Dyson, Jr., led a UM team back to Iran.

In the two decades between 1959 and 1979, archaeology flourished in Iran perhaps more

popularization of Iranian art and archaeology on an international level. Laudable as these achievements were, they were largely self-serving, and there was virtually no provision for the training of Iranians who could conduct independent archaeological research, staff museums, or educate the next generation.

Throughout most of Godard's tenure, the only Iranians involved in excavations were those working for antiquities dealers and, up until the 1950s, only three Iranians (Mahdi Bahrami, Issa Behnami, and Mohsen Moqaddam) managed to obtain doctorates in Iranian art and archaeology from French universities. The Post-World War II Period: 1945-1979

The accidental discovery of the fabulous early-first-millennium-b.c. golden hoard at Ziwiyeh in northern Kurdistan in 1947 gained widespread international interest, but foreign fieldwork still recommenced rather slowly after World War II. The French returned to Susa promptly enough in 1946 under a new director, Roman Ghirshman, who held the post until 1967 when he was succeeded by Jean Perrot (1967-1990), who introduced modern stratigraphic methods there. The British returned to the field in 1948, and the IAS was increasingly active following the completion of work at Persepolis. The IAS

were joined by a Japanese team led by Norio Egami (Tokyo University) in 1956, and in 1957, Robert Dyson, Jr., led a UM team back to Iran.

In the two decades between 1959 and 1979, archaeology flourished in Iran perhaps more

vigorously than anywhere else in western Asia. There was a virtual explosion of international activity with expeditions from Britain, the United States, canada, West Germany, France, sweden, italy, japan, belgium, and denmark. In 1976, for example, there were seventeen archaeological surveys and thirty excavation projects. By 1978, the number of foreign expeditions in Iran had risen to over fifty, the majority of them being major projects. For the first time, some balance was achieved in chronological coverage, at least in western Iran, and other previously neglected areas began to be explored.

Though some important achievements occurred in Paleolithic studies, this subfield continued to lag. Iran's great environmental diversity and complex geography of deserts, mountain valleys, and coastal plains are reflected in the numerous cultural adaptations in prehistory. For this reason, archaeologists have eschewed syntheses of larger areas and time periods in favor of constructing prehistoric regional sequences (see Voigt and Dyson 1992). This period also saw the introduction of modern excavation standards and close attention to stratigraphy, so necessary when dissecting complex mound settlements, and, by the mid-1960s, the impact of the theoretical and methodological innovations of "the new archaeology." In addition, there was a rapid and intense development of surface survey strategies, perhaps more so than anywhere else in western Asia. This was inspired by gordon willey's virú valley project in peru in 1953 and the extensive surveys conducted in both Iraq and Khuzistan by robert mccormick adams.

Survey data were used to identify administrative hierarchies; stylistic, functional, and chronological variability; trading networks; population dynamics; and so forth through the employment of such methods as gravity modeling, rank size indexing, cluster analysis, multidimensional scaling, and statistical analysis. A number of important ethno-archaeological projects were also conducted, especially Patty Jo Watson's and Carol Kramer's separate studies of two villages in central-west Iran. There was a notable increase of fieldwork done by the IAS as well as an increase in the number of Iranians being trained not only in Iran but also in Europe and North America. In 1958, Ezatollah Negahban, himself a graduate of the OIC, created the Institute of Archaeology at the University of Tehran. The institutional framework was further strengthened with the appearance of the Iranian Centre for Archaeological Research (ICAR), directed by Firouz Bagherzadeh, and also the National Organization for Restoration of Historical Monuments. By 1961, both the British Institute of Persian Studies and a German institute had been opened in Tehran, and the American Institute of Iranian Studies was opened soon afterward. Specialized journals appeared, especially *Iran* (1962), *Iranica Antiqua* (1965), *Archaologische Mitteillungen aus Iran,* new series (1967), and *Cahiers de la Délégation Archéologique Française en Iran* (1971), and in addition, numerous international colloquia, symposia, conferences, and exhibitions were organized.

History of Paleolithic Research in Iran

Because of the relative lack of overlap between Paleolithic research and that of later periods, the history of Paleolithic archaeology in Iran is most effectively dealt with separately. Compared to other areas of western Asia, Paleolithic research in Iran was very late to develop. Stone tools were recovered from a Pleistocene context near the Caspian Sea in the late nineteenth century by de Morgan, and further discoveries were reported from river terraces in Seistan. De Morgan's belief that, during the Pleistocene, the mountains and plateaus of Iran would have been uninhabitable possibly dissuaded further interest. Indeed, much of the country is at such a high altitude that it is likely that the entire Paleolithic sequence of Iran will be consistently marked by hiatuses around glacial maxima.

dorothy garrod's pioneering research in southern Iraqi Kurdistan in 1928 documented Lower, Middle, and Upper Paleolithic occupations at the surface site of Chemchemal and in the caves of Zarzi and Hazar Merd near Sulaimaniya, and it was expected that similar evidence would be discovered in Iran. In

1934, Middle Paleolithic flints were recovered near Shiraz in Fars Province, and Herzfeld, in the first published synthesis of Iranian archaeology,

emphatically endorsed a Paleolithic occupation of the entire country, though he could say nothing beyond that (Herzfeld 1935, 1). It was not until 1949 that the U.S. physical anthropologist Carleton S. Coon (UM) conducted the first excavations with the objective of discovering the western Asian antecedents to the European Upper Paleolithic. Coon excavated in Hunter's Cave at Bisitun (Kurdistan), Tamtama Cave near Rezaiyeh (Azerbaijan), and the Khunik rock shelter (southern Khorasan near the Afghan border), all of which contained only Middle Paleolithic deposits. In Belt Cave (Ghar-I Kamarband) on the Caspian foreshore and in nearby Hotu Cave, Coon found evidence of Mesolithic, Neolithic, and later occupations.

In the 1960s and 1970s, there was a brief flurry of activity in Paleolithic research with projects emanating from Britain, Canada, Denmark, France, Italy, and the United States. For example, in 1959 and 1960, robert braidwood (OIC) conducted a survey and excavated several Middle and Upper Paleolithic sites in the region of Kermanshah. Between 1962 and 1964, charles mcburney (University of Cambridge) investigated Mesolithic levels in the cave of Ali Tappeh near Beshshahr (1964) and Middle Paleolithic deposits in Mazandaran (1963). In 1969, McBurney also surveyed a number of rock shelters in the Zagros and a Middle Paleolithic rock shelter (Houmian) in Luristan and as well as several caves in the mountains around Mashad, including a very large one at Moghan. Frank Hole (Rice University) and Kent Flannery (University of Michigan) identified a Middle Paleolithic “main component” at Kunji Cave in the Khorramabad Valley, central-west Iran, in 1963. In the 1960s and 1970s, Paleolithic research concentrated in the Zagros region, but shanidar cave (Iraqi Kurdistan), with its rich Mousterian sequence, is still the preeminent site for the general area. Notwithstanding considerable foreign activity, interest in the Paleolithic among Iranian archaeologists has been virtually nonexistent.

Achievements to 1979

One person's periphery is another person's center. By the end of the period from 1959 to 1979 it had become apparent that, far from being peripheral to the development of civilization in western Asia, Iran had played an important part in the Neolithic transition, the development of agriculture and pastoralism, and the development of urbanism. Western and southern Iran had generated polities that had brought about the collapse of the once-mighty Assyrian empire and had gone on to conquer much of western Asia under the Achaemenids, the Parthians, and the Sassanians. In addition, it was now possible to construct a prehistoric chronology for Iran based primarily on internal evidence rather than on parallels to Mesopotamia and other adjacent areas.

Post-Achaemenid Archaeology in Iran

Limited references thus far to the work of Iranian archaeologists belies their overall contribution since much of their work has focused on the post-Achaemenid period. For the Parthian period alone, major excavations have been conducted in the Parthian cemetery at Hamadan (M. Azarnoush, ICAR), in the Anahita temple complex at Kangavar (Sayfollah Khambakhsh-Fard, ICAR), and in the city of Bishapur (Ali Akbar Sarfaraz, IAS). Also worthy of note is the extensive survey of Mazanderan and associated excavations at Qal'eh-i Kharab Shar in the late 1970s by M.Y. Kiani (ICAR).

There have also been several major foreign projects that have focused on the post-Achaemenid period. These include excavation of Shahr-i Qumis (ancient Hecatompylos), occupied in the Parthian, Sassanian, and Islamic periods; a Sassanian fire temple at Takht-i Sulaiman; the sprawling elite Sassanian complex at Qal'eh-i Yazdegird; Sirjan, the late Sassanian and early Islamic capital of Kirman Province and largest city in southern Iran by the tenth century a.d.; Islamic Ghubayra; Siraf, the famous medieval seaport on the Gulf, south of Bushire, with trade connections to India, china, and the eastern Mediterranean; and the rich Islamic site of Tepe Dasht-i- Deh.

Postrevolutionary Archaeology in Iran

Archaeological fieldwork came to a virtual standstill in the decade following the Islamic Revolution. In the early 1990s, work resumed on a moderate scale under the supervision of

Archaeological fieldwork came to a virtual standstill in the decade following the Islamic Revolution. In the early 1990s, work resumed on a moderate scale under the supervision of

PREV NEXT

the Cultural Heritage Organization directed by Serajuddin Kazerouni. Reports have been published in *Guzarishha-yi bastanshinasi* [Archaeological Reports] and *Majalleh-ye Bastanshinasi va Tarikh* [Journal of Archaeology and History], but little has appeared in international journals. The focus of research seems heavily weighted to the Islamic period, but this is hardly a break with earlier patterns, and excavation of both prehistoric and early historic sites has also occurred.

Important projects have been conducted on the citadel mound of the ancient Median capital of Ecbatana at Hamadan (Muhammad Sarraf); at Ziwiyeh (Nosratollah Motamedi); on the Apadana mound at Susa (Mir-Abedin Kabuli); at Shahdad (Kabuli); at the Sassanian site of Borazjan on the Persian Gulf (Ehsan Yaghmaei); in prehistoric mass graves in Luristan (Alireza Farzin); at Tepe Mil, a prehistoric, Sassanian, Seljuk, and Islamic site near Rayy (Zarintaj Sheibani); and in the important Sassanian complex at Kuh-i Khwaja in eastern Seistan. In 1995, the governments of Iran and Germany signed an accord on scientific and cultural cooperation, but assistance on the archaeological front was limited to educational exchanges. Although foreign scholars may visit and study in Iran, foreign archaeological projects remain prohibited.

Isaac, Glyn Llywelyn

(1937-1985)

Born in South Africa, Isaac went to Cambridge University, received his Ph.D. in 1961, and became

the Cultural Heritage Organization directed by Serajuddin Kazerouni. Reports have been published in *Guzarishha-yi bastanshinasi* [Archaeological Reports] and *Majalleh-ye Bastanshinasi va Tarikh* [Journal of Archaeology and History], but little has appeared in international journals. The focus of research seems heavily weighted to the Islamic period, but this is hardly a break with earlier patterns, and excavation of both prehistoric and early historic sites has also occurred.

Important projects have been conducted on the citadel mound of the ancient Median capital of Ecbatana at Hamadan (Muhammad Sarraf); at Ziwiyeh (Nosratollah Motamedi); on the Apadana mound at Susa (Mir-Abedin Kabuli); at Shahdad (Kabuli); at the Sassanian site of Borazjan on the Persian Gulf (Ehsan Yaghmaei); in prehistoric mass graves in Luristan (Alireza Farzin); at Tepe Mil, a prehistoric, Sassanian, Seljuk, and Islamic site near Rayy (Zarintaj Sheibani); and in the important Sassanian complex at Kuh-i Khwaja in eastern Seistan. In 1995, the governments of Iran and Germany signed an accord on scientific and cultural cooperation, but assistance on the archaeological front was limited to educational exchanges. Although foreign scholars may visit and study in Iran, foreign archaeological projects remain prohibited.

Isaac, Glyn Llywelyn

(1937-1985)

Born in South Africa, Isaac went to Cambridge University, received his Ph.D. in 1961, and became

a protégé of louis leakey. During the 1970s Isaac helped desmond clark establish the University of California, Berkeley, as a center for the study of African archaeology. In 1983 he transferred to Harvard University.

Isaac became one of the most significant prehistoric archaeologists of his generation as a result of his brilliant excavation of major sites in East Africa such as olorgesailie, Naivasha, and Peninj and his novel and challenging interpretations of hominid behavior occurring millions of years ago. From 1970 until his early death he was codirector with Richard Leakey of the East Turkana Research Project, which contributed a great deal of new information about fossil hominids and the environments in which they lived. He was also responsible for educating, encouraging, and working with a new generation of African archaeologists from African nations. Isaac died at a tragically young age, very much at the height of his powers.

Island Southeast Asia

This essay includes both prehistoric and historical archaeology. The definition of Island Southeast Asia depends on the distinction between Island Southeast Asia and Mainland Southeast Asia. This definition was made at the Eleventh Pacific Science Congress, held in Tokyo in 1966, and was approved as Resolution 2.2 of the Congress (Solheim 1967a, 2). This resolution presented, for the first time, the terms *Mainland Southeast Asia* and *Island Southeast Asia.* The ad hoc committee of the Anthropology Division of the Congress that submitted this resolution, first to the Anthropology Division and then to the Council of the Pacific Science Association, further presented tentative boundaries as follows: “Mainland Southeast Asia would extend from the thirtieth parallel of latitude (approximately the Yangzi River) to the south as far as Singapore, and from the Irrawaddy River to the South China Sea; Island Southeast would include all the islands off the coast of Mainland Southeast Asia, from Formosa around to the Andaman Islands” (Solheim 1967a, 3; 1967b, 896). As presented and as used here, both terms are capitalized. For the record, the ad hoc committee that developed these terms was made up of Tom Harrisson, R.P. Soejono, and the author.

There was little communication between historical and prehistoric archaeologists working in Southeast Asia until recently. Historical archaeologists have been interested primarily in monumental architecture and art (stone and bronze sculpture in particular) and have done very little excavation. An attempt to bring historians, historical archaeologists, and prehistoric archaeologists together on the transition from prehistoric to historic times in Southeast Asia was the “London Colloquy on Early South East Asia” held in 1973 (Smith and Watson 1979). Until recently, historical archaeologists depended primarily on ancient Chinese records for the interpretation of their finds previous to European contact in the area.

Art history has been an important approach to historical archaeology but, unfortunately, there has also been little communication between archaeologists involved in prehistoric archaeology and art historians. In an attempt to bring art historians and archaeologists together, a symposium on “Early Chinese Art and its Possible Influence in the Pacific Basin” was organized by the Department of Art History and

Archaeology of Columbia University (Barnard 1972). While art historians were saying that Chinese art styles, primarily of late Chou times, were an important influence on Pacific Basin art, in part by way of the spread of Dongson art through Indonesia into the Pacific, archaeologists were pointing out that virtually all of the specific examples presented were earlier in Southeast Asia than in china and that the influence was Southeast Asian rather than Chinese. There was little communication between the two different approaches.

It is not possible to establish a universal periodization for this history as to some extent each country (and even each portion of a country as

large as indonesia) has a different history. The one thing that all these countries share is that the first stage of archaeological study for each was initiated and carried out by foreigners. Only gradually did the original inhabitants of the countries become involved and finally take over, through archaeology, the study of their own past. There is one other element of this history that is shared by all the countries of Island Southeast Asia, and that is that World War II marked the end of the total domination of archaeological research by foreigners. Following the war there was a short period of adjustment when a few new foreigners entered the field and quickly started training local archaeologists. As these countries, except for Brunei and, to a lesser degree, Taiwan, are developing countries, they do not have big budgets for archaeological research. While they are able to locally train archaeologists needed for the jobs available, they need an increase in trained archaeologists to keep up with development and to start covering the whole area of their countries.

Island Southeast Asia is treated here country by country, within three very generalized time periods: pre-World War II, the short adjustment period following the war, and the last thirty-five years of the twentieth century, when local archaeologists became the primary research force.

Colonial Archaeology, 1700-1942

Indonesia

The first archaeological research in Island Southeast Asia, as elsewhere, was the making and recording of surface collections. For Southeast Asia, this continued to be the major source of archaeological data until after World War II. In Island Southeast Asia, as in much of the rest of the world, it was, and still is, widely believed that polished stone artifacts are supernatural objects of extraterrestrial origin, brought to earth through thunder and/or lightening. As a result these ancient stone tools, when discovered, were kept by the finders as amulets for protection against fire started by lightening, for protection of crops in the fields, and for personal protection. Much of the early collections was created by purchasing these artifacts from local farmers and villagers. The earliest-known such collector in Indonesia, who published data on his collections, was G.E. Rumphius (1705; Soejono 1969, 68-69; Solheim 1969a, 31-32).

Soejono (1969, 70-73) lists a number of collectors who published on polished adzes, bronze drums and weapons, megalithic and cave sites, human skeletal remains, and ancient beads during the nineteenth and early twentieth centuries. (*See* Soejono 1969, 70-73 for details on this work.) Heine-Geldern (1945, 129) states that "the first systematic excavation of a prehistoric site ever to be undertaken in the Archipelago…. was that of the Toala Caves in Southwest Celebes by Paul and Fritz Sarasin in 1902." A major event was the discovery of the *Pithecanthropus* skull cap in Trinel, Java, by eugene dubois in 1891. Between 1907 and 1908 a follow-up German expedition, led by Frau L. Selenka, searched in Trinel but found nothing else. Soejono also said:

During the first quarter of the twentieth century, intensive studies were done in cave cultures, kettledrums, and the Megalithic culture.... It was suggested that the megalithic tradition was introduced by peoples of the Mediterranean; differing racial groups were assumed to be the producers of the different cave cultures; and ancient beads were thought to have an interconnection with regions in Asia and the Mediterranean. The Archaeological Service,…. however, did not pay much attention to drums, caves, megaliths, or beads, as its greatest concern was the survey and preservation of "Hindu-Javanese" movements. The existence of a prehistoric stage preceding the Hinduized cultural level was still a matter of obscurity.

(1970, 12-13)

Historical archaeology had its beginnings almost as early as prehistoric archaeology, but in the form of

written references to historic sites rather than collections of artifacts. In 1733 a Dutch official mentioned the Prambanan temples, which he had visited, in his diary, and toward the end of the eighteenth century F. von Boekholz described them in detail. In 1805 J.H. Cornelious was ordered by the Dutch administrator to explore them (Soekmono 1969, 93).

The existence of a prehistoric stage preceding the Hinduized cultural level was still a matter of obscurity.

(1970, 12-13)

Historical archaeology had its beginnings almost as early as prehistoric archaeology, but in the form of

written references to historic sites rather than collections of artifacts. In 1733 a Dutch official mentioned the Prambanan temples, which he had visited, in his diary, and toward the end of the eighteenth century F. von Boekholz described them in detail. In 1805 J.H. Cornelious was ordered by the Dutch administrator to explore them (Soekmono 1969, 93).

World War II, but was finally able to publish it in 1959.

East Malaysia and Brunei

The early period of random finds in Sarawak, Brunei, and Sabah produced very little. “It did include, however, a time of world attention on Sarawak in the late 1870s when exploration of Sarawak caves and the Great Cave at Niah, in particular, was sponsored by Darwin, Huxley, and Wallace (Harrisson 1958, 550-560; 1970, 19) in an attempt to find the so-called 'missing link' in the evolution of man” (Solheim, et al. 1985, 12). “The reported results were that 'cave deposits of this part of Borneo are wholly without interest except to local naturalists'” (Solheim 1983, 35). This survey did, however, establish that there were cave and open sites with prehistoric and early historic remains, not only at Niah but also at the Bau Caves in southwestern Sarawak and at Santubong, at the mouth of the Kuching River (Harrisson 1954, 1958; Harrisson and O'Connor 1969, 3-6; Solheim 1961). No reports on these findings were published.

Banks, as an early curator of the Sarawak Museum, published a few descriptions of prehistoric artifacts he came across in Sarawak, and Ivor Evans, in what was then British North Borneo, did the same for North Borneo (1913, 154-158; 1922).

Philippines

There are several publications on the history of Philippine archaeology (Beyer 1947; Evangelista 1969; Solheim 1952a, 1953, 1968). This history refers primarily to the articles by Evangelista and Solheim (1968).

The one true archaeological survey during the nineteenth century was done by Frenchman Alfred Marche. In 1881 he made a systematic survey, primarily of cave sites, on two of the central Visayan Islands, the more important being of Marinduque. He published a travel account of this in French (1887), which has been translated into English (1970). Most of his collections are now in the Musée de l'Homme in Paris, while a few artifacts are in the Museum of Madrid. A brief article was published on a few of the wood carvings in the Musée de l'Homme that he had recovered (Solheim and Gaynor 1978).

“Caves and open sites were casually explored in several localities in the Philippines by Feodor Jagor in 1860, J. Montano and Paul Rey from 1878-1881, and by Jose Rizal, Filipino national hero, and his party, in 1894. However, nothing significant resulted from these investigations” (Evangelista 1969, 99). Following Rizal's activities in Mindanao, until 1921 there was no further known archaeological activity. In 1921 henry otley beyer started gathering data on possible prehistoric finds. Up until this time it was believed that no “stone age” had existed in the Philippines.

From 1922 to 1924 Carl Guthe led an archaeological survey program, primarily in the Visayan Islands, on behalf of the University of Michigan. He had a boat to work from and as the result of about 15,000 miles of travel by sea and land about thirty-one tons of artifacts from 542 sites had been collected. He had been instructed to make only surface collections, but he was unable to follow these instructions at all times and, as a trained archaeologist, he made small test excavations at a few prehistoric sites. The expedition was focused on locating sites with Chinese and Southeast Asian porcelains and stonewares. Guthe published only three short reports on the expedition (1927, 1934, 1937; Solheim 1964a, 3).

Beyer, the father of Philippine anthropology and archaeology, first came to the Philippines in 1905 as a government ethnographer. He had no training in archaeology when he became interested in the prehistory of the Philippines. He did no fieldwork in archaeology before 1926. In late 1925 he was preparing to return to the United States to join the Department of Anthropology at Harvard when he fell

and broke his leg. While he was recuperating, work on the dam and reservoir at Novaliches, to provide water for Manila, began and archaeological sites were discovered. When he was able he went to visit the sites and thereupon decided to forgo Harvard and organize excavation at Novaliches (Solheim 1969b).

Beyer was not a trained archaeologist and his methods were self taught, based on common

World War II, but was finally able to publish it in 1959.

East Malaysia and Brunei

The early period of random finds in Sarawak, Brunei, and Sabah produced very little. “It did include, however, a time of world attention on Sarawak in the late 1870s when exploration of Sarawak caves and the Great Cave at Niah, in particular, was sponsored by Darwin, Huxley, and Wallace (Harrisson 1958, 550-560; 1970, 19) in an attempt to find the so-called 'missing link' in the evolution of man” (Solheim, et al. 1985, 12). “The reported results were that 'cave deposits of this part of Borneo are wholly without interest except to local naturalists'” (Solheim 1983, 35). This survey did, however, establish that there were cave and open sites with prehistoric and early historic remains, not only at Niah but also at the Bau Caves in southwestern Sarawak and at Santubong, at the mouth of the Kuching River (Harrisson 1954, 1958; Harrisson and O'Connor 1969, 3-6; Solheim 1961). No reports on these findings were published.

Banks, as an early curator of the Sarawak Museum, published a few descriptions of prehistoric artifacts he came across in Sarawak, and Ivor Evans, in what was then British North Borneo, did the same for North Borneo (1913, 154-158; 1922).

Philippines

There are several publications on the history of Philippine archaeology (Beyer 1947; Evangelista 1969; Solheim 1952a, 1953, 1968). This history refers primarily to the articles by Evangelista and Solheim (1968).

The one true archaeological survey during the nineteenth century was done by Frenchman Alfred Marche. In 1881 he made a systematic survey, primarily of cave sites, on two of the central Visayan Islands, the more important being of Marinduque. He published a travel account of this in French (1887), which has been translated into English (1970). Most of his collections are now in the Musée de l'Homme in Paris, while a few artifacts are in the Museum of Madrid. A brief article was published on a few of the wood carvings in the Musée de l'Homme that he had recovered (Solheim and Gaynor 1978).

“Caves and open sites were casually explored in several localities in the Philippines by Feodor Jagor in 1860, J. Montano and Paul Rey from 1878-1881, and by Jose Rizal, Filipino national hero, and his party, in 1894. However, nothing significant resulted from these investigations” (Evangelista 1969, 99). Following Rizal's activities in Mindanao, until 1921 there was no further known archaeological activity. In 1921 henry otley beyer started gathering data on possible prehistoric finds. Up until this time it was believed that no “stone age” had existed in the Philippines.

From 1922 to 1924 Carl Guthe led an archaeological survey program, primarily in the Visayan Islands, on behalf of the University of Michigan. He had a boat to work from and as the result of about 15,000 miles of travel by sea and land about thirty-one tons of artifacts from 542 sites had been collected. He had been instructed to make only surface collections, but he was unable to follow these instructions at all times and, as a trained archaeologist, he made small test excavations at a few prehistoric sites. The expedition was focused on locating sites with Chinese and Southeast Asian porcelains and stonewares. Guthe published only three short reports on the expedition (1927, 1934, 1937; Solheim 1964a, 3).

Beyer, the father of Philippine anthropology and archaeology, first came to the Philippines in 1905 as a government ethnographer. He had no training in archaeology when he became interested in the prehistory of the Philippines. He did no fieldwork in archaeology before 1926. In late 1925 he was preparing to return to the United States to join the Department of Anthropology at Harvard when he fell

and broke his leg. While he was recuperating, work on the dam and reservoir at Novaliches, to provide water for Manila, began and archaeological sites were discovered. When he was able he went to visit the sites and thereupon decided to forgo Harvard and organize excavation at Novaliches (Solheim 1969b).

Beyer was not a trained archaeologist and his methods were self taught, based on common

sense and a very organized mind. His methods would not be considered “good” archaeology today, and criticism in the Philippines has tossed out most of his conclusions. However the generalizations he made, without presenting the data on which he based them, were on the whole quite accurate. His reconstructions of “waves of migration” have been shown to be most unlikely, but the dating for these waves and the areas from which he said they came match very well the times and areas with which contact has been hypothesized. His 1947 publication presents a very detailed history of archaeological finds in the Philippines.

In 1940 Olov R.T. Janse came to the Philippines from Vietnam to see if there were Dongson connections between the two areas. Thinking that Beyer was an amateur collector he did not work through him, and as a result found nothing of interest (Janse 1941, 1944, 1946). During World War II Beyer was not interned until the final six months of the war due to the intercession of Tadao Kano, a Japanese archaeologist in charge of museums in the Philippines. While he was unable to do any fieldwork during this time, he did much research and writing.

Taiwan

Probably the best history of Taiwan archaeology was one by Takeo Kanaseki and Naoichi Kokubu (1950). Written in Japanese, it was translated into Chinese. A brief history of Taiwan archaeology by Wu (1969) is the primary source for this article.

Archaeological research in Taiwan has not followed the trajectory that it did in the other Southeast Asian countries because the traditions that developed in Taiwan were the result of Japanese colonialism rather than western colonialism. Archaeology developed in close relationship with ethnology and the early Japanese focus in archaeological research was to relate the ethnic groups that were being studied at the time with prehistoric cultures. There are few if any reports suggesting any archaeological activities in Taiwan before the Japanese occupation began there in 1895.

There was very little communication between Japanese and western archaeologists until after the end of World War II. All publications on the archaeology of Taiwan were in Japanese or Chinese, resulting in an almost complete ignorance in the western world of what went on in Taiwan prehistoric research until well after the end of World War II. The first effective contact between Taiwan archaeology specialists and western archaeologists was in 1953 at the Eighth Pacific Science Congress and the Fourth Far-Eastern Prehistory Congresses Combined, held in Manila, where both Chinese and Japanese archaeologists from Taiwan took part.

Reports on archaeological subjects started appearing immediately in 1895 in the form of field notes that appeared in the Japanese archaeological journal *Zenruiqaku Zasshi*. “Three kinds of work may be distinguished among the sources: (1) Simple field notes, which include travel reports, site reports, and the description of artifacts; (2) Reports on excavations; and (3) Interpretations, which include theoretical analyses of data, discussions on the relationship between artifacts and the peoples, and discussions on the connections between Taiwan and other areas” (Wu 1969, 106).

In early 1897 Moshinori Ino and others discovered the Yuan-shan shell mound, one of the most important sites in Taiwan. Ino was an ethnographer and was the first to report impressed geometric decoration on pottery of the Ping-pu ethnic group, a kind of pottery latter found in archaeological sites. “He was the first person to carry out excavations in Peng-hu Island, and found that prehistoric communication existed between Taiwan and the Ryukyus and between Taiwan and Micronesia” (Ino 1907a, 1907b; Wu 1969, 106).

Ryuzo Torii presented the idea that the Yuan-shan culture might be related to a non-Taiwan culture

(1897a). He was the first person to report the existence of the site of Pei-nan on the southeast coast of Taiwan (1897b), now the location of the largest excavation yet made in Taiwan. He also pointed out that there were prehistoric sites in the mountainous interior of Taiwan (1900). Torii authored one of the most important excavation reports of this early period (1911), and in his last paper (1926) he presented the first report on the megalithic culture in Taiwan.

PREV NEXT

It is not known under what authority or what source of funding this archaeological research took place. Wu has stated, however, that "a new trend, conducting organized excavations, had developed for the study of Formosan prehistory after the establishment of the Lecture Room of Folklore and Ethnology, Taihoku Imperial University" (1969, 107). Apparently, from about 1929 both authority and funding came through the Imperial University. New professional archaeologists became prominent in the field from this time. The most important of these were A. Matsumura, Takeo Kanaseki, Naoichi Kokubu, and Tadao Kano.

In about 1927 Matsumura discovered the Ken-ting site at the southern tip of Taiwan. Excavations were undertaken there in 1930, but other than brief preliminary papers, no final reports were published. In 1929 Kano listed 151 prehistoric sites that had been discovered and reported previous to that time. Many more were discovered in following years but little was published by other than those mentioned. The information on these sites comes from the Kanaseki and Kokubu report (1950). Kano was the most active, continuing fieldwork and publication until 1943, at which time he was moved by the Japanese military government to the Philippines to be in charge of the museums there. He worked closely with Beyer and informed him of Taiwan prehistory so that in later publications Beyer was the only English-writing archaeologist to be able to include data on Taiwan prehistory.

Adjustment Years, 1942-1959

Taiwan was the only country in Island Southeast Asia where fieldwork continued during World War II. In all the other countries fieldwork came to a virtual standstill with the beginning of the Japanese invasions. Unlike the abrupt beginning of this period at the end of the war, the ending varied for each country and was gradual in most cases. The year 1959 is an approximate average.

Indonesia

R. Soekmono, the director of the National Archaeological Institute of Indonesia in 1968, had this to say about the Dutch Archaeological Service after the end of World War II:

When the Dutch came back to Indonesia after World War II and found that the Archaeological Service had become an institution of the Republic of Indonesia, they established another archaeological service that was staffed with the expert personnel of the prewar period, but it lacked the needed resources. It was not until 1950 that the Archaeological Service became united again with its branches at Prambanan and Bali. Since then it has functioned normally under the direction of Professor Bernet Kempers.

(Soekmono 1969, 96)

Prehistoric research continued during the Japanese occupation, but at a much reduced pace. W. Rothpletz made a survey of the Bandung hill region in West Java, his report on which was published after the war (1951), as was the report by Bandi (1951) on the Bandung obsidian artifacts.

H. R. van Heekeren was the only prehistorian working with the Archaeological Service after the war. During the war he was a Japanese prisoner of war working on the Thai-Burma railroad, where he made archaeological discoveries. He returned to work in Indonesia in 1946, doing fieldwork in Central and South Sulawesi until the early 1950s on Paleolithic sites (1949a), Toala sites (1949b), and at Kalumpang (1950). D.A. Hooijer, the paleontologist, examined animal remains recovered by van Heekeren (1949). Van Heekeren continued working for the Archaeological Service until 1956, when he returned to the netherlands. He excavated in caves on Flores (1958b), on Patjitan sites in Java (1955a), in sites with stone sarcophagi in Bali (1955b), and urn burial sites in Java (1956b) and East Sumba (1956a).

The three generalized periods of archaeological activity in this region vary a bit for Sarawak because of one man, Tom Harrisson. Although he had visited Sarawak in the 1930s, his archaeological work there started after World War II, in 1947, and continued until his retirement in

It is not known under what authority or what source of funding this archaeological research took place. Wu has stated, however, that "a new trend, conducting organized excavations, had developed for the study of Formosan prehistory after the establishment of the Lecture Room of Folklore and Ethnology, Taihoku Imperial University" (1969, 107). Apparently, from about 1929 both authority and funding came through the Imperial University. New professional archaeologists became prominent in the field from this time. The most important of these were A. Matsumura, Takeo Kanaseki, Naoichi Kokubu, and Tadao Kano.

In about 1927 Matsumura discovered the Ken-ting site at the southern tip of Taiwan. Excavations were undertaken there in 1930, but other than brief preliminary papers, no final reports were published. In 1929 Kano listed 151 prehistoric sites that had been discovered and reported previous to that time. Many more were discovered in following years but little was published by other than those mentioned. The information on these sites comes from the Kanaseki and Kokubu report (1950). Kano was the most active, continuing fieldwork and publication until 1943, at which time he was moved by the Japanese military government to the Philippines to be in charge of the museums there. He worked closely with Beyer and informed him of Taiwan prehistory so that in later publications Beyer was the only English-writing archaeologist to be able to include data on Taiwan prehistory.

Adjustment Years, 1942-1959

Taiwan was the only country in Island Southeast Asia where fieldwork continued during World War II. In all the other countries fieldwork came to a virtual standstill with the beginning of the Japanese invasions. Unlike the abrupt beginning of this period at the end of the war, the ending varied for each country and was gradual in most cases. The year 1959 is an approximate average.

Indonesia

R. Soekmono, the director of the National Archaeological Institute of Indonesia in 1968, had this to say about the Dutch Archaeological Service after the end of World War II:

When the Dutch came back to Indonesia after World War II and found that the Archaeological Service had become an institution of the Republic of Indonesia, they established another archaeological service that was staffed with the expert personnel of the prewar period, but it lacked the needed resources. The three generalized periods of archaeological activity in this region vary a bit for Sarawak because of one man, Tom Harrisson. Although he had visited Sarawak in the 1930s, his archaeological work there started after World War II, in 1947, and continued until his retirement in

1967. His research on Sarawak archaeology continued from a distance until 1975 and was published, after his death, in early 1976 (Solheim and Jensen 1977). His primary activities, as the Director of the Sarawak Museum in Kuching, were at Santubong, near Kuching, and at the Niah Caves, far to the northeast.

Harrisson's first indicated interest in Sarawak archaeology started in 1946 or 1947 when he was still with the British military (Solheim 1977a, 4). He was involved in the mapping of iron deposits at Santubong using military mine detectors and trained military personnel. When he visited the Niah Caves in 1947 to check on birds-nest collecting he noted possible prehistoric material there. Actual excavation started in the Bao Caves in 1949, not so much for the data to be obtained but as part of the training of future Sarawak Museum staff and of Harrisson himself. Harrisson, with no archaeological training himself, brought in Michael Tweedie, the Director of the Raffles Museum in Singapore, to provide the archaeological background (Harrisson and Tweedie 1951).

Excavations at six main sites in Santubong were the main training in archaeology for both Harrisson and the Sarawak Museum staff. Santubong had been known since the nineteenth century for stray finds of gold ornaments, stone and glass beads and bracelets, porcelains and stone wares, and a large quantity of iron slag. Common Chinese coins dated between a.d. 976 and 984. “The first Santubong digging was in 1949 and the first excavation in 1952. The Santubong archaeology through 1956 could be considered the completion of the training period of Sarawak archaeology” (Solheim 1983, 36-37). Harrisson published on a wide variety of archaeological subjects, based primarily on library research, during this period (Solheim and Jensen 1977).

The primary site in Brunei to date is Kota Batu (two miles from Brunei town), the location of the first Brunei Sultanate capital, with beginnings well before Islam came to the area. Tom Harrisson started looking over the area in 1951, did some testing in 1952, and, with Barbara Harrisson, made a preliminary excavation in 1953 (Harrisson and Harrisson 1956).

Philippines

Much of Beyer's valuable archaeological and ethnological library in his two houses in Ermita was destroyed during the battle of Manila. While he was able to save most of the ethnographic collections of the National Museum during the battle, the section of the museum where the archaeological collections were stored was gutted, the shelves and cabinets burned, and the artifacts deposited in a midden up to two meters deep on the basement floor. Beyer's office in a building near the palace was not hurt, so a portion of his library and collections were saved (Solheim 1969b, 12). Following the hostilities he completed the writing of his two major archaeological reports on the Philippines, published in 1948. Most of his collaborators were gone and he had lost contact with most of his collectors in the provinces so there was no field activity until 1950. In 1953 the Philippines hosted the Eighth Pacific Science Congress and Beyer organized the Fourth Congress of Far Eastern Prehistorians, held jointly. This was a major event in Southeast Asian and Pacific archaeology (*see* Indo-Pacific Prehistory Association).

Solheim came to the Philippines in late 1949 and spent a month in the field in 1950 excavating in a jar burial site on the Bondok Peninsula in southern Tayabas, southeast of Manila (Solheim 1951). In 1951 and 1953 Solheim was again in the field with several Filipino archaeology students, surveying and excavating on Masbate (Solheim 1954, 1968). In 1951 the first survey and excavation was of Batungan Mountain in Masbate, one of the small Visayan Islands. Several cave and rock shelter sites were tested and pottery similar to the earliest pottery in Micronesia was recovered from two sites. From other sites, pottery was discovered that was similar to the pottery from the Kalanay Cave Site. From one of these sites the first C-14 dating in the Philippines was done, giving a date of 2,710±100 years ago (L274)

(Solheim 1968). The excavation of the Kalanay Cave site on Masbate, in combination with the study of the earthenware pottery recovered by Guthe in the 1920s, led to the presentation of the Kalanay Pottery Complex in the Philippines (Solheim

1957c, 1964c), and later to the Sa-huynh-Kalanay Pottery Tradition, found widely in Island Southeast Asia and Vietnam (1959a, 1967c). In addition, proposed in the 1964 publication was the Bau-Malay Pottery Tradition, also found widely in Island and Mainland Southeast Asia (1959b, 1967d). In 1952 Solheim surveyed on Fuga Island, one of the Babuyan Islands just north of Luzon, and found several burial jar sites. In 1953 he made a small excavation of a burial jar on Batan Island, in the Batanes Islands north of the Babuyan Islands. The Fuga and Batan burial jars led to a summary article on burial jars in Island Southeast Asia (Solheim 1960).

Robert Fox completed his Ph.D. in cultural anthropology at the University of Chicago, but when he returned to the Philippines he became involved in archaeology. The three primary areas of exploration, excavation, and publication undertaken by Fox were at Calatagan, Batangas, the Tabon Caves in Palawan, and the Cagayan Valley of northern Luzon. As the chairman of the Department of Anthropology of the National Museum for many years Fox was involved in much more than those areas. In 1956 Fox and Evangelista surveyed and made small excavations in two jar burial sites in Sorsogon and Albay Provinces on the Bicol Peninsula (Fox and Evangelista 1957a, 1957b).

The Calatagan peninsula is at the very southwestern tip of Batangas Province, about 100 kilometers south of Manila. It was known that fourteenth- and fifteenth-century porcelains had been found there in the 1930s and some small excavations had been made by Janse in 1940 and Solheim in 1952 through 1953. Major excavations of several extensive burial sites were started by Fox in 1958 and a report was published in 1959. A description of the Calatagan earthenware pottery was published in 1982 (Main and Fox 1982). More details can be found in the Philippine section of *Asian Perspectives* Volumes 1 through 3 (1957-1959).

Taiwan

The transition period saw a change in the archaeologists in Taiwan from Japanese to Chinese. No fieldwork of note happened after the end of World War II until 1949 when Professor li chi founded the Department of Archaeology and Anthropology. While the department was active in research on the prehistory of the mainland, the group of eminent Chinese archaeologists that had moved from the mainland and were either with the university department or with Academia Sinica were not greatly interested in Taiwan's archaeology.

The first change appears to have developed as a result of the number of Chinese and Japanese archaeologists and cultural anthropologists who took part in the Eighth Pacific Science Congress and Fourth Far-Eastern Prehistory Congress held in Manila in 1953. As noted by Beyer (1956, 271-272) in the proceedings of the Congress, the five papers presented on Formosan archaeology were all by Japanese archaeologists. Shortly after the Congress Beyer received two letters from Li Chi telling him of two newly started excavations undertaken by the Department of Archaeology and Anthropology in Taiwan.

The first general knowledge of Taiwan prehistory among non-Chinese reading archaeologists came with a short article by kwang-chi chang (1956). Chang edited a much more ambitious review of the archaeology of Taiwan in 1963, which presented a foundation for the real beginning of Taiwan archaeological research by Chinese in Taiwan. This review included a site report on Tap'enk'eng by Pin-hsiung Liu of excavations made in 1962. The review provided the launching platform for a rejuvenated and reoriented program of Taiwan archaeology.

Local Archaeologists Take Over

In the 1960s local archaeologists gradually took over archaeological research in most of the countries of

Southeast Asia. The training of local archaeologists was a major problem for all countries and the solution varied from country to country. None of the countries had a sufficient number of archaeologists to even approach extensive coverage for the total area of their country. Publication was and is another major problem, with the tradition of publishing final reports on excavated sites not yet established in Southeast Asia. Those reports that are

1957c, 1964c), and later to the Sa-huynh-Kalanay Pottery Tradition, found widely in Island Southeast Asia and Vietnam (1959a, 1967c). In addition, proposed in the 1964 publication was the Bau-Malay Pottery Tradition, also found widely in Island and Mainland Southeast Asia (1959b, 1967d). In 1952 Solheim surveyed on Fuga Island, one of the Babuyan Islands just north of Luzon, and found several burial jar sites. In 1953 he made a small excavation of a burial jar on Batan Island, in the Batanes Islands north of the Babuyan Islands. The Fuga and Batan burial jars led to a summary article on burial jars in Island Southeast Asia (Solheim 1960).

Robert Fox completed his Ph.D. in cultural anthropology at the University of Chicago, but when he returned to the Philippines he became involved in archaeology. The three primary areas of exploration, excavation, and publication undertaken by Fox were at Calatagan, Batangas, the Tabon Caves in Palawan, and the Cagayan Valley of northern Luzon. As the chairman of the Department of Anthropology of the National Museum for many years Fox was involved in much more than those areas. In 1956 Fox and Evangelista surveyed and made small excavations in two jar burial sites in Sorsogon and Albay Provinces on the Bicol Peninsula (Fox and Evangelista 1957a, 1957b).

The Calatagan peninsula is at the very southwestern tip of Batangas Province, about 100 kilometers south of Manila. The review provided the launching platform for a rejuvenated and reoriented program of Taiwan archaeology.

Local Archaeologists Take Over

In the 1960s local archaeologists gradually took over archaeological research in most of the countries of

Southeast Asia. The training of local archaeologists was a major problem for all countries and the solution varied from country to country. None of the countries had a sufficient number of archaeologists to even approach extensive coverage for the total area of their country. Publication was and is another major problem, with the tradition of publishing final reports on excavated sites not yet established in Southeast Asia. Those reports that are

published are usually preliminary reports, with very little detail.

Andaman Islands

The first archaeological work to be done in the Andaman Islands was by P.C. Dutta (1962) in 1959-1960. In 1985 Zarine Cooper located thirty-nine shell middens and excavated in some of these. Her first report was primarily concerned with the sites and the second (Cooper and Raghavan 1989) with the pottery recovered.

Indonesia

Peter Bellwood has published two different books that review the prehistory of Island Southeast Asia. The first of these (1978, 203-232) is a brief summary while the second (1985) is a detailed and lengthy account; however, both of these were the first coverage of Island Southeast Asian prehistory as a whole.

Bellwood and I.M. Sutayasa started a program of research in northern Sulawesi and the Talaud Islands, a string of islands running between eastern Mindanao in the Philippines and Sulawesi. The sites they discovered and reported (Bellwood 1976, 1980) date from 6000 b.c. to the present. The late-prehistoric to early-historic pottery reported showed a close relationship to pottery in the Philippines.

The first program of archaeological research in eastern Indonesia started in Irian Jaya in 1975, when Solheim began a one-year program of survey and excavation in coastal Irian Jaya, primarily on islands in Cenderawasih Bay, Waigeo, off the western tip of the Vogelkop, and east and west from Kaimana on the south coast. This program continued in 1990 with the testing of a site near Sorong on the north coast of the Vogelkop and a survey on Ternate and northwestern Halmahara in the Moluccas. In 1990 Bellwood started a program on Morotai, the most northerly of the Moluccas Islands. In 1992 the University of Hawaii, jointly with Universitas Pattimura on Ambon and the National Research Center of Archaeology, started a long-term program in the Moluccas. The program includes archaeological survey and excavation on the islands of Buru, Seram, and Ambon, under the direction of Bion Griffin of the Department of Anthropology, University of Hawaii.

In 1993 Irian Jaya Studies, a priority program of the Netherlands Organization for Scientific Research, started a long-term program of research of the Vogelkop (Birdshead) of Irian Jaya. Included in that multidisciplinary project is an archaeological survey and excavation under the direction of Gert-Jan Bartstra.

Much of the archaeological publication during the Dutch governance of Indonesia was in Dutch. As the Lembaga Purbakala dan Peninggalan Nasional and now the Pusat Penelitian Arkeologi Nasional (National Research Center of Archaeology) took over responsibility for archaeological research, most of their reports were published in Indonesian with only general surveys published in English. To keep up with Indonesian archaeology it is necessary to read Indonesian, which I do not do. Very kindly John Miksic has summarized the recent history of archaeology of Indonesia for me. Miksic taught archaeology for several years at Gaja Mada University in Yogyakarta and is now with the Department of History, Singapore National University. I present his paper in its original form, with thanks.

Indonesian Archaeology, 1957-1994

Archaeological research in Indonesia was practically dormant during the late 1950s and 1960s, as Indonesia experienced political turbulence. The most important research conducted in the 1960s was that of R.P. Soejono at Gilimanuk in western Bali, a large site containing many late prehistoric burials. Excavations were undertaken in 1963, 1964, 1973, and 1977. In 1977 Soejono obtained his Ph.D. in archaeology with a dissertation on late prehistoric burial sites in Bali. Gilimanuk occupied a major

portion of this study, along with the sites of stone sarcophagi.

The tempo of archaeological research picked up in the 1970s, particularly after 1975, when administrative restructuring transformed the old system inherited from the Dutch of a single institution in charge of both research and conservation. Research became the sole responsibility of the newly formed National Research

published are usually preliminary reports, with very little detail.

Much of the archaeological publication during the Dutch governance of Indonesia was in Dutch. As the Lembaga Purbakala dan Peninggalan Nasional and now the Pusat Penelitian Arkeologi Nasional (National Research Center of Archaeology) took over responsibility for archaeological research, most of their reports were published in Indonesian with only general surveys published in English. To keep up with Indonesian archaeology it is necessary to read Indonesian, which I do not do. Very kindly John Miksic has summarized the recent history of archaeology of Indonesia for me. Miksic taught archaeology for several years at Gaja Mada University in Yogyakarta and is now with the Department of History, Singapore National University. I present his paper in its original form, with thanks.

Indonesian Archaeology, 1957-1994

Archaeological research in Indonesia was practically dormant during the late 1950s and 1960s, as Indonesia experienced political turbulence. The most important research conducted in the 1960s was that of R.P. Soejono at Gilimanuk in western Bali, a large site containing many late prehistoric burials. Excavations were undertaken in 1963, 1964, 1973, and 1977. In 1977 Soejono obtained his Ph.D. in archaeology with a dissertation on late prehistoric burial sites in Bali. Gilimanuk occupied a major

portion of this study, along with the sites of stone sarcophagi.

The tempo of archaeological research picked up in the 1970s, particularly after 1975, when administrative restructuring transformed the old system inherited from the Dutch of a single institution in charge of both research and conservation. Research became the sole responsibility of the newly formed National Research

of Borobudur, which was eventually completed in 1983. Other significant long-term projects were conducted in Trowulan, East Java, between 1976 and 1990 (fifteen years), and Banten Lama, West Java (1976-1985).

In the research strategy adopted for Trowulan, the center carried out a surface survey of an area 10 kilometers by 10 kilometers. The center's historical archaeologists then conducted excavations in several sectors: the Pendopo Agung (“Great Pavilion”), Pandan Sili, Klinterejo, Sentonorejo, Nglinguk, Sumurupas, Kejagan, Kedaton, Batok Palung, Wringin Lawang, and Blendren. Large quantities of artifacts were recovered, along with data on architecture, including nonreligious buildings. This site, the probable capital of the kingdom of Majapahit (thirteenth to sixteenth centuries) has been identified as the largest precolonial urban site in Indonesia.

Research has also been conducted sporadically in Sumatra. A branch office of the center has finally been established in Palembang, south Sumatra, and data are gradually accumulating on the kingdom of Srivijaya that was based there during the seventh to eleventh centuries (Manguin 1992), as well as later periods during which the site continued to be occupied. Other sites, including a trading post of the eleventh to thirteenth centuries at Kota Cina, north Sumatra, and a large complex of monuments at Muara Jambi of approximately the same period have also been investigated.

Research at the site of Banten Lama in West Java began in 1976 and continued for ten years. Banten continues the urban history of Indonesia from Trowulan, late classic period, into the early Islamic era. Excavation and survey here has succeeded in identifying units of activity within the site, including residential and occupational zones.

At all these sites, the work of analysis continues long after the excavations have been completed. Urban archaeology in Indonesia has made a promising beginning. Systematic surveys using standard sampling techniques are now employed, and there is reason to expect that the history of early complex society in Indonesia may soon become clearer.

Epigraphy, one of Indonesian archaeology's oldest subdisciplines, has contributed some important new information despite the small number of specialists in the field. Boechari, before his untimely death, contributed important new readings of Sumatran and Javanese inscriptions, as has Sukarto Kartoatmojo. J.G. de Casparis continues to add to his astounding output of valuable translations in a multitude of languages and scripts, facilitated by his incomparable experience in both South and Southeast Asia. In addition to new information provided by reading inscriptions discovered before 1957, new inscriptions continue to be found. One of the most important is the Wanua Tengah III inscription of a.d. 908. Discovered in November 1983 in Temanggung, Central Java, the find consists of two copper plates issued by King Balitung. The plates give a king list, the second of whom is said to have taken the throne in a.d. 746.

In the realm of spectacular discoveries, the Wonoboyo Hoard must assume a prominent place. In 1991 in this village near the site of the great Hindu complex of Prambanan, central Java, local residents discovered an enormous deposit of gold items, including coins and various other objects including jewelry and ritual accessories. The weight of gold recovered exceeds 30 kilograms. Although much gold of the Classic period is held in private and museum collections, this is by far the largest and best documented discovery. The fact that the gold was properly reported and delivered safely to the National Museum is an excellent indication of the level of awareness of modern Indonesians regarding the importance of archaeological studies and the pride that most Indonesians feel for their heritage.

John Miksic

Tom Harrisson continued as director of the Sarawak archaeology program for another ten years, having developed a much more ambitious program and a number of well-trained staff. The major program under way was the exploration and excavation of the Niah Caves (Harrisson, T. 1957, 1958, 1959). While he published many papers, very few of these were site reports, and the two that could be so considered were done with Barbara Harrisson (Harrisson and Harrisson 1957; Harrisson, T., 1968). For Niah, Barbara Harrisson(1958, 1965, 1967, 1977a) published more substantive reports than Tom Harrisson.

While one questionable date of 95 b.c. was reported, the body of the dates was between a.d. 600 and 1300. Tom Harrisson was one of the pioneers in Southeast Asia in the study of beads. He summarized a number of these papers in a report (1973) comparing the beads recovered in Brunei to those that had been recovered in Sarawak.

Because of peaty soil and a high water table, much organic material, including wood, has been preserved in the Kota Batu site, the only such archaeological site known in Southeast Asia. Tom Harrisson (1974) reported on the wood remains excavated the first season at Kota Batu. He divided his subject into five parts: tree wood-1,577 pieces, coconut shell-399, other “nuts”-42, dammar (resin)-1,103, and charcoal-2,232. The tree wood included whole or partial: trays, bowls, and covers-16; dishes or wheels-6; kitchen utensils-11; tools for splitting or securing wood-8; spinning and weaving apparatus-17; fishing gear and boat parts-6; and toys-3 (8-10) The richness of this material from the small test excavation points to the wealth of the material that can be recovered when extensive excavations are made.

A site on the Tanjong Batu beach, the northeastern tip of Brunei, sixteen miles from Bandar Seri Begawan, the capital of Brunei, was discovered in 1974. A total of 199 primarily basal shards of small bowls were recovered, suggesting the possibility of a nearby shipwreck (Omar 1975). The shards were all considered to be Sung period (a.d. 917-1279), making them earlier than the great majority of the ceramics at Kota Batu and Sungai Lumut. Museum staff continued inspecting the site regularly and late in 1975 they discovered a polished stone adze, the first to be found in Brunei. Within days after this first discovery three more stone tools were turned over to the museum. All three of these were from the same area and had been found at about the same time as the first one (Omar and Shariffuddin 1976).

A new site, Kupang, was excavated by Omar and resulted in his M.A. thesis (1978). Unfortunately it has not been published; it appears to have been an important report for its treatment of the locally made earthenware. A brief report on the earthenware is included in an article on trade patterns between Brunei and neighboring areas from a.d. 700 to 1500 (Bellwood and Omar 1980). The site was first occupied around a.d. 750 according to C-14 dating. The earthenware is very similar to that reported by Solheim (1965a) from Tanjong Kubor in Sarawak. Bellwood and Omar name this pottery complex Tanjong Kubor (TK) ware. While they agree with Solheim that the TK ware is similar to pottery excavated in Cebu City in the Philippines, at Johore Lama in southern Malaysia near Singapore, and reported from Hong Kong, they do not go along with Solheim's calling this Bau-Malay and saying that it is found widely from about a.d. 700 up to the recent past in Island Southeast Asia, including the central and southern Philippines.

Philippines

Robert Fox continued as the primary archaeologist in the Philippines until he had a stroke in 1978. As chairman of the Department of Anthropology at the National Museum for many years, Fox helped to develop a number of well-trained Filipino archaeologists on the staff. He and his staff cooperated with the Department of Anthropology of the University of the Philippines in training a number of young archaeologists.

A great deal of archaeological fieldwork has been done by the National Museum, but unfortunately the museum does not have a regular publication. Many of the publications are short reports, put out on glossy paper for sale at the museum, and these do not receive wide circulation. A look at Fox's bibliography, which is considerable, shows that many of his works were short pieces issued with special museum exhibits, newspaper articles, articles in trade journals, and articles in other sorts of publications that did not receive circulation outside the Philippines. Looking at references to papers by the staff of the

museum presented at international conferences you see that many references are to required reports to the museum on completed fieldwork. One Philippine journal that has carried a number of archaeological reports is *the Philippine Quarterly of Culture and Society,* published by San Carlos University in Cebu

at the Royal Captain Shoal, a coral reef west of Palawan, in 1985; the *Griffin,* an East India Company boat found in 1985 northwest of Basilan, south of Zamboanga, Mindanao; and the galleon *San Jose,* found in 1986 near Lubang Island, Mindoro Province. In 1991 a two-season underwater project was started on the Spanish warship *San Diego,* which sank near Fortune Island on 14 December 1600. Over 34,000 artifacts were recovered from this ship, including porcelains and stonewares, earthenware vessels, a navigational compass and a maritime astrolabe, and organic materials.

The National Museum is conducting survey and limited excavation, led by Dizon and Santago, of stone remains not unlike the castles found on Okinawa, on the Batanes Islands, the most northerly of the Philippines Islands. These sites are located on hilltops and have been dated to the twelfth century. The most recent article summarizing Philippine prehistory was published in Hawaii in 1992.

Taiwan

The first major interdisciplinary program on Taiwan prehistory was organized by K.-C. Chang and carried out from July 1964 to July 1965 by the Department of Anthropology, Yale University, and the Department of Archaeology and Anthropology, National Taiwan University. The team was made up of five archaeologists, a palynologist, and a geologist. The primary sites excavated were Pa-li (the name shifted later to Tapenkeng), near Taipei, and Fengpitou, in southwestern Taiwan (Chang et al. 1969).

Chang organized an even more interdisciplinary team for a second major project in 1972 through 1974, sponsored by the same two institutions plus Academia Sinica in Taiwan. The team included experts in botany and palynology, archaeology, cultural anthropology, geography, geology, geomorphology, soil sciences, and zoology. Concerning this breadth Chang said: “Its breadth is not only intradisciplinary (for example, the study of the archaeology, the ethnohistory, and the ethnography of the modern inhabitants) but also interdisciplinary. Ours is a 'saturation' approach; we investigate many natural and humanistic scientific aspects of a small region-two river valleys-and seek to examine their interaction through a study of the ecosystems throughout their recent history” (Chang et al. 1974, 40-41). The two river valleys fall midway between the two major sites of the earlier program so the project also aimed to discover the relationships between the different cultures found at those sites. One of the archaeologists from Yale in this program produced two reports that present much of the archaeological results of this project (Dewar 1977, 1978).

Wen-hsun Sung made a small excavation at O-luan-pi, at the very southern tip of Taiwan, in 1966 (Sung et al. 1967) and reported extended burials in stone cist coffins with many associated artifacts but no metal. Later than the cist burials came a culture, which may have had metal associated, with flexed burials not in coffins. Another site at O-luan-pi, called O-luan-pi site II, was excavated in part by Li (1983) in 1982. He found four distinct cultural layers: OLP Prehistoric Cultural Phase I, without pottery, dated at about 5,000 years ago; OLP Prehistoric Cultural Phase II, with the same culture reported by Sung et al. (1967), dated about 4,000 years ago; OLP Phase III, with painted pottery, dated to about 3,000 years ago; and OLP Prehistoric Cultural Phase IV, with plain pottery, dated to about 2,500 years ago (Li 1983, 79-81). This report has 169 full-page color plates.

Li, in 1977, excavated at a site that has been called K'en-ting, about eight kilometers northwest of O-luan-pi, which had been discovered in 1930. The final report was his Ph.D. dissertation at SUNY-Binghamton University and unfortunately has not been published. However, he did publish an article, “Problems Raised by the K'en-ting Excavation of 1977” (1983). In this article he raised questions about Chang's considering the fine red ware phase as an invasion of a Lungshanoid culture from the China mainland. He presented reasonable arguments that the fine red ware evolved out of the earlier Corded Ware culture. This suggestion has come to be generally accepted. One of the important

finds at K'en-ting was the impression of rice husks on several fine red ware shards. This gives the earliest date for rice in Taiwan. This date has been reported as ca. 3000 b.c. by Bellwood

Israel

Archaeological fieldwork and research in Israel began long before the founding of the modern state in 1948. This article treats the history of archaeology in the region in nineteenth- and twentieth-century western Palestine in brief and then deals with developments in Israel after 1948 in greater detail.

The Formative Period in the Nineteenth Century

Archaeology in "the Holy Land," as Palestine under Ottoman Turkish rule was often called, began as part of the general rediscovery of the long-lost ancient Near East in the early to mid-nineteenth century. Discoveries of major monuments in Egypt and mesopotamia, as well as the recovery and decipherment of the earliest known written documents, beginning in the 1840s, soon galvanized interest in Palestine-especially as some of the most spectacular finds seemed to "prove the Bible."

Palestinian archaeology is generally said to have had its beginnings in the journeys of the Americans Edward Robinson and Eli Smith in 1838, pioneer mapmakers who first correctly

identified more than 200 biblical and other ancient sites. The first actual clearance of ruins, however, was undertaken in 1850 by a French consular official, Felicien de Saulcy, who brought to light the so-called tombs of the kings in Jerusalem. The real archaeological turning point came with the great Survey of Western Palestine, which was sponsored between 1872 and 1878 by the British Palestine Exploration Society (PEF) and produced the first modern, reasonably accurate surveys and maps of western Palestine. The PEF also sponsored the first systematic below-ground explorations in Palestine, the soundings of C.W. Wilson and C. Warren near the Temple Mount in Jerusalem. The PEF's journal, the *Palestine Exploration Quarterly*, began publication in 1867 and is still published today. Other foreign archaeological societies for exploration and fieldwork in Palestine were founded at this time by the Americans (1870), Germans (1878), and French (1892).

The first real excavations, however, were those of the legendary sir william matthew flinders petrie at Tell el-Hesi in southern Palestine in 1890 (followed by the American F.J. Bliss in 1893). It was Petrie, long experienced in archaeology in Egypt, who intuitively laid the two foundations for all subsequent fieldwork: (1) stratigraphic excavation of multilayered tells or mounds and (2) comparative ceramic typology and chronology.

Twentieth-Century Palestinian Archaeology until World War I

The early twentieth century saw a flurry of large-scale archaeological projects in Palestine under several auspices. Excavations included those of Britain at Gezer (1902-1909); the United States at Samaria (1908-1910); and Germany at Ta'anach (1902-1904), Megiddo (1903-1905), Jericho (1907-1909), and Galilean synagogues (1905). Most of these excavations were amateurish when judged by more modern standards. Furthermore, results were often compromised by the typical combination of the excavators' colonialism, nationalism, adventurism, and above all by the "biblicism" that has been irresistible in this branch of archaeology. Only george reisner's work at Samaria in 1908-1910 rose above these limitations, but he was primarily an Egyptian archaeologist and the delay in the publication of his final report volumes until 1924 blunted his impact on the field. A final limitation on the development of Palestinian archaeology was the inefficient and even corrupt administration of antiquities and sites under Ottoman rule.

Archaeology from 1918 until 1948

The years between the two world wars constituted a "golden age" for Palestinian archaeology. The British Mandate government of 1918 established a modern Department of Antiquities and new antiquities laws. The department's journal, the *Quarterly of the Department of Antiquities in Palestine*, was published until 1950. The British themselves, often under the auspices of the PEF and the British School of Archaeology in Jerusalem, sponsored significant work at Ashkelon (1920-1922), Jerash in Transjordan (1923-1928), and the Carmel prehistoric caves (1925-1934) as well as work by Petrie at sites in the Gaza area (1926-1934), Jericho (1930- 1936), Samaria (1930-1935), Lachish (1932- 1938), Kh. el-Mefar (1935-1938), and other sites. In 1938, the Department of Antiquities, along with its collections and library, moved to a magnificent new facility, the Palestine Archaeological Museum, built in Jerusalem with funds from the Rockefeller family in the United States.

U.S. archaeology also flourished, largely under the aegis of the american school of oriental research, founded in 1900 and directed from 1920 to 1929 and 1933 to 1936 by william foxwell albright, the leading U.S. archaeologist of his era and considered by many the father of "biblical archaeology." Among the U.S. excavations were those by Albright himself at Tell el-Fûl (1922), Bethel (1934), and especially Tell Beit Mirsim (1926-1934); by others at Tell en-Nasbeh (1926-1935) and Beth-shemesh (1928-1933); and Nelson Glueck's explorations in Transjordan (1932-1947). Parallel to "the Albright

school" and its biblical orientation were large projects undertaken by secular U.S. institutions such as the University of Pennsylvania at Beth-Shan (1921-1933), the oriental institute of the university of chicago at

identified more than 200 biblical and other ancient sites. The first actual clearance of ruins, however, was undertaken in 1850 by a French consular official, Felicien de Saulcy, who brought to light the so-called tombs of the kings in Jerusalem. The real archaeological turning point came with the great Survey of Western Palestine, which was sponsored between 1872 and 1878 by the British Palestine Exploration Society (PEF) and produced the first modern, reasonably accurate surveys and maps of western Palestine. The British themselves, often under the auspices of the PEF and the British School of Archaeology in Jerusalem, sponsored significant work at Ashkelon (1920-1922), Jerash in Transjordan (1923-1928), and the Carmel prehistoric caves (1925-1934) as well as work by Petrie at sites in the Gaza area (1926-1934), Jericho (1930- 1936), Samaria (1930-1935), Lachish (1932- 1938), Kh. el-Mefar (1935-1938), and other sites. In 1938, the Department of Antiquities, along with its collections and library, moved to a magnificent new facility, the Palestine Archaeological Museum, built in Jerusalem with funds from the Rockefeller family in the United States.

U.S. archaeology also flourished, largely under the aegis of the american school of oriental research, founded in 1900 and directed from 1920 to 1929 and 1933 to 1936 by william foxwell albright, the leading U.S. archaeologist of his era and considered by many the father of "biblical archaeology." Among the U.S. excavations were those by Albright himself at Tell el-Fûl (1922), Bethel (1934), and especially Tell Beit Mirsim (1926-1934); by others at Tell en-Nasbeh (1926-1935) and Beth-shemesh (1928-1933); and Nelson Glueck's explorations in Transjordan (1932-1947). Parallel to "the Albright

school" and its biblical orientation were large projects undertaken by secular U.S. institutions such as the University of Pennsylvania at Beth-Shan (1921-1933), the oriental institute of the university of chicago at

Megiddo (1925-1939), and Yale University at Jerash (1928-1934).

The Beginnings of a National School

It was during the period between the two world wars that Jewish scholars began to do firsthand work on the historical topography and archaeology of Palestine, then undergoing several waves of Jewish settlement from abroad. The Jewish Palestine Exploration Society had been founded in 1914 and was succeeded by the Israel Exploration Society after 1948.

The former society conducted the first Jewish excavations at the Hammath Tiberias Synagogue in 1921-1922, but the real pioneer of Jewish archaeology in Palestine was Eliezer Lipa Sukenik, who founded the Department (now the Institute) of Archaeology at the Hebrew University of Jerusalem shortly after its opening in 1925. Sukenik excavated the synagogue at Beth Alfa (1929) as well as many Jewish burials in Jerusalem and at Tel Gerisa (Tell el-Jerisheh, 1927). He also participated in the joint expedition to Samaria led by J.W. Crowfoot (1930- 1935) alongside another pioneer of Jewish archaeology, Nahman Avigad. Another distinguished Jewish archaeologist and historian of the formative era was Benjamin Mazar (Maisler), who together with Avigad carried out extensive excavations in the Jewish necropolis at Beth Shearim (1936-1960). After joining the faculty of the Hebrew University, Mazar became the doyen of Jewish and later Israeli archaeology, training most of the next generation.

Other pioneer Jewish archaeologists of the British Mandate period were the prehistorian Moshe Stekelis; the classical archaeologist and art historian Michael Avi-Yonah; Ludwig A. Mayer, in Islamic art and archaeology; Immanuel Ben-Tor, Ruth Amiran, later chief archaeologist of the Israel Museum; and Shmuel Yeivin, later first director of the Israel Department of Antiquities. Other Jewish scholars in related fields of ancient Near Eastern, classical, and biblical studies were also active at this time, both at the Hebrew University and in the British-directed Department of Antiquities.

Although many publications appeared and interest in popular circles, especially among Jewish settlers in Palestine, grew enormously, no distinctive “Jewish school” emerged. Thus, foreign archaeologists continued to dominate the field under the colonialist regime in Palestine, as elsewhere in Transjordan, Syria, and Iraq. Nevertheless, by the eve of World War II, when all fieldwork came temporarily to an end, Jewish archaeologists were poised to come into their own. This pioneer generation-“the fathers of Israeli archaeology”-were deeply imbued with a love and firsthand knowledge of “the land of Israel” (Eretz-Israel), steeped in the classical academic tradition of European universities, influenced by the best of foreign scholarship and research (especially that of the Albright school), and experienced in field excavation.

Archaeology in the State of Israel

Almost immediately after the foundation of the state of Israel in 1948, Israeli archaeologists began work on their own even though they were now restricted to parts of western Palestine and even excluded from the Old City of Jerusalem. Israelis were also isolated from most foreign archaeologists, both archaeologists in Syria and jordan and archaeologists from the United States, Great Britain, france, Germany, and other countries, as nearly all of them now chose to work in the West Bank or Transjordan. All the foreign institutes of archaeology, as well as the Rockefeller Museum and its facilities and publications, and even the Hebrew University of Israel were beset by enormous difficulties, including the war of independence, the absorption of a massive influx of immigrants, and severe economic and social difficulties. Archaeology was accorded a low priority.

Despite overwhelming odds, Israel quickly established a Department of Antiquities, on the old British model, and continued the tradition of the quarterly publication of the Department of Antiquities in

Palestine with the launching of the *Israel Exploration Journal* in 1950. Limited salvage and excavation projects began, including Yeivin's work on many salvage projects, Mazar's excavations at Tel Qasile near Tel Aviv (1949-1950), and soon after the discovery and acquisition of some of the dead sea scrolls, pioneer work in the publication of those manuscripts.

PREV NEXT

1960s-1980s, however, ranging from Paleolithic to Islamic, from north to south, and including the Israeli-occupied territories as well. In addition, the first systematic surveys were carried out in the latter regions, especially by younger archaeologists of the third generation, many of them from the Tel Aviv Institute of Archaeology carrying out the emphasis of their mentor, Aharoni, concerning regional archaeology. Particularly noteworthy were the intensive surveys of the Galilee (Z. Gal and Y. Frankel), of the Samaria region (A. Zertal and I. Finkelstein), the Judean highlands (A. Ofer), and the Sinai (E. Oren, Y. Beit-Arieh, and others). In Israel proper, surveys along the Mediterranean coast continued (R. Gophna and others), and there were very extensive surveys in the Negev (R. Cohen, M. Heimann, Y. Dagan, and others).

Classical archaeology was not neglected in the 1960s-1980s as there was a revival of interest in synagogues and Jewish settlements, with excavations by both local and foreign archaeologists. Other classical and later period sites included sites in the Golan Heights, Caesarea, Herodian, Jericho, and the Herodium, and several Byzantine sites in the Negev as well as early Christian monasteries and churches. Underwater and coastal archaeology also began in earnest, especially under the aegis of the Center for Maritime Studies of Haifa University. Finally, prehistoric sites were not overlooked; indeed research burgeoned.

In the 1990s, the Israeli school matured and several newer or intesified emphrases developed:

1. 1. In 1989, the old Department of Antiquities of the Ministry of Education and Culture was transformed into an independent body, the Israel Antiquities Authority, which has some 200 employees, and greatly expanded resources and responsibilities. It continues to publish the serial *Antigot* in both Hebrew and other languages as well as *Excavations and Surveys in Israel* and other materials.

2. 2. More modern stratigraphic methods, hotly debated in the 1970s and even into the 1980s, were now taken for granted by a younger generation of archaeologists.

3. 3. Some of the underlying socioanthropological theory and the emphasis on quantitative methods, advocated by “the new archaeology” of the 1970s-1980s in America, was finally adopted in Israel, although very selectively.

4. 4. New large-scale projects were undertaken, often with subsidies from the Antiquities Authority designed to restore and develop key sites for tourism. The largest such project was the massive clearance and restoration of Roman-Byzantine Beth-shan, which even surpasses another Decapolis city, Jerash in Jordan. Other sites that underwent large-scale restoration were Dan, Hazor, Caesarea, Lachish, Beersheba, and Arad.

5. 5. Both the Antiquities Authority and the several institutes of archaeology placed more emphasis on prompt publication, and the younger generation set a higher mark than their predecessors, both in preliminary and final reports.

6. 6. It may be said that “the third generation” of Israeli archaeologists had finally “come of age” with the creation of a self-conscious, highly professional national school, one that was well organized and well supported. This school easily dominated the scene, in comparison with the few remaining foreign-sponsored projects; few other than American projects persisted, and these were often joint Israeli-American enterprises.

Conclusion

Despite its rapid growth in just under fifty years and its complex character, Israeli archaeology throughout has had a certain consistent, distinctive character. First, it has been deeply grounded in traditional ancient Near Eastern scholarship. Second, it has taken the Bible (i.e., the Hebrew Bible or Old Testament) seriously, yet unlike American (and some European) "biblical archaeology," it has maintained a professional, specialized, and thoroughly secular character, utilizing the Bible, not as confessional literature, but largely as the foundation of national history and culture. Third, it has remained largely pragmatic, grounded in the realia, and has been preoccupied more with description and classification than with explanation and little concerned with anything but the most basic theory.

Fourth, Israeli architecture emphasized large-scale architectural exposure rather than

detailed stratigraphy and microphasing, and special emphasis has been laid on the clearance of living surfaces and exhaustive attempts to restore pottery assemblages. Fifth, Israeli archaeology (excluding prehistory) has been allied almost exclusively with the disciplines of history, philology, and comparative literature with anthropology playing a minor role, if any-in contrast to New World archaeology. Its adoption of aspects of the new archaeology has been slow, sporadic, and limited to such obvious practical strategies as ecological studies, regional surveys, and applied science in the analysis of certain materials. Deliberate, explicit research design is rare, and nomothetic approaches are almost unheard of. As Israelis argue, their connection with the land and its history is "direct and emotional," not theoretical; in any case, the urgency of salvage work and the necessities and hardships of so many excavations leave little time for reflection or comparisons with archaeology in other parts of the world. Thus, if archaeology in Israel is understandably somewhat parochial, it is also probably more intense, both professionally and popularly, than archaeology anywhere else.

A word should be added about foreign archaeology in Israel. Excavations sponsored by other nations have continued since the formation of the state of Israel, although on a relatively smaller and still-decreasing scale because of the dominance of the Israeli national school. The first postwar large-scale U.S. excavations were at Gezer (1964-1974, 1984, 1990); directed by G.E. Wright, W.G. Dever, and J.D. Seger, these excavations had a far-reaching significance in introducing methods of the new archaeology.

That tradition has continued largely with Gezer-trained excavators at Tell el-Hesi, a series of Galilean synagogue sites (E. M. and C. Meyers, J.F. Strange), at Lahav (J. D. Seger), at Tel Miqne/Ekron (S. Gitin, with T. Dothan), at Ashkelon (L. E. Stager), and other sites, both in Israel and Jordan. The old American School of Oriental Research, renamed the W.F. Albright Institute of Archaeological Research in 1968, continued its operations as a permanent in-country research institute. The British, French, and German institutes also continue to operate, although all transferred most of their fieldwork to jordan after 1948. Alongside the *Israel Exploration Journal,* the journals of the foreign schools disseminate important information about archaeology in Israel, namely, the *Bulletin of the American Schools of Oriental Research, Levant and the Palestine Exploration Journal, Revue Biblique,* and the *Zeitschrift des Deutschen Palastina-Vereins.*

J. C. Harrington Medal in Historical Archaeology

In 1981, the society for historical archaeology (SHA) created the J.C. Harrington Medal, the highest award offered in the discipline. Medalists are selected for a lifetime of contributions to the field centered on scholarship. The first copy of the medal was struck in silver and was presented in January 1982 in a surprise ceremony to jean carl (pinky) harrington at the annual SHA conference in Philadelphia. All other copies are in antique bronze.

The J. C. Harrington Medal. The face bears the quotation "…beyond the strictly historical…," from one of Harrington's famous articles; the obverse shows the ground plans of three of the most famous sites Harrington and his wife,Virginia, excavated: Raleigh's 1585 Fort,Washington's 1754 Fort Necessity, and the nineteenth-century Mormon temple at Nauvoo.

(Courtesy of the University of Pennsylvania Museum of Archaeology and Anthropology)

The list of recipients below reflects in a very general way the historical evolution of the discipline. To date, all medalists have been from North America (United States and canada), the region where the field has the deepest history going back to the 1930s, although the award is worldwide in scope. The names also in a vague fashion show the history of the discipline. The list includes researchers who were based in governmental agencies, museums, or similar institutions (cotter, fontana, Harrington, hume, kidd, Quimby, South, and Woodward), transitional figures who started in such settings but spent much of their career in the academic world (Fairbanks, Jelks, and Smith), people who were always academics (Bass, deetz, Gilmore, Salwen, and Sprague), and, finally, Roberta S. Greenwood, the first archaeologist whose major contributions to scholarship were grounded in what has become

Jamestown, Virginia

Jamestown was the first North American community of European settlers to be the subject of a comprehensive, planned, and funded archaeological investigation. It was the first permanent English settlement in 1607, on Jamestown Island, Virginia, and is now part of Colonial National Historical Park. The archaeological work was begun in 1934 and was conducted in three campaigns, the last one continuing to 1997.

In 1934, work began with the objective of providing structure foundation plans for the newly established National Survey of Historic Sites and Buildings. This effort led to intractable differences between architects Henry Chandlee Forman and John Zaharov and archaeologists William John Winter, H. Summerfield Day, and Alonzo Pond. In 1936, order and firm direction were instituted by jean c. harrington, who was trained in both architecture and archaeology and had a grounding in data gathering. The project advanced under Harrington's effective direction with Civilian Conservation Corps labor until all work ended after the onset of World War II, which put an end to relief-supported archaeology in 1942. By then, Harrington's able staff of archaeologists, researchers, curators, and conservators had imposed orderly recording, data analysis, and conservation in the laboratory and had left a complete and extensive record of operations.

Investigations of Jamestown recommenced in 1954, with budgeted national park funds, under the

direction of john l. cotter and with the assistance of Edward Jelks, Joel Shiner, Bruce Powell, Louis Caywood, and the curator, Paul Hudson. The deadline of 1957 was set, the 350th anniversary of the founding of Jamestown, for Cotter to compile all data into a single volume, *Archaeological Excavations at Jamestown, Virginia,* to be published in 1958 by the National Park Service.

In 1992, a five-year archaeological survey was established to extend archaeological sensing and testing over the entire island and to conduct an intensive search for archival data. This survey, conducted by a consortium of researchers from the College of William and Mary and Colonial Williamsburg, Inc., and funded by the National Park Service, was to bring Jamestown research up-to-date for the 400th anniversary in 2007.

Archaeological Sites in Japan

Premodern Interest in Archaeological Remains

Archaeological artifacts and features are mentioned in some of the earliest extant historical records (such as Kojiki 712, Fudoki 713, and Nihongi 720) that date to the early eighth century a.d. As elsewhere, these objects were attributed to supernatural origins, for example, stone arrowheads that often appeared after rainstorms were regarded as alarming signals from heaven that called for special rituals (Saito 1974, 1-12; Teshigawara 1988, 23, 26-28).

A rational approach to these remains beganduring the Tokugawa period (a.d. 1603-1868) when peace prevailed and arts and scholarship flourished. One of the intellectual traditions out of which the "almost archaeology" of the Tokugawa period (Bleed 1986) grew was neo-Confucianism, which provided the ideological support for the hierarchical regime. For example, Arai Hakuseki (1656-1725), who served as an adviser to the Shogun government, came to believe that stone arrowheads were not the weapons of a heavenly army that had fallen from the sky but had been manufactured by human beings in ancient times.

Another tradition on which the "almost archaeology" of the Tokugawa period was based was the *kokugaku* ("national learning") school, which rejected the secular rationalism of Confucianism and turned instead to studies of such ancient texts as the *Kojiki*. It has been suggested (e.g., Yazawa 1985) that the concept of the ethnic homogeneity of the Japanese nation, which would be advocated by the national government in later years and which forms the theme of popular archaeology books today, originated with this group of scholars. The reverence for ancient emperors that the *kokugaku* promoted led to field studies of burial mounds *(kofun),* with a view to their conservation and repair. Based on textual descriptions, but without firm evidence, many *kofun* were identified as imperial tombs. Although the identification had the positive effect of protecting the tombs from pot hunters, it also resulted in the current restriction on archaeologists' access to these remains.

Finally, there were a number of antiquarian groups active in Japan. One of these was the Rosekisha (Rock Fondlers' Club), of which the central figure was Seikitei Kiuchi (1728-1808), a wealthy official who lived near Kyoto. This group had several hundred members from various levels of society, including aristocrats, samurai, and Buddhist priests, who collected stones of unusual appearance, both natural and artifactual; held meetings to show their collections and compare notes; and published their findings with detailed descriptions and illustrations. These collectors represented the beginning of a broadly based amateur interest in archaeology, fostering the idea that archaeological inquiry was both fun and respectable. The club provided the necessary pool of human resources when, in response to threats to archaeological sites posed by the rapid economic development of the post-World War II years, a national system of salvage archaeology had to be put into place quickly.

Archaeology in the New Nation State

The political process that overthrew the Tokugawa Shogun government in 1868, reestablishing direct imperial rule (in theory at least), is referred to as the Meiji Restoration. The new Meiji government was committed to bringing Japan out of its isolation and to make it a modern nation state, and the introduction of archaeology as practiced in nineteenth-century Europe and America was a by-product of the arrival in Japan of scientists and technical experts whose special knowledge and skills were deemed useful by the new government. These experts included John Milne (1850-1913), an English seismologist who in 1876 became professor of geology at Tokyo University, where he remained until 1894; William Gowland (1843-1922), an English chemist who served as a consultant to the Mint from 1872 to 1888; and Edward Sylvester Morse (1838-1925), whose research trip to Japan in 1877 to study mollusks turned into a two-year appointment as professor of zoology at Tokyo University and who is generally credited, through his excavation of the Omori shellmound in Tokyo (Morse 1879a), as being the father of modern archaeology in Japan.

These scholars wrote books and articles about Japanese archaeology, most of which were published abroad in foreign languages and were read by very few Japanese. Nor did these men leave students who would become archaeologists. Being avocational archaeologists themselves, their impact on early Meiji Japan seems to have been through interaction with their Japanese counterparts, about whom it has been remarked "that there were more people interested in archaeology in Japan than anywhere else in the

world" (Morse 1879b). Some examples of the interaction, where benefits seemed to have flowed in both directions, are summarized in English by Peter Bleed (1986) and Fumiko Ikawa-Smith (1982).

Although the introduction of the methods and concepts of western archaeology was accidental, the Meiji government took some deliberate measures to preserve the nation's archaeological heritage. It issued a series of edicts in 1871, 1874, and 1881 to help preserve ancient objects and to restrict the excavation of ancient tombs. It introduced the Law for the Preservation of Ancient Temples and Shrines in 1899, which was to become the basis for the 1950 Law for the Protection of Cultural Properties. The government also initiated, as early as 1871, the process that resulted in the establishment of the imperial museum (today's Tokyo National Museum) as the depository of the nation's heritage.

Archaeology as Science and Archaeology as History

The first generation of Japanese professional archaeologists was led by Shogoro Tsuboi (1863-1913), and he, along with several other science students of the time, formed the Anthropological Society of Tokyo (the precursor of the Anthropological Society of Nippon) in 1884. Having been sent to England to study anthropology (1889-1892), Tsuboi was appointed professor of anthropology within the College of Science at the University of Tokyo in 1893. Tsuboi is said to have emphasized the fact that he had not studied anthropology under Morse and made disparaging remarks about him (Goto 1977; Kudo 1977). Yet Tsuboi believed that anthropology should be considered part of zoology, and his position in what was to be called the *Jinshu ronso* (“race controversy”) was the same as that of Morse.

The controversy was over whether the cord-marked *(jomon)* pottery from shellmounds was made by the ancestors of the aboriginal Ainu people who lived in northern Japan or by pre-Ainu inhabitants mentioned in Ainu legend. Morse, like Tsuboi, believed that the pottery makers were the pre-Ainu people while Heinrich von Siebold, John Milne, and Yoshikiyo Koganei (1859-1944) maintained that the pottery had been made by the Ainu. Koganei was a professor of anatomy at the University of Tokyo who had studied in Germany for five years (1880-1885). He based his arguments on anthropometric data while Tsuboi, dismissing such data as useless, promoted the use of archaeological remains and ethnographic analogies. This preoccupation with the ethnic identity of the prehistoric pottery makers was to continue until Tsuboi's death.

This group of archaeologists was referred to as “the race archaeology school” or “the university school,” in contrast to another group of archaeologists based at the Imperial Museum. Since the museum at that time employed scholars who continued the Tokugawa antiquarian tradition, the latter group was nicknamed “the museum school” or “the antiquarian school” (Terada 1980). Government policy at the time was to deposit the remains from prehistoric shellmounds in the Tokyo University Anthropology Department and those pertaining to the proto-historic and historic periods in the museum. The Anthropology Department of Tokyo University continued to be the major center for prehistoric research with a natural science orientation while more historically oriented work was conducted at the museum.

An additional major center for the latter kind of archaeology was created in 1913 when specialization in archaeology was formally recognized within the History Department of Kyoto University. Kosaku Hamada (1881-1938) was appointed professor of archaeology at Kyoto on his return from Europe in 1916. Most of his time in Europe (1913-1916) had been spent in England, where he studied with sir william matthew flinders petrie. Hamada's *Tsuron Kokogaku* (1922) is considered to be the first systematic statement in Japanese on the methods and theory of archaeology.

Stratigraphy, Typology, and Chronology

Hamada put archaeological methodology into practice at a series of excavations and in site reports, emphasizing the importance of stratigraphy and the need to define artifact types explicitly (e.g., Hamada 1918, 1919). At about the same time, Hikoshichiro Matsumoto (1919) used the stratigraphic principles

of paleontology to argue that variations in ceramics were the result of chronological, rather than tribal, differences. From the 1920s until the end of World

Although the introduction of the methods and concepts of western archaeology was accidental, the Meiji government took some deliberate measures to preserve the nation's archaeological heritage. It issued a series of edicts in 1871, 1874, and 1881 to help preserve ancient objects and to restrict the excavation of ancient tombs. It introduced the Law for the Preservation of Ancient Temples and Shrines in 1899, which was to become the basis for the 1950 Law for the Protection of Cultural Properties. The government also initiated, as early as 1871, the process that resulted in the establishment of the imperial museum (today's Tokyo National Museum) as the depository of the nation's heritage.

Archaeology as Science and Archaeology as History

The first generation of Japanese professional archaeologists was led by Shogoro Tsuboi (1863-1913), and he, along with several other science students of the time, formed the Anthropological Society of Tokyo (the precursor of the Anthropological Society of Nippon) in 1884. Having been sent to England to study anthropology (1889-1892), Tsuboi was appointed professor of anthropology within the College of Science at the University of Tokyo in 1893. Tsuboi is said to have emphasized the fact that he had not studied anthropology under Morse and made disparaging remarks about him (Goto 1977; Kudo 1977). Yet Tsuboi believed that anthropology should be considered part of zoology, and his position in what was to be called the *Jinshu ronso* (“race controversy”) was the same as that of Morse.

The controversy was over whether the cord-marked *(jomon)* pottery from shellmounds was made by the ancestors of the aboriginal Ainu people who lived in northern Japan or by pre-Ainu inhabitants mentioned in Ainu legend. Morse, like Tsuboi, believed that the pottery makers were the pre-Ainu people while Heinrich von Siebold, John Milne, and Yoshikiyo Koganei (1859-1944) maintained that the pottery had been made by the Ainu. Koganei was a professor of anatomy at the University of Tokyo who had studied in Germany for five years (1880-1885). He based his arguments on anthropometric data while Tsuboi, dismissing such data as useless, promoted the use of archaeological remains and ethnographic analogies. This preoccupation with the ethnic identity of the prehistoric pottery makers was to continue until Tsuboi's death.

This group of archaeologists was referred to as “the race archaeology school” or “the university school,” in contrast to another group of archaeologists based at the Imperial Museum. Since the museum at that time employed scholars who continued the Tokugawa antiquarian tradition, the latter group was nicknamed “the museum school” or “the antiquarian school” (Terada 1980). Government policy at the time was to deposit the remains from prehistoric shellmounds in the Tokyo University Anthropology Department and those pertaining to the proto-historic and historic periods in the museum. The Anthropology Department of Tokyo University continued to be the major center for prehistoric research with a natural science orientation while more historically oriented work was conducted at the museum.

An additional major center for the latter kind of archaeology was created in 1913 when specialization in archaeology was formally recognized within the History Department of Kyoto University. Kosaku Hamada (1881-1938) was appointed professor of archaeology at Kyoto on his return from Europe in 1916. Most of his time in Europe (1913-1916) had been spent in England, where he studied with sir william matthew flinders petrie. Hamada's *Tsuron Kokogaku* (1922) is considered to be the first systematic statement in Japanese on the methods and theory of archaeology.

Stratigraphy, Typology, and Chronology

Hamada put archaeological methodology into practice at a series of excavations and in site reports, emphasizing the importance of stratigraphy and the need to define artifact types explicitly (e.g., Hamada 1918, 1919). At about the same time, Hikoshichiro Matsumoto (1919) used the stratigraphic principles

of paleontology to argue that variations in ceramics were the result of chronological, rather than tribal, differences. From the 1920s until the end of World

War II in 1945, the separate disciplines of archaeology and anthropology were increasingly professionalized. In both cases, empirical evidence, based on stratigraphy, measurements, and typological classification and comparisons, were emphasized, with the ultimate goal of establishing a sound chronology.

It has been pointed out by many authors that the sociopolitical climate in the 1930s and 1940s favored such devotion to details rather than debate of any larger or more political issues. By this time, two kinds of prehistoric pottery, representing two separate cultures, were known. “Jomon,” the Japanese translation of “cord marking” was used by Morse as a descriptive term for the Omori shellmound pottery, and it became established as the name for pottery found in similar shellmounds and, by extension, the name for the culture and the Stone-Age people who made it. A different kind of pottery, first recovered in Tokyo in 1884, was understood to belong to the bronze-using rice growers of the Yayoi period, a period that lasted a few centuries before and after the beginning of the Christian era. The occupation of the archipelago by these groups could not be easily reconciled with the official version of national history based on the eighth-century history texts of *Kojiki* and *Nihongi,* which attributed the founding of the imperial state to the descendant of the Sun Goddess in 660 b.c. Scholars who persisted in using archaeological data to interpret prehistory and proto-history ran the risk of losing their jobs, or even being imprisoned. Given those circumstances, the excessive empiricism of chronology building, with no apparent reference to “national history,” was the prudent approach.

Early Post-World War II Years: Freedom of Inquiry

The end of World War II in 1945 meant the lifting of restrictions on historical inquiries, which made it possible to rewrite the history of Japan based entirely on archaeological evidence. The excavation of a Yayoi settlement site at Toro, near Shizuoka, between 1947 and 1950 dramatically underscored the new role that archaeology was to play in construction of national history in postwar Japan. Beginning shortly after the war, with severe shortages of such basic necessities such as shovels and food for the excavation crew, the Yayoi excavation was of a scale that had never occurred before in Japan, in terms of both expenditure and the number of participants. The investigation was both interdisciplinary and multi-institutional, with a large number of professionals and students and numerous local volunteers participating in unearthing the first rice paddies from an archaeological site as well as many artifacts, including wooden agricultural tools and building materials used for residential and storage structures. The excavation results were widely reported in the media, which raised the awareness of archaeology among the general public (Fawcett 1995). As W. Edwards (1991) notes, the image of the ancient, peaceful rice-growing village, re-created through archaeological investigation, supplied the new metaphor of continuity for the Japanese cultural and national identity, replacing the old mythological one made unacceptable by the war and defeat.

Another significant excavation took place in 1949, following the 1947 discovery of stone artifacts from an exposed Pleistocene formation by Aizawa Tadahiro (1926-1989), an amateur archaeologist, at Iwajuku about ninety kilometersnorth of Tokyo. The excavation by a team from the Meiji University provided the first convincing evidence for the existence of a Paleolithic period in Japan (Sugihara 1956). Within a few years of the excavation, the evidence for Paleolithic occupation had been confirmed at a number of other sites (Serizawa 1954; Serizawa and Ikawa 1960). The Iwajuku excavation not only added great temporal depth to the nation's history, it also gave the evidence a firm scientific basis: human occupation of the archipelago began in the geological past during the Ice Age, not in the mythical “age of gods.”

The “scientific” approach during the early postwar years also involved making generalizations about the nature of past societies with reference to the theoretical framework of historical materialism. Seiichi

Wajima (1909-1971) used the data and insights he had accumulated during the 1930s and 1940s to present an interpretative

PREV NEXT

statement about prehistoric and proto-historic settlement systems, inferring social transformations that would have led to an early state with class differentiation (Wajima 1948). Similarly, Yukio Kobayashi (1911-1988) attributed class differentiation and state formation during the Kofun period (a.d. 300-600) to a rise in agricultural productivity that resulted from the widespread use of iron tools (Y. Kobayashi 1952). Such attempts at generalizations, however, were exceptional. For the majority of archaeologists, the particularist approach, with its emphasis on stratigraphic and typological evidence, which had been strongly entrenched in the 1930s, continued-and, in fact, continues to this day.

It was during this early postwar environment of freedom of speech, at a symposium in 1948, that Namio Egami first presented his thesis that the Japanese imperial family's ancestors had arrived relatively late in Japan and were the riders of horses from the continent (Egami 1962, 1964). Although this idea continues to be very popular with the reading public in Japan, and gained support of some foreign scholars (e.g., Hong 1988; Ledyard 1975), most Japanese archaeologists have dismissed it as being speculative and not worthy of serious rebuttal. It was only recently that one scholar decided to remedy the situation by presenting a counterargument (Sahara 1993).

A pottery jar from the Nagano-Ken jomon culture (3000-2000 B.C.), probably used for storing food

International Contacts

Many Japanese archaeologists had studied abroad before World War II, and even during the early phase of the war, and a number of them had been engaged in archaeological investigations in the newly occupied areas of Manchuria, china, Indochina, and the Pacific islands. As the war progressed they became increasingly isolated, and this isolation continued in the early postwar decades when foreign travel and the importation of foreign books were severely limited by economic conditions. Isolation ended gradually when a small number of young archaeologists were given the opportunity to study abroad and a few senior scholars were able to attend international meetings. International interaction has increased rapidly since the 1970s, and Japanese archaeologists are once again engaged in overseas expeditions in places such as peru, Alaska, and the Middle East.

Newly developed archaeological methods and techniques were introduced. Soon after radiocarbon dating was developed, it was applied to samples from several Jomon sites, with occupation forces personnel and visiting U.S. archaeologists acting as intermediaries (Crane 1956; Crane and Griffin 1962; Libby 1951). These and subsequent determinations produced internally consistent, and surprisingly early dates, suggesting that Japanese pottery making was the earliest in the world.

A curious debate over the legitimacy of using radiocarbon dates in archaeological interpretation began. As noted elsewhere (Ikawa-Smith 1975,15-17), the debate had little to do with the reliability of the method itself but instead concerned the integrity of archaeology as a historical discipline whose expertise resided in its ability to construct a chronology based on the

study of artifacts rather than on technology. The resistance to the use of radiocarbon dating, however, was an exception. Other methods of dating were more readily accepted, as were various methods and techniques for identifying the sources of stones and clay, for enhancing artifact conservation, or for extracting more information about the use of plant and animal resources.

The periodical *Kokogaku to Shizen-kagaku* (Archaeology and Natural Science) was inaugurated in 1968, and the Association for Natural Science Approaches to Cultural Properties *(Bunkazai Kagakukai)* was formed in 1982. Its membership in 1998 was 830 and was evenly distributed between the natural sciences and humanities disciplines. A relatively large proportion of the work in this category is published in English (e.g., Akazawa 1980; Akazawa and Watanabe 1968; Koike 1979, 1986a, 1986b; Koike and Ohtaishi 1985; Matsui 1995, 1996; Minagawa and Akazawa 1992; Sato 1999; Yamamoto 1990).

In contrast to specific methods and techniques for analysis and conservation, theoretical and methodological concerns, particularly those of "the new archaeology" of the 1960s and 1970s, were not popular in Japan. This lack of interest was owing to North American archaeologists' concerns that archaeology should contribute to understanding the regularity of human behavior (Binford 1962; Longacre 1964; Taylor 1948)-a concern not shared by Japanese archaeologists. Archaeology in Japan had its roots in the Anglo-Saxon tradition of general anthropology in the 1880s, but early in the twentieth century it became a branch of history while *anthropology* came to mean biological anthropology alone.

One topical area in which the theoretical interests of both Japanese and Anglo-Saxon archaeologists overlapped was in the study of settlement systems. In the case of Japanese archaeology, however, this was the continuation of an interest that dated back to the 1930s (e.g., Akamatsu 1937; also see Sasaki 1999) rather than a new direction. North American settlement archaeology was presented in summary translations (Keally 1971) and its historical background explained (T. Kobayashi 1971). The large-scale excavations in Japan that began in the late 1960s provided an opportunity to put this methodology into practice. In the settlement pattern studies that developed as a result (T. Kobayashi 1980; T. Kobayashi, Oda, Hatori, and Suzuki 1971; Oda and Keally 1973), however, the emphasis was on the construction of settlement typology, in the empirical tradition of Japanese archaeology.

Economic Expansion and the Restructuring of Archaeological Operations

As the Japanese economy recovered through the 1950s and 1960s, large development projects threatened a number of archaeological sites. There was a popular movement to protect the nation's cultural heritage, which led to the revision of the 1950 Law for the Protection of Cultural Properties in 1959, making it mandatory to investigate sites, at the developer's expense, if the development project could not be modified to avoid site destruction. In the same year (1959), 345 notices of excavation were filed, of which 227 were purely academic in purpose and 118 were to investigate sites to be destroyed. The ratio of the academic to salvage excavations became reversed in 1963, when the former numbered 209 as opposed to 227 salvage operations. This reversal marked the beginning of a radical change in the nature and scope of archaeological operations in Japan.

Ten years later, in 1973, the figures were 203 academic versus 1,863 emergency excavation notices, for a total of 2,066. In 1983, academic excavations went down to 137 while emergency excavation notices shot up to 14,403. The figure for the fiscal year of 1997 was 409 academic excavations and 34,957 emergency operations, for a total of 35,366 notices (down from 41,555 in 1996, presumably the result of the economic situation). The total expenditure for emergency excavations in 1997-1998 was 132 billion yen (Center for Archaeological Operations 1975, 1989, 1999). The expenditure for the academic excavations is not known, but it would be miniscule by comparison.

Japan now has a very elaborate system of salvage archaeology involving three levels of government (national, prefectural, and municipal) and affiliated nonprofit corporations

PREV NEXT

(Barnes 1990; Fawcett 1990, 1995; Habu and Fawcett 1999; T. Kobayashi 1986; Pearson 1992; Tanaka 1984; Tsuboi 1986; and Tsude 1995). According to the Center for Archaeological Operations (1999), the total number of people employed at the prefectural and municipal levels as administrative archaeologists in 1997-1998 was 6,872. There must have been an additional hundred or so working at the national level with the Agency for Cultural Affairs and its institutes in Tokyo, Nara, and elsewhere.

Hiroshi Tsude (1995), using figures from a few years earlier, estimates the total number of archaeologists in Japan at 5,700, of which 300 are in academic departments, 700 in museums, and the remaining 4,700 (or 82 percent) engaged in the administration of cultural resources management. In spite of their large numbers, cultural resources management archaeologists are always pressed for time, starting one operation after the other, conducting excavations, and preparing mandatory excavation reports, which are technically excellent but purely descriptive. They have little time to fully digest their findings and formulate any syntheses. Nor could the very small number of "academic" archaeologists keep up with the rapidly accumulating data and come up with syntheses and theoretical formulations. Japanese archaeologists are drowning in a flood of data.

The Archaeology of National Origins

The allocation of such huge resources to archaeological activities is feasible in Japan because of the high level of interest in the discipline by the tax-paying public. Spectacular results of excavations are widely reported on television and in newspapers and attract a large number of visitors to the sites. The Sannai Maruyama site, a very large Jomon period site at the northern end of Honshu, dating to about 3500-2000 b.c., featuring six enormous wooden structures and about 700 pit-house remains, received over 1 million visitors between 1994 and 1997 (Habu and Fawcett 1999). At the opposite end of the archipelago, some 160,000 visitors went to the Uenohara site to see evidence of settled village life as early as 9,500 years ago when the site was opened to the public over the summer holidays in 1997 (*Weekly Asahigraph* 1997, 17). These on-site interpretation events are some of the measures Japanese archaeologists have taken to keep the public informed of the significance of their activities, but they are, in fact, responding to the public's demand for information about the nation's past.

Public interest in archaeology in Japan is the legacy of long-term antiquarianism, but the level of the interest has risen in recent years, partly because of a series of spectacular finds, starting with the 1972 discovery of a painted tomb of Takamatsuzuka. There is also an increasing and perceived need for the Japanese people to define their distinctiveness as Japan takes its place the among the nations of the world. The interest in archaeology grew hand in hand with the growth of the discourse called *Nihonjinron* ("theory about the Japanese") and *Nihonbunkaron* ("theory about Japanese culture"), both of which purported to explain what was distinctly Japanese. Archaeological finds became relevant within this context because archaeological remains, even those of the 9,500-year-old Jomon villagers, are perceived as the remains of Japanese ancestors. A large number of archaeology books are published, some with beautiful photographic illustrations and others in convenient pocketbook format, bearing titles and subtitles like "The Origins of the Japanese," "Japan's Cultural Roots," and "Where Did the Japanese Come From?"

Archaeology thrives in Japan because it is perceived not as an abstract academic exercise but as a means to elucidate the nation's past, as a substantial contribution to increasing the Japanese peoples' understanding of who they are. In Japan, archaeology is national history, helping to define the present with reference to the past.

Jarmo

Most famous as the focus of robert braidwood's research into the history of the domestication of plants and animals, Jarmo is a Neolithic village site in the Zagros Mountains of Iraqi Kurdistan. The site was occupied for several centuries between 9000 and 8000 b.p., and the careful excavation of the site by Braidwood and his multidisciplinary team between 1948 and 1954 made it possible for archaeologists to examine evidence of plant and animal remains as well as more traditional information, such as artifacts and architecture.

Jefferson, Thomas

(1743-1826)

Statesman, president of the United States of America, diplomat, scientist, revolutionary, and architect, Thomas Jefferson was born on the frontier in Virginia, the son of a surveyor/explorer who had married into one of the best families in the district. He had a classical education and from 1760 to 1762 studied mathematics, science, and philosophy at the College of William and Mary. Jefferson began to study law and was admitted to the bar in 1767, working as a successful lawyer until the beginning of the War of Independence in 1776, when he began a full-time career in politics.

Jefferson had been left substantial property by his father, on which he began to design and build the

mansion of Monticello. In 1770 he was appointed county lieutenant and in 1773 surveyor of the county, and he soon became involved in local politics, being elected as a member of the county government and contributing to the framing of local legislation. He was elected by the Virginia convention to serve in Congress and was then elected along with others to draw up the Declaration of Independence. At the age of 33 Jefferson helped to found a new nation.

After some time as governor, congressman, and American diplomat in Paris, Jefferson became the first secretary of state under the constitution from 1790 until he retired briefly to Monticello in 1793, vice-president in 1795, and president from 1800 until 1809, with albert gallatin as his secretary of the treasury. The high point of his administration was the Louisiana Purchase, which added impetus to the proposed Lewis and Clark expedition. Jefferson was passionately interested in and supportive of this expedition, and wrote the biography of the explorer Meriwether Lewis, who had been his private secretary.

Jefferson was also involved in the intellectual life of the new nation. The American Philosophical Society (APS), based on the model of the Royal Society of London, had been founded in 1743 by a small group of eminent Americans. Under the presidency of Thomas Jefferson (1797-1815) the society became an intellectual influence on post-Revolutionary and newly nationalist

Jarmo

Most famous as the focus of robert braidwood's research into the history of the domestication of plants and animals, Jarmo is a Neolithic village site in the Zagros Mountains of Iraqi Kurdistan. The site was occupied for several centuries between 9000 and 8000 b.p., and the careful excavation of the site by Braidwood and his multidisciplinary team between 1948 and 1954 made it possible for archaeologists to examine evidence of plant and animal remains as well as more traditional information, such as artifacts and architecture.

Jefferson, Thomas

(1743-1826)

Statesman, president of the United States of America, diplomat, scientist, revolutionary, and architect, Thomas Jefferson was born on the frontier in Virginia, the son of a surveyor/explorer who had married into one of the best families in the district. He had a classical education and from 1760 to 1762 studied mathematics, science, and philosophy at the College of William and Mary. Jefferson began to study law and was admitted to the bar in 1767, working as a successful lawyer until the beginning of the War of Independence in 1776, when he began a full-time career in politics.

Jefferson had been left substantial property by his father, on which he began to design and build the

mansion of Monticello. In 1770 he was appointed county lieutenant and in 1773 surveyor of the county, and he soon became involved in local politics, being elected as a member of the county government and contributing to the framing of local legislation. He was elected by the Virginia convention to serve in Congress and was then elected along with others to draw up the Declaration of Independence. At the age of 33 Jefferson helped to found a new nation.

After some time as governor, congressman, and American diplomat in Paris, Jefferson became the first secretary of state under the constitution from 1790 until he retired briefly to Monticello in 1793, vice-president in 1795, and president from 1800 until 1809, with albert gallatin as his secretary of the treasury. The high point of his administration was the Louisiana Purchase, which added impetus to the proposed Lewis and Clark expedition. Jefferson was passionately interested in and supportive of this expedition, and wrote the biography of the explorer Meriwether Lewis, who had been his private secretary.

Jefferson was also involved in the intellectual life of the new nation. The American Philosophical Society (APS), based on the model of the Royal Society of London, had been founded in 1743 by a small group of eminent Americans. Under the presidency of Thomas Jefferson (1797-1815) the society became an intellectual influence on post-Revolutionary and newly nationalist

America, a de facto scientific adviser to the government. The society wrote the charter for the government's great western exploratory expedition led by Lewis and Clark, and later contributed to the Lond Expedition of 1819 and the Wilkes Expeditions of 1838 and 1842, both of which were anthropological in objective. Under Jefferson's presidency the APS took an interest in archaeology, linguistics, and anthropology.

Thomas Jefferson

(Ann Ronan Picture Library)

Jefferson was a pioneer in the study of archaeology, paleontology, ethnology, geography, and botany in America and he amassed a collection of Indian vocabularies that were unfortunately lost. Through the APS Jefferson became associated with the important scientific societies of Europe and America. He was elected in 1801 to the Institute of France in recognition of his reputation in france as an intellectual-and not as a politician. He corresponded with a great many scientists across the world and across America and wanted the best of foreign knowledge to be available to Americans. After his final retirement from politics he helped to found the University of Virginia and he established a school of builders in Virginia and tried to establish formal instruction in architecture. He kept up with his voluminous correspondence and he continued to advise his political colleagues. To reduce his debts Jefferson sold his collection of some10,000 books to the new Library of Congress.

Jenné and Jenné-jeno

Jenné and Jenné-jeno (ancient Jenné) are successive tell settlements in the upper inland Niger Delta of Mali, and together, they span over two millennia of continuous occupation on the floodplain. Both have been designated World Heritage Sites by the United Nations Educational, Scientific, and Cultural Organization. The forty-five-hectare tell of Jenné is inhabited today by a population of about 10,000.

Historical sources, such as the account of the French explorer Réné Caillié (1830) and local *tarikhs* (histories written in Arabic), detail the central role that Jenné has played in the commercial activities of the western Sudan during the last 500 years. In the famous “golden trade of the Moors,” gold from mines far to the south was transported overland to Jenné, then transshipped on broad-bottom canoes (pirogues) to Timbuktu, and then sent by camel to markets in North Africa and Europe (Bovill 1968; Levtzion 1973). Leo Africanus (1896) reported in 1512 that the extensive boat trade on the middle Niger involved massive amounts of cereals and dried fish shipped from Jenné to provision arid Timbuktu. Today, the stunning mud architecture of Jenné in distinctive Sudanic style is a legacy of the settlement's early trade ties with North Africa.

Systematic archaeological research at Jenné began in 1994 with a coring project (McIntosh et al. 1996) and continued with excavations in 1998 on the proposed site of the new Jenné museum. Cultural deposits descended over six meters and began with material dating to the early second millennium a.d.

Three kilometers to the southeast, the thirty-three-hectare mound of Jenné-jeno attracted little attention during the colonial period despite its thick surface carpet of broken pottery and numerous mud brick wall foundations. Scientific excavations in the 1970s and

1980s revealed that Jenné-jeno was founded ca. 250 b.c. by iron-using peoples who cultivated rice, millet, and sorghum; herded stock; and engaged in fishing and hunting (S. K. McIntosh 1995; S.K. McIntosh and R. McIntosh 1980). The deposits dating to this early period are almost six meters down from the highest part of the mound.

Careful evaluation of deposits from numerous other excavation units at Jenné-jeno and two other nearby sites provided evidence for the rapid growth of the mounds throughout the first millennium a.d. Jenné-jeno itself reached its maximum extent of over seventy-five acres by a.d. 850. Intensive surface survey of the mounds located within a four-kilometer radius of Jenné (sixty-nine in all) indicated that the majority were occupied by at least a.d. 800-1000, creating a remarkable concentration of population (10,000-27,000 people) within the integrated multisite system known as the Jenné-jeno urban complex.

Those discoveries marked the end of assumptions that urban settlements and long-distance trade in West Africa were secondary to the development of the trans-Saharan trade by North African Arabs after the ninth century. Settlement at Jenné-jeno declined after a.d. 1200, and the settlement was completely abandoned by a.d. 1400. Most of the nearby mounds followed the same pattern. Their demise was concomitant with the period of early settlement documented at Jenné, but the reasons for this shift in settlement location are not yet understood.

Johnny Ward's Ranch

In late 1959 and early 1960, volunteer members of the Arizona Archaeological and Historical Society carried out excavations on eleven Sundays in a period site in southern Arizona designated Ariz. EE: 5:6 in the Arizona State Museum survey system. The efforts were directed by archaeologists bernard l. fontana and J. Cameron Greenleaf, but of the fifty-eight people who volunteered their efforts, only four or five had had previous archaeological experience.

Fontana had chosen the site because he mistakenly believed it represented the adobe ruins of San Ignacio de Sonoitac, a mid-eighteenth-century mission visiting station built and administered by Jesuit missionaries before their expulsion from New Spain in 1767. Excavations and subsequent documentary research indicated the site was instead one that had been occupied between 1859 and 1903 and had served variously as a ranch for the family of Johnny Ward and other English-speaking settlers, headquarters for a mining and milling company, a house and store, and a dwelling for Chinese gardeners.

Not wanting to disappoint the volunteers

1980s revealed that Jenné-jeno was founded ca. 250 b.c. by iron-using peoples who cultivated rice, millet, and sorghum; herded stock; and engaged in fishing and hunting (S. K. McIntosh 1995; S.K. McIntosh and R. McIntosh 1980). The deposits dating to this early period are almost six meters down from the highest part of the mound.

who had worked so diligently on the excavation, Fontana and Greenleaf analyzed the artifacts, nearly all of them mass produced and machine-made, as carefully as if they had been hand-crafted objects of the pre-Industrial Revolution. The results of their analyses were published as “Johnny Ward's Ranch: A Study in Historic Archaeology” in the society's journal, *The Kiva* (28, no. 12, October-December 1962).

Johnny Ward's Ranch (January 16, 1961), Patagonia, Arizona. Excavation of this late nineteenth-century site by Bernard L. Fontana, J. Cameron Greenleaf, and members of the Arizona Archaeological and Historical Society helped to initiate an expansion in the type and age of historic sites worked on in the American West.

(Bernard Fontana)

The study was the first in the annals of U.S. archaeology to take seriously the products resulting from the ideas of interchangeable parts and mass production by machines. Pioneering descriptive and historical studies of square-cut nails, wire nails, tin cans, metallic cartridges, ironstone ceramics, machine-blown bottles, and similar artifacts were presented. The report became the first to give credence and respectability to what came to be labeled “tin can archaeology,” and as such it became a landmark in the history of archaeology in the United States.

Jordan

The area known today as Jordan (Transjordan) lies between Palestine (Cisjordan or modern israel and the Palestinian Territories) and mesopotamia and is intimately connected to these surrounding regions of the Near East, in both geography and history (see map). This brief survey of the development of archaeology in Jordan will outline the major phases of exploration and the relationship of work in this region to the broader development of archaeology in the Middle East.

The Earliest Phase of Exploration, 1805-1918

“Who that has ever traveled in Palestine has not longed to cross the Jordan valley to those mysterious hills that close ever eastward view with their long horizontal outline, their overshadowing height, their deep purple shade?”

With these words from his 1856 travel log, Arthur Stanley, the dean of Westminster in London, summed up the relationship between Palestine and Transjordan for the earliest explorers

who had worked so diligently on the excavation, Fontana and Greenleaf analyzed the artifacts, nearly all of them mass produced and machine-made, as carefully as if they had been hand-crafted objects of the pre-Industrial Revolution. The results of their analyses were published as “Johnny Ward's Ranch: A Study in Historic Archaeology” in the society's journal, *The Kiva* (28, no. 12, October-December 1962).

Jordan

The area known today as Jordan (Transjordan) lies between Palestine (Cisjordan or modern israel and the Palestinian Territories) and mesopotamia and is intimately connected to these surrounding regions of the Near East, in both geography and history (see map). This brief survey of the development of archaeology in Jordan will outline the major phases of exploration and the relationship of work in this region to the broader development of archaeology in the Middle East.

The Earliest Phase of Exploration, 1805-1918

“Who that has ever traveled in Palestine has not longed to cross the Jordan valley to those mysterious hills that close ever eastward view with their long horizontal outline, their overshadowing height, their deep purple shade?”

With these words from his 1856 travel log, Arthur Stanley, the dean of Westminster in London, summed up the relationship between Palestine and Transjordan for the earliest explorers

and Amman/Philadelphia (Seetzen) and Petra (Burckhardt). Others followed, including the Americans Edward Robinson and Eli Smith, who, though their visits were brief, are considered to be the fathers of historical geography in the region. Unfortunately, their extensive work in Palestine (1837-1838, 1851-1852) was not duplicated east of the Jordan River.

One of the reasons why comparatively little exploration was undertaken through the 1800s was the political instability of the region. The population was a combination of settlers living in villages and Bedouin tribes, although under Ottoman Turkish rule, there was little protection or rule outside the more densely populated regions. The activities of the Bedouin, who were occasionally aggressive toward the villages and travelers, made exploration difficult and often dangerous. Foreigners' visits to Transjordan were therefore sporadic and usually directed to specific known sites, since their primary focus was on the “Holy Land” (Cisjordan or Palestine) and its historical geography.

By the mid-nineteenth century Ottoman dominance of the region began to increase, and Ottoman governors were eventually appointed at Irbid to oversee the district of Ajlun (1851) and at Salt to oversee the central district of Belqa (1868). One of the main reasons for this growing political dominance of Transjordan was the need to control the Haj route for Islamic pilgrims to make their way to Mecca between Damascus and the Hejaz. And one of its outcomes was an increase in the exploration of the region by westerners.

The Development of Jordanian Archaeology during the British Mandate, 1918-1946

After World War I came to a close, the Sykes-Picot agreement established a British mandate in Palestine and Transjordan in 1918, and the area came under the control of the British Empire. Appropriately, the authorities established a department of antiquities in Palestine in 1920, led by the English archaeologist john garstang, and three years later a department of antiquities was set up in Amman to oversee the region of Transjordan.

With the advent of British rule, archaeologists found the territory more accessible and safer to explore, and during the mandate period they laid some of the major groundwork for our understanding of the archaeology and history of these regions. Research was not, however, restricted to British interests: several international schools, including some from france, Germany, and the United States, carried out significant projects in the southern Levant in these years.

A great deal of the work was concentrated in Palestine, but some was also conducted at various major sites of classical antiquity in Transjordan, including Amman, Jerash/Gerasa, and Petra. At Petra the earliest systematic excavations were undertaken in 1929 by George Horsfield, the first director of the Transjordan Department of Antiquities. Horsfield, a student of Garstang, worked on several of the major tombs of Petra, including the Palace Tomb, al-Kazneh, the Urn Tomb, and the Tomb of the Roman Soldier. In 1924 he also initiated the first work at Gerasa/Jerash, where he devoted considerable energy to clearing and reconstructing several of the site's major monuments, including the south and north theaters, the Propylaeum of the Temple of Artemis, and the Nymphaeum. Four years later he was joined by an Anglo-American expedition from the British School of Archaeology in Jerusalem and Yale University, led by John Crowfoot; in 1930 a team from the american schools of oriental research (ASOR), under the direction of Clarence Fisher and later Nelson Glueck (in 1933 and 1934), also began to work with Horsfield. At Amman work on the citadel was carried out by the Italian Archaeological Mission beginning in 1927 and concluding in the 1930s, and from 1936 on other parts of the city were studied by the director of the Transjordan Department of Antiquities, G. Lankester Harding. Overall, these excavations revealed the exceptional state of preservation of many of the sites of classical antiquity. Efforts were begun to preserve them from the destruction that would ensue from

development and expanding populations in the region.

Other notable projects in the British mandate period included the discovery of Teleilat el-Ghassul,

by those working in Jordan, and although it contained some errors, it was, in general, remarkably accurate. His two popularizations of the archaeology of the region, *The Other Side of Jordan* (1940) and *Deities and Dolphins: The Story of the Nabataeans* (1966), brought the antiquities of Jordan to a wider readership. Glueck also undertook two excavations in Transjordan, first (1937-1938) at Khirbet et-Tannur, a Nabataean temple site in the Wadi al-Hasa, and later (1938-1940) at the site of Tell el-Kheleifeh, which he believed to be Solomon's seaport Ezion Geber. These two periods of the Iron Age and the Nabateans were to be the main focus of Glueck's career, which was inspirational to the generation of archaeologists that followed.

Archaeology in the Hashemite Kingdom of Jordan, 1946-1967

After 1946, when Transjordan became an independent kingdom under the rule of the Hashemites, the area underwent a period of steady growth in terms of the development of a national archaeology. The retreat of British sovereignty in the region did not mean an immediate withdrawal of British interests or support, and G.L. Harding continued as director of what was now the Department of Antiquities of Jordan until 1956. Harding served as director of this department for twenty years (1936-1956) and was instrumental in the formation of archaeological policies that helped to establish the national school of archaeology in Jordan. In 1951 he founded the *Annual of the Department of Antiquities of Jordan,* which reported on the yearly archaeological work in the country, and later he wrote the first major popularization of the archaeology of Jordan, *The Antiquities of Jordan* (1959).

During the Hashemite period and following the partition of Palestine and the formation of the state of Israel (in 1948), the Department of Antiquities of Jordan was also responsible for the archaeology of the portion of Palestine that came to be known as the West Bank. This region included many of the major biblical sites, among them Jerusalem. Many of the international schools preferred to continue to work in this region, and major excavations in the former Transjordan were less frequent than might otherwise have been expected.

Some of the best-known projects include those by English archaeologist kathleen kenyon, who carried out a series of excavations at Jericho from 1952 to 1958, when she was director of the British School of Archaeology in Jerusalem (BSAJ); later, from 1961 to 1968, Kenyon excavated in Jerusalem itself at the “City of David” (Ophel), working with a multinational team under the auspices of the Palestine Exploration Fund. The 1956-1968 fieldwork directed by G.E. Wright at Tell el-Balatah (Shechem), which was sponsored by Drew University and McCormick Theological Seminary (and later Harvard University) and affiliated with ASOR, was the principal U.S. excavation during this period. The École Biblique et Archéologique Française excavated the site of Tell el-Farah, associated with biblical Tirzah, under the direction of R. De Vaux from 1946 to 1960 and later conducted studies at Qumran (as will be discussed).

Outside of the West Bank and in Jordan proper, excavations began at the site of ancient Dhiban/Dibon under F. Winnett, W. Reed, and D. Tushingham (1950-1956) and at Deir 'Alla under H.J. Franken and a Dutch team from Leiden University (1960-1967). The German Evangelical Institute also began work at Umm Qeis, the Decapolis city of Gadara, in 1966. Other notable work included that by British archaeologist Peter Parr and U.S. archaeologist Philip Hammond, who led teams at Petra between 1954 and 1968, as well as renewed work at Teleilat Ghassul by R. North and the PBI (1960) and later Basil Hennessey under the auspices of the BSAJ (1967). U.S. work conducted with ASOR affiliation was also undertaken at 'Iraq el-Amir (1961-1962) and at Bab edh-Dhra (1965-1967) under Paul Lapp, then director of the American School in Jerusalem.

Perhaps the most spectacular archaeological achievement of this period was the discovery of the dead

sea scrolls. Local Bedouin found these biblical and extrabiblical texts dating to the first and second centuries a.d. in caves along the northwestern shore of the Dead Sea. This discovery led to a series of concentrated excavations

PREV NEXT

at the various caves and later at Khirbet Qumran under the Jordanian Department of Antiquities, the Palestine Archaeological Museum, and the École Biblique et Archéologique Français under the direction of De Vaux (1951, 1953-1956). The finds from both the caves and the nearby site at Qumran (thought to be the complex associated with the writers of many of the scrolls, the Essenes) have significantly influenced modern research on the Bible, enabling insights into the early biblical communities in the region.

This period of archaeological research both in the West Bank and in Jordan itself established a pattern of archaeological fieldwork being conducted by schools from most of the major western powers; it also represented the longest phase of uninterrupted research in the region. The effects of this work are still being felt, with many of the principal researchers in the field of Levantine archaeology having "cut their teeth" during this time and on many of these projects; these individuals (who are only now retiring) have in turn been instrumental in establishing the study of Levantine archaeology in many countries. The 1946-1967 period also established the practice of having the Jordanian Department of Antiquities partner with of the international schools in the documentation, publication, and preservation of the rich archaeological heritage of Jordan.

Archaeology in Jordan, 1967 to the Present

Following Jordan's loss of the West Bank during the Six-Day War in 1967, Jordanian archaeology once again focused on land east of the Jordan River. Many of the international schools (British, U.S., German) set up "temporary" offices in Jordan (Amman) at this time, in order to continue archaeological research but avoid excavation in the Israeli occupied territories, which would have breached UN rules. The American Schools of Oriental Research in Jerusalem was the first institution to set up a "branch office" in support of research in Jordan in 1968, and British researchers soon followed suit. Within a few years, in 1971, the American Center for Oriental Research (ACOR) was founded, and somewhat later, in 1978, British archaeologists formalized their shift from Jerusalem to Amman via the establishment of the British Institute at Amman for Archaeology and History (now the Council for British Research in the Levant), under the direction of Crystal Bennett.

The founding of headquarters in Amman for many of the international schools at this time marked a transition or a break in the direction of archaeological research in Jordan and in Israel and the West Bank. From this point forward archaeological work in Israel and Jordan developed along independent lines, with increasingly little contact between the scholars of both countries. This situation was equally true for the indigenous archaeologists (Israeli and Jordanian) and for the archaeologists from the international schools. In particular, many of those formally working in Jordan were reluctant to jeopardize the situation by making contacts and pursuing active research west of the Jordan Rift. Consequently, archaeology in Israel developed on an independent trajectory and along specific national lines in a way that was distinctly different from the archaeology in Jordan.

The national school in Israel sought its roots in the archaeology of ancient Israel and Judah and in Jewish history in general, but archaeology in Jordan was less political. The populations in Jordan were largely Bedouin and were not particularly interested in developing a history of occupation for the region along the lines being pursued by Israeli biblical archaeologists: they claimed no distinctly historical links with either the Nabataeans or the Iron Age kingdoms of Ammon, Moab, and Edom. Given this move away from a focus upon a narrowly defined and specific culture-historical approach, archaeological work in Jordan was much more diverse, and a number of specific subfields of archaeology were free to develop.

Nonetheless, some Jordanian researchers were interested in biblical archaeology and the study of the Bronze and Iron Ages, as expressed in the excavations of Crystal Bennett in Edom at sites such as Tawilan and the ancient Edomite capital at Buserieh (1968-1974, 1980). There were, however, just as

many scholars who focused upon the world of classical and late Antiquity,

to) Adnan Hadidi, Ghazi Bisheh, Safwan Tell, and Fawaz al-Khrayshah.

The future of archaeology in Jordan is bright, with many Jordanians taking an active interest in the history and archaeology of their country, as evidenced by the thriving archaeology departments at the University of Jordan (Amman), Yarmuk University (Irbid), and Mutah University (Kerak). Many of the graduates in the field are employed in the Department of Antiquities and other aspects of Jordanian heritage. Often working in partnership with international research projects, they are now creating a distinctive Jordanian archaeology.

Journal of Field Archaeology

The *Journal of Field Archaeology (JFA),* a quarterly periodical, was founded in 1974 by James R. Wiseman and has been substantially supported since that time by Boston University, whose trustees hold the copyright. Originally the journal was published at Boston University on behalf of the Association for Field Archaeology, but when that organization was dissolved in 1989, its remaining assets were

transferred to *JFA*. Three years earlier, the general editorship had passed to Creighton Gabel, who continued in that capacity until 1994. In 1995, Ricardo J. Elia became editor. During most of the *JFA*'s history, the managing editor has been Al B. Wesolowsky, another professional archaeologist, while David Ford, as the long-term art director, has contributed greatly to the quality of the graphics.

The stated purpose of the journal was, in particular, to provide a forum for the publication of field reports in recognition of the fact that such venues were becoming increasingly limited even as the discipline grew. At the same time, the *JFA* has welcomed submission of specialized technical and methodological studies, ranging from materials science and field techniques to ethno-archaeology and experimental archaeology. On occasion, survey articles providing historical perspectives on, or summarizing recent research in, major world areas also have been published. No restrictions have ever been placed on the geographical or temporal focus of contributions.

In addition to full-length articles and briefer research reports, some special feature sections have appeared for a number of years. One was "The Archaeometric Clearinghouse" edited by Curt W. Beck (Vassar College) from 1974 to 1993; with a new title, "Archaeological Science Review," this special section subsequently came under the editorship of Julian Henderson of Sheffield University in England. Reflecting the growing concern about the illicit trafficking in antiquities, "The Antiquities Market" section likewise began to appear in the first year of publication, with Karen Vitelli (Indiana University) assuming direct responsibility for it in 1976, replaced by Ellen Herscher of Washington, D.C., in 1984 and by Timothy Kaiser (University of

K

Karageorghis, Vassos

(1929-)

Vassos Karageorghis dominated Cypriot archaeology in the latter half of the twentieth century. He studied archaeology at the Institute of Archaeology at London University (Ph.D. awarded in 1957). Shortly after cyprus gained independence from Great Britain, he became director of the Department of Antiquities, and after retiring from that position, he established the Archaeological Research Unit of the newly founded University of Cyprus. He has been a visiting scholar at a variety of universities in Europe and the Americas and is currently director of the Leventis Foundation. His primary field of research has been on the Iron Age and the late Bronze Age of Cyprus, with major, large-scale excavations at Salamis, Kition, Maa-Palaekastro, and Pyla-Kokkinokremnos; the results of all have been efficiently and comprehensively published. He has written widely on specific Cypriot issues as well as on the relationship between Cyprus and surrounding regions. Among his major contributions is a series of monographs on Cypriot terracotta models. Through the Leventis Foundation he has provided funds to several major museums to develop new displays of their Cypriot material, and he has done much to establish the place of Cyprus internationally, in part by encouraging foreign excavators to work on the island. His activities in repatriating looted antiquities have also been of particular significance.

David Frankel

Karnak and Luxor

The temples of Karnak and Luxor are located on the east bank of the Nile at the modern city of Luxor (ancient Thebes) in southern Egypt. The two temples formed the religious heart of the city of Thebes. The urban remains of ancient Thebes cluster around Karnak extending southwards toward Luxor temple. Much of the standing remains of these great stone temples were exposed through unscientific excavation during the nineteenth century. However, modern archaeological excavation and epigraphic recording of scenes and texts, as well as the analysis and interpretation of these massive buildings, is likely to continue for the foreseeable future. Conservation and reconstruction of the Karnak and Luxor temples continues to be a major activity of the Egyptian Supreme Council of Antiquities and numerous foreign projects conducting work at Luxor.

The majority of the visible architecture of the Karnak and Luxor temples dates to the New Kingdom (Dynasties 18-20, ca. 1550-1070 b.c.) and later periods. Alterations and additions to Karnak and Luxor temples did not cease until the beginning of the Christian Periodin the first century a.d. Karnak and Luxor temples are among the best-preserved temple sites in Egypt. Profusely decorated with scenes and texts, the temples provide an unparalleled glimpse into the religious life of ancient Egyptian society.

The main temple at Karnak (known in ancient Egyptian as *Ipet-Sut*) was dedicated to the god Amun(-Re), a deity who rose to prominence in the Middle Kingdom (ca. 2050-1750 b.c.) and who became the premier state god during the New Kingdom. Flanking the Karnak precinct of Amun-Re on its south and north side respectively are satellite precincts dedicated to Mut (the consort of Amun-Re) and Montu (a falcon god associated with warfare). Shrines and subsidiary temples dedicated to many additional gods (including Khonsu, Osiris, Maat, and others) are located within these three main precincts. The Luxor temple (which was known as *Ipet-Resyt*) is located two kilometers south of Karnak. The temple was dedicated to a form of the god Amun known as Amenope. In ancient times,

the Luxor and Karnak temples were linked by a processional route that is still lined today with human-headed sphinxes added by the Late Period king Nectanebo I. An annual religious festival known as the Opet Festival was the most significant religious ceremony in the life of ancient Thebes. During this festival a statue of Amun was carried out of the Karnak temple to Luxor temple for the enactment of religious rites that celebrated the association between the pharaoh and Amun.

Kastelic, Jožef

(1913-)

The Slovenian archaeologist, ancient historian, and poet Jožef Kastelic graduated in classical philology and ancient history from the University of Ljubljana in 1939 and completed his Ph.D. at the same university in 1943. Between 1942 and 1968, Kastelic worked at the National Museum in Ljubljana and became its director in 1945. He was also professor of classical archaeology, Roman provincial archaeology, and ancient history at the University of Ljubljana between 1968 and 1983 and professor of ancient history at the University of Maribor (Slovenia) between 1985 and 1989. Kastelic is a member of German Archaeological Society, the Institute of Etruscan and Italic Studies in Florence, and the Italian Institute of Pre- and Protohistory.

One of the most influential archaeologists in slovenia, Kastelic is credited along with colleague josip korošec for the revival of archaeological work in Slovenia and Yugoslavia after World War II. He continued the National Museum's long tradition as the central and national archaeological institution and established some of the important series and journals: *Arheoloski katalogi, Situla,* and *Argo.* Kastelic organized many influential exhibitions, such as *Umetnost alpskih Ilirov in Venetov* (Situla Art between Po and Danube) in Ljubljana in 1962. He was one of the founders of early Slavic archaeology in Slovenia after 1945. Between 1948 and 1949, he excavated at large early Slavic cemetery in Bled (see *Slovanska nekropola na Bledu* [Ljubljana 1950] and *Slovanska nekropola na Bledu* [Ljubljana 1960]). Kastelic excavated a large barrow in stična between 1946 and 1953 and participated in many joint Yugoslav research projects, among them research in Yugoslav Macedonia at the sites of Demir Kapija and Trebeniste. As the head of the Department of Archaeology at the University of Ljubljana, he decisively molded and defined its new and articulated structure in the 1960s and 1970s.

Keller, Ferdinand

(1800-1881)

Ferdinand Keller was the founder of the lake-dwellings theory, a member of the old bourgeoisie of Zurich, and an English teacher at the Technicum there, and he was the most prominent archaeologist in switzerland in the nineteenth century.

After studying theology and then natural science in Paris, Keller went to England where he was a private

tutor, and where he met sir richard colt hoare in Wiltshire. Colt Hoare was the owner of a rich collection of prehistoric relics, and although Keller was primarily fascinated by Celtic antiquities, he was strongly influenced by a visit to the Salisbury burial mounds and Stonehenge.

He returned to Zurich and discovered the Burgholzli mounds, which led him to found the Antiquarian Society of Zurich in 1832, the first organization of its kind in Switzerland. His interests went beyond prehistory to include all vestiges of the past, from Roman colonies to religious architecture, not forgetting medieval paleography. Thanks to his eclecticism, his mastery of languages, and his easy social nature, he was constantly in contact with a very large network of archaeologists and antiquarians both in Switzerland and abroad. His correspondence remains an extraordinary source of original information, and much of it is yet unpublished.

Despite the variety and quantity of his research, it was the discovery of the lake dwellings themselves that gave him exceptional fame. During the winter of 1853-1854, a record lowering of the water level in Lake Zurich led to the discovery, in Obermeilen, of pile fields accompanied

Keller, Ferdinand

(1800-1881)

Ferdinand Keller was the founder of the lake-dwellings theory, a member of the old bourgeoisie of Zurich, and an English teacher at the Technicum there, and he was the most prominent archaeologist in switzerland in the nineteenth century.

After studying theology and then natural science in Paris, Keller went to England where he was a private

tutor, and where he met sir richard colt hoare in Wiltshire. Colt Hoare was the owner of a rich collection of prehistoric relics, and although Keller was primarily fascinated by Celtic antiquities, he was strongly influenced by a visit to the Salisbury burial mounds and Stonehenge.

He returned to Zurich and discovered the Burgholzli mounds, which led him to found the Antiquarian Society of Zurich in 1832, the first organization of its kind in Switzerland. His interests went beyond prehistory to include all vestiges of the past, from Roman colonies to religious architecture, not forgetting medieval paleography. Thanks to his eclecticism, his mastery of languages, and his easy social nature, he was constantly in contact with a very large network of archaeologists and antiquarians both in Switzerland and abroad. His correspondence remains an extraordinary source of original information, and much of it is yet unpublished.

Despite the variety and quantity of his research, it was the discovery of the lake dwellings themselves that gave him exceptional fame. During the winter of 1853-1854, a record lowering of the water level in Lake Zurich led to the discovery, in Obermeilen, of pile fields accompanied

by potsherds and tools of stone, antler, and wood. Informed of the discovery by a schoolteacher, Keller immediately recognized the significance of the find and interpreted the remains as dwellings on pile-supported platforms above the water. Thus, even though pile stumps had been observed a few years before on the shores of Lake Bienne, it was only when Keller got interested in them that research on the Swiss lake dwellings began to get real attention in Europe.

It is with regard to the lake dwellings that Keller's contribution to archaeological research in Switzerland can best be evaluated. Although his work was always serious and well documented, it was not intrinsically innovative; neither was he a master of archaeological excavation. Even if Keller did observe a three-age division in the remains, he did not attach much importance to it. In fact, he gathered all remains from the Neolithic to the Iron Age together and attributed them to a homogeneous Celtic population.

Keller's genius lay in his ability to extrapolatematerial from data on lake dwellings and other sites to provide coherent and global interpretations. The force of Keller's dynamism swept along numbers of specialist naturalists, geologists, botanists, and zoologists. He also managed to interest the public and to keep its interest without entering into or using ethnic customs and religion as explanations. Keller controlled and dominated Swiss archaeology, and his interpretations, however erroneous, remained almost irrefutable and encouraged research instead of blocking it. He can be seen as more of a learned nineteenth-century antiquarian, because of his background in the natural sciences, than as an archaeologist.

Kendrick, Sir Thomas Downing

(1895-1979)

Kendrick was born in Birmingham, England, and won a scholarship to Oriel College, Oxford, in 1913. He joined the army and survived the fighting in France, although he was severely wounded. He returned to Oriel in 1919 and read anthropology and later studied and published on the prehistoric archaeology of

the Channel Islands.

In 1922 he began working at the british museum in the department of British and medieval antiquities. He became assistant keeper in 1928, keeper in 1938, and director and principal librarian from 1950 until his retirement in 1959. Kendrick's primary interest was in Anglo-Saxon art and he was responsible for the display of the great sutton hoo treasure to the public after the war. He also made the his area of expertise accessible, publishing *The Axe Age* (1925), *The Druids* (1927), *A History of the Vikings* (1930), *Anglo-Saxon Art to ad 900* (1938) and *Late Saxon and Viking Art* (1949). He ensured that the museum was as significant to scholars as it was popular.

Kendrick maintained his interest in archaeology, publishing *Archaeology in England and Wales 1914-1931* with christopher hawkes in 1932 and editing several volumes of *The County Archaeologies*. His greatest contribution to the history of archaeology was his magnificent *British Antiquity* (1950), which remains essential reading in this field. He was made a fellow of the British Academy in 1941 and was a fellow of the

Society of Antiquaries, of which he was secretary from 1940-1950.

Kent's Cavern

Kent's Cavern, a limestone cave on the Devonshire coast near Torbay, England, was first excavated in a systematic and serious way by John MacEnery, a local Catholic priest, in 1825, 1826, and 1829. MacEnery found what he considered to be clear evidence of the bones of extinct animals and ancient stone tools in the same strata. Geologist william buckland persuaded MacEnery that this could not be the case, and the publication of his memoir on the site had to wait until 1859, eighteen years after his death.

The site was excavated twice before 1859, in 1841 by R.A.C. Austen and in 1846 by william pengelly, who was later to gain fame as the excavator of brixham cave. Both excavators were persuaded of the association that Buckland had so strongly opposed. After the recognition of high(greater or longer) human antiquity, the British Association for the Advancement of Science funded Pengelly's return to Kent's Cavern between 1865 and 1878.

Kenyon, Kathleen Mary

(1906-1978)

Kathleen Kenyon

(Image Select)

Kathleen Mary Kenyon, the eldest daughter of Sir Frederic Kenyon, was born on 5 January 1906 in England and died at the age of seventy-two on 24 August 1978 at her place of retirement in South Wales. Her father was keeper of manuscripts at the british museum. She attended St. Paul's Girls' School in London and her studies were so successful there that she became “head girl.” She then studied at Somerville College, Oxford University, and received her degree in history in 1929. As she had already decided to make archaeology her career, she seized the opportunity she was offered upon graduation from college to become a photographer and excavator with gertrude caton-thompson on a British Association expedition to great zimbabwe in southern Rhodesia (modern Zimbabwe).

Between 1930 and 1935, Kenyon continued her training and fieldwork with the legendary sir mortimer wheeler at the Roman town of Verulamium near St. Albans, England. Her important contribution was the uncovering of the Roman theater there, the only public monument of its kind in the British Isles.

Kenyon spent the summer months from 1931 to 1934 on her first Near Eastern archaeological project.

She worked on the Palestine Exploration Fund's Crowfoot expedition to Samaria. She applied and refined her Romano-British field-training techniques to her excavations at Samaria, which made her a pioneer along with sir william matthew flinders petrie, george a. reisner, and Clarence Fisher in the introduction of methods of stratigraphical digging to archaeological excavations, with drawn sections, at ancient Near Eastern sites.

In 1935, Kenyon helped Wheeler establish the Institute of Archaeology at London University.

Kent's Cavern, a limestone cave on the Devonshire coast near Torbay, England, was first excavated in a systematic and serious way by John MacEnery, a local Catholic priest, in 1825, 1826, and 1829. MacEnery found what he considered to be clear evidence of the bones of extinct animals and ancient stone tools in the same strata. Geologist william buckland persuaded MacEnery that this could not be the case, and the publication of his memoir on the site had to wait until 1859, eighteen years after his death.

The site was excavated twice before 1859, in 1841 by R.A.C. Austen and in 1846 by william pengelly, who was later to gain fame as the excavator of brixham cave. Both excavators were persuaded of the association that Buckland had so strongly opposed. After the recognition of high(greater or longer) human antiquity, the British Association for the Advancement of Science funded Pengelly's return to Kent's Cavern between 1865 and 1878.

Kenyon, Kathleen Mary

(1906-1978)

Kathleen Kenyon

(Image Select)

Kathleen Mary Kenyon, the eldest daughter of Sir Frederic Kenyon, was born on 5 January 1906 in England and died at the age of seventy-two on 24 August 1978 at her place of retirement in South Wales. Her father was keeper of manuscripts at the british museum. She attended St. Paul's Girls' School in London and her studies were so successful there that she became “head girl.” She then studied at Somerville College, Oxford University, and received her degree in history in 1929. As she had already decided to make archaeology her career, she seized the opportunity she was offered upon graduation from college to become a photographer and excavator with gertrude caton-thompson on a British Association expedition to great zimbabwe in southern Rhodesia (modern Zimbabwe).

Between 1930 and 1935, Kenyon continued her training and fieldwork with the legendary sir mortimer wheeler at the Roman town of Verulamium near St. Albans, England. Her important contribution was the uncovering of the Roman theater there, the only public monument of its kind in the British Isles.

Kenyon spent the summer months from 1931 to 1934 on her first Near Eastern archaeological project.

She worked on the Palestine Exploration Fund's Crowfoot expedition to Samaria. She applied and refined her Romano-British field-training techniques to her excavations at Samaria, which made her a pioneer along with sir william matthew flinders petrie, george a. reisner, and Clarence Fisher in the introduction of methods of stratigraphical digging to archaeological excavations, with drawn sections, at ancient Near Eastern sites.

In 1935, Kenyon helped Wheeler establish the Institute of Archaeology at London University.

Khirokitia-Vouni

The world heritage site Khirokitia-Vouni is the most extensively excavated aceramic Neolithic settlement on cyprus. It was initially excavated by porphyrios dikaios between 1936 and 1946. Limited work was later carried out by Nicholas Stanley Price and Demos Christou, and since 1977 Alain Le Brun has continued excavations at the site. It is the type site for the Cypriot aceramic Neolithic period(early Neolithic or Khirokitia culture).

A very extensive area of the site has been cleared, revealing a closely packed array of circular houses of varied size. Most have very substantial stone foundations, with mud brick superstructure and flat roofs. In the larger examples, interior space may have been increased by platforms or mezzanine floors. A substantial stone "wall" running up the slope the full length of the excavated area has been variously interpreted, most recently as a formal boundary of the settlement marking off the safe interior from a hostile exterior. As the settlement grew, new houses were erected outside the wall, and a new wall, with a complex entry, was built. Intramural burials are a feature of the site. The economy of Khirokitia was based on an array of plants, many or which were imported to Cyprus at the beginning of the Neolithic period, and by a range of imported animals, primarily sheep, goat, pig, and deer.

Kidd, Kenneth E.

(1906-1994)

Kenneth E. Kidd was the pioneer founder of Canadian historical archaeology. His initial training and fieldwork were in ethnology (his M.A. thesis at the University of Toronto was on Blackfoot ethnography) and prehistoric archaeology. In 1935, he joined the Department of Ethnology at the Royal Ontario Museum where he was assigned in 1941 to excavate one of the most famous sites in canada, the Jesuit Mission of Sainte-Marie (1639-1649) established in Huron Territory (Ontario). His two-year project at this site basically created Canadian historical archaeology and his book, *The Excavation of Ste. Marie I,* is very likely the first professional site report for any historic site in North America published as a separate book (Kidd 1941).

Unlike a number of his contemporaries in the United States, including j. c. harrington and john l. cotter, Kidd did not abandon prehistoric studies for Euro-American sites. His primary interest in the contact period kept him firmly committed to both types of archaeology. In 1948 he authored a significant report, "The Excavation of a Huron Ossuary," and that article was followed by a popular synthesis, *Canadians of Long Ago: The Story of the Canadian Indian,* published in 1951 (Kidd 1948, 1951). His career-long focus on contact situations drew him into a lifelong study of European trade goods, especially glass beads, and in 1970, he and his wife, Martha Ann Kidd, summarized years of museum and archival research in "A Classification System for Glass Beads for the Use of Field Archaeologists" (Kidd and Kidd 1970). This system, although weakened by his choice of an impressionistic color-coding typology, was the first important guide to an artifact category found in historic sites on

every continent.

In 1964, Kidd left the museum world to become the first holder of chair of the new Department of Anthropology at Trent University in Peterborough, Ontario, where he taught until his retirement in 1973. At Trent he made historical archaeology central to the curriculum and also established one of the first Indian-Eskimo studies programs in Canada.

Kidd was one of the few members of his pioneering generation who had a keen interest in the history of archaeology. He synthesized and surveyed Ontario archaeology in several articles across the decades and his article “Historical Site Archaeology in Canada” (Kidd 1969) is the only national history for that field in Canada.

In 1985, the Society for Historical Archaeology honored Kidd with its highest award, the j. c. harrington medal, and in 1993, he was presented with the Commonwealth Medal for the

Kidder, Alfred Vincent

(1885-1963)

Kidder grew up in Cambridge, Massachusetts, and as a young man befriended many of Harvard's great scientists, such as geologists raphael pumpelly and Alexander Agassiz and anthropologists lewis henry morgan and frederic ward putnam from the peabody museum, through his family connections. Kidder began studying medicine at Harvard in 1904, but changed to archaeology after participating in edgar lee hewett's field school and meeting Alfred Marsten Tozzer, professor of archaeology.

In 1909 Kidder entered graduate school at Harvard to begin work on his doctorate in anthropology under the supervision of Egyptologist george reisner, art historian George Chase, and anthropologist Franz Boas. Kidder continued to excavate during the summer, in 1910 in Newfoundland, and in 1912 at historic Pueblo ruins in the Gobernador and Largo canyons in New Mexico. In 1914 Kidder received his Ph.D. on the style and decorative motifs of Pueblo pottery, suggesting that ceramic materials could be used as a gauge of cultural development in the American Southwest, similarly to what was being done by archaeologists at Old World sites in Europe, Africa, and Asia.

Kidder is best remembered for his pioneering approach to the study of Pecos Pueblo (1915-1924) in New Mexico, which had been occupied in both prehistoric and historic times. The connection between potsherds and stratigraphic excavation would be the hallmark of Kidder's work at Pecos Pueblo, conducted on a massive scale. His use of stratigraphy not only introduced this method of relative dating to archaeology but also brought a sense of the spatial distribution of territory under the control of a specific prehistoric culture. Moreover, Kidder established the value of stratigraphy to Americanist archaeology. While waiting to be inducted into the army in 1917 Kidder spent two months living at the First Mesa in Hopi Indian country and traveling around Hopi territory. Using ethnographic data from cultural anthropology and melding it with excavation data into a workable whole, Kidder's data from this period raised the science of archaeology to a new interpretive level. In 1920 Kidder was able to return to Pecos Pueblo, where he employed a multi-disciplinary approach to resolve its archaeological problems-physical anthropologists, pottery analysts, ethnographers, engineers, and agronomists were

some of the members of the team that studied the Pecos Pueblo material-the first long-term and multi-disciplinary project in North American archaeology.

In 1929 Kidder began the second half of his archaeological career by becoming the director of the Carnegie Institute's Division of Historical Research in Washington, D.C. Kidder now turned his attention for the most part to the maya of Central America, and introduced his “pan-scientific”/multi-disciplinary approach to resolving Mayan archaeological problems. While this approach was never fully realized, it did succeed in collecting data about the Mayan habitat, agricultural base, technology, and living descendants. Kidder and Charles A. Lindbergh worked jointly on the aerial discovery of Mayan sites throughout the Yucatán and in other locations and began to use the airplane as a tool to trace possible trade routes between Mayan cities. Kidder employed longtime friend and colleague sylvanus g. morley to continue his groundbreaking work deciphering Mayan hieroglyphics. Kidder himself excavated the Kaminaljuyu

mounds in guatemala, and encouraged the careers of two Mayan archaeologists: Anna O. Shepard and tatiana proskouriakoff. During this time Kidder was also concerned with the importance of the environment and its influence on human culture. He included a concentration on environmental factors in his program of Mayan archaeology, a far-sighted move in 1953, since today's archaeology considers this type of research as routine for most field/site analysis.

After World War II the Carnegie Institution began to allocate more of its resources to the "hard sciences" and less to the human and social ones, eventually closing down the Division of Historical Research, but not before Kidder proposed that the institution underwrite the use of radiocarbon dating for archaeology. Kidder retired in 1950, but until his death he continued to act as mentor for many archaeology students and colleagues and he taught a graduate course in archaeology at the University of California at Berkeley. As a reflection of the esteem in which he was and is still held, the Alfred Vincent Kidder medal was created by the society for american archaeology, and is awarded every three years to an outstanding Americanist.

Kings Bay Plantations

Because of construction of the Kings Bay Naval Submarine Base, researchers from the University of Florida investigated six plantations on the southernmost part of the Georgia coast from 1977 to 1985-Cherry Point, Kings Bay, Harmony Hall, Marianna, Point Peter, and New Canaan. These plantations were small, middle, and large according to land- and slave-holdings categories developed by historians. Charles H. Fairbanks and Robin Smith conducted the testing from 1977 to 1980, while William H. Adams directed the testing and data recovery phases from 1981 to 1985. Thomas H. Eubanks directed the excavation of the McIntosh Sugarhouse in 1981 and 1985, and in 1981, this project was the first to make field use of microcomputers linked as smart terminals to the mainframe. In 1985, the project also made the first use of video camera/computer interfacing to produce artifact illustrations successfully.

The Kings Bay project was unique because it investigated all the plantations located between Crooked River and St. Marys River, a distance of over eight miles, and these were historically linked into a single community. Previous plantation archaeology had generally focused on big plantations, but at Kings Bay small and middle-sized ones were also investigated.

Because these plantations were geographically close, the environmental differences were largely nil, an especially important point for the zooarchaeological study. The faunal analysis done by William Richard Adams at Indiana University was by far the most detailed for historical sites on the coast-27,353 bone fragments from planter sites and 10,552 fragments from slave sites. Using calculations of meatweight, it was found that planters ate considerably more wild food than slaves did and utilized a wider variety of wild species.

Ceramic analysis, coupled with analogous historical documentation, suggests that slaves on task-system plantations like these had the ability and capital to engage in the market economy to support themselves. This greater economic freedom and market participation by slaves provided them with a means to control much more of their own lives than on the more-paternalistic gang-system plantations.

Kitchenmidden Committee

The Danish zoologist japhetus steenstrup began researching the shell banks of northern denmark in the 1820s in order to understand sea- and land-level changes. Initially, he believed that the enormous mounds of shells were the result of geological change-that they had been washed up by the sea. However, in the course of his excavations he found artifacts, bones, and hearths that he dated to the Stone Age period.

In 1848, the Danish Academy of Sciences established a multidisciplinary committeeto study shell middens, or kitchen middens, and geological and sea-level changes. Steenstrup, the geologist Forchammer, and the archaeologist jens jacob worsaae reexamined the shell banks. In 1850, they discovered the enormous shell bank at Melgaard and recovered numerous implements and bones from it. Although it was Worsaae who suggested that the enormous piles of shell represented the remains of meals eaten by Stone Age people over a long period, Steenstrup coined the name *kitchen middens*.

All three men studied and recorded over fifty shell banks habitation sites in Jutland and Zealand in Denmark and in Scania in sweden. In the early 1850s, they published six volumes of reports on these kitchen middens, demonstrating that they were of human origin and mapping patterns in accumulation. They also proved that the middens were occupied seasonally, and this fact, along with the distributions of hearths and artifacts, provided evidence of human behavior and activities.

Steenstrup disagreed with Worsaae about the age of the middens, believing that they were Neolithic or Stone Age but that they were contemporaneous with the builders and occupants of the Megalithic tombs. Worsaae rightly believed them to be earlier. In lectures in 1857, Worsaae argued for a chronological division of the Stone Age into two periods; the shell bank kitchen middens were from the earlier period, and the Megalithic tomb period was later.

Steenstrup's successful collaboration with Forchammer and Worsaae was the first of many successful collaborations between archaeologists, geologists, and biologists in Scandinavia and elsewhere. Steenstrup proved the importance of understanding the paleoenvironment to the study of archaeology, and his pioneering study of post-glacial flora was among the first of many significant contributions by biologists to archaeological chronology-with palynology, dendochronology, and carbon-14 dating reaching their apogee in the twentieth century.

Klemenc, Josip

(1898-1967)

The Slovenian archaeologist and ancient historian Josip Klemenc graduated in archaeology in 1920 and in history and geography in 1921 from the University of Zagreb, Croatia. He received his Ph.D. in archaeology from the same university in 1929 for his thesis on the dislocation of the Roman Army in Pannonia in the first century a.d. Between 1922 and 1942, he worked in the Archaeological Museum in Zagreb, where he became a curator. In 1946, Klemenc was appointed professor of classical archaeology and ancient history in the newly established Department of Archaeology at the University of Ljubljana, slovenia, which produced the first generation of Slovenian archaeologists after World War II.

Klemenc's professional interests focused principally on the ancient topography, epigraphy, and numismatics of the Roman provinces of Noricum and Pannonia. In pre-World War II Yugoslavia, he initiated the study of archaeological topography, and between 1936 and 1939, he published three volumes of *Archaeologische Karte von Jugoslawien: Blatt Ptuj* (1936), *Blatt Zagreb* (1938), and *Blatt Rogatec* (1939), the first and the third with B. Saria. However his most influential work is associated with his discovery of Roman funerary art in Slovenia. In the Roman cemetery in Sempeter near Celje, the Roman colony of celeia, he discovered and studied sculptural remains that today

represent the best examples of high-quality provincial art in Noricum.

Although the German archaeologist heinrich schliemann had sought permission from the Turkish authorities to excavate at Knossos in the 1880s, the site is inextricably linked with the career of sir arthur evans. Knossos lies in the north part of central Crete, quite close to the present coastline. Although settlement is thought to have begun around 6000 b.c., it is clear that the large palace structure that lies at the core of

the site existed by about 1900 b.c. Evans's excavation of Knossos began in 1900, and the task was to tax his excavation and conservation skills until 1929. Although there has been considerable discussion of the conservation strategies followed by Evans and his associates, and about his emphasis on the "Minoan" civilization as being of Indo-European origin, there is no doubting the magnificent achievement of his major publication of the site, *The Palace of Minos at Knossos* (four volumes between 1921 and 1935). At Knossos, Evans had "found" the Minoan civilization, and, following Schliemann, he had further enhanced the links between myth and history.

Kondakov, Nikodim Pavlovich

(1844-1925)

The son of a freed serf and steward of princely estates, Kondakov went to school in Moscow, and in 1861 was sent to study at the University of Moscow with Slavic historian, philologist, and folklorist Ivonvich Buslayev. In deference to his teacher's dislike of Darwinism and prehistoric archaeology, Kondakov studied Classical and Byzantine art, graduating in 1866 and becoming a teacher at his old school.

In 1871, after traveling abroad to study classical monuments, Kondakov was appointed to the professorial chair of the theory and history of art at Novorossiysk University in Odessa. Scholars at this university were actively studying the local classical monuments of the Northern Black Sea coast and Kondakov participated in the excavation of the necropolis of the ancient Nimphaeum in Kerch, in the Crimea, where members of both the Greek and Scythian aristocracy were buried-the best excavated, researched, and recorded necropolis in the ancient world. Between 1873 and 1884 Kondakov traveled to major centers in Europe and the Near East, visiting libraries and museums and writing a monumental synthesis on the history of Byzantine art, his doctoral thesis *The History of Byzantine Art and the Iconography of the Miniatures of Greek Manuscripts.* This won the Gold Medal of the Russian Archaeological Society

and resulted in his appointment to the influential Emperor's Archaeological Commission, whose three members were in charge of all archaeological activity in russia.

In 1888 Kondakov became professor of art history at Petersburg University and principal curator of medieval antiquities at the Imperial Hermitage Museum. In 1889 he became an academician (member of an imperial academy of eminent academics). He published six volumes of *Russian Antiquities in Monuments of Art* and a work on Russian archaeology, *Russian Hoards,* in 1898. In the latter Kondakov researched burial mounds, hoards, and other finds "in all aspects of their style, typical form of subjects, (and) its historical changes," using the iconographic typology developed in his thesis and transforming it into an archaeological typology. Kondakov continued to travel extensively and to publish his research on Byzantine art, which he described as the result of three different cultural and aesthetic traditions and influences-Hellenism, Greek-Egyptian-Near Eastern Orientalism, and the nomads from the steppes of the Black and Caspian Seas, Central Asia, and Southern Siberia.

At the end of the nineteenth century Russian prehistoric archaeology came of age. In 1899 aleksander spitsyn's *The Settling of Ancient Russian Tribes According to Archaeological Data* and gorodcov's "Russian Prehistoric Ceramics" were published, the latter becoming the basis of all typological work by Russian archaeologists. Kondakov returned to the analysis of Byzantine art, writing *Iconography of Our Lady, Connections of Greek and Russian Icon-Painting with Italian Painting of the Early Renaissance* in 1911 and the two-volume *Iconography of Our Lady* in 1914-1915.

Kondakov's work, which redefined Russia and Russian culture as an expression of the Orthodox East as distinct from the cultural traditions of the West, also argued for Byzantium as the prototype for the contemporary Tzarist Russian empire. Both had unified Europe and Asia, and both justified Orthodoxy and autocracy. However this meant that liberal intellectuals and revolutionaries identified Byzantine influence with the maintenance of the monarchy and the social and political order. Kondakov was socially and politically conservative despite his background; closely connected with the church, he was readily admitted to the palace of Tsar Nicholas II as the court's expert on icon-painting.

Kondakov was 73 when the Russian Revolution began. During the Civil War (1918-1920) he lived in Odessa in territory occupied mainly by anticommunist White Russians and by supporting troops of the European powers. When they lost he went into exile in Istanbul, Sofia, and finally in Prague in Czechoslovakia in 1921, where his pupils organized what became the Kondakov Institute after his death in 1925. The institute became important for the study of czech Byzantine art and Slav philology and history, moving to Belgrade, Yugoslavia, after the German invasion, where it was destroyed in 1944 during a German air raid. Kondakov's numerous pupils have occupied leading positions within Soviet academe. He is now recognized as the founder of Russian archaeology.

Korea

Archaeological research on Korean Peninsula has about 100 years of history, which can be roughly divided into two halves. During the first half, Japanese scholars had exclusive access to, and control of, archaeological research and interpretation in the few years before the Japanese annexation of Korea in 1910 and during their colonial rule of the peninsula from 1910 to 1945. The second half started with the

defeat of japan at the end of World War II and the division of the Korean Peninsula into North and South Korea in 1945. Archaeological developments in the divided Korea have taken place with very little interaction between the two Koreas.

Archaeological Research before 1945

Before the modern discipline of archaeology was introduced to Korea, a number of Korean writers provided their own interpretations of archaeological sites and artifacts such as dolmens,

and resulted in his appointment to the influential Emperor's Archaeological Commission, whose three members were in charge of all archaeological activity in russia.

In 1888 Kondakov became professor of art history at Petersburg University and principal curator of medieval antiquities at the Imperial Hermitage Museum. In 1889 he became an academician (member of an imperial academy of eminent academics). He published six volumes of *Russian Antiquities in Monuments of Art* and a work on Russian archaeology, *Russian Hoards,* in 1898. In the latter Kondakov researched burial mounds, hoards, and other finds "in all aspects of their style, typical form of subjects, (and) its historical changes," using the iconographic typology developed in his thesis and transforming it into an archaeological typology. Kondakov continued to travel extensively and to publish his research on Byzantine art, which he described as the result of three different cultural and aesthetic traditions and influences-Hellenism, Greek-Egyptian-Near Eastern Orientalism, and the nomads from the steppes of the Black and Caspian Seas, Central Asia, and Southern Siberia.

Archaeological Research before 1945

Before the modern discipline of archaeology was introduced to Korea, a number of Korean writers provided their own interpretations of archaeological sites and artifacts such as dolmens,

South Korean Archaeology after 1945

After the defeat of Japan in 1945, the Korean Peninsula was divided into southern and northern halves by the Allied forces. In South Korea, which was controlled by the U.S. forces, the newly founded National Museum in Seoul started archaeological activities in 1946 with the excavation of a Silla tomb in Kyongju. Kim Jae-won was appointed as the first director of the museum. He had received his postgraduate education in archaeology in Europe during the colonial era, but he had no experience of excavation in Korea. Excavations of tombs of the historical period continued, but the museum's work was soon halted by the outbreak of the Korean War (1950-1953).

In the 1950s, the National Museum and a few university museums excavated prehistoric and historical sites of various kinds. The people who participated in the excavations include some of the first generation of Korean archaeologists, such as Jin Hong-seop, Yun Mu-byeong, Kim Won-yong, and Kim Jeok-hak, most of whom had no formal training in archaeology. However, the organization of an exhibition of Korean art that toured major museums in the United States and Europe between 1958 and 1960 resulted in limited archaeological excavation because of the limited number of museum staff members who were available for fieldwork.

In 1961, the Department of Archaeology and Anthropology was established at Seoul National University, and Kim Won-yong, who had recently received his Ph.D. from New York University, became the senior member of the faculty, marking a new era of formal education in Korean archaeology. A doyen of Korean archaeology, Kim Won-yong played the most significant role in training young archaeologists and establishing the basics of Korean prehistory and art history. Graduates from this department have become the major players in Korean archaeology and art history as professors in universities, curators in national and private museums, and bureaucrats in government offices in charge of managing cultural properties.

During the 1960s and 1970s, most archaeological fieldwork was conducted by university museums, the National Museum, and the newly established Institute of Cultural Properties. Excavations of two royal tombs of Silla, the Tomb of Heavenly Horse and the Great Tomb of Hwangnam, in Kyongju and the discovery of the Tomb of King Muryeong, the only intact royal tomb of a great king of Baekje, in Gongju, were of great significance during this period. In addition, the first examples of Acheulean hand-axes in East Asia were discovered in Jeongokni. A Neolithic shell midden site at Yeoncheon in Busan, and a number of Bronze-Age settlement and burial sites were excavated, all of which filled significant gaps in Korea's prehistory.

One of the major accomplishments of Korean archaeology during this period was to overcome the colonial legacy of Japanese archaeologists. In both North and South Korea, archaeologists discovered a number of Paleolithic sites that confirmed a long sequence of cultural development on Korean Peninsula. They also proved that the Japanese interpretation of the so-called Chalcolithic age was wrong by confirming the existence of Neolithic and Bronze Ages in successive chronological order. As archaeological data accumulated, it became apparent that the Korean Peninsula was neither a backward nor a stagnant area of prehistoric cultural development, as the Japanese scholars had tried to portray it. On the contrary, newly discovered archaeological data in both Korea and Japan suggested that the major sources of stimulus for new cultural development in the Yayoi and Kofun periods of Japan were often the ancient societies of the Korean Peninsula.

Since the 1980s, enormous economic development has caused the destruction of numerous archaeological sites, and in order to protect the cultural heritage, legal codes were revised to require mandatory archaeological fieldwork before public and private construction projects could begin. In an

attempt to meet the increasing demand for archaeological fieldwork, a number of new archaeological institutions for cultural resource management (CRM) were launched. These institutions took much of the CRM burden from the university museums, which had conducted most of the archaeological excavations until the 1980s. In order to cope with the changing environment of archaeological

research, a number of new scholarly associations were organized in the late 1980s around research areas and topics. These included the Yeongnam Archaeological Society, the Honam Archaeological Society, the Hoseo Archaeological Society, and the Society for the Study of Korean Neolithic Age. These associations continue to help develop more-detailed studies of each area and thematic topics, but they could lead to an overspecialization and minimal scholarly communication across regional or thematic boundaries.

In recent years, an enormous amount of new archaeological data has been produced each year from hundreds of excavations by CRM projects. As a result of this explosion in archaeological fieldwork, a new picture of Korean prehistory and early history is slowly emerging. Chronological and geographical blanks in the archaeological data are being rapidly filled in, and new archaeological information has forced scholars to reexamine the traditional views of Korean pre- and proto-history.

North Korean Archaeology after 1945

In North Korea, the archaeological and historical interpretation of the past has always been closely intertwined with the political and ideological currents of the North Korean regime. After the Soviet forces took control of the northern half of Korean Peninsula at the end of World War II in 1945, the socialist authorities paid immediate attention to archaeological and historical heritage. In 1946, the Provisionary People's Committee of North Korea promulgated laws and regulations for the preservation of national treasures, ancient sites, scenic spots, and natural monuments. The authorities also established historical museums and organized the Committee for the Preservation of Ancient Sites in Pyongyang and in each province. In the same year, a Neolithic shell midden in Songpyeongdong, Unggi, was excavated by North Korean archaeologists, the first recorded case of an excavation by Koreans. The excavation of a number of prehistoric sites continued until the outbreak of the Korean War.

After that war, archaeological fieldwork was actively carried out in conjunction with national reconstruction and industrialization projects. The leader of the archaeological team was Do Yu-ho, who had studied prehistory at the University of Vienna in Austria during the colonial period. He trained a number of other scholars, including Kim Yong-gan, Hwang Gi-deok, and Kim Yong-nam. Archaeological surveys and excavations in the 1950s accumulated new archaeological data and made it possible for North Korean archaeologists to establish a basic chronology for Korean archaeology, confirming the existence of Paleolithic and Bronze-Age cultures in Korea and overcoming the colonial legacy of Japanese archaeologists.

With this new body of accumulated archaeological data, North Korean scholars began to develop their own interpretations of early Korean history in the 1960s. Their attention focused on the issue of Gojoseon (Old Joseon, or Korea) and its location, territory, cultural sphere, time of formation, and nature of its social organization. The location of Gojoseon on the Liaodong Peninsula in northeastern China was accepted in the 1960s. This period was a golden age for North Korean archaeology, and it was much more advanced than that of South Korea. The most important cultural and historical archaeological theories were Marxism, historical materialism, and unilinear cultural evolutionism.

In the early 1970s, a new state doctrine of *juche,* or self-reliance, was established as the pillar of political ideology and propaganda in an attempt to idolize the North Korean leader Kim Il-sung. As a result, archaeological interpretation was under the direct influence of the ideology of the state and the ruling Workers' Party, and consequently, archaeology and historiography in North Korea became stagnant. In the 1980s and 1990s, archaeological research in North Korea was not as active as it had been in the 1960s, primarily because of the poor economic conditions of the country. The number of archaeological sites that were discovered and excavated decreased. Archaeological research in North

Korea became dormant, with few archaeological discoveries reported and few original archaeological studies published.

In the early 1990s, a new framework for Korean prehistory was developed by North Korean

archaeologists after the alleged discovery of the so-called tomb of Dangun in the Pyongyang area. This was scientific evidence of the existence of the mythical first Korean ancestor, born as the result of a union between a she-bear and the son of heaven according to various written sources of the twelfth century a.d. In order to emphasize the importance of the cultural accomplishments of Dangun and his successors, the earlier chronological framework of the 1960s was abandoned and a totally new picture of prehistoric Korea presented, but without any objective evidence. Archaeology in North Korea has now become a tool of state doctrine, part of the political propaganda of a chauvinist nationalism, and it can no longer be regarded as an independent scientific discipline.

Korean Archaeology in the New Millennium

Korean archaeologists will face many daunting challenges in the early decades of the new millennium. There is so much new archaeological data reported each year in South Korea that it has almost become impossible for even a Korean archaeology specialist to digest and make sense of it all. It is becoming more difficult to synthesize data and provide consistent and comprehensive interpretations of Korean prehistory and early history. This task will only be possible if there is cooperative work among specialists from different periods and themes.

Korean archaeology will need an independent framework of interpretation for both prehistoric and historical archaeology. Archaeological interpretation in Korea remains superficial, with most research being focused on typological studies and the periodization of artifacts and sites, with rudimentary explanations based on diffusion and migration. Historical archaeology does not provide alternative explanations. Historical records are considered to be of primary importance, and this attitude limits and dictates the interpretation of archaeological data. Korean archaeology must become more independent in its theory and methodology so it will be no longer considered a subdiscipline of historiography.

In both North and South Korea, archaeological research was almost exclusively practiced by Koreans in the last half of the twentieth century. Foreigners are still not allowed to excavate an archaeological site in South Korea, and in North Korea, there is no known case of foreign archaeological research. Except for only a few Japanese scholars and still fewer western scholars, Korean archaeology is still very much isolated from the outside world. In order to internationalize Korean archaeology, reports and papers must be published with English abstracts, cooperative fieldwork with foreign institutions should take place, and Koreans should be trained in foreign archaeology. There is still only a single monograph on Korean archaeology in English, and that by a western scholar (Nelson 1993).

The last, but hardly the least, challenge to be faced by Korean archaeologists may be the possible reunification of the two Koreas. Between North and South Korea there are huge differences in theory, methodology, empirical data, and the very practice of archaeology. Even before unification there should be some kind of constructive engagement among archaeologists from the two Koreas, which should include joint field surveys and excavations as well as the exchange of personnel and archaeological collections.

Korošec, Josip

(1909-1966)

The Slovenian archaeologist Josip Korošec was involved with Neolithic, Eneolithic, and early Slavonic archaeology in slovenia in the first

PREV NEXT

decades after World War II. He graduated in classical philology in Belgrade in 1936 and specialized at Karl's University in Prague (receiving his Ph.D. in 1939). Between 1939 and 1945, he was curator of archaeology in the Provincial Museum in Sarajevo, between 1945 and 1947, he was curator in the City Museum at Ptuj, and beginning in 1947, he was at Ljubljana University where he founded the Department of Archaeology and was professor of prehistoric and early Slavonic archaeology.

In 1948, Korošec was one of the initiators of the Institute of Archaeology at the Slovenian Academy of Arts and Sciences. He founded the central national archaeological journal *Arheoloshi vestnik* in 1950, and in 1964, he founded the journal for Paleolithic, Neolithic, and Eneolithic archaeology, *Porocilo o raziskovanju paleolita, neolita in eneolita v Sloveniji.* He was also a correspondent member of the Yugoslav Academy of Arts and Sciences in Zagreb, the deutsches archäologisches institut (German Archaeological Institute) in Berlin, and the Institute for Pre- and Protohistory in Florence.

Besides academic and organizational work, his contribution to field archaeology was significant. Korošec conducted several excavations, of which the most important were the prehistoric and early Slavonic site of Ptuj, the Ljubljana marshes, and the Neolithic site of Drulovka, all in Slovenia. In the other republics of the former Yugoslavia, Korošec excavated Danilo near Sibenik and Bribir near Zadar (both in Croatia) as well as Amzabegovo in Macedonia. He collaborated on fieldwork and analyses with his colleague and wife, Paola Korošec.

Korošec introduced vere gordon childe's concept of culture into Slovene archaeology. According to Korošec, culture could be divided into the material and spiritual. The cultural group was determined culturally, geographically, chronologically, and ethnically, providing an entity with a certain degree of common economic and social organization. In 1947, Korošec published his first large synthesis on the history of Slavs in Slovenia, *Staroslovenska grobisca v severni Sloveniji.* This work was opposed to Nazi archaeology, which had also sought support for German ethnogenesis in sites in Slovenia in order to justify German geopolitical appetites. Paradoxically, the conceptual framework of gustav kossinna's *Siedlungsarchaeologie* (settlement archaeology), the basis of German expansionist theses, was nevertheless applied to Korošec research on early Slavonic sites. However, Korošec 's work on the theoretical considerations and definitions of archaeology, and its relationships with other social and humanist sciences and history, set the pattern for the future development of archaeology in Slovenia. He published numerous works-13 books, 116 discussions, 106 book reviews, 20 surveys-and his synthesis *An Introduction to the Material Culture of the Slavs in Early Medieval Period* (1952) is still one of the cornerstones of Slovenian national archaeology.

Kossinna, Gustaf

(1858-1931)

Born in East Prussia, the son of a secondary school teacher, Kossinna absorbed the German nationalist ethic prevalent in the education system of the time-the direct result of contemporary politics when Prussia was leading German unification. He attended the Universities of Gottingen, Leipzig, Berlin and

Strasbourg. In Berlin Kossinna studied German philology, history and geography, but it was lectures on German and Indo-European linguistics that particularly interested him, and the problem of the location of the original Indo-German homeland (Urheimat) was to preoccupy him for his entire life. In 1881 he received a doctorate for his thesis on the linguistic subject “Ancient Upper-Frankian Written Monuments.” In 1892 he started to work as a librarian at the University of Berlin.

Kossinna's interests in the original German homeland, and the roots of the German language and its ancient vocabulary sparked his interest in the material culture of ancient Germans.

PREV NEXT

Kostenki

First excavated in 1879 by Russian archaeologists A. Polyakov and a. spitsyn, Kostenki was the focus of long-term excavation for much of the twentieth century. Extending about 10 kilometers on the banks of the River Don to the south of Voronezh, Kostenki is in fact a complex of twenty-five surface and stratified open sites, which in some instances extend up to 2 kilometers away from the river.

The excavation of these sites has produced a large assemblage of items of material culture for the period 35,000 b.p.-11,000 b.p., including stone and bone tools, ivory Venus figurines, animal figurines carved from bone and stone, and features that have been interpreted as rectangular long houses. Although that interpretation is now being questioned on the basis that what was thought to be contemporary evidence now seems more likely to be the result of multiple occupations. The other "dwellings"-small houses made of mammoth bone-continue to be accepted as evidence of single occupations.

Kostrzewski, Józef

(1885-1969)

Józef Kostrzewski was an outstanding Polish prehistorian. He initially studied medicine at the University of Wroclaw, but in 1909-1910 he took two semesters of archaeology under Wlodzimierz Demetrykiewicz at the Jagiellonian University in Cracow. He continued prehistoric studies in Berlin under gustaf kossinna and received his Ph.D. in 1914. The first year of his studies was spent in London, engaged in self-education at the british museum. In 1912, the first year of his independent research, Kostrzewski excavated a site in Siedlemin, near Jarocin (Wielkopolska) in poland. In 1914, his first book, *Wielkopolska w czasach przedhistorycznych* (Wielkopolska in the Prehistoric Period), was published. A second edition was published in 1923, the same year he became an assistant in the prehistory section of the Museum of the Society of Friends of Sciences in Poznan. He defended his postdoctoral dissertation on prehistory, written under the supervision of the anthropologist Jan Czekanowski, the classical archaeologist Edmund Bulanda, and the geologist Jozef Siemiradzkion, at Jan Kazimierz University in Lvov in 1919.

Józef Kostrzewski

(Arkadiusz Marciniak)

Kostrzewski was one of the founders of the Poznan University, in 1919, and he became head of the Department of Archaeology there. In 1920, he was one of the coorganizers of the Polish Prehistoric Society, whose aim was to support studies in prehistory and to encourage archaeology. It was composed of fans of archaeology from all over Poland and its journal, *Przeglad Archeologiczny* (Archaeological Review), has been published ever since.

In 1924, Kostrzewski successfully combined the collections of the two Poznan museums: the Polish one, or Mielzynskis's Museum, and the German one, or Wielkopolskie Museum. A prehistoric section located in the Wielkopolskie Museum was established with Kostrzewski as its head, and it came to

contain one of the most valuable archaeological collections in Poland. Kostrzewski began to develop his autochthonic theory of the origin of Slavs, and in 1926, he began editing the popular journal *Z Otchlani Wiekow* (From the Abyss of Ages), which became not only a great success but also an excellent instrument for the propagating of archaeology among the general public. His work at the museum

synthesize particular fragments of the prehistory of Polish territories.

The second edition of his *Wielkopolska w czasach prehistorvcznych* (Wielkopolska in the Prehistoric Period), published in 1923, was considered the fundamental model for all approaches to the synthesis of the prehistory of the territories of Poland. Kostrzewski was particularly interested in synthesizing long periods in the prehistory of Poland, for example, from the Neolithic Age to the great migration period, considered in *Prehistoria ziem polskich* (1948; Prehistory of the Polish Lands) and *Pradzieje Polski* (1965; Prehistory of Poland). He was also the author of regional syntheses: the one already mentioned about Wielkopolska as well as others about Pomerania and Silesia.

Koumbi Saleh

The forty-four-hectare tell of Koumbi Saleh is one of the great urban sites of Africa. In the eastern Hodh, several miles from Mauritania's border with Mali, the site comprises over sixty mounds, delimited by large streets, of debris from collapsed buildings constructed with plaques of locally available schist. A main attraction of the site since its discovery in 1914 by Bonnel de Mezières, a French civil servant, has been its putative identification as the capital of the Empire of Ghana as described by the Arab chronicler al B'akri in 1068. Virtually all pre-1970s archaeological work at the site, by Bonnel de Mezières, Raymond Mauny, and others, was undertaken primarily to evaluate this identification.

The archaeological material encountered in the course of these early, quite extensive excavations was given only summary treatment, and no full excavation reports were ever published. Beginning in 1975, French archaeologist Sophie Berthier's excavations, by contrast, considered the site in archaeological rather than historical terms and focused on the study of architectural evolution at the site and the characterization of material culture through time. Berthier's work was undertaken as part of more extensive excavations at and around the Koumbi Saleh mosque that were directed by Serge Robert. To date, Berthier's work is the only publication to have emerged from that extensive project.

Berthier conducted excavations during four field seasons on a single building in the north central part of the site not far from the Grande Place, a large public area. She concluded that of the thick deposits encountered, half belonged to a period of “grand urbanization,” dated by twelve radiocarbon determinations on charcoal to the eleventh-fourteenth centuries. Architecture at that time was very distinctive and commonly included rectangular and triangular wall niches, the use of paving stones on floor, step, and terrace surfaces, and the use of painted schist wall plaques. By the late fourteenth century, the buildings had been abandoned.

Strongly focused on architectural evolution, Berthier's work is thin with regard to analyses and interpretations that illuminate the changing nature of subsistence and trade at the apparent capital of the empire. The extensive areas of Koumbi Saleh that lack stone ruins still remain to be investigated, and among these may be the remains of the indigenous town in which the pagan king (ghana) lived, described by al-Bakri as separate from the stone-built town inhabited by Muslims and northern traders.

Kourion

Kourion (Curium), an Iron Age and Roman site on the south coast of cyprus, has been the target of numerous projects. Some of the best-known finds by luigi palma di cesnola (including much gold jewelry now in the Metropolitan Museum in New York) came from his work on Iron Age royal tombs in 1873. Additional recent work by Demos Christou (Department of Antiquities, Cyprus) has clarified details of those tombs and of Cesnola's activities.

There have been numerous and extensive excavations of the classical city by a series of archaeologists. Between 1933 and 1954, George McFadden and others excavated on behalf of the Pennsylvania University Museum. The Department of Antiquities has been conducting excavations on the Acropolis since 1964, and A.H.S. Megaw worked on the early Christian basilica for Dumbarton Oaks in Washington, D.C. Between 1980 and 1983, Diana Buitron and David Soren excavated at the Sanctuary of Apollo. The site has well-preserved Roman buildings, including a theater, many of which are decorated with mosaics. The theater and many other structures have been substantially restored.

Kozłowski, Leon (1892-1944)

Leon Kozłowski was one of the most important Polish archaeologistsof the first half of the twentieth century, and he represented a generation of archaeologists who, for the first time, had professional careers in archaeology. He was a student of Erazm Majewski, studied archaeology under Wlodzimierz Demetrykiewicz at the Jagiellonian University in Cracow in 1912-1913, and continued under the supervision of R. Schmidt at the University of Tübingen in Germany. In 1921-1939, he was professor of archaeology at the Jan Kazimierz University in Lvov.

Kozłowski was the author of very modern syntheses about the Paleolithic, Neolithic, and Bronze Ages in poland. These are *Starsza epoka kamienna* (1922; Palaeolithic or Early Stone Age), *Mlodsza epoka kamienn*a (1924; Neolithic or Late Stone Age), and *Wczesna, starsza i srodkowa epoka bronzu w Polsce w swietle subborealnego optimum klimatcznego i jego wplyw na ruchy etniczne i zaludnienie Polski* (1928; Early and Middle Bronze Ages in Poland in the Light of Subboreal Climatic Optimum and Its Influence on the Ethnic Movements and Population of Poland). In his work on the Neolithic period, he distinguished many archaeological cultures that have remained correct until the present, and he presented a very clear chronological division for the period.

Leon Kozłowski

(Arkadiusz Marciniak)

Kozłowski s works are characterized by methodological correctness. He would define the notions present in archaeological discourse, for example, that of archaeological culture, and his work contained geological backgrounds, hydrographic conditions, climate and soil characteristics, and an assessment of their impact on prehistoric settlement systems. While analyzing flint assemblages he focused his attention

on raw materials, the technology used, and tool functions. His works were richly illustrated

Kozłowski, Leon (1892-1944)

Leon Kozłowski was one of the most important Polish archaeologistsof the first half of the twentieth century, and he represented a generation of archaeologists who, for the first time, had professional careers in archaeology. He was a student of Erazm Majewski, studied archaeology under Wlodzimierz Demetrykiewicz at the Jagiellonian University in Cracow in 1912-1913, and continued under the supervision of R. Schmidt at the University of Tübingen in Germany. In 1921-1939, he was professor of archaeology at the Jan Kazimierz University in Lvov.

Kozłowski was the author of very modern syntheses about the Paleolithic, Neolithic, and Bronze Ages in poland. These are *Starsza epoka kamienna* (1922; Palaeolithic or Early Stone Age), *Mlodsza epoka kamienn*a (1924; Neolithic or Late Stone Age), and *Wczesna, starsza i srodkowa epoka bronzu w Polsce w swietle subborealnego optimum klimatcznego i jego wplyw na ruchy etniczne i zaludnienie Polski* (1928; Early and Middle Bronze Ages in Poland in the Light of Subboreal Climatic Optimum and Its Influence on the Ethnic Movements and Population of Poland). In his work on the Neolithic period, he distinguished many archaeological cultures that have remained correct until the present, and he presented a very clear chronological division for the period.

Leon Kozłowski

(Arkadiusz Marciniak)

Kozłowski s works are characterized by methodological correctness. He would define the notions present in archaeological discourse, for example, that of archaeological culture, and his work contained geological backgrounds, hydrographic conditions, climate and soil characteristics, and an assessment of their impact on prehistoric settlement systems. While analyzing flint assemblages he focused his attention

on raw materials, the technology used, and tool functions. His works were richly illustrated

with detailed tables. His other important works are *Wenedowie w zrodlach historycznych i w swietle kartografii przedhistorycznej* (1937; Weneds in Historical Sources and in the Light of Prehistoric Cartography) and *Zarys pradziejow Polski poludniowo-wschodniej* (1939; Prehistory of South-East Poland, an Outline).

Kozłowski s scientific activities are characterized by the collection of different kinds of data and by the formulation of generalizations regarding particular periods, areas, and problems. These two characteristics were important features of Polish archaeology during the first half of the twentieth century and his work is still stimulating for later generations of Polish archaeologists. He introduced the results of European archaeological research on relative chronology into the milieu of Polish archaeology, and he regarded a typological-comparative method as fundamental for archaeology. Kozłowski emphasized the necessity of withdrawing from simple nineteenth-century evolutionism, with its linear perception of the development of cultural phenomena. He noticed the importance of environmental factors and diffusion in shaping the development of prehistoric communities, mainly their migration. He carried out many large-scale excavations and numerous field surveys, and his excavations, modern for their time, were characterized by methodical correctness and complexity.

Kozłowski was active politically. In the 1930s he was minister for agriculture and agricultural reforms, undersecretary in the Ministry of Finance, and prime minister of the Polish government from 1933 to 1934.

Krukowski, Stefan

(1890-1982)

Stefan Krukowski was an influential Polish archaeologist and a great personality. His only teacher of prehistory was Erazm Majewski, and he never completed any formal studies in archaeology, being completely self-taught. He was commissioned to conduct his first fieldwork by Majewski in 1908. In 1911, he published his first paper, on studies carried out in the Kielce district. In 1914, he started working in the anthropology workshop of the Warsaw Scientific Society, and this event marked the beginning of his almost total devotion to the Stone Age. At the same time, he also began important studies of the caves in the Cracow-Wielun range, such as Okiennik Cave. During World War I, he continued his research in Russia, in the Caucasus, on the Paleolithic site of kostenki.

Krukowski's professional career and research were especially intense between 1919 and 1939. From 1918 to 1925, he worked in the prehistory section of the Institute of Anthropological Studies of the

Warsaw Scientific Society. At the same time, he was keeper of archaeological monuments for the southern Warsaw district until 1928, and in that year he became a curator in the newly founded State Archaeological Museum in Warsaw. His research focused on the development of proper scientific methods applicable both in fieldwork and in interpretation, and his work was closely associated with the natural sciences, primarily geology.

Of great importance was his collaborations with the outstanding geologist Jan Samsonowicz. Their work led to the discovery of a unique mine of striped flint in krzemionki opatowskie in 1922, shallow mines of chocolate-colored flint near Lysogory, and grey-white spotted flint in Swieciechow near Annopol. In 1928, he took up the study and protection of the mine in Krzemionki Opatowskie, and in 1939, he published *Krzemionki Opatowskie,* a research questionnaire in which the author described the standard features of the mine such as the mining field, shafts, underground headings, dumps, and mining tools. He also discussed the organization of the work, the spatial relations between mines and the settlements they were connected to, and the social aspects of the distribution of flint axes.

Krukowski was a researcher of Paleolithic cave camps such as Ciemna and Okiennik, of loess and sand sites, and of mines. He examined the locations of the sites in poland of Piekary, Gora Pulawska, Grzybowa Gora, Swidry Wielkie, Wieliszew, and Oronsko. He also organized and led a research campaign to Rydno, in which he focused on the systematic identification of a settlement complex in connection with the oldest mine, hematite processing and distribution, and a chocolate-colored rock bed.

After World War II, he had trouble finding a permanent position. In 1956, he received the title of professor extraordinarius.

Stefan Krukowski

(Arkadiusz Marciniak)

The first part of his first work, synthetic in character, *Pierwociny krzemieniarskie gornictwa transportu i handlu w holocenie polskim* (Beginnings of Flint Mining, Transportation, and Trade in Holocene of Poland) was published in 1920, and the second part was published in 1922. In this work, Krukowski was concerned with the origins of material used for flint tools. He described his search for siliceous rocks in the territory of Poland, drew differences among them, and illustrated their influence on the morphological diversity of flint inventories. He examined the possibility and mechanics of studying raw materials distribution and the possible ways that prehistoric societies obtained them. His work matched the highest standards of the day.

He was also the author of an overview of the Paleolithic age of Poland, published in 1948 as the synthesis *Prehistoria ziem polskich* (Prehistory of the Polish Lands), written jointly with jozef kostrzewski and Roman Jakimowicz. In 1976, Krukowski published another synthesis of the Polish Paleolithic and Mesolithic ages entitled *Skam 71*, in which he presented his theory of genetic prehistory. It was an original study, but because of its complicated terminology and hermetic language, its reception was limited. He also created a dictionary of concepts to be used in archaeology.

Genetic prehistory, Krukowski's original contribution, was an attempt to provide new directions in Stone Age archaeology, and developed toward the end of the 1960s, it was hoped it would provide an alternative to traditional Paleolithic prehistory. Krukowski pointed out the necessity of studying all flint assemblages, such as raw material, blanks, and waste, not just tools. The objective of genetic history was to determine the origin, formation, and purpose of stone tool industries. A crucial aspect in its determination was the study of flint blanks, which enabled him to recognize the unintended effects of the producers on the basis of a detailed analysis of all artifacts making up a given inventory. Genetic prehistory and the flint blank method permitted the separation of industries in mixed inventories.

Arkadiusz Marciniak

Krzemionki Opatowskie

The site of Krzemionki Opatowskie is located about ten kilometers southeast of Ostrowiec Swietokrzyski, Tarnobrzeg voivodeship, in poland. It is the best known as “the black and white striped flint mine,” within an agglomeration of some excellent and characteristic flint mines in the northern and northeastern parts of

between 1924 and 1927. stefan krukowski and Zygmunt Szmit started their researches in Krzemionki Opatowskie in 1928. In the same year Krukowski became the curator of the mine. The mine has been protected by law since 1928. Krzemionki Opatowskie is an open archaeological museum at present, and it is still a center of archaeological interest, mainly from the State Archaeological Museum in Warsaw.

L

La Madeleine

La Madeleine is the type site of the Magdalenian industry of the Upper Paleolithic period in Europe, about 16,000-10,000 b.c. The rock shelter lies on the outskirts of Les Eyzies in the Perigord region of southwestern france and was excavated in the mid-nineteenth century by édouard lartet and henry christy . The site yielded stone and bone tools of distinctive form, but it is most notable for producing evidence of mobiliary (portable or parietal) art in the form of carved and incised bone, antler, stone, and ivory. The people who made these are referred to as Magdalenian and they hunted deer or ibex.

La Tène

The eponymous site of the later phase of Iron Age civilization (500 b.c. until the Roman Conquest) of La Tène, switzerland, covers the whole of Celtic Europe. Discovered in 1857 by Hans Kopp, who "fished" for Friedrich Schwab, the archaeologist of Bienne, the site was first considered to be a lake dwelling based on examples of Stone and Bronze Age villages on the Swiss lakes. Such an interpretation had the advantage of extending the custom of lake dwelling, which was felt to be specifically Swiss, until the Roman occupation.

In no time, La Tène achieved international fame. In 1872, hans hildebrand suggested giving the name to a specific culture of the Iron Age, and the definition was ratified by an international congress held in Stockholm in 1874. Hildebrand, however, attributed the differences between the two cultures that he had defined, Hallstatt (early Iron Age) and La Tène (later Iron Age), to geographical variation. It was edouard desor, an archaeologist and geologist from Neuchâtel, who deserves all the credit of having, as early as 1865 (and more explicitly in 1868), clearly established a chronological succession for the Iron Age. This feat was achieved by means of comparisons with Tiefenau (Bern), Alesia (France), and the Celtic site of Marzabotto (northern Italy) on the one hand and the burial mounds of the Swiss Neuchâtel area and the Austrian burial place of Hallstatt on the other.

The site of La Tène includes two bridges, named Vouga and Desor after the early excavators. The bridges crossed a lateral, little active (or maybe dead) arm of the river Thielle, which was totally filled in when discovered. The bridges are near the Thielle's egress from Lake Neuchâtel, which is linked by this river to Lake Bienne. The river separates the foothills of the Jura mountain chain from the Swiss plateau, and this archaeologically rich site has seen successive excavations. Unfortunately, some of the work has not been a credit to Swiss archaeology. During the fifty years following La Tène's discovery, looting of the site was more common than archaeological research, particularly during the first Jura Surface Waters Regulation Scheme (1869-1883), which lowered water levels by 2.70 meters and left the surface of the site exposed.

The difficulty of excavating the site, by dragging or fishing and then by excavating in the water,

La Venta

A major Olmec site in Tabasco, mexico, near the southern coast of the Gulf of Mexico, La Venta is located on top of a salt dome and is surrounded by swampy terrain. The site was discovered in 1925, when large earth structures and massive stone monuments were found. It was once thought to be a “vacant” ceremonial center, with little cultivable land in the immediate environs and the surrounding rural populace using the uninhabited site for public rituals. Recent excavations, however, have revealed that this view was in error. We now know that by 2000 b.c. there were already farmers in the region, subsisting on its maize and rich estuarine and marine resources. The prized land for farming was along river levees, annually renewed with rich silt.

The farming hamlets gradually grew into larger villages, and signs indicate a developing social stratification. By 1150 b.c. construction had begun on the large earth mounds that formed the ritual heart of the site. After the downfall of the nearby olmec site of San Lorenzo, about 900 b.c., La Venta became the most important site in the region. The ceremonial center of La Venta includes dozens of earth mounds and platforms. Its largest pyramid, over 30 meters high, has been argued by some to have the form of an effigy volcano. Another earth platform, possibly the royal palace compound, is over 320 meters long, 260 meters wide, and up to 7 meters high.

(Image Select)

Excavations in La Venta in the 1940s revealed additional huge stone monuments that are among the hallmarks of Olmec civilization. Some eighty monuments have been found to date, weighing up to 35 tons. They include colossal heads (probably the portraits of rulers), thrones, and a wide variety of other sculptures. Later in La Venta's history, probably after 800 b.c., a more narrative art was executed. Monuments called “stelae” portray scenes of several interacting figures, carved in low relief.

Among the most dramatic discoveries at La Venta are the appropriately called “massive offerings.” One of these offerings involved the digging of a huge pit, which was then filled with twenty-eight layers of roughly shaped serpentine blocks, weighing 1,000 tons in total. The offering was covered with a mosaic mask, also made of serpentine blocks, and different-colored clays.

La Venta's heyday was between 900 and 400 b.c. The site displays many of the hallmarks of later Mesoamerican civilization: an extensive ceremonial heart for the enacting of public rituals, rich dedicatory offerings, carved stone monuments, elaborate burials, writing, objects carved in jade, and so on.

Some time around 400 b.c. the site was destroyed. Many of its stone monuments were smashed or defaced, and the ceremonial center was abandoned. Offerings made after the site's abandonment indicate that it may have remained a place of pilgrimage for centuries; even a Spanish colonial olive jar has been found at the site, apparently buried as an offering.

Laetoli

Lying on the edge of the African Serengeti to the south of olduvai gorge in northern Tanzania, the site of Laetoli was discovered by louis leakey and mary leakey in 1935. The area was subsequently worked on by Ludwig Kohl-Larsen (1938-1939), and its status as a fossil locality was confirmed. Mary Leakey returned to the area (particularly the nearby Garusi River valley) in 1974 and recovered hominid fossils that have been classified as *Australopithecus afarensis* or *africanus.* These are the remains of small, lightly built human ancestors. *Afarensis* is dated 3.75-3 million years ago, while *Africanus* lived about 3-2 million years ago. More exciting was the 1978 discovery by Paul Abell of trails of hominid footprints left in the volcanic ash, which made it clear that these hominids walked upright.

Language and Archaeology

Introduction

The criteria for integrating linguistic and archaeological evidence vary according to the nature of the problem and the questions posed. The use of linguistic evidence in archaeological analysis also varies in type and degree depending upon the theoretical approach of the researcher. Generally, linguistic reconstructions

help archaeologists to test hypotheses regarding social and political change and regional interactions, to explain the distribution of intrusive archaeological assemblages and changes in settlement patterns, and to identify the linguistic structure and identity of ancient texts.

Archaeology and historical linguistics also intersect when written texts survive for or about the culture under study. Although written texts may provide a rich source of information, historical references can be vague, inaccurate, or culturally biased. Oftentimes hypotheses tested without them can be equally productive.

Historical Linguistics

Nineteenth-century European linguists working at the University of Leipzig, referred to as Neogrammarians by their elders, developed principles and a method of comparison that successfully accounted for linguistic change over time. They demonstrated that the linguistic processes that produced change in prehistoric languages are observable and operative in transforming living languages. They showed how most of the modern linguistic groups in Europe and some others in the Near East and India developed from a common ancestral language, Indo-European. Neogrammarians were able to reconstruct a basic vocabulary and associated cultural traits for a proto-language they called Proto-Indo-European and to propose a geographic homeland for the Indo-European people (Labov 1994).

Research in the past twenty-five years has demonstrated that the degree of regularity and the mechanical principles of the Neogrammarians are essentially correct. Refinements in typological classifications and linguistic geography and advances in sociolinguistic methods of data collection and quantitative analysis have all helped to illuminate some features of the past that previously remained unexplored and beyond explanation (ibid.).

Combining Archaeology and Language

European scholarship conceived the seminal theoretical and methodological models for archaeological, historical, and linguistic investigations that continue to be reworked, discarded, and rediscovered today. Europe has also provided the proving ground for interdisciplinary debates (Trigger 1989). In the early twentieth century, European archaeologists combined the reconstructions of historical linguists with their own empirical evidence to propose locations for an Indo-European homeland and to reconstruct the lifeway of Indo-Europeans (Mallory 1991).

As the number of excavated sites increased and the stratigraphic and geographic distributions of artifacts became clearer, disputes arose among archaeologists over the origins of specific European cultures. Fueled by nationalist and regional fervor of the early twentieth century, archaeologists like gustaf kossinna insisted upon a local origin for the succession of artifact types while Carl Schuchhart identified materials from different areas with separate ethnic groups whose migrations could be identified by their material remains (Mallory 1991). vere gordon childe favored continuous diffusion of cultural traditions from outside Europe (Renfrew 1987). The active role that interdisciplinary scholarship played in these debates lessened considerably after World War II as a result of the misuse of combined archaeological and linguistic findings by Nazi Germany to substantiate Nazi racial beliefs and to justify German territorial expansion (Mallory 1991).

The debate over independent local innovation versus cultural diffusion (see Childe's theory above) has been ongoing in archaeology since the turn of the century, and similar debates have also set the course of research in linguistics. By the 1960s the importance of internal factors as the cause for change took precedence in some research over external factors (Trigger 1989). Those scholars whose results were

partly based upon diffusion, migration, and interdisciplinary data found it necessary to argue their case on several fronts. Such a defense was necessary in 1987 after the publication of Collin Renfrew's book, *Archaeology and Language: The Puzzle of Indo-European Origins.* Scholarly response to Renfrew's proposal linking the spread of agriculture into Europe with the arrival of Indo-Europeans raised both strong objections and support from other scholars and his use of linguistic data has made a

Lartet, Édouard

(1801-1871)

Lartet studied law in Toulouse before going to Paris in 1821 as a young lawyer, where he became interested in archaeology and paleontology. He returned to work as a lawyer in southwestern france and was paid by his clients with fossil bones and prehistoric tools, which they knew were his passion. He began to study the local Tertiary deposits, and in 1834 discovered the rich fossil site of Sansan.

Further encouraged by famous scientists at Paris's National Museum of Natural History, Etienne Saint Hillaire and, later, Adrien Jussieu, Lartet continued to search the fossil deposits of France. In 1837 he found the remains of a fossil ape called Pliopithecus, and in 1856 remains of another fossil ape-Dryopithecus. In 1853 he returned to Paris to undertake full-time paleontological research, where he met jacques boucher de perthes. Lartet began to believe that animals and humans had evolved over a much longer period of time than was thought, and that Boucher des Perthes's discoveries in the Somme gravels were proof of this. Lartet also presented his finds from the Aurignac rock shelter in the French Pyrenees as evidence of humans being contemporary with extinct animal species, and, like the work of Boucher des Perthes, it was rejected by the Academies des Sciences in Paris.

In 1861 Lartet proposed a chronology for human skeletal and cultural remains based on fossil animal bones found with them in cave sites. While his chronology eventually proved to be limited, it established him as one of the founders of human paleontology. Sponsored by English prehistorian and banker henry christy, he began to explore cave sites in the Perigord and Dordogne regions of France, where he discovered the famous Paleolithic sites of la madeleine, Les Eyzies and le moustier, providing further evidence of phases of human development based on archaeological stratigraphy. Lartet also published on the development of the human brain in fossil mammal species.

Lascaux

Lascaux, a cave occupied during the Magdalenian period in the Dordogne region of france, was discovered by four boys in 1940, and it remains among the most spectacular collection of Paleolithic wall art yet found. It is best known for its 600 magnificent paintings of aurochs (wild cattle), horses, deer, and signs of various kinds, but it also contains almost 1,500 engravings dominated by horses. The best-known feature is the great Hall of the Bulls, which contains several great auroch figures, some of them five meters in length, the largest figures known in Ice Age art. The hall also contains an enigmatic figure, called “the unicorn.” A shaft features a painted scene of what seems to be a bird-headed man with a wounded bison and a rhinoceros, and the scene has often been interpreted in shamanistic terms, though with little justification.

Archaeologist exploring Lascaux Caves

(Gamma)

Stone tools for engraving were found in the cave as well as many lamps, 158 fragments of pigment, and color-grinding equipment. Scaffolding was clearly used in some galleries to reach the upper walls and ceiling. Much of the cave floor was lost when the site was adapted for tourism, but it was probably never a habitation-it is more likely it was visited only briefly for artistic activity or ritual. Charcoal fragments from the cave floor have provided radiocarbon dates around 17,000 years ago and in the ninth millennium b.p.

The cave was closed to tourists in 1963 because of pollution that resulted in a “green sickness,” consisting of a proliferation of algae, and a “white sickness” of crystal growth. It was possible to reverse the effects of the green sickness and arrest the development of the white, but to ensure the survival of the cave's art, the number of visitors had been drastically reduced. As compensation, a facsimile cave, a complete copy of the original cave and its details, Lascaux 2, is now open nearby.

The Main Periods in the History of the Archaeology of Latvia

For a long time after World War II the traditional subdivision of time concerning the investigation of the history of archaeology in the main publications and surveys (Moora 1952; Graudonis 1967; Šnore 1974) was into four periods. This division is based on the political situation in the Baltic states during the eighteenth through the twentieth centuries. The *first period* of archaeological study, from the middle of the

artifacts. Surveys of Old Town Rīga (1998) and the castles of the Archbishop of Rīga during the Livonian period and later (1999) were detailed and included architectural studies across the territories of present-day Latvia. Publication of the compiled works of the talented Latvian archaeologist Fēliks Jākobsons (1896-1930) is the best example of the strong interest in Latvian cultural heritage (1999). A connoisseur of Eastern Prussian archaeological materials, Jākobsons, who graduated from the Albertus University in Koenigsberg, described and illustrated the archaeological material lost during World War II in Eastern Prussia (now the Kaliningrad district of Russia).

The organization of international conferences in Latvia-especially for discussing themes concerning the Baltic Sea during the Stone and Bronze Ages (1995) and in the Middle Ages (1992)-helped to make contacts between archaeologists from opposite sides of the Baltic. Such important changes mark new approaches in the development of the archaeology of Latvia. New projects, such as the excavation of a Neolithic ritual place of the inhabitants of Litorina littoral of 5000 b.c. and a study of the influence of Stone Age people on the environment in the Lake Lubāna Wetland, began. Another prospective project is in the area of the Dubna River system (a tributary of the Daugava), which includes the excavation of the hillfort Jersika, inhabited during the Iron Age and early Middle Ages. Two stone and brick castles of the Livonian period-Turaida and Cēsis (1974-1999)have been excavated. The archaeological excavations in Old Town Rīga continue. Special attention is being paid to the "Black-heads building"-the only secular building that has survived since the fourteenth century. A special work about the "Black-heads building" project is scheduled for publication.

Personalities

Archaeologist *Jānis Apals* (1930-) received his doctorate in history from the State University in Rīga. He is a senior researcher in the Department of Archaeology at the Institute of History of Latvia and pioneered investigations of underwater Viking age monuments in the lakes of Latvia, where remains of ten underwater fortresses were discovered. He was an organizer of the excavations at Lake Āraiši-the primary extensively excavated and reconstructed monument of the Viking age in the Baltic states.

Professor Dr. Francis Balodis (1882-1947) was the first academically educated Latvian archaeologist and the founder of the Latvian National School of Archaeology. Balodis studied in Dorpat (Tartu), Moscow, and Munich Universities and is a specialist in the archaeology of the Iron and Middle Ages, Egyptology, and the History of Art. Balodis was a professor at the universities of Moscow and Saratov (Russia) from 1918 to 1924, the chair of Archaeology and the dean of the faculty of Philosophy and Philology in Rīga (1924), the pro-rector of the State University in Rīga (1931-1933), head of the Monument Protection Board (1932-1940), and the editor of the periodical *Senatne un Māksla* (*Antiquity and Art*) from 1936 to 1940. Balodis excavated the Middle Age hillfort Jersika (Gersike) and the Raunas Tanisa hillfort. Beginning in 1940, he worked in Sweden as an Egyptologist.

Ernests Brastiņš (1892-1941) studied at the Art School in Saint Petersburg. During World War I he worked in the Russian Army as a topographer. Brastiņš was a pioneer in the field of, and the author of a topographic survey of, Latvian hillforts with the remains of wooden constructions, surveying in total 282 sites between 1922 and 1927. He was the director of the Museum of War in Rīga, where a Department of Latvian Hillforts was organized. He was arrested and deported by Soviet political bodies to Astrakhan (Lower Volga), where he was sentenced to death in 1941.

Voldemārs Çinters (1899-1979), a Ph.D., studied at the state universities in Rīga and Koenigsberg. Çinters was the director of the State Museum of History in Rīga from 1934 to 1945. He specialized in the archaeology of the Middle Ages and was one of the best methodologists of excavations. Çinters organized investigations at hillforts in Daugmale and Mežotne (1938- 1939; 1942). At the end of World

War II Ginters emigrated to Sweden, where he became a researcher at the State Museum of History in Stockholm.

PREV NEXT

and castle (thirteenth-seventeenth centuries), and the Salaspils stone castle of the Livonian order (thirteenth-seventeenth centuries). Stubavs was the foremost specialist in the classification and elaboration of the main types of Latvian hillforts.

Professor Dr. *Eduards Šturms* (1895-1959) studied at the State University in Rīga and at Koenigsberg. Šturms was the pioneer of systematic investigations of Stone and Bronze Age monuments in Latvia (1927-1940, 1943), including the Sārnate peat bog settlement, Pūrciems dune dwellings on the littoral of the Litorina sea, an Iča settlement in the Lake Lubāna wetland, and Rēznas barrows of the Bronze Age. At the end of World War II Šturms emigrated to West Germany. He led the Latvian Department of the Institute of Investigations of Baltic States from 1953 to 1955 and was guest professor at the University of Bonn from 1955 to 1959 and a corresponding member of the deutsches archäologisches institut (German Archaeological Institute) from 1954 to 1959.

Vladislavs Urtāns (1921-1989) received his doctorate in history at the State University in Rīga. Arrested and deported to Siberia by Soviet political bodies in 1941, Urtāns returned to Rīga in 1946, and graduated from the State University in 1949. Urtāns was a researcher in the Archaeology Department at the Museum of the History of Latvia from 1947 to 1950 and at the Museum of History and Art in Madona from 1951 to 1958 and senior researcher at the Museum of the History of Latvia from 1958 to 1976. Specializing in the archaeology of the Iron and Viking Ages, Urtāns was one of the best specialists of typology studies of the Iron Age of Latvia. He led large-scale excavations in the flooded zones of the Pļaviņas and Rīga hydro-stations, and at the Daugmale, Aizkraukle, and Madalāni hillforts of the tenth through the twelfth centuries (1966-1987).

Lūcija Vankina (1908-1989) received a doctorate in history at the State University in Rīga and then became head of the Department of Archaeology of the Museum of the History of Rīga from 1946 to 1986. Vankina specialized in the Stone Age Archaeology of Latvia and excavated at the Sārnate wetland settlement from 1949 to 1959.

Anna Zariņa (1921-) studied at the Latvian Academy of Agriculture. Zariņa is a pioneer and a primary specialist in the investigation and reconstruction of the archaeological textiles of the ancient Livs and Letgallians. She led large-scale excavations in the flooded zones of the Pļaviņas, Rīga, and Daugavpils hydro-stations from 1963 to 1986.

Archaeological Monuments

Latvian hillforts are fortifications on hills that had special wooden palisade defensive systems and a high rampart and ditches on one side. Dwellings and buildings for special crafts were located inside the plateau and the outer fort. Chronologically hillforts can be dated to a wide period, from the beginning of the first millennium b.c. until the tenth through thirteenth centuries a.d. A topographic survey of these forts was done by E. Brastiņš in the 1920s and the work was continued by specialists from the State Inspection of Monument Protection beginning in 1950 under the guidance of J.T. Urtāns.

Abora is the main permanent settlement of the Late Neolithic Corded Ware Culture (CWC) in the Lake Lubāna Wetland of Latvia, where remains of material culture from 4490 to 3770 b.p. were preserved in peat. The wooden dwelling constructions, fishing devices, and some burials of flexed individuals of the CWC were discovered between 1964 and 1965 and in 1970 and 1971. Abora is the main location where amber is processed in present-day Latvia. From there amber artifacts and ornaments were exchanged across Eastern Europe-in the basins of the Volga and Dnieper Rivers (4490-3770 b.p.). Abora is the main source of information on the subsistence strategies of CWC people in Latvia, who were hunter-gatherers, and there is evidence of farming and stock breeding.

Āraiši Lake Fortress is a Viking Age fortress on an island on the Āraiši Lake in eastern Latvia, discovered by Count C.G. Sieverss in 1876 and excavated by Latvian archaeologist Jānis Apals from 1965 to 1969 and from 1975 to 1979. The fortress was the subject of extensive discussions as to whether it was a pile dwelling in the lake

PREV NEXT

later Rex Nameisis renewed the hillfort, but in 1280, because it was so difficult to fight against the very active invaders, the Semigallians burned down their own wooden castle and went to the southern part of northern Lithuania.

Turaida was the brick castle of the archbishop of Rīga in the thirteenth and fourteenth centuries. The remains of the Livs hillfort (eleventh-twelfth centuries) were discovered under the cultural layers of the remains of the castle. The Turaida castle of the Livonian period, situated on the high bank of the river Gauja in the eastern part of Latvia, was investigated fully and reconstructed partly between 1974 and 1999.

Zvejnieki, a Stone Age burial field in the northeastern part of Latvia, is the biggest in Northern Europe. It was excavated by Francis Zagorskis (1929-1986) during the period from 1965 to 1971. Single, double, and group burials of the late Mesolithic and early, middle, and late Neolithic periods (6775-5100 b.p.)-totaling 308 individuals-were discovered. Rich bone, flint, and slate implements represented the funerary inventory. Red or blue clay masks with amber disks and rings in the eye sockets were discovered in some graves of people of the Comb and pit ceramic cultures. Figurines of elk heads, birds, male faces, and female figures were ritual objects.

Zvidze, in the Lake Lubāna Wetland, is a Neolithic settlement of the first farmers in the eastern Baltic region that is situated on the border of moraine plain and the ground of the old Lake Lubāna basin. Zvidze was excavated from 1973 to 1975 and from 1981 to 1984. The archaeological evidence of farming-wooden tools; spades; mattocks; cereal and grain processing tools; spinning and weaving implements; and tools for processing hemp, nettles, and flax-were discovered inside the remains of the wooden dwellings, which were of standing pole construction with ridged roofs. It was suggested that these people adopted agriculture as a result of diffusion between 5000 and 4700 b.p.

Baltic Nationalities

Curonians-Western Baltic people (*kurši*) described in early written chronicles such as Heinrici Chronicon and Livlandische Reimschronik as *curones,* who lived in the eighth through the thirteenth centuries a.d. in the territory of the western part of Latvia and the northwestern part of Lithuania.

Lettgalians-Eastern Baltic people (*latgaļi*), described in Heinrici Chronicon and Livlandische Reimchronik as *Letti* or *Letthigalli,* who lived in the eighth through the thirteenth centuries in the territory of the eastern part of present-day Latvia, east of the river Daugava.

Livs-Finno-Ugric people (*lībieši*), described in Livlandische Reimchronik as *Līven* or *Līwen,* who lived during the tenth through the thirteenth centuries in the lower flow of the rivers Gauja and Daugava, as well on the littoral of northwestern Latvia. The main excavated monuments are two villages and a cemetery dating to the tenth through the thirteenth centuries, Salaspils Laukskola in the lower part of the river Daugava. A rich inventory included bronze ornaments, tortoise-shaped fibulas, and remains of textiles including small bronze ornaments on the edges of the villaine, a special cape worn by women (Zariņa).

Selonians-Baltic people (*sēļi*), described in Heinrici Chronicon as *sēlen,* who lived in the ninth through the thirteenth centuries in the territory of the southeastern part of present-day Latvia, to the south of the river Daugava, and in the northern part of present-day Lithuania.

Semigallians-Baltic people (*zemgaļi*), described in Heinrici Chronicon and Livlandische Reimchronik as *Semigally,* who lived in the basin of river Lielupe and in the northern part of present-day Lithuania during the ninth through the thirteenth centuries. The main excavated archaeological monuments are the

hillforts Mežotne (excavated by Voldemārs Ģinters) and Tērvete.

Institutions

Latvian Board of Antiquities (1923-1940)-A protection, registration, documentation, coordination, and administration center for archaeological monuments in Latvia. The Monument Protection law was accepted in the independent republic of Latvia in 1923 and supplemented in 1932, when professor Francis Balodis became the head of the board. More than 1,412 monuments

Laugerie Haute and Laugerie Basse

First dug in 1868 by édouard lartet as part of his Dordogne campaign with henry christy and subsequently explored by denis peyrony and françois bordes, these two adjacent rock shelters in the vicinity of Les Eyzies in the Dordogne have, between them, yielded a complete sequence of Upper Paleolithic industries in southwestern france. The Laugerie sites are type sites for the Aurignacian, Gravettian, Solutrean, and Magdalenian periods, and there is a particularly fine representation of Magdalenian art objects in Laugerie Basse.

Layard, Sir Austen Henry

(1817-1894)

Born in Paris and raised in switzerland, Layard studied law and then practiced for six years, at the end of which he set out to ride overland to Ceylon. He got no further than iran, where he spent a year with a group of nomads. Arriving in Baghdad in 1842 he was sent back to Constantinople (later Istanbul) to brief the British Ambassador on his travels. On the way he visited what was thought to be the ancient city of nineveh, at Khorsabad, where French diplomat paul emile botta was excavating.

Austen Henry Layard

(Ann Ronan Picture Library)

After several years as a diplomatic agent in Turkey Layard persuaded the British Ambassador Sir Stratford Canning to sponsor his excavation of the mounds in northern mesopotamia-in competition with the French. In 1845 at the mound of nimrud Layard discovered several Assyrian royal palaces, one of which was that of Ashurnasirpal II, and bas-reliefs similar to those discovered by Botta at nearby Khorsabad. Both Layard and Botta were only interested in the most spectacular finds of statuary and portable architectural remains to be displayed in their national museums. Tunneling and trenching around these larger pieces destroyed much other archaeological information and smaller or fragile artifacts.

In 1847 Layard began shipping his finds back to London where reports of them had already caused a sensation. They were put on display in the british museum where they aroused not only great public interest but also further sponsorship

Layard, Sir Austen Henry

(1817-1894)

Born in Paris and raised in switzerland, Layard studied law and then practiced for six years, at the end of which he set out to ride overland to Ceylon. He got no further than iran, where he spent a year with a group of nomads. Arriving in Baghdad in 1842 he was sent back to Constantinople (later Istanbul) to brief the British Ambassador on his travels. On the way he visited what was thought to be the ancient city of nineveh, at Khorsabad, where French diplomat paul emile botta was excavating.

Austen Henry Layard

(Ann Ronan Picture Library)

After several years as a diplomatic agent in Turkey Layard persuaded the British Ambassador Sir Stratford Canning to sponsor his excavation of the mounds in northern mesopotamia-in competition with the French. In 1845 at the mound of nimrud Layard discovered several Assyrian royal palaces, one of which was that of Ashurnasirpal II, and bas-reliefs similar to those discovered by Botta at nearby Khorsabad. Both Layard and Botta were only interested in the most spectacular finds of statuary and portable architectural remains to be displayed in their national museums. Tunneling and trenching around these larger pieces destroyed much other archaeological information and smaller or fragile artifacts.

In 1847 Layard began shipping his finds back to London where reports of them had already caused a sensation. They were put on display in the british museum where they aroused not only great public interest but also further sponsorship

of Layard's work by the English government. Returning to Mesopotamia in 1849 Layard excavated the mound of Kuyunjik opposite Mosul, which was in fact Nineveh (and not Khorsabad as Botta had claimed). He found Sennacherib's palace, and the royal library and archives, which contained thousands of clay tablets. Layard continued to dig the mounds around Mosul and then moved into southern Mesopotamia where he tested the sites of Babylon and Nippur. In 1851 he supervised the packing of another hundred or so cases of Assyrian artifacts and returned to England where he published *Discoveries in the Ruins of Nineveh* and *Babylon and the Monuments of Nineveh* (1853), both of which were bestsellers. The exhibition of these extraordinary finds generated an Assyrian fashion and style in contemporary jewelry, hair and beard styles, theatrical productions, decoration, painting, poetry, and architecture, and provoked much controversy among scholars about biblical credibility and progress.

Layard himself left archaeology and took up politics and diplomacy. He became a member of Parliament and English ambassador to Madrid and Constantinople. In the latter position he was to encounter and help heinrich schliemann. The British excavation of Mesopotamia was continued by Hormuzd Rassam and William Kennett Loftus until 1855, and sponsored by the British Museum and a private Assyrian Excavation Fund. Scholars such as henry rawlinson began to decipher the cuneiform tablets that Layard had shipped home, although it was to take another thirty years to complete the task.

Le Mas D'Azil

Le Mas D'Azil, a cave system with occupation deposits, is the type site of the Azilian industry dated to the Mesolithic/Epipaleolithic period (about 11,500-9500 b.p.) in france. Located in the Ariège region in the French Pyrenees, this huge and complex site, first dug by French historian eduoard piette in 1887, is also rich in Aurignacian and Magdalenian artifacts, particularly

carved and incised antler and bone art works as well as painted pebbles.

Le Moustier

Le Moustier is the type site of the Mousterian industry (from the Middle Paleolithic period, 180,000-30,000 years ago) found in Europe and northeastern Africa and into central Asia. The rockshelter site was first excavated by édouard lartet and henry christy as part of their work in southwestern france, which began in 1863. Although there is still debate about the nature of Mousterian assemblages, it is often assumed that there is an association between Neanderthal remains and the Mousterian. Difficult problems related to the explanation of variability within Mousterian assemblages remain and were at the center of celebrated exchanges between prehistorians françois bordes and lewis binford.

Leakey, Louis Seymour

(1903-1972)

Leakey was born in Kenya, East Africa, to missionary parents and grew up among the tribal Kikuyu. He went to secondary school in England and then to St John's College Cambridge in 1922 where he studied languages, archaeology, and anthropology. In 1926 he returned to East Africa and began to investigate the prehistory of the Rift Valley, which he published in *Stone Age Cultures of Kenya Colony* (1931). He married the artist and archaeological draftsperson Mary Douglas Nichol in 1936.

Between 1936 and 1962 many examples of Australopithecus (small-brained, bipedal hominid fossils, extant between five million and one million years ago) were found in South Africa (at the sites of Sterkfontein, kromdraai, Makapansgat, and swartkrans), firmly establishing the study of the earliest archaeological records in the world. Unlike many of his European contemporaries Louis Leakey

believed that Africa, and not Central Asia, was where humanity had originated. During the 1940s Louis and mary leakey pioneered Paleolithic “living-floor” archaeology at olorgesailie, investigating fossil pollens and paleo-environmental data in an attempt to more fully interpret the stone tools from the same levels. They also began looking for the makers of the Oldawan stone tools they had found in the ancient deposits of the olduvai gorge, an ancient lake basin in northern Tanzania in the East African Rift Valley. In 1959 the hominid cranium, called *Zinjanthropus* (East African man) *boisei* or OH 5 was found. “Zinj” was the first hominid to be dated by the potassium-argon (K/Ar) method, a new technique, and was found to be 1.7 million years old. *Zinjanthropus* was also the first hominid to be excavated on television, and event that not only captured public imagination but also grabbed the attention of the American National Geographic Society, who were to provide ongoing financial support for the Leakeys' work. “Zinj” also caused some scientific controversy.

Louis Leakey first concluded that OH 5 was *the* ancestor of modern humans and not another ancestral form of the South African Australopithecines-which in fact it subsequently became. Then the remains of another, more advanced hominid (i.e., with a larger brain capacity) were found close by, and in 1964 Leakey claimed that this find, *Homo habilis,* superceded OH 5 as *the* early human ancestor, directly connected to *Homo sapiens.* While Leakey's simplistic views on human evolution have now been generally rejected, his finds were a significant contribution to the knowledge of fossil human evolution. International funding for research in this area increased and archaeologists and Paleo-anthropologists from America and Europe began to work in Africa searching for the origins of the whole of humanity. Leakey's work had shifted interest from Europe and Asia

International funding for research in this area increased and archaeologists and Paleo-anthropologists from America and Europe began to work in Africa searching for the origins of the whole of humanity. Leakey's work had shifted interest from Europe and Asia

to the southern hemisphere, and to the development of world archaeology and prehistory.

Louis and Mary Leakey excavating in Tanganyika, 1961

(Bettmann/Corbis)

In addition to the Olduvai material, Louis Leakey's work on the Miocene fauna of western Kenya and the early hominid remains from Rusinga Island, Songhor, and Fort Ternan were great contributions to African prehistory. He spoke Kikuyu fluently and his 1937 to 1939 detailed study of the people and their culture was published in 1977 by his wife. Louis Leakey became curator of the Coryndon Museum in Nairobi in 1940, and he established the Centre for Prehistory and Paleontology in 1962, which became the International Louis Leakey Memorial Institute for African Prehistory after his death.

Leakey, Mary Douglas

(1913-)

Mary Leakey is the daughter of the landscape painter Erskine E. Nichol and the great-great-great-granddaughter of john frere, the antiquarian squire who argued for the antiquity and human origins of stone tools at the end of the eighteenth century. Mary Douglas Nichol had an informal education and was a talented artist with an interest in archaeology. She illustrated gertrude caton-thompson's book *The Desert Fayum* (1934), and, impressed by her talents, louis leakey asked her to illustrate his popular book on prehistory, *Adam's Ancestors* (1934). They were married in 1936 and worked together in East Africa for more than thirty years.

Before 1972 it is almost impossible to separate Mary's contributions to East African archaeology from Louis's-they were an archaeological field team. Mary was there at Rusinga, olduvai, and olorgesailie, and she contributed to and wrote many of the scholarly publications on their work. She seems to have left the publicity, funding, and the big-picture debates to Louis and to have preferred to continue

with and supervise the painstaking analysis required by every find at every excavation.

After Louis Leakey's death in 1972 Mary began to work at the Pliocene site of laetoli, southeast of Olduvai. From 1974 to 1981 she and her collaborators found numbers of new mammalian species, among which, dated to about 3.7 million years ago, were the hominid fossils of what was called *Australopithecus afarensis.* In 1976 a trail of fossil animal footprints were found, some of which were hominid, and in 1978 two long trails of fossil hominid footprints were uncovered and dated to about 3.5 million years ago. These footprints confirmed what had only been inferred from skeletal remains, that the small-brained *Australopithecus* hominids were bipedal.

Mary Leakey also contributed to the practice of field archaeology through her paleo-environmental "living floor" work and through her development of field museums, where finds were left in-situ. She also conducted a major study of rock art at Kondoa-rangi in Tanzania, published in her book *Africa's Vanishing Art: the Rock Paintings of Tanzania* (1951).

Lepinski Vir

Excavated by Serbian archaeologist Dragoslav Srejovic' between 1967 and 1971, Lepinski Vir lies in the Djerdap Gorge of the Danube River in Serbia. Lepinski Vir has an interesting and long sequence of occupations from hunter-gathering/foraging/agricultural societies. Although there are disagreements about the dating of the site, it is generally believed that it was occupied around 7000 b.c. by people foraging in the forests for game and in the river for fish, and that by 5000 b.c., the occupants of the site were managing cattle, sheep, pigs, and goats. Lepinski Vir is also notable for the remains of houses found on the site and the presence of limestone sculptures found in the remains of the houses. There is some speculation that the site was in fact occupied by the local farming Starcero cultures.

Tim Murray

Lepsius, Karl Richard

(1810-1884)

Lepsius was born in Germany and educated at the universities of Leipzig, Gottingen, and Berlin. After completing his doctorate in Classical archaeology in 1833 Lepsius went to Paris to further his studies. jean françois champollion's new ancient Egyptian grammar had just been published and Lepsius became interested in Egyptian hieroglyphics. He supported and defended Champollion's system of decipherment and he contributed to further understanding of ancient Egyptian through his recognition of syllabic signs and their similarities to Coptic.

Lepsius spent many years visiting the European collections of Egyptian antiquities before traveling to Egypt in 1842 with the Prussian Expedition (1842-1845). He was accompanied by a number of

Prussian scholars and skilled draftsmen to survey and record monuments and collect antiquities. The expedition sent back more than 15,000 artifacts, papyri, and plaster casts, drawings, plans, and maps to Prussia. Between 1849 and 1859 Lepsius published *Monuments in Egypt and Ethiopia,* the results of the expedition, in twelve folio volumes. The Swiss Egyptologist edouard naville completed another five volumes in the series after Lepsius's death.

In 1865 Lepsius became keeper of the Egyptian collections in the Berlin Museum. He returned to Egypt the following year to record the monuments of the eastern Delta and the Suez regions, during which he discovered Tanis, the capital of Egypt during the twenty-first dynasty. Here he excavated the Canopus Decree, a useful linguistic adjunct that helped to prove that the Rosetta Stone was translated correctly. Lepsius edited the principal German journal of Egyptology, which is still published today, for over twenty years and completed over 142 publications on ancient Egypt. His last visit to Egypt was for the opening of the Suez Canal in 1869.

Leroi-Gourhan, André

(1911-1986)

André Georges Léandre Leroi-Gourhan was born in Paris on 25 August 1911. He acquired his education almost entirely outside any conventional context. Although he did attend the seminars given by the sociologist Marcel Mauss and the sinologist Paul Granet during the 1930s, Leroi-Gourhan remained proudest of the autodidactic and eclectic periods of his life, probably because they allowed him to stay outside an academic system that did not impress him.

After World War I, the Durkheimian school, under Marcel Mauss, opened up to oriental studies, to linguistics, and to a comparative approach. Leroi-Gourhan founded a school of prehistory in its own right, countering the existing culture-historical and typological vision of archaeology with the synthetic, anthropological, and semiological approach of "prehistoric ethnology."

During the 1930s, Leroi-Gourhan was in charge of reorganizing the Arctic section of the Trocadéro Museum (later the Musée de l'Homme) in Paris, and this daily involvement with artifacts and collections was to have a lasting effect on him. It was during this period that he became conscious that the comparative method could be substituted for the standard approach of the "hard" sciences, i.e., that he would be able to validate his interpretation of archaeology only when it could be based on an abundance of data and a range of varied regularities so that no other interpretation could account for all of them.

Leroi-Gourhan laid the foundations for the ethnology of stone toolmaking techniques, a very original approach that combines a systemic analysis of comparative syntheses with the development of methodological tools to be used for particular case studies. The publication of *évolution et techniques* (Evolution and Techniques) in 1943 established the specific epistemology for this technological approach and announced the concept of *chaîne opératoire* (chain of operation). *Évolution et techniques* is in fact an *inventaire raisonné* (reasoned inventory) that allows us to appreciate the physical effectiveness and the relative complexity of a tool or a toolmaking technique as well as to identify possible substitutes for it. Moreover, this inventory allows us to discern the principles shared by the techniques used in a community and to understand their ethnicity.

Leroi-Gourhan presented his *inventaire raisonné* in the form of tree-like diagrams, or dendrograms. Those ubiquitous and recurrent instances of solutions that were physically functional were brought together under the term *tendance* ("tendency"), and he broke each technical process or artifact down into a group of attributes he included in the category he called *faits* ("instances of techniques"). Between the two extremes of *tendance* and *faits,* the dendrogram represents a hierarchical classification of artifacts and technical processes according to their *degrés de fait* ("degrees of specificity"). If we move from the trunk (the *tendance,* or the invariant aspect of technique) toward the branches, the technical characteristics retained in the diagram are further and further apart, i.e., they are increasingly culturally different from one another. But reading it the other way around, we gradually move from the different instances to what these different phenomena have in common.

In proposing the notion of "favorable environment," Leroi-Gourhan also indicated how the "continuity of the technical environment" plays a role in the adoption or rejection of a borrowed item or an innovation: the intellectual assessment of this novelty should be compatible with the mental representations that the group has of its techniques. The criteria distinguished by Leroi-Gourhan to establish technical

classifications were those he thought would be able to elucidate the evolution of human technical behavior, and those that would allow him to understand the logic of transformations that accounted for the existence of forms of techniques judged to be increasingly effective.

He believed that the study of techniques had to be linked to the question of the technicity of living beings, “dealing simultaneously with” organic structures, neuro-motor equipment and manifestations of the mind. This fundamental

Lhwyd, Edward

(1660-1709)

Lhwyd was born into a well-established Welsh family and educated at Jesus College, Oxford, where he became a friend of Dr. Robert Plot, philosopher, antiquarian, and first keeper of the ashmolean museum. Lhwyd assisted with the development of the natural science collections of shells and botanic specimens and became interested in the study of fossils, or "formed stones." He was convinced they were the petrified remains of organisms that had died long ago, and like the eminent Oxford scientist Robert Hooke thought they might be evidence of huge changes to the earth. Lhwyd identified, classified, and published a large range of fossils in the Ashmolean's collection in 1691.

Lhwyd's interests broadened from fossils to include stone implements and British antiquity in general, and he became friends with the antiquarian john aubrey. He was recruited in 1693 to contribute to Edmund Gibson's revised edition of william camden's *Britannia,* the first attempt at an update of this great work since it had been translated into English in 1610 and gone out of print in 1637. Lhwyd eventually becameresponsible for researching and writing about the whole of Wales, and he undertook an antiquarian tour in support of this task during the summer of 1693.

Lhwyd's additions to the Welsh sections of *Britannia* were outstanding. Indeed, his additions transformed the Welsh sections from a rather inadequate sketch of unfamiliar terrain to the most rewarding part of the new volume when it was published in 1695. In his contributions Lhwyd did more than any of his predecessors to enlarge the understanding of the societies that inhabited Britain before the Romans. He formed a picture from material remains supplemented by folklore and Classical reports, and drew attention to the high degree of social organization and technical prowess needed to erect the great stone complexes. He made it clear, too, that the Britons had considerable metalworking skills, noting the discovery of several caches of weapons, axe-heads, bolts, daggers, and swords.

Lhwyd's research for *Britannia* inspired him to undertake a work that would bring together his knowledge of Celtic languages and ancient British antiquities and his interest in natural history. In 1707 he published his *Glossography,* the first part of the projected larger *Archaeologia Britannica,* which confirmed Lhwyd's preeminence as a Celtic scholar. The *Glossography* was a substantial folio and a remarkable achievement of comparative philology. Lhwyd demonstrated the relationship between the Celtic languages surviving in western Europe, and he included Welsh and Irish dictionaries and a Cornish grammar. He was able to make some progress in reconstructing the ancient Gallic language spoken in Gaul in Roman times. Lhwyd's travels between 1697 and 1701 were an impressive testimony to the thoroughness of his research. He made the first antiquarian tour of the Scottish highlands and visited Scottish antiquaries. He collected Gaelic manuscripts and local customs and folklore. He recorded local dialects and details of towns, villages, and local place names. He sought information about barrows, burial chambers, standing stones, and inscribed stones. He looked at coins and brass utensils, flint arrowheads, and prehistoric implements and fossils.

Unfortunately much of the vast store of information Lhwyd accumulated was lost. After the *Glossography* his heath failed and he never completed the second part of the *Archaeologia Britannica,* the proposed great compendium of the Celtic culture of western Britain. He died in 1709 and his papers were dispersed, and many of them were later destroyed by fire. Because of the limited appeal of the *Glossography* and its incomplete status Lhwyd's reputation was not as great as it should have been. Yet his work is a lasting record of his exceptional powers as an interpreter of prehistoric remains and proves his worth as an incomparable topographer and local historian. His philological research effectively laid the foundations for all later study of the Celtic languages of the British Isles and Brittany.

Li Chi

(1895-1979)

Li Chi was born in Hubei province in china into a wealthy family. In 1918 he went to the United States to study psychology and sociology at Clark University in Massachusetts, and then to Harvard University, where he earned a Ph.D. in anthropology in 1923, after which he returned to China and taught at Nankai University.

Between 1925 and 1926 Li excavated a Neolithic Yangshao Culture site in southern Shanxi province, making him the first Chinese scholar to undertake modern archaeological fieldwork. In 1928 he became the first head of the department of archaeology at the Academia Sinica, established to excavate the three-thousand-year-old capital of the Shang culture at anyang. These excavations shaped modern archaeology in China through their recruitment and training of young Chinese archaeologists (including xia nai, later director of the Institute of Archaeology) and their use of modern field archaeology techniques in combination with traditional Chinese historiography and antiquarianism. The site also yielded oracle bone inscriptions that proved to be the first written documents in China, and the ceramic and bronze vessel nomenclature and typology used by Li at Anyang still dominates the archaeology of China. His book *The Formation of Chinese People: An Anthropological Inquiry* was published in 1928.

The Sino-Japanese War in 1937 and then World War II put an end to all archaeology in China. In 1949 Li went to Taiwan with the Nationalist government, and he did not work on mainland China again. He founded the Department of Archaeology and Anthropology at National Taiwan University, the first university program in China to train professional archaeologists, and published his synthesis of archaeological and historic material *The Beginnings of Chinese Civilization* in 1957. Li spent most of his time on the conservation and publication of the Anyang material, which was completed as *Anyang Excavations* in 1977.

Libby, Willard Frank

(1908-1980)

Born in Colorado and raised in California, Willard Libby was a farmer's son. He began studying mining engineering at the University of California, Berkeley, in 1927 and changed to chemistry, which interested him more. He received a Ph.D. in 1933 after studying low-energy radioactive nuclei. From 1933 to 1941 he taught chemistry at Berkeley.

In 1941 Libby joined the Manhattan Project (the development of a nuclear bomb) at Columbia University in New York City, where he worked on gas diffusion techniques for separating uranium isotopes into fissionable material. In 1945 he became professor of chemistry at the University of Chicago and began working at the Institute of Nuclear Studies. It was here that Libby proved that the amount of radiocarbon in all living plants and animals begins to decay at death at a known rate-so that it would be possible to measure the amount of time since the organism has died by measuring the amount of radiocarbon remaining in it. The accuracy of this technique was tested by comparison with proven other dating techniques such as tree-ring dating, and the first actual C-14 dates appeared in 1949.

Radiocarbon dating revolutionized archaeology in the twentieth century. It began a new era-no longer did archaeologists have to spend so much time developing and testing chronologies for their material-they had an accurate method for dating any organic material from the last 70,000 years and they could now pursue other imperatives and new ideas and new directions in their discipline. In 1959 Libby became professor of chemistry at the University of California, Los Angeles, and in 1960 he received the Nobel Prize for chemistry for his work on radiocarbon dating.

Libby was one of the United States' major postwar nuclear scientists. In 1954 he was appointed by President Eisenhower to serve on the Atomic Energy Commission, the first chemist to do so. He was mainly interested in the effects of nuclear fallout and was also involved in international efforts for peaceful uses of nuclear power, serving as vice-chairman of the American delegation to the First International

Douglass, Andrew Ellicot

Lindenschmidt, Ludwig

(1809-1893)

German prehistorian and scholar who helped to found the Romisch-Germanische Zentral Museum at Mainz, where he was director until his death.

During the first half of the nineteenth century Germany, like England, was full of enthusiastic antiquarians eagerly excavating and founding museums and equally eager to establish a significant and ancient German past. This latter obsession was the result of contemporary German political fragmentation, which would persist until the 1870s. Political fragmentation was reflected in the fragmentation of collections of archaeological material-of find contexts and artifacts and scholarship-unlike in Scandinavia, where christian j. thomsen, bror hildebrand, and hans hildebrand were beginning to organize and study large, national, and lengthy homogenous archaeological collections and consequently develop theories, such as the three age system, about European prehistory.

In 1866 Lindenschmidt was one of the founding editors of the periodical *Archiv fur Anthropologie*, which became the forum for German anthropologists who lacked any formal and national organizations. In 1870, the same year as German political unification, the German Society for Anthropology, Ethnology and Prehistory was founded. The *Archiv* became its journal, and continued to be published until World War II. Lindenschmidt, like his fellow prehistorians, was interested in "archae-geography," the elucidation of ethnic questions via archaeological evidence, issues that occurred in the work of rudolf virchow and continued with gustaf kossinna. This preoccupation explains their critical stance toward, and even rejection of, the Three-Age theory. Until the 1880s Lindenschmidt refused to accept the idea of separate Bronze and Iron Ages and continued to emphasize the importance of southern Europe and the Mediterranean for the development of prehistoric metallurgy in central Europe.

Linear A/Linear B

The Linear B script was in used in Minoan Crete and Mycenaean greece in the period between 1450 and 1200 b.c. An earlier script, called Linear A, had been devised in Crete in the period between 1700 and 1450 b.c. Linear B has been translated, but Linear A still provides a challenge.

The story of the decipherment of Linear B really begins with English archaeologist sir arthur evans at knossos, the royal city of Crete, at the beginning of the twentieth century. During his excavations at that site, Evans discovered many small clay tablets covered with linear script. These were different from the hieroglyphs, which he had also observed carved into seals and small gems, found by himself (and others) on Crete and in Greece. Beginning in 1909 with the publication of *Scripta Minoa I,* Evans was able to publish only a small fraction of the tablets he had excavated by the time the fourth volume of the *Palace of Minos* was published in 1935. The point has often been made (not least by those most directly responsible for the translation of Linear B) that this slow rate of publication may have delayed the eventual decipherment of Linear B, but it is equally true that subsequent discoveries such as American archaeologist carl blegen's 1939 recovery of the Mycenaean archive at the Palace of Nestor at Pylos in Greece provided vital clues.

Building on work by A.E. Cowley, Alice Kober, and E.J. Bennett, Jr., a young English architect Michael Ventris (1922-1956)-at first working essentially alone but later with the Cambridge philologist John Chadwick-was able to overcome the problems posed by the shortage of published texts to produce the fundamentals of a decipherment of Linear B in

The point has often been made (not least by those most directly responsible for the translation of Linear B) that this slow rate of publication may have delayed the eventual decipherment of Linear B, but it is equally true that subsequent discoveries such as American archaeologist carl blegen's 1939 recovery of the Mycenaean archive at the Palace of Nestor at Pylos in Greece provided vital clues.

Building on work by A.E. Cowley, Alice Kober, and E.J. Bennett, Jr., a young English architect Michael Ventris (1922-1956)-at first working essentially alone but later with the Cambridge philologist John Chadwick-was able to overcome the problems posed by the shortage of published texts to produce the fundamentals of a decipherment of Linear B in

1952. The most significant element of his decipherment was the argument that Linear B was, in fact, an ancient form of Greek. Ventris and Chadwick went on to complete the task of decipherment in the years before the former's untimely death in a road accident.

It is not without some irony that the first major test of the Ventris-Chadwick decipherment was provided by none other than Carl Blegen, who had returned to Pylos in 1952 and discovered a further 300 tablets. The fact that these could be read, even though they (and other Linear B documents) are primarily invoices and the "paperwork" involved in the administration of palace business, at once brought history closer to the Minoan and Mycenaean world. The fact that the last kings of Crete were Greek speakers has led to a reevaluation of Evans's argument that the Minoans had conquered the Mycenaeans. It is now thought that the reverse is true and that around 1450 b.c. Knossos was conquered by the same people who ruled at Pylos and Mycenae.

Lithic Analysis

Stone artifacts are studied by archaeologists because they are durable and frequently found on archaeological sites of almost every age. Consequently, much has been written about their analysis and interpretation. This article considers the history of three approaches to the study of stone artifacts: (1) factors contributing to variation in the composition and characteristics of stone artifact assemblages, (2) functionalist interpretations of artifact assemblages, and (3) idealist interpretations of material remains.

Functionalist and idealist approaches reflect a fundamental debate in archaeology about whether humans are passive participants or active agents in their worlds. Functionalist approaches seek to explain the role of artifacts in the evolution and/or behavior of different groups. Idealist approaches seek to understand the knowledge and belief systems of the makers of artifact assemblages. Fundamental to both approaches is an understanding of why recurring artifact forms (i.e., types) exist, as well as the factors contributing to variation in the composition of artifact assemblages.

Dimensions of Artifact Variability

For much of the twentieth century, archaeologists attributed the similarities and differences between artifact assemblages to a single variable: the cultural idiosyncrasies, or traditions, of different groups of people. The best known work in this regard is françois bordes's study of variation in Lower and Middle Paleolithic assemblages from southwest France (Bordes 1961). Bordes formulated a typology to describe the sixty-three different tool types (i.e., artifact forms) recognized as regular components of Lower and Middle Paleolithic assemblages. He then characterized the artifact assemblages recovered from the various layers of different rock-shelter deposits in terms of the relative proportion of each made up by those sixty-three tool types. Comparison revealed repeated patterns

Lithic Analysis

Stone artifacts are studied by archaeologists because they are durable and frequently found on archaeological sites of almost every age. Consequently, much has been written about their analysis and interpretation. This article considers the history of three approaches to the study of stone artifacts: (1) factors contributing to variation in the composition and characteristics of stone artifact assemblages, (2) functionalist interpretations of artifact assemblages, and (3) idealist interpretations of material remains.

Functionalist and idealist approaches reflect a fundamental debate in archaeology about whether humans are passive participants or active agents in their worlds. Functionalist approaches seek to explain the role of artifacts in the evolution and/or behavior of different groups. Idealist approaches seek to understand the knowledge and belief systems of the makers of artifact assemblages. Fundamental to both approaches is an understanding of why recurring artifact forms (i.e., types) exist, as well as the factors contributing to variation in the composition of artifact assemblages.

Dimensions of Artifact Variability

For much of the twentieth century, archaeologists attributed the similarities and differences between artifact assemblages to a single variable: the cultural idiosyncrasies, or traditions, of different groups of people. The best known work in this regard is françois bordes's study of variation in Lower and Middle Paleolithic assemblages from southwest France (Bordes 1961). Bordes formulated a typology to describe the sixty-three different tool types (i.e., artifact forms) recognized as regular components of Lower and Middle Paleolithic assemblages. He then characterized the artifact assemblages recovered from the various layers of different rock-shelter deposits in terms of the relative proportion of each made up by those sixty-three tool types. Comparison revealed repeated patterns

particular features of artifacts as indicative of specific cultural traditions.

Different researchers hold quite varied views about the role played by style in human societies, about the types of information that style conveys, and, therefore, about how style can be identified. Some archaeologists, such as Wiessner, regard style as a form of nonverbal communication that conveys information about both individual and group identity. For cognitive archaeologists (such as Ian Hodder) style is a symbolic expression of social relations, and the aim of analysis is to investigate the meaning of the symbols that style embodies. However, there is no general agreement that style is always symbolic or that it is always intended to convey specific information. For example, J.R. Sackett (1982) distinguishes between style as symbol (iconological style) and style that simply reflects the choices that individual artisans made in producing functionally equivalent objects (isochrestic style). He also distinguishes between passive style (regularity in artifact form, arising from shared traditions) and active style (intended to convey specific information).

Attempts to refine the concept of style and make it more amenable to archaeological analysis and interpretation do not actually resolve the archaeologist's dilemma about whether stylistic causes and effects operate independently of functional causes and effects. The obvious solution is to hold one source of variation constant in order to identify the effects of another. However, this approach assumes that it is possible to identify functionally equivalent artifacts and/or that it is possible to identify the options from which the prehistoric knapper made his or her choices during artifact manufacture. This notion is not as straightforward as it might at first seem. Types or attributes that appear to be functionally redundant in one context may not be so in another. Furthermore, what is functionally redundant in any context is actually in the mind of the maker, and it is therefore impossible to assess interpretations of patterned variation as isochrestic style. Consequently, techniques for identifying the contribution of style to differences (and similarities) in the composition of artifact assemblages are not well developed, and they rely on reductive analytical strategies, which presuppose the independence of the different dimensions of artifact variability.

In the final analysis current arguments about style are based on different ideas about the information contained in patterned archaeological data. On the one hand, the debate involves a return to the dispute between Bordes and Binford: whether artifact assemblages are cultural markers or markers of functionally distinct tool kits. On the other hand, much has been learned about the interdependence of different dimensions of artifact variability in different contexts. Reductive analytical techniques cannot incorporate all the potential contributors to stone artifact assemblage variability, but there can be no doubt that these have enhanced archaeologists' understanding of the factors contributing to the similarities and differences between artifact assemblages from different time periods. Archaeologists can now pursue a broader array of interpretative approaches, depending on the information they choose to generate from the artifact assemblages under investigation.

Functionalist Approaches

Functionalist approaches use ecological and evolutionary theory, together with paleoenvironmental information, to investigate the interrelationships between ecological and environmental variables and aspects of a society's economic, social, and political structures-in particular, the role these institutions played in the survival and success of different human societies. Debate about the causes of Middle Paleolithic artifact variability underscored how little was known about the relationship between stone artifact assemblage composition, site function, site layout, and seasonal variation in foraging activities. As a consequence, Binford, JohnYellen, and others initiated ethno-archaeological research during the 1960s designed to identify in human behavior those regularities that can be assemblages.

Binford's study of the activities of the Nunamiut people of Alaska ultimately provided the theoretical underpinning for an approach to stone artifact analysis and interpretation that became known as technological organization (Nelson

from each other in terms of the amount of planning involved in their execution.

Curated technologies are those that involve anticipation of future needs, which may include the acquisition, transport, and stockpiling of raw materials and/or finished tools. Time is invested in preparing and transporting raw materials and in making, maintaining, and transporting tools. The reward for this is the immediate availability of usable tools when the need for them arises. Expedient technologies are those in which tools are made and repaired at the place of use. In contrast to curated technologies, expedient technologies involve an expenditure of minimal time and energy on the manufacture, reshaping, and resharpening of tools. Finally, opportunistic technologies are those that involve no forward planning at all. The acquisition of raw materials and the manufacture and maintenance of tools are flexible and reflect immediate responses to unanticipated conditions. Typically, artifacts are manufactured from whatever materials are at hand and are discarded immediately after use.

Attempts have been made to relate these different types of technologies to the forms of particular tools and to the composition of entire artifact assemblages through two interrelated concepts: tool design and site function. Archaeologists whose artifact assemblages contain tools that were used in food procurement (as opposed to those used to make other tools) have expended some effort in trying to develop ways of analyzing tool design. These researchers argue that tools used at the moment that a prey item is captured or harvested are subject to the greatest design constraints. As a consequence, most of the relevant studies have focused on various forms of weapons, such as spear points and other types of projectiles.

A number of researchers have used the concept of risk to analyze patterns of group mobility, insofar as mobility can be reconstructed on the basis of the distribution of artifacts made from raw materials of known origin. It is suggested that highly mobile groups tended to accumulate artifact assemblages containing a wide range of raw materials, collected from various raw material sources visited in the course of other subsistence activities (i.e., the collection of raw materials was an embedded activity). This collecting strategy would have reduced the risk of being without a raw material when it was needed for tool manufacture. Assemblages associated with highly mobile groups also tend to contain only small numbers of artifacts: tools and tool blanks made from large blocks of durable and easily worked materials that could be readily fashioned into functionally specific tools (thus, the risk of being without a particular tool when it was needed was also minimized). Less-mobile groups tended to make more use of local material because distant sources of stone were visited only rarely. These groups also economized on the use of exotic stone by resharpening as much as possible tools made from the less accessible materials.

In sum, functional studies have continued to emphasize investigating the multiple causes that give rise to artifact form. Various approaches to modeling the reasons for variable artifact form and assemblage composition have been undertaken, integrating aspects of technology, tool design, resource acquisition, and mobility. The common theme of these studies is the desire to understand the role stone artifacts played in the evolution and/or behavior of different human groups.

Idealist Approaches to Artifact Analysis

Discussions about the art, religion, and beliefs of ancient peoples have been present throughout the history of the discipline of archaeology, but the development of formal analytical and interpretative frameworks for the study of these phenomena dates only to the early 1980s. Just as there are a variety of ways of investigating the functional (or evolutionary) significance of artifacts, there are also a variety of ways of investigating what artifacts can reveal about the cognitive abilities of our ancestors or about the conceptual frameworks of past human societies. Some researchers have applied concepts and methods

developed in linguistics or psychology to the problem of interpreting artifact assemblages in cognitive terms, but the most influential of the current approaches to this problem of gaining insight into the prehistoric mind

about the value past societies placed on different activities. Such inferences can be made on the basis of an examination of the distribution of artifacts marking different stages in the production and use of tools.

Conclusion

The history of approaches to the study of stone artifacts charts the enrollment of an increasing number of variables to explain variation in artifact form and assemblage composition. The early- to mid-twentieth-century preoccupation with artifact form as a means of accessing information about past cultures has been replaced by a broader array of approaches that investigate both the reasons for the existence of different artifact types and the variations in their patterns of co-occurrence. These approaches investigate the impact of raw material properties, techniques of artifact manufacture, the uses to which artifacts were put, and the effects of resharpening on artifact form and assemblage composition, in addition to style. Both functionalist and idealist approaches recognize the importance of analyzing stone artifacts in relation to other artifacts and in relation to other categories of archaeological data, including their position on a landscape. Attempts are made to integrate information generated from the analysis of different categories of archaeological data in order to assess the behavioral information that can be gleaned from the stones themselves. The ubiquity and durability of stone artifacts means that they will always be an important source of information about past human behavior.

Lithuania

The history of archaeology in Lithuania mainly began in the nineteenth century. The first information about single archaeological objects was obtained during the sixteenth century, while Lithuania was a grand duchy, but during the period when Lithuania and poland formed a single state (1569-1795), there was little interest in the past, and only a few mentions about stray finds survive from that era.

Lithuania as Part of the Russian Empire (1795-1918)

It was while Lithuania was part of the Russian Empire that the study of archaeology began, with the main feature being the search for the oldest roots and evidence of states and nations. Archaeology in Lithuania started in a small local museum in Barzdz˘iai in western Lithuania in 1812. The museum was founded by the landowner

of his work. In 1884, Fiodor Pokrovskij (1855-1903) was appointed director of the Museum of Antiquities in Vilnius. He revived the study of archaeology at the museum, excavated burial mounds in eastern Lithuania, and published reports of these excavations. He questioned and interviewed local people about archaeological sites and finds and collected and published all of this information in archaeological maps (Pokrovskij 1893, 1899). In 1893, the Ninth Congress of Russian Archaeology was held in Vilnius, and this meeting presented the achievements of archaeology to the local people and encouraged their further support of it.

At beginning of twentieth century, the Russian Imperial Archaeological Commission in Saint Petersburg began to take some interest in, and control of, archaeological excavations in Lithuania. It issued permits and demanded reports and information concerning finds. Large excavations were begun and photographed. The commission sent archaeologists to investigate burial mounds and hill-forts, and it supported the work of interested amateurs. One of these was Ludwik Krzywicki (1859-1941), who, during his summer vacations between 1900 and 1913, surveyed and excavated hill-forts and published information concerning their artifacts. From 1911 to 1914, the local archaeological commission in Vilnius registered artifacts from a medieval-new age town, and this information was published in Russian, Polish, and Lithuanian. At the end of nineteenth and during the early years of the twentieth century, private archaeological collections and amateur excavations to enrich them became popular. World War I terminated the work of non-Lithuanian archaeologists and was responsible for the destruction of the majority of extant archaeological collections.

First Lithuanian Republic (1918-1940)

The main feature of the history of archaeology during the period of the first republic was the creation of a national school of archaeology. In 1919, the State Archaeological Commission was established to protect sites of cultural significance, but the initial activities of the commission were not productive because of conflict over different methods of conservation and protection.

In fact, archaeology in Lithuania was primarily the work of individuals. In the 1920s, the Russian aleksander spicyn (spitsyn) (1858- 1931) was invited to write the first general work about the antiquities of Lithuania using prewar data (Spicyn 1925), which had been already divided into different archaeological cultures. At the same time, Colonel Petras Tarasenka (1892-1962) collected information about different archaeological sites and finds, and between 1926 and 1928 he published three books about archaeological knowledge and the protection of archaeological heritage. His most important c ontribution in these books was the first comprehensive archaeological map of Lithuania (Tarasenka 1928). In 1930-1934, General Vladas Nagevičius (1881-1954) excavated the hill-forts of Apuolė and Impiltis in western Lithuania, and with the support of specialists from different sciences, he used aerial photography and film-making and completed many different analyses of the material found. The 1920s also saw the foundation of many regional museums in Lithuania to house collections of finds from destroyed archaeological sites.

In 1934, the State Archaeological Commission was reorganized, and the protection and registration of archaeological sites was improved, with guards placed at various sites to stop their destruction by plough. In 1936, the new museum of Vytautas Great was established in Kaunas. It strove to create separate laws of cultural values to protect and rescue sites from destruction by excavation. The head of prehistory department in this museum, Jonas Puzinas (1905-1978), became the first professional Lithuanian archaeologist. Having taken an archaeology degree in Germany, Puzinas divided all the archaeological material in the museum into the common Baltic periods and chronological order. In 1938, the museum opened a new archaeological exhibition, the study of which was published (Puzinas 1938) and became the first scientific manual of Lithuanian archaeology. Puzinas trained a new generation of

Lithuanian archaeologists. In 1939, the capital of Lithuania, Vilnius, which had been occupied

by the Polish since 1920, was returned, and the center of Lithuanian archaeology was transferred there.

Part of the U.S.S.R. (1940-1991)

World War II and the subsequent Soviet occupation of Lithuania interrupted any further archaeological work, and publications stopped. In 1940, the occupation government passed a law of cultural monuments protection, which had been prepared by an independent Lithuania and was really only a piece of political propaganda. Archaeology was centralized in order to achieve greater Soviet control. In 1941, the Academy of Sciences was created; in it, was an Institute of History and within that, a Department of Archaeology. During fighting in Lithuania, many parts of archaeological collections in local museums were destroyed. In 1944, to escape repression, Puzinas and his best student, Marija Gimbutienė (or Gimbutas, 1921-1994), went to western Europe. Gimbutienė completed her thesis in Germany in 1947, writing on Lithuanian grave-field data and separating it into cultural-chronological groups linked to some historic Baltic tribes. In Lithuania, the field archaeologist Pranas Baleniūnas (1900-1965) was arrested and imprisoned in northern Russia.

The main features of Lithuanian archaeology during the years the country was a Soviet socialist republic were the accumulation of archaeological sources and the investigation of the ethnic genesis of the Baltic tribes. In 1945, Lithuania had only four archaeologists left, and they had sole responsibility for re-creating and developing the discipline. The training of archaeologists never stopped, testimony to the work of Pranas Kulikauskas (b. 1913) and Regina Kulikauskienė (b. 1916). Marxism was compulsory, and its impact on Lithuanian archaeology directed research into areas of socioeconomic formation, productive forces, and relations to production. The Russian language was used, and the works of former investigators were ignored. The center for archaeology in Lithuania became the Institute of History, which issued the permits for excavations. Archaeology at Vilnius University consisted only of producing students.

Archaeological surveys and excavations of grave fields began in 1948, and before long, excavations became large and rapid-however, there were no journals in which to publish archaeological articles in the first postwar decade in Lithuania. In 1949, P. Kulikauskas finished his thesis on a grave field at Kurmaic˘iai in western Lithuania. At the beginning of Soviet rule, archaeologists copied prewar work but included the necessary Marxist changes. This work was narrow and purely historical in treatment, written according to preconceived social evolutionary schemes created by the Communist Party, and there was only one way to investigate and publish results. The highest achievement of this Stalinist style of Marxism in archaeology was the preliminary edition of the *History of Lithuanian SSSR* (*Lietuvos TSR istorija* 1953), which divided prehistory into the stages of development of primitive society.

After the death of Joseph Stalin in 1953, the Soviet states started to become more liberal, and so did archaeology. During this time, new humanitarian directions were created, and archaeological investigations were included in economic development projects. A new postwar generation of archaeologists started to work. Excavations took place at new building sites and large infrastructure building projects, such as the building of the Kaunas water reservoir in 1953-1957, excavations at Castle Trakai in 1951-1962, and work on the Vilnius lower castle in 1955-1961, which led to the adaptation of some of these buildings as museums. However, the law for the protection of cultural monuments was often ignored at the time, and many archaeological sites were destroyed. Still, new kinds of archaeological monuments, such as Stone Age settlements, were excavated. The liberalization of archaeology spread to the analysis of archaeological material using traditional chronological-typological methods, more choice in the direction of investigations, and the creation of larger archaeological generalizations, which could include the material of former investigators.

The first books on Lithuanian archaeology since World War II were published, including those dealing with archaeological finds, hill-forts

PREV NEXT

(Tarasenka 1956), and archaeological stones (Tarasenka 1958). Marxist interpretations of prehistory were consolidated in the *History of Lithuanian SSR* (*Lietuvos TSR istorija* 1957, 5-37), and the main achievement of this period in archaeology was a synthesis of Lithuanian prehistory (Kulikauskas, Kulikauskienė, and Tautavičius 1961). This book built on the prewar work of Puzinas and used new information from archaeological investigations and thirteenth-century materials and earlier. Written in Lithuanian, it consolidated the periodization of prehistory and the main typology and chronology of its artifacts.

After 1961, Lithuanian archaeology began a period of systematization of archaeological materials. In 1962, the leader of Lithuanian archaeology was Adolfas Tautavičius (b. 1925), a graduate of Soviet times. Archaeological conferences were held every two years, and since 1966, a scientific-information edition was published every two years (*Archeologiniai*, eighteen issues before 1999). A general work concerned with trade relations was published (*Lietuvos gyventoju prekybiniai rysiai* 1972), and the results of the period of systematization of archaeological materials in 1974-1978 were published in four volumes of collective work by ten people (*Lietuvos TSR archeologijos atlasas* 1974-1978), which describes Stone Age settlements, hill-forts, grave fields, burial mounds, and some artifacts.

There were many different innovations in archaeology, such as plastic facial reconstruction, the filming of excavations (from 1965 by Vytautas Urbanavičius), investigations of the Bronze Age (from 1967 by Algimantas Merkevicius), and investigations of iron smelting (from 1969 by Jonas Stankus). In 1965, radiocarbon analysis began, and human skeletal material has been collected and investigated since 1970. Large-scale excavations of medieval-new age grave fields began in the oldest Lithuanian towns. R. Kulikauskienė and Rimutė Rimantienė completed the first doctorate in archaeology (Rimantienė 1971; Volkait-Kulikauskienė 1970), and a list of state-protected archaeological sites (3,367 objects) was prepared and published (*Lietuvos TSR istorijos ik kultûros paminklu sarasas* 1973).

In 1979, Lithuanian archaeologists began to investigate ethnic genesis. There was a huge amount of accumulated archaeological material that required new qualitative research and synthesis, so interrepublic conferences concerning ethnic genesis and ethnic history were organized in 1979, 1981, and 1991. Investigations became complex and included historians, ethnologists, linguists, and anthropologists. Also in 1979, the first volume of nonperiodical archaeological information was published (*Lietuvos archeologija* 1979-1999), which opened up the market for larger publications about excavated materials and for separate investigations. The first synthetic studies for different prehistory periods were published-the Stone Age (Rimantien 1984) and the old Iron Age (Michelbertas 1986)-as well as a general work about Lithuanian ethnic genesis (*Lietuviu etnogeneze* 1987).

In 1988, a short but eventful period of perestroika, which took the shape of a national independence movement in Lithuania, began. This policy was manifest in archaeology by the creation of new organizational structures. For instance, a separate group of archaeologists was organized by the Society of Lithuanian archaeologists and founded within the Institute of History in 1989, the result of excavations in Vilnius lower castle, and a chair of archaeology was founded at Vilnius University in 1990. Also in 1990, the inspection of cultural heritage, a serious attempt at protecting archaeological heritage, was established. In 1989, the first archaeological museum in Kernavė opened. Existing archaeological organizations were enlarged, and new archaeologists were allowed to be independent. In science, censorship was abolished, and computers began to be used. Relations among the archaeologists in the various Soviet socialist republics were broken up, and the search for new contacts in archaeology from the West started-with Poland and Sweden.

Second Lithuanian Republic (1991-)

After the putsch of August 1991 in Moscow, Lithuania, which had proclaimed its independence in 1990, became a recognized independent state, and after liberation from Marxist fetters, archaeology returned to fundamentals. New directions

Ljubljansko Barje

Ljubljansko Barje, known also as the Ljubljana Marsh or the Laibacher Moor, is a complex of prehistoric pile-dwelling sites in slovenia. The term *Ljubljansko Barje* is frequently used as a synonym for Copper- and Bronze Age pile dwellings in the marshland south of Ljubljana in a Pleistocene tectonic depression of approximately 170 square kilometers. It is presumed that a shallow lake existed there before the formation of marshes in about 2000 b.c.

The first pile dwellings were discovered by dragotin (karl) dezman, curator of the Provincial Museum of Carniola, Ljubljana, in 1875 near the village of Ig, fifteen kilometers south of Ljubljana. Between 1875 and 1877, he conducted several excavation campaigns in which he researched an area of more than 10,000 square meters. Archaeological excavations revealed very rich, ornamented pottery; clay figurines; stone, wooden, and bone implements; and some of the earliest metal finds in Slovenia. These finds made the Ig pile dwellings one of the most various and attractive prehistoric sites of central Europe at the time. Nevertheless, Dezman succeeded in publishing only brief notices and some interim excavation reports.

Initially, the pile dwellings were attributed to the Stone Age, but later they were thought to be Bronze Age in origin. The first more-detailed cultural attribution of the dwellings was given by M. Hoernes in 1898, who placed the finds from Ig into the context of the Bandkeramik culture. European archaeologist vere gordon childe, in *The Danube in Prehistory* (1929), associated the Ig pile dwellings with Slavonian culture and placed them in the Copper Age (Danubian IV phase). The Slovenian archaeologist rajko lozar attributed "the Ljubljana pottery" to the northern cultural circle, especially to the Globular Amphora culture of the late Neolithic period.

After World War II, from 1953 to 1981, the Department of Archaeology at the University of Ljubljana (consisting of josip korošec, Tatjana Bregant, and Zorko Harej) organized several larger excavations on newly discovered sites in the Ljubljansko Barje. The results of these excavations demonstrated the existence of a long-lived settlement system extending from the late Neolithic to the early Bronze Age. The first catalog of finds from the Ig dwellings was published by the Slovenian archaeologists Josip Korošec and Paola Korošec in 1969. They classified the pottery from Ig into two cultural and chronological groups originating from the Slavonian (Vucedol) culture complex. The first Ig phase was placed in the early Copper Age, and the second, in the late Copper Age and transition to the Bronze Age.

The most complete chronological and cultural study of pottery from Ljubljansko Barje was published by Hermann Parzinger (Parzinger 1984). He defined seven phases (from the end of the Neolithic to the early Bronze Age) and placed the Ljubljansko Barje pile dwellings in the context of the middle Danubian cultural region (Lengyel, Baden, Vucedol cultures). However, he also demonstrated the presence of cultural elements associated with northern Italian cultures (Lagozza, Remedello, and Polada).

Louvre

Established in 1793, the Musée du Louvre in Paris, france, originally included the royal collections and artifacts seized from émigré royalists and the church after the revolution. The museum's collection (which included a large number of pieces derived from the Classical Roman and Greek cultures) was dramatically increased when art works looted from italy by the victorious French armies were sent back to Paris after 1794. Although many of these works were returned after Napoleon's fall in 1815, the nucleus of the great museum called the Louvre was firmly established. Although it is justly famous for its collection of paintings, the Louvre also houses major collections of antiquities, particularly those drawn from the classical world, Egypt, and ancient Assyria.

The classical collection had its roots in the royal collections of François I and Henri IV, and it was supplemented by purchases of materials originally looted by the French armies. After 1815, the collection was expanded by donations (such as *Venus de Milo* in 1821), by purchase, and by pieces retrieved from excavations. The Egyptian collection has a long history as well. Founded by jean-francois champollion in 1827, the collection was greatly expanded through the efforts of French collectors and excavators in Egypt, the most notable being auguste mariette working at Saqqara. Of almost equal importance is the Assyrian collection founded in 1847, which is based around the work of paul-emile botta and Ernest Renan. Staff members of the Louvre continue to be active in archaeological research all over the world.

Lozar, Rajko

(1904-1985)

The Slovenian archaeologist, ethnographer, and art historian Rajko Lozar graduated in art history and classical archaeology from Ljubljana University in 1925 and received his Ph.D. in Roman provincial archaeology in Vienna in 1927. Between 1928 and 1940, he was curator of archaeology in the National Museum in Ljubljana, in 1940-1945, he was director of the Slovene Ethnographic Museum in Ljubljana, and in 1941-1942, he was a lecturer in prehistory at the University of Ljubljana. After 1945, he migrated first to Austria and then, in 1950, to the United States where he was director of the Rahr Civic Center and Public Museum in Manitowoc, Wisconsin, between 1956 and 1969.

Lozar was predominant in Slovenian archaeology in the period between the two world wars, mainly owing to the fact that he was the only professional archaeologist in slovenia at the time. This research and museum work encompassed archaeology, art history, and ethnography as well as the protection of cultural monuments and university teaching. As a scholar with a background in Classical and humanist sciences, he was influenced by the culture-history approach in central European archaeology during the first decades of the twentieth century. He applied the specific approach that he had developed first as an art historian to his archaeological studies in prehistory, to the Roman and early medieval archaeology of Slovenia, and to the study of the evolution of style and key forms. He partly ignored typological studies based on discretely delimited units and contexts, considering form as the general expression and synthesis of individual and local cultural development, not as a manifestation of the spiritual culture only. His major works in this area are “Ornamenti noriskopanonske kamnoseske industrije” (1934a;

Ornaments of the Norico-Pannonian Stonecutting Industry), “Predzgodovina Slovenije, posebej Kranjske, v luci zbirke Mecklenburg” (1934b; Prehistory of Slovenia, especially Carniola, in the Light of Mecklenburg Collection), and “Studija o ljubljanski keramiki” (1941b; Study of Pottery from the Late Copper Age Sites in Ljubljana Marsh).

He was also one of the pioneers of early Slavic archaeology in Slovenia. His study on Slavonic pottery, “Staroslovansko in srednjevesko loncarstvo v Sloveniji” (1938; Early Slavic and Medieval Potmaking in Slovenia), was the first attempt at a chronological and typological

He was also one of the pioneers of early Slavic archaeology in Slovenia. His study on Slavonic pottery, “Staroslovansko in srednjevesko loncarstvo v Sloveniji” (1938; Early Slavic and Medieval Potmaking in Slovenia), was the first attempt at a chronological and typological

systematization of pottery from Slavic sites in Slovenia. At the end of his professional career in archaeology in Ljubljana, he published the first historical and critical synthesis of Slovenian archaeology: "Razvoj in problemi slovenske arheoloske vede" (1941a; Development and Problems of Slovenian Archaeological Discipline). As an ethnographer, Lozar edited and contributed important texts to the *Narodopisje Slovencev* (*Ethnography of the Slovenes*) published in 1944.

After 1945, Lozar left Slovenia for political reasons. He lived in Austria until 1950 when he moved to Manitowoc, Wisconsin, where he worked as the director of local city museum. After leaving Slovenia, he lost all professional contacts with contemporary Slovenian archaeologists.

Lyell, Sir Charles

(1797-1875)

Born in Scotland, Lyell studied geology at Oxford University with william buckland. In 1819 he moved to London to study law and was admitted to the bar, but never practiced. Instead he took up the study of geology and scientific writing, supporting himself financially through private means and from the sale of his enormously influential books. Lyell was professor of geology at King's College, London, between 1831 and 1833 and was knighted in 1848.

His three-volume *Principles of Geology* (1830-1833) described modern and uniform long-term geological changes and argued against the prevailing catatstrophism of his time as unscientific and based on biblical chronology. Lyell also contributed to the development of paleontology and Tertiary studies and helped to establish the Eocene, Miocene, and Pliocene periods, based on animal extinctions.

While Lyell rejected Lamarck's evolutionism, he argued that extinction was the normal course of nature. He gradually accepted Charles Darwin's theories after the publication of *On the Origin of Species* (1859) but the question of human origins and human-ape connections remained a problem for him. In his book *Geological Evidence of the Antiquity of Man* (1863) he promoted arguments for the long antiquity of human history, convinced by evidence, provided by william pengelly and hugh falconer from brixham cave and other sites, of man-made tools being found with extinct fauna. In 1859 Lyell and the rest of the committee of the Geological Society of London followed joseph prestwich and john evans to

Abbeville in France to pass judgment on the validity of the fossil and tool finds in the

M

Machu Picchu

Located to the northwest of Cuzco in peru, the site of Machu Picchu is spectacularly situated on a ridge high in the Andes. The settlement comprises temples, tombs, houses, and agricultural terracing made from local stone with the same high-quality techniques that were so common among the inca. A place of considerable mystery, this "lost" city was brought to the attention of the outside world in 1911 by Hiram Bingham, an American explorer. He photographed the site and returned the next year to complete the job of mapping and undertaking limited excavations-in part funded by the national geographic society. Subsequent research has dispelled much of the mystery surrounding the site. It is now quite generally accepted that the site was not unknown to the Spanish and that it was built during the reign of the Inca king Pachacuti (a.d. 1438-1471).

Madagascar

Madagascar, situated in the western Indian Ocean, is the fourth-largest island in the world. About 400 kilometers from Africa, which lies to the west, the island is itself a small continent with diversity in all aspects of the environment: physical, climatic, and biological. Archaeology is the main discipline that can help to reconstruct the past in Madagascar. Apart from an Arab script of perhaps the fourteenth century, written sources are available only from the nineteenth century, and oral traditions go back no further than the fifteenth century.

A brief review of the philosophical approaches to understanding Madagascar's past from an archaeological point of view is useful. Madagascar is about 1,580 kilometers north to south and 580 kilometers east to west and covers some 587,000 square kilometers. Human settlements, right from the beginning, seem to have adapted to its different physical environments. The arid southern and western part, the cool central highlands, and the humid eastern forests have developed societies with economies comprising, respectively, gathering and hunting, herding, irrigated rice cultivation or swidden (slash and burn) cultivation. Although Madagascar is not far from Africa, the language used throughout the island is of Southeast Asian origin, an Austronesian language close to the one spoken on Borneo. Nevertheless, some African vocabulary does exist, and this linguistic synthesis has defined the much-studied problem of the first human settlement of Madagascar, which has fascinated researchers, including archaeologists, for more than a century.

The origin and settlement of Madagascar have been key research problems since the beginning of the twentieth century. Based on evidence, settlement is believed to be less than 2,000 years old. Who were the first inhabitants and when did they arrive? Folktales record myths about first inhabitants and past environments. These myths, for example, refer to “the Lalomena,” “the red beast,” perhaps the pygmy hippopotamus, and “the Vorombe,” “the big bird,” perhaps the Aepyornis, both of which are indigenous to Madagascar.

Interest in the past is important for the Malagasy people themselves, and the Malagasy concept of the past and its periodization are consistent across the island. Six main periods, sometimes with subdivisions, characterize this concept of the past: faha-gola (“faha, in the Malagasy concept, states the period, and “gola” is used to point very old times, the unknown first settlement), faha-vazimba (the vazimba are said to have been the first inhabitants met on the island by new migrants around the fifteenth century), faha-gasy (the period when the ancestors of actual inhabitants settled on the island), faha-mpanjaka (the period when the kings reigned), faha-vazaha or faha-zanatany (the period of colonization), and faha-leovantena (the period of independence). This periodization also comes down from oral traditions.

Linguistic and historic studies provide some chronological points of reference that are useful in understanding the settlement of Madagascar. The seventh to the tenth centuries a.d. marked the coming of migrants from Southeast Asia via Africa. In the eleventh century, Shirazi migrants reached the Comoros and the northern part of Madagascar, and in the twelfth and thirteenth centuries, Islamized groups, the Zafiraminia, arrived in the southeastern part of the country. The thirteenth and fourteenth centuries saw the arrival of two other Islamized groups, the Zafikazimambo and the Anakara, in the same region. About 1500, the supremacy of the Arab traders in the Indian Ocean declined and the Europeans arrived.

The past has always fascinated all Malagasy people, and each family has traditions about its own history. Among the better known nineteenth-century scholars who began to record the history of Madagascar was Raombana, secretary to Queen Ranavalona I (1828-1857). When very young, Raombana and his twin brother Rahaniraka had been sent to England by King Radama I to be educated, and they stayed

there for ten years. Because Raombana was descended from a former king and princes in the highlands and because of his English education, he developed an interest in the past of his country. He visited and described house foundations and other archaeological features at Ifanongoavana,

Magdalenska Gora

Magdalenska Gora is an early-Iron Age site in Dolenjska (lower Carniola) in slovenia. It comprises a hill-fort settlement covering an area of about thirteen hectares. Some forty earthen burial barrows have been documented in its immediate vicinity, and twenty-two of them, containing at least 1,000 graves, were the subject of extensive excavations at the end of the nineteenth century and the beginning of the twentieth by the Narodni Muzej or National Museum; the Naturhistorisches Museum, Vienna; and the peabody museum, Harvard University. Burial was largely inhumation, although a considerable number of cremation graves in the barrows have been found as well. The number of graves in the barrows varies from 2 to more than 350, but the average number of graves per barrow is between 20 and 60.

The burials cover a period of approximately 500 years, from the eighth to the fourth century b.c., with the majority of graves belonging to fifth or fourth century. Numerous rich princely and warrior graves make Magdalenska Gora one of the important centers for the Dolenjska group of the Hallstatt (early Iron Age) culture. The graves are characterized by ornamented bronze vessels of the situla type, different types of helmets, horse-riding equipment, weapons (axes, spearheads, arrowheads), great quantities of personal ornament (fibulae, pendants, necklaces, bracelets), and elaborate ceramic vessels. The site was not completely abandoned after the fourth centuryb.c., as some la tène (later Iron Age) cremation graves were found in the cemetery as well.

Maghreb

The study of prehistoric archaeology in the Maghreb (Morocco, Algeria, Tunisia) has been dominated

by French archaeologists. The earliest were primarily avocational (Sheppard 1990), and they maintained close ties with archaeological and anthropological societies of metropolitan France and often published their findings in journals such as *L'Anthropologie,* although they also developed active local societies with a strong archaeological focus (e.g., La Société de Géographie et d'Archéologie de la Province d'Oran, La Société Archéologique de Constantine, and La Société de Préhistoire de Tébessa). In the late 1920s and 1930s and again in the 1970s, research by North Americans brought different perspectives to the interpretation of the later prehistory of the region (Sheppard 1990).

From its inception, the study of prehistoric archaeology in the Maghreb has concentrated on later prehistory (i.e., late Pleistocene and Holocene). This trend began with one of the earliest of the avocational archaeologists, Duprat, who first remarked in 1894 on the distinction in stone artifact size at various landsnail shell middens (called escargotières, see Gobert 1937). For the next forty or fifty years, archaeological research and debate in the Maghreb centered on these materials and those that either immediately preceded or succeeded them.

In 1910-1911, in a serial article, De Morgan, Capitan, and Boudy reported stratified assemblages

by French archaeologists. The earliest were primarily avocational (Sheppard 1990), and they maintained close ties with archaeological and anthropological societies of metropolitan France and often published their findings in journals such as *L'Anthropologie,* although they also developed active local societies with a strong archaeological focus (e.g., La Société de Géographie et d'Archéologie de la Province d'Oran, La Société Archéologique de Constantine, and La Société de Préhistoire de Tébessa). In the late 1920s and 1930s and again in the 1970s, research by North Americans brought different perspectives to the interpretation of the later prehistory of the region (Sheppard 1990).

From its inception, the study of prehistoric archaeology in the Maghreb has concentrated on later prehistory (i.e., late Pleistocene and Holocene). This trend began with one of the earliest of the avocational archaeologists, Duprat, who first remarked in 1894 on the distinction in stone artifact size at various landsnail shell middens (called escargotières, see Gobert 1937). For the next forty or fifty years, archaeological research and debate in the Maghreb centered on these materials and those that either immediately preceded or succeeded them.

In 1910-1911, in a serial article, De Morgan, Capitan, and Boudy reported stratified assemblages

Mallowan, Sir Max

(1904-1978)

Born in London and educated at New College, Oxford, Max Mallowan claimed to have first excavated Victorian china shards when he was four years old in Bedford Gardens, Kensington. In 1925, after finishing university and hoping to avoid a career in the Indian Civil Service, he was taken on as a field assistant at the Iraqi site of Ur of the Chaldees by English archaeologist sir leonard woolley. It was there that Mallowan met the novelist (Dame) Agatha Christie, whom he married in 1930.

Mallowan worked in mesopotamia with Woolley for five years and became field director for joint excavations by the british museum and the British School of Archaeology in Iraq, which had been founded by a legacy from gertrude bell. He excavated at the Quyunjik mound at nineveh, at the village site of Arpachiyah, and

PREV NEXT

then in Syria at Chagar Bazaar and Tell Brak, where he discovered third-millenium shrines and the Palace of Naram-Sin.

Between 1940 and 1945, he served as a liaison officer with the Allied forces in North Africa. In 1947, Mallowan took up the chair of western Asiatic archaeology at London University and returned to Iraq as director of the British School, where he began to excavate sir austen henry layard's great site of nimrud. Over the next twelve years the site provided a wealth of architectural remains, artifacts, and texts, which were published in the monumental two-volume work *Nimrud and Its Remains* (1966). In 1962, he returned to Oxford as a fellow of All Souls College, was vice-president of the British Academy in 1961-1962, and trustee of the British Museum from 1973 to 1978. He was editor of *Iraq* (1948-1971) and an advisory editor of *antiquity*. He became a commander of the Order of the British Empire in 1960 and was knighted in 1968.

Max Mallowan and his wife, Agatha Christie, leave their home in London at the start of their journey to northern Iraq for archaeological research.

Malmer, Mats P.

(1921-)

Malmer was born in Scania, sweden, and studied prehistory at Lund University, receiving his Ph.D. in 1962. Malmer moved to Stockholm to become head of the Stone and Bronze Age Department at the Museum of National Antiquities in 1959, where he began to publish on archaeological methodology and theory while continuing extensive excavations. In 1970 he became professor of archaeology at Lund University, and in 1973 he was appointed to the chair of archaeology at the University of Stockholm.

Malmer is a key figure in discussions within Scandinavian archaeology on quantitative and taxonomic methods and the interpretation of archaeological data. His most significant influence has been to introduce and argue for the rational replacement of the predominant inductive

approach with a rational use of hypothesis and verification, a method in line with the hypothetico-deductive methods of logical positivism.

Malmer has also published in the area of rock carvings and museum studies, and his excavations of sites, and papers and reports on these, range from the Mesolithic to the medieval.

Mariette, Auguste

(1821-1881)

Auguste Mariette was born in Boulogne, France, and briefly lived and taught drawing and French in England. He developed an interest in Egyptology through the illustrations and notes of his cousin Nestor L'Hote, who had been a draftsman on jean-françois champollion's expedition to Egypt between 1828 and 1829. Mariette taught himself hieroglyphics from Champollion's grammar and dictionary, studied Coptic, and began working at the louvre Museum, where he completed an inventory of all of the Egyptian inscriptions in the collection.

In 1850 the Louvre sent him to Egypt to collect papyri but instead he began excavating the Saqqara Serapeum, the huge subterranean gallery containing the sacred Apis bulls. He also located the Fifth Dynasty tomb of Ti at saqqara. In 1855 the Louvre appointed him Assistant Conservator and he returned to Egypt to excavate at Giza, Thebes, abydos, and Elephantine.

The Temple of Horus at Edfu, one of the most complete extant temples in Egypt and one of the many sites excavated by Auguste Mariette

(Marilyn Bridges/CORBIS)

In 1858 Mariette was appointed the first director of the new Egyptian Antiquities Service by the joint ruling Pashas of Egypt. The National Museum in Cairo was founded in that same

year, the first museum of its kind in the Near East. As director of the service Mariette was in charge of all the excavations in Egypt, preventing the wholesale pillaging and plundering of sites, and ensuring that the museum began collecting, conserving, and preserving antiquities.

Mariette himself excavated more than thirty-five sites in Egypt over the next thirty years, which included 300 tombs at Saqqara and the clearance of the temples of Luxor, Medinet Habu, Dendera, and Edfu. Despite later criticism by william matthew flinders petrie and george reisner for his unscientific excavation techniques, Mariette's contributions to Egyptian archaeology were enormous. He published five volumes on *Dendera* (1875), and a catalogue of finds from *Abydos* (1880). He helped with the libretto for Verdi's great Egyptian opera *Aida,* which celebrated the opening of the Suez Canal. He was succeeded by Gaston Maspero.

Marshall, John Hubert

(1876-1951)

John Hubert Marshall became director-general of the Archaeological Survey of India in 1902 and relinquished the position in 1928, although he continued to work for the survey in nonadministrative positions until 1934. When the English viceroy of India, Lord Curzon, arrived in India in 1900, he felt it necessary to formulate an integrated archaeological policy on the part of the government of India rather than depending on a few "surveyors" in the provinces for archaeological investigations and the Public Works Department for monument conservation. Curzon chose Marshall as the director-general for the formulation and execution of this policy.

Conservation policy was laid down in an official resolution in 1903 and subsequently incorporated in a manual (Marshall 1923), which still remains the bible of conservators in India. The main emphasis was on the preservation of the originality of the monument. The Ancient Monuments Preservation Act of 1904 empowered the government to acquire nonliving monuments (i.e., monuments not being used for current religious worship) for conservation, to prohibit traffic in antiquities both to and from British India, to provide for keeping antiquities in situ or in site museums, and, finally, to prohibit the excavation of ancient sites by irresponsible persons.

In 1906, the Archaeological Survey of India became a permanent central government department with an elaborate and well-controlled hierarchy of officials, various administrative circles, and a "branch" of epigraphy. What has happened since then is an increase in the number of "circles" and "branches" with consequent changes in territorial jurisdictions and responsibilities. However, the basic pattern laid down by Marshall has remained intact. The work of excavation and exploration was divided among circles,

and reports appeared in the survey's Annual Reports, the publication of which-for the year 1902-1903-began in 1904. There was a well-defined policy regarding the basic research based on the exigencies of Indian conditions and best expressed by Marshall himself:

From the time of its reorganization in 1902 it has been the design of the Department to take in hand the excavation of the great buried cities of antiquity; but, before this design could be carried out, it was deemed advisable to re-examine some of the Buddhist sites which had already been partially uncovered, in order to co-ordinate the results obtained by earlier excavators and to check the often unreliable conclusions which they had drawn. For all practical purposes this part of the program was completed in 1910, by which time much solid work had been done at Charsada, Rajgir, Saheth-Maheth, Kasia, Sarnath, and other spots, and secure foundations laid for operations in another and more difficult field. Then followed the exploration of the town of Bhita, a small and well-defined site near Allahabad. Here, for the first

year, the first museum of its kind in the Near East. As director of the service Mariette was in charge of all the excavations in Egypt, preventing the wholesale pillaging and plundering of sites, and ensuring that the museum began collecting, conserving, and preserving antiquities.

Mariette himself excavated more than thirty-five sites in Egypt over the next thirty years, which included 300 tombs at Saqqara and the clearance of the temples of Luxor, Medinet Habu, Dendera, and Edfu. Despite later criticism by william matthew flinders petrie and george reisner for his unscientific excavation techniques, Mariette's contributions to Egyptian archaeology were enormous. Marshall, John Hubert

(1876-1951)

John Hubert Marshall became director-general of the Archaeological Survey of India in 1902 and relinquished the position in 1928, although he continued to work for the survey in nonadministrative positions until 1934. When the English viceroy of India, Lord Curzon, arrived in India in 1900, he felt it necessary to formulate an integrated archaeological policy on the part of the government of India rather than depending on a few "surveyors" in the provinces for archaeological investigations and the Public Works Department for monument conservation. Curzon chose Marshall as the director-general for the formulation and execution of this policy.

Conservation policy was laid down in an official resolution in 1903 and subsequently incorporated in a manual (Marshall 1923), which still remains the bible of conservators in India. The main emphasis was on the preservation of the originality of the monument. The Ancient Monuments Preservation Act of 1904 empowered the government to acquire nonliving monuments (i.e., monuments not being used for current religious worship) for conservation, to prohibit traffic in antiquities both to and from British India, to provide for keeping antiquities in situ or in site museums, and, finally, to prohibit the excavation of ancient sites by irresponsible persons.

In 1906, the Archaeological Survey of India became a permanent central government department with an elaborate and well-controlled hierarchy of officials, various administrative circles, and a "branch" of epigraphy. What has happened since then is an increase in the number of "circles" and "branches" with consequent changes in territorial jurisdictions and responsibilities. However, the basic pattern laid down by Marshall has remained intact. The work of excavation and exploration was divided among circles,

and reports appeared in the survey's Annual Reports, the publication of which-for the year 1902-1903-began in 1904. There was a well-defined policy regarding the basic research based on the exigencies of Indian conditions and best expressed by Marshall himself:

From the time of its reorganization in 1902 it has been the design of the Department to take in hand the excavation of the great buried cities of antiquity; but, before this design could be carried out, it was deemed advisable to re-examine some of the Buddhist sites which had already been partially uncovered, in order to co-ordinate the results obtained by earlier excavators and to check the often unreliable conclusions which they had drawn. For all practical purposes this part of the program was completed in 1910, by which time much solid work had been done at Charsada, Rajgir, Saheth-Maheth, Kasia, Sarnath, and other spots, and secure foundations laid for operations in another and more difficult field. Then followed the exploration of the town of Bhita, a small and well-defined site near Allahabad. Here, for the first

time in India, well-preserved remains of houses, shops and streets, dating as far back as the Mauryan epoch, were laid bare, and numerous minor antiquities recovered, which help us materially to visualize the everyday life of the towns-people in those early days. These discoveries gave a promise of a still richer spoil awaiting the spade at the more important centers of ancient civilization; and this promise has since been amply fulfilled. At Taxila the results obtained have been epoch-making.

The site of Pataliputra, the capital of the great Mauryan empire, which was singled out for excavation simultaneously with that of Taxila, offers to the digger a far less favourable field than the latter; for it has been inundated for centuries past by the waters of the Ganges, and its monuments, if they have not altogether perished, are buried at a depth of 20 feet or more below the surface.

(Marshall 1916, 24-27)

After 1924, the focus of archaeological effort shifted to indus valley civilization sites and to the excavations at Taxila, where Marshall himself excavated until the early 1930s. The method of excavation adopted by him and his officers may simply be described as excavating stratum by stratum, the component of each stratum being structures. Several publications by Marshall will always be regarded as being among the great volumes of Indian archaeology: the report of his detailed work at the Buddhist monument site of Sanchi (Marshall and Foucher 1983), the report of his work at Taxila (Marshall 1951), his analysis of Indus civilization (Marshall, ed. 1931), and last, but not least, his *Conservation Manual* (Marshall 1923).

Marshall also wrote two guidebooks on Sanchi, which contains Buddhist stupas from the third century b.c. onward, and a third guidebook on Taxila, which contains the ruins of Indian cities from pre-third-century-b.c. levels to early centuries a.d. The modern Archaeological Survey of India, and to some extent its counterparts elsewhere in south asia, have continued this tradition of producing definitive guidebooks on various monuments and sites under their care. The main emphasis of Marshall's interpretation of the Indus civilization was on its indigenousness and its intimate blending with the later Indian historic tradition.

The impact of John Marshall on the Indian archaeological scene will be clear from the tribute paid to him by a nationalist Indian archaeologist more than fifty years after his departure from the Indian archaeological scene:

The large exposed and conserved sites we see, the gardens around the monuments which we appreciate, the museums we enter and the objects we admire, the objects on which much of our own perception of our past is based-these are all intimately linked with the period which we here have called “the John Marshall period” in the history of Indian archaeology. It was an orderly and secure archaeological universe which, despite threats of retrenchment and financial stringency, went about its own way, building up the archaeological image of and ancient India in its manifold colours and nuances.

Maya Civilization

One of the great cultures of mesoamerica, Maya civilization extended throughout southern mexico and northern Central America. The Maya territory included what are now the southernmost Mexican states of Yucatán, Campeche, Quintana Roo, Tabasco, and Chiapas, as well as all of belize and guatemala and the westernmost parts of Honduras and el salvador.

In terms of geography the Maya area is often divided into three regions. The northern two regions (called the northern and southern lowlands, respectively) are formed by the low, limestone shelf that is the Yucatán Peninsula. Here the natural vegetation is tropical forest, featuring true high-canopy "jungle" in the south but becoming increasingly low and thorny as one moves to the northwest of the peninsula. Because of the porous limestone bedrock, there are few rivers in these regions. Particularly in the northern lowlands, access to water has traditionally been from *cenotes,* or natural sinkholes, in the limestone formations. The third region, the southern highlands, is much more mountainous, formed in large part by a string of volcanoes that lie along the Pacific coast.

The florescence of Maya civilization was the classic period, from a.d. 250 to 900, and it was centered in the Maya lowlands. Before this time, however, there was a long period of cultural development, both in the lowlands and in the southern highlands.

The history of human occupation in the Maya area stretches back at least 12,000 years, as shown by the scattered remains of hunting camps. A subsistence based on hunting and gathering lasted for millennia, but evidence suggests that by about 2000 b.c. there were farming villages in some parts of the Maya area and that by 1000 b.c. most of the Maya area was inhabited by village agriculturalists.

Until very recently, it was thought that the earliest development of more complex cultures in the Maya area began in the south-along the rich terrain of the Pacific piedmont and in the adjacent highlands of Guatemala and Chiapas-with temple-pyramids and carved stone monuments, as well as settlement and burial evidence indicating an increasingly stratified society. Although there certainly was impressive development in the southern highlands, it is now clear that there was also very early cultural development in the southern lowlands. In northern Guatemala, excavations at sites such as Nakbe and El Mirador have uncovered the remains of huge temple-pyramids built in the late centuries b.c. and possibly extending back as far as 600 b.c. By the late centuries b.c. there were numerous cities with massive public architecture in the southern Maya lowlands, and by the early centuries a.d. society was becoming increasingly stratified under hereditary rulers who probably gained most of their power initially through their reputations as spiritual leaders and their ability to mediate with the supernatural world on behalf of

their people. Huge mask panels modeled in stucco adorned the front facades of many pyramids: these incorporated symbols of kingship on heads that were surrounded by cosmological symbolism. The stage was set for the greatest florescence of Maya civilization-the classic period.

The classic period was initially defined by the span of time during which carved stone monuments incorporating hieroglyphic dates were erected at a host of Maya cities. Conventionally, the period ranges from a.d. 250 to 900. During this time dozens of cities grew up, each with its own hereditary kings and each controlling a territory usually not more than about 50 kilometers in diameter. These city-states, as they have

and are still important sources of information. He was also the author of two popular science books: *Woman's Share in Primitive Culture* (1894) and *The Origin of Inventions* (1895). Maya Civilization

One of the great cultures of mesoamerica, Maya civilization extended throughout southern mexico and northern Central America. The Maya territory included what are now the southernmost Mexican states of Yucatán, Campeche, Quintana Roo, Tabasco, and Chiapas, as well as all of belize and guatemala and the westernmost parts of Honduras and el salvador.

In terms of geography the Maya area is often divided into three regions. The northern two regions (called the northern and southern lowlands, respectively) are formed by the low, limestone shelf that is the Yucatán Peninsula. Here the natural vegetation is tropical forest, featuring true high-canopy "jungle" in the south but becoming increasingly low and thorny as one moves to the northwest of the peninsula. Because of the porous limestone bedrock, there are few rivers in these regions. Particularly in the northern lowlands, access to water has traditionally been from *cenotes,* or natural sinkholes, in the limestone formations. The third region, the southern highlands, is much more mountainous, formed in large part by a string of volcanoes that lie along the Pacific coast.

The florescence of Maya civilization was the classic period, from a.d. 250 to 900, and it was centered in the Maya lowlands. Before this time, however, there was a long period of cultural development, both in the lowlands and in the southern highlands.

The history of human occupation in the Maya area stretches back at least 12,000 years, as shown by the scattered remains of hunting camps. A subsistence based on hunting and gathering lasted for millennia, but evidence suggests that by about 2000 b.c. there were farming villages in some parts of the Maya area and that by 1000 b.c. most of the Maya area was inhabited by village agriculturalists.

Until very recently, it was thought that the earliest development of more complex cultures in the Maya area began in the south-along the rich terrain of the Pacific piedmont and in the adjacent highlands of Guatemala and Chiapas-with temple-pyramids and carved stone monuments, as well as settlement and burial evidence indicating an increasingly stratified society. Although there certainly was impressive development in the southern highlands, it is now clear that there was also very early cultural development in the southern lowlands. In northern Guatemala, excavations at sites such as Nakbe and El Mirador have uncovered the remains of huge temple-pyramids built in the late centuries b.c. and possibly extending back as far as 600 b.c. By the late centuries b.c. there were numerous cities with massive public architecture in the southern Maya lowlands, and by the early centuries a.d. society was becoming increasingly stratified under hereditary rulers who probably gained most of their power initially through their reputations as spiritual leaders and their ability to mediate with the supernatural world on behalf of

their people. Huge mask panels modeled in stucco adorned the front facades of many pyramids: these incorporated symbols of kingship on heads that were surrounded by cosmological symbolism. The stage was set for the greatest florescence of Maya civilization-the classic period.

The classic period was initially defined by the span of time during which carved stone monuments incorporating hieroglyphic dates were erected at a host of Maya cities. Conventionally, the period ranges from a.d. 250 to 900. During this time dozens of cities grew up, each with its own hereditary kings and each controlling a territory usually not more than about 50 kilometers in diameter. These city-states, as they have

peninsula in cities that had flourished for hundreds of years.

Over the decades many causes have been proposed to explain this societal and demographic collapse, from earthquakes, hurricanes, floods, or droughts to peasant revolt or civil war. Recent research has revealed that the collapse was probably the result of a combination of factors that snowballed to the point at which they overwhelmed classic Maya society. Ecological problems and warfare seem to have been foremost among these factors.

Evidence shows there were massive ecological problems in the Maya lowlands during the eighth and ninth centuries a.d., when deforestation appears to have caused sheet erosion in some regions; no doubt, changes to rainfall patterns occurred as well. Skeletal evidence indicates that dietary deficiency (reflecting both a growing population and an inadequate supply of food resources to support that growth) was an increasing problem by the beginning of the eighth century. The situation was critical by the ninth century.

There is now evidence that warfare was endemic in the Maya lowlands, especially during the second half of the classic period. In large part this was due to the fierce rivalry between polities, but it also seems that an increasing factor in the violence was competition over resources, including food. Evidence even suggests there were fortified maize fields by late in the classic period.

Some scholars have argued that the word *collapse* is, in fact, inappropriate for describing the momentous events of the ninth century in the Maya lowlands. It is clear that the century saw the demise of the ruling elites who had dominated Maya society for the previous 700 years or longer: stone monuments documenting royal histories were no longer carved, and some palaces were sacked. In certain sites, such as Tikal, there is also evidence of massive population loss, but whether this was due to warfare and such factors as endemic disease or to out-migration is not clear. What is clear, however, is that in many parts of the Maya lowlands, life continued. In Belize the effects of the “collapse” do not seem to have been so severe, but it is northern Yucatán where most of the dramatic postclassic developments took place.

In late-classic times there were many large cities in northern Yucatán. One of them, chichén itzá, would come to dominate most of the northern part of the peninsula for the terminal classic period, and some scholars extend this site's dominance as far as a.d. 1200. After the decline of Chichén Itzá, politics in the northern peninsula were again factionalized until a new city arose to dominate the area. This was the city of Mayapan, which flourished between about a.d. 1280 and 1450. Following the collapse of Mayapan, which documentary sources of the sixteenth century ascribe to internal revolt, the peninsula again reverted to petty competing kingdoms. This was the situation that the Spaniards encountered when they arrived on the scene in the early 1500s. It was also a factor in the Spaniards' conquest of Yucatán. It took the Spaniards over twenty years to gain a secure foothold in northern Yucatán, and one kingdom in the central part of the peninsula remained independent, practicing traditional Maya ceremonies (including human sacrifice) until 1697.

The heritage of classic Maya civilization is still very much alive. Approximately seven million Maya people still live in their ancient homeland, and two dozen Mayan languages continue to be spoken today. In some cases Maya people continue to practice traditional rituals, such as house dedication ceremonies, that are almost identical with those described in ancient hieroglyphic texts.

Knorosov, but even since the 1960s tremendous advances have been made. Syllabic readings of some 150 signs have been deciphered, and the majority of logograms can also be read, in large part because they are often accompanied by "phonetic complements" that give partial phonetic clues to their reading. Most of the Maya inscriptions in stone, wood, and other media can be almost completely read in ancient Mayan and translated. Although many contain erudite references to long-lost rituals and esoteric ceremonies, they are increasingly understood with the aid of archaeological findings, ethnohistorical and ethnographical parallels, and, in some cases, knowledge of the practices of contemporary Maya.

The Maya hieroglyphs were written over almost 2,000 years. The script contains about 800 different signs, some 400 of which were in use at any one time. Of these, between one-quarter and one-third were syllabic signs, the rest being logograms. Inscriptions were generally arranged in a system of double columns, in which the material would be read from left to right and top to bottom within two columns of text, before proceeding to the next two columns on the right. The script is written predominantly in one language (called Eastern Cholan), which is most closely related to a subgroup of Mayan languages still spoken across the base of the Yucatán Peninsula. The script was later adopted and used for inscriptions in at least one other language (Yucatec Mayan, still spoken in the northern half of the peninsula).

Most of the surviving Maya inscriptions are historical in general content, although they also contain a wealth of information on sociopolitical and geopolitical structure as well as details of ceremonies and rituals. Four Maya bark-paper books survive; they deal principally with astronomical and astrological matters. Various sixteenth-century commentators said the script was used to record information on history, genealogy, prophecy, maps, trade and tribute, astronomy, astrology, ritual and religious ceremonies, mythology, songs and poetry, and disease and medicine. Most of these topics are at least touched upon in the corpus of Maya hieroglyphic inscriptions that survives as testimony to the wonderful achievements of this ancient American civilization.

McBurney, Charles

(1914-1979)

Charles McBurney was a distinguished Paleolithic archaeologist who spent his entire professional career at Cambridge University, apart from his war service in North Africa-an experience that led him to return to Libya, where he did much of his fieldwork.

McBurney was born in the United States and lived in Stockbridge, Massachusetts. He was privately educated in Europe before going to Cambridge in 1933, where he studied under dorothy garrod, Miles Burkitt, and grahame clark. After graduating he began a doctoral dissertation on the Lower Paleolithic of Europe, embracing the major geographic study of the distribution of the Acheulean or hand-axe industries. The principal conclusions of this work were published in 1950.

World War II shaped much of McBurney's career. After its conclusion he returned to Cyrenaica, in Libya, to work with the geologist Richard Hey, and he discovered numbers of Mousterian, Aterian, and Upper Paleolithic sites. Henceforth, his interests were firmly fixed on this period, covering the last 150,000 years, although he remained highly conversant with problems of the Lower Paleolithic. In Cyrenaica McBurney first excavated the open site of Hajj Creiem and the cave of Hagfet et Dabba,

where he found a new industry that he named the Dabban. Then, in 1948, he found the great cave that most attracted his attention: the haua fteah near the coast in northern Cyrenaica. This vast sinkhole, 60 meters in diameter, was large enough to contain the whole camp. Excavations proceeded to a depth of 13 meters. The Haua Fteah became one of two very major pieces of fieldwork in McBurney's career, and it presented a classic archaeological sequence through the last glaciation. Its publication in monograph form in 1967 was a signal achievement. The site

since the beginnings laid by jacques boucher de perthes and édouard lartet; his greatest achievement is not so much to have taught a fourth generation but to have sewn ideas and strongly inspired a successor generation that is broadly scattered around the world.

Meadowcroft Rock Shelter

Meadowcroft is a rock shelter in southwestern Pennsylvania (United States) with a long series of stratified, multicomponent deposits spanning a period from 14000 b.c. to ca. a.d. 18. Fortunately, Meadowcroft is not subject to weathering degradation due to freezing and thawing, which can either preserve or destroy the archaeological record, as limestone rock shelters often are. Meadowcroft is oriented east-west with a southern exposure about 15 meters above Cross Creek, a tributary of the Ohio River. The overhang is 13 meters above the present floor. Local springs are abundant and the prevailing wind across the shelter opening ventilates smoke and insects.

The environment surrounding Meadowcroft was favorable to both occupation and preservation 16,000 years ago. The site was occupied intermittently by groups representing all major cultural stages in North America and has some of the earliest reliable evidence of people in North America. The climate indicated by pollen studies suggests an open spruce/pine forest with some open tundra and little hardwoods for occupation at around 16,000 years ago. Elsewhere in similar environments caribou and mastodon would be subsistence mainstays, but there are no extinct Pleistocene fauna at Meadowcroft.

This raises the question of whether the age of the site dates to the Holocene or whether it was used during a warmer climate that supported different species.

Meadowcroft is the oldest documented site for Paleo-Indian occupation. The site contains lithic blades dating to 14,000 years ago, following migration over the Bering Strait. Excavation begun in 1973 by Adovasio et al. began with mapping and trenching; all artifacts were processed and labeled on site. The most common cultural features found were firepits, ash and charcoal lenses, firefloors, and refuse or storage pits. A total of seventy samples were prepared for radiocarbon dating from the excavation at that time, and some forty more have been obtained since. The radiocarbon dating confirms an early (pre-Clovis) occupation of 14,000 years ago. Other artifacts recovered include lithic, bone, wood, shell, basketry, cordage, and ceramic materials. The lithic collection is not only the earliest securely dated collection of tools in eastern North America, but also among the earliest reliably dated assemblages recovered in the Western Hemisphere.

since the beginnings laid by jacques boucher de perthes and édouard lartet; his greatest achievement is not so much to have taught a fourth generation but to have sewn ideas and strongly inspired a successor generation that is broadly scattered around the world.

Medieval Archaeology in Europe

Introduction

Medieval archaeology as a subject with its own identity is a relatively recent phenomenon, but the study of the material culture of the Middle Ages has a much longer history, set in the context of a series of cognate disciplines. This fact is important for understanding the development of the subject as many of the areas of concern and types of research questions have derived from these other disciplines. Moreover, just as Roman archaeology was often undertaken by people who had a background and interest in classical sources, with the inevitable biases in the evidence collected and researched, the same is the case with medieval archaeology. Medieval archaeology as a distinct academic discipline taught through defined modules and courses in universities is an even more recent phenomenon, as yet present in only some European countries, with the result that much of medieval archaeology is practiced by people trained in other branches of archaeology or in cognate disciplines. This situation continues to affect the research questions and priorities in the subject, although medieval archaeology has matured considerably over the last half century.

Many of the major structures and sites of importance in medieval archaeology have never been abandoned or forgotten and continue in use, albeit often in a very different context. These range from churches and cathedrals to castles and palaces and more mundane structures such as water mills,

bridges, and field systems. Moreover, many portable artifacts, which tend to have belonged to the elite, have never entered the archaeological record but have continued to serve a function to the present day. These include religious items such as illuminated manuscripts, reliquaries, and church plate and secular objects such as royal regalia, armor, and weaponry. A great deal of the study of the material culture of the Middle Ages has been undertaken by architectural historians, art historians, historical geographers, and historians of particular activities such as naval or military historians, and numismatists. To varying degrees these scholars have incorporated the primary study of material evidence into their research and even have carried out excavations to reveal such remains.

Medieval archaeology has two separate traditions, early and late. The first is associated with the early Middle Ages, also often called the migration period, which ran from the end of the Roman period in those areas affected by the Roman Empire until the eleventh to thirteenth centuries a.d. depending on the region. Medieval Archaeology in Europe

Introduction

Medieval archaeology as a subject with its own identity is a relatively recent phenomenon, but the study of the material culture of the Middle Ages has a much longer history, set in the context of a series of cognate disciplines. This fact is important for understanding the development of the subject as many of the areas of concern and types of research questions have derived from these other disciplines. Moreover, just as Roman archaeology was often undertaken by people who had a background and interest in classical sources, with the inevitable biases in the evidence collected and researched, the same is the case with medieval archaeology. Medieval archaeology as a distinct academic discipline taught through defined modules and courses in universities is an even more recent phenomenon, as yet present in only some European countries, with the result that much of medieval archaeology is practiced by people trained in other branches of archaeology or in cognate disciplines. This situation continues to affect the research questions and priorities in the subject, although medieval archaeology has matured considerably over the last half century.

Many of the major structures and sites of importance in medieval archaeology have never been abandoned or forgotten and continue in use, albeit often in a very different context. These range from churches and cathedrals to castles and palaces and more mundane structures such as water mills,

bridges, and field systems. Moreover, many portable artifacts, which tend to have belonged to the elite, have never entered the archaeological record but have continued to serve a function to the present day. These include religious items such as illuminated manuscripts, reliquaries, and church plate and secular objects such as royal regalia, armor, and weaponry. A great deal of the study of the material culture of the Middle Ages has been undertaken by architectural historians, art historians, historical geographers, and historians of particular activities such as naval or military historians, and numismatists. To varying degrees these scholars have incorporated the primary study of material evidence into their research and even have carried out excavations to reveal such remains.

Medieval archaeology has two separate traditions, early and late. The first is associated with the early Middle Ages, also often called the migration period, which ran from the end of the Roman period in those areas affected by the Roman Empire until the eleventh to thirteenth centuries a.d. depending on the region. The second is concerned with the late Middle Ages when the power of the international church and

often they are limited in their range of subject matter), which means that much prejudice still remains concerning the archaeology of this period. For example, in Belgian-Dutch bibliographical reviews, archaeology is included only up to the ninth century a.d. In many countries, medieval archaeology refers only to the later Middle Ages, though gradually the term *medieval* is being applied to both early and late periods.

The development of early and later medieval archaeology needs to be distinguished given the diverse attitudes to each held in the past. Different traditions developed in each country, often related to the relative visibility of remains and the associations of structures and artifacts with the development of nation states and national identities, although sometimes traditions have been shaped by the influence of particular individuals and their concerns. Nevertheless, each subject area can be followed through a series of phases that, with roughly the same chronologies, can be traced across much of Europe.

Early Descriptions and Investigations

Medieval archaeology in one sense began in the Middle Ages when excavations were made to recover the physical remains and associated belongings of saints, although both the methods and motivations would be alien to archaeologists today. Most early antiquarian records deal with prehistoric and Roman antiquities, but some early medieval material was noted. In England, the works of John Leland, william camden, and william stukeley all included a small amount of medieval ecclesiastical material. Scandinavian scholars, including Henrik Rantzau, johan bure, and ole worm, recorded runestones and burial monuments.

One of the most notable discoveries was that of the Frankish King Childeric's grave, found in 1653 in Tournai, Belgium, at the church of St. Brice. A range of artifacts, including the king's seal ring, were recovered and published by Jean-Jacob Chifflet in 1655. Unfortunately, much of the material was stolen in 1831 and has never been recovered. It was in the eighteenth and the first part of the nineteenth century that medieval archaeological remains became of increasing interest, although the period of the Enlightenment in the eighteenth century encouraged an emphasis on classical ruins at the expense of those from the Middle Ages.

In early medieval archaeology, the focus was on the recovery of grave goods, largely from chance discoveries of unmarked cemeteries on the Continent, and recovery was sometimes followed by more systematic digging. Barrows attracted the attention of antiquarians, and while many had prehistoric origins, some were early medieval in date and others had been reused at that time and contained early medieval burials. Some of the earliest excavations conducted with some scientific rigor were those by the antiquarian and scholar Professor Olaf Rudbeck at Old Uppsala, sweden, in the late-seventeenth century. In England during the early eighteenth century Saxon barrows were unearthed in Kent; at the time they were considered casualties of Caesar's invasion. Later in the century the antiquarians Bryan Faussett and James Douglass were active in excavating barrows and tumuli; they also kept excellent records, and their archives and some finds are now in British museums. Work in Wiltshire was subsequently carried out in style by william cunnington and richard colt hoare.

With the rise of the Romantic movement during the early nineteenth century, medieval ruins attracted much more attention than ever before, although this attention did not often lead to greater study. Rather, the neglected structures were to create an impact and stir the emotions, and some were modified by additions or selective demolition to heighten their effect, although some clearance of rubble did take place, as with the Cistercian abbeys of Tintern in Wales and Fountains in England. This increased awareness did lead to more serious research in some cases, such as the discovery of architectural fragments and grave slabs, and made such sites well known to subsequent generations. More obviously,

archaeological interest relating to later medieval evidence at this time was also engaged with regard to remains, either ruins or buildings, still in use. In denmark, churches were recorded by N.L. Høyen, and in Sweden, P. Härnquist made a study of a Franciscan convent before a new building was constructed on

top of it, but such work was exceptional for the time. In England, Britton and Rickman identified the major styles of architecture and placed them in chronological sequence.

An Antiquarian Structure

Two important parallel developments in the nineteenth century affected the development of the various strands of medieval archaeology. One was the establishment of national and local societies with an interest in archaeology, and the other was the development of legislation to protect monuments and (of special importance for later medieval archaeology) buildings such as abbeys and castles. Universities did not develop a great interest in medieval archaeology at this stage, although a chair in the archaeology and history of medieval art was established at the University of Cracow (in Poland) in 1866.

More national societies developed to enlarge the small number, such as the society of antiquaries of london, that had been founded in the later eighteenth century, and many of them included early and later medieval archaeology within their interests. Examples include the British Archaeological Association for the Encouragement and Prosecution of Researches into the Arts and Monuments of the Early Middle Ages, founded in 1843, which soon had 1,200 members. The following year, the Society for the Preservation of Norwegian Antiquities was established, marking the change in that country to a more organized attitude to medieval archaeology. The joint German historical and antiquarian societies agreed in 1852 to found two museums, an act that institutionalized the divide between early and late medieval archaeology. Early medieval archaeology was within the purview of the Central Roman and Germanic Museum in Mainz, which also dealt with prehistoric and Roman material, and late medieval evidence was the responsibility of the Germanic National Museum established in Nuremberg for Christian German material with an emphasis on high art linked to architecture.

By the middle of the nineteenth century, many regions across Europe had or were establishing local museums and antiquarian societies. Members of the landed gentry and minor aristocracy, professional classes, and the more intellectual of the merchant and industrial classes were able to share their interest in the past, of which the medieval was a part and often a very visible one. Much of the archaeology had direct links with the present ecclesiastical structures and the estates and castles of the elite; other elements related to earlier medieval evidence associated with ethnic groups that had migrated and established the precursors of the developing nation states. In Germany, local societies began to emerge in the 1820s, and the Christian Middle Ages became a popular subject of interest in antiquarian circles, following on from developing interests in classical and prehistoric archaeology. Local societies in Italy began to form in the later nineteenth century, though medieval material was of only marginal interest in that country.

Merovingian cemeteries were excavated across france, often because of accidental discoveries caused by building work, and the finds were recorded by local antiquarian societies and sometimes partially published in their proceedings. Despite the seventeenth-century Childeric find, there was much doubt as to the dates and cultural attributions of the graves until the middle of the century. Major row-grave cemeteries were excavated at Nordendorf and Oberflacht in Germany in the 1840s, and the dating of such graves was ascertained through associated coin finds at Selzen, near Mainz, published in 1848. In eastern Europe, most attention was also given to early medieval material, particularly from cemeteries.

Barrow digging continued as an antiquarian pursuit throughout the nineteenth century. In russia, barrow cemeteries of the ninth to thirteenth centuries a.d. were investigated, most notably at Gnezdovo near Smolensk. Bateman, Atkinson, and Mortimer worked extensively in northern England, and by this time Anglo-Saxon burials were being clearly distinguished from prehistoric ones. Finds in all countries were often reported at local and national meetings; some finds were put in local museums at this time while

others remained in private hands either to be lost, sold on the antiquities market, or later deposited in an institution. Some burials

Poland, work began at Kobiernice in the 1880s as well as on the castle hill of Halich (now in Russia).

Urban archaeology received some attention at this time, but it was patchy. The institutional buildings of Göteborg, Sweden, were studied by Berg, but when he extensively excavated at the town of Kunghälla, he did not note structural evidence from the town itself, despite the many finds, but he did report on a monastery and castle adjacent to the settlement. An unusual example of continuous research on an urban center from the later nineteenth century can be seen at Lund, Sweden, where Karlin collected finds and recorded structures and stratigraphy while sewers were being dug. He later carried out excavations in various parts of the city. During the construction of railway works in Oslo, Norway, the architects recorded finds and deposits revealed by that construction.

Intermittent Interest

In the early twentieth century, there was a shift in activity associated with later medieval archaeology, and the clearance of ruins and their display for the public became common at this time. In England, the Office of Works carried out many programs. For instance, the visible ruins of the late medieval town of Old Sarum near Salisbury were excavated and consolidated before World War I, and after the war there was a program to work on abbeys such as Fountains, Byland, and Whitby. Even poor-quality excavation recovered significant amounts of early medieval material, though its context remains difficult to interpret.

In spain, the study of medieval archaeology was largely architectural, such as Asturian, Visigothic, and Mozarabic buildings of various kinds. Later medieval studies of castles and churches were also carried out. In Bohemia, the Benedictine abbey on Ostrov Island in Prague was excavated by Davle. A study of castles was carried out by the architect G. Fischer for Norway, and work began on the Prague castle, which has been continuously investigated since 1925. British official interest in recording archaeological and architectural heritage was reflected in the establishment of royal commissions for England, Wales, and Scotland, and county volumes appeared steadily after 1908.

The discovery of timber buildings through the identification of postholes by Carl Schuchhardt in the first decade of the twentieth century would lead in due course to tremendous changes in research interests and interpretation, but at the time, such discovery was not widely appreciated. The first large-scale excavation of a medieval settlement was in the 1930s when P. Grimm excavated Hohenrode, in Germany, which was occupied from the tenth to the fourteenth centuries a.d. The resulting wide-ranging report indicated the potential of such studies, but the excavation was not emulated. Rescue excavations on Frankish settlements included Gladbach and an Alemannic settlement at Merdingen, in Germany. One of the great discoveries of the period was that of the Viking Oseberg ship and its contents in Norway in 1904.

There was some important academic consolidation, and some important museum studies were undertaken on the collections assembled during the nineteenth century. Notable examples of such work for early medieval material include the typological classification of Germanic art styles by B. Salin, typologies of Anglo-Saxon brooches by. E.T. Leeds, and corpora of Viking material across Europe by Shetelig. Work on classification was stimulated and continued, with coin-dated Austrasian material published by Werner. Cemetery evidence was dominant, and it was often used to indicate settlement patterns, with variables of time, space, and ethnicity. Examples include K. Schuhmacher for the Rhineland and Leeds for England. The possibility of understanding Slavic material culture was appreciated by L. Niederle, who published a series of volumes on such evidence over a period of fifteen years. Later medieval artifact studies developed in some areas at this time, such as on Bohemian ceramics and on a range of finds in London, which were cataloged and published extensively for the first

time.

Urban archaeology continued at Lund, Sweden, but the efforts in this city were not emulated elsewhere. Instead, evidence was collected by amateurs, often local government officials, clergymen, or architects. Such piecemeal recording

was widespread in Scandinavia, examples being the work of O.A. Digre, who examined many development sites in Trondheim, Norway, and P. Fardelin, who did the same on the island of Gotland, Sweden. Research excavations by H. Jankuhn began at Hedeby, in southern Denmark, in the 1930s and was continued after World War II.

A range of specialities developed during this period. These are most obvious in early medieval archaeology, where subdivisions based on regional and chronological units, often linked to ethnic groups, were established. These still continue to this day, and since World War II have been supported by specialist societies or conferences, which may also incorporate multidisciplinary work by literary, toponymic, historical, and art history scholars.

Post-World War II Expansion

The massive urban destruction in many parts of Europe during World War II resulted in an unrivaled opportunity to examine urban evidence for medieval towns, though the possibility was not always seized with great enthusiasm. Great progress was made in northern Europe and to a certain extent in Britain, but in other countries, such as France, rebuilding took place without excavation. It was in this period that the full potential of urban archaeology began to be realized, although often the organizational structure and methods of funding were adequate in only a few regions. Elsewhere much evidence was lost, but at least the loss was noted, and in subsequent decades better facilities could be established for urban excavation.

In eastern Europe, state archaeological services were founded that accepted the importance of medieval archaeology. Each country established an academy of sciences, and within such a framework research programs were established and linked to nationalist and political themes. These included examination of the great Moravian state in Czechoslovakia and the Old Russ in Russia. In Poland, a center for the study of the Polish state was established in 1948, and about a third of all excavations in that country up to the mid-1960s were on medieval sites. The massive destruction of Warsaw and many trading cities on the Baltic coast gave opportunities for excavation before reconstruction or redevelopment.

In Britain, a pressure group called Rescue lobbied for excavation on many threatened medieval sites, and the importance of urban archaeology was highlighted by Carolyn Heighway. Excavations of the city of Winchester by Martin Biddle of the University of Pennsylvania were influential in Britain and some areas of Europe for indicating the potential for large open-area excavation in towns and for the examination within one town of various elements that, together, allowed for overall urban development to be understood within a historic framework. Methodological developments such as the design of recording forms and the elaboration of the Harris matrix for the elucidation and display of stratigraphic sequences also had widespread repercussions for medieval archaeology and beyond.

In France, the University of Caen has been the leading academic center for medieval archaeology, particularly through its Medieval Research Center, established in 1951 by Michel de Bouard. It has stimulated a number of initiatives, including biennial Chateau Gaillard conferences on castles, studies of pottery production, and urban archaeology. It was through the center that the journal *Archéologie Medievale* was first published in 1971.

Castle excavations have continued, and in Germany information concerning significant assemblages of pottery and other finds began to be published in the 1960s; previously only architectural details and sequences of structures had received much attention. In England, the origin of earthen castles was the focus of a concerted research campaign in the 1960s, and a similar study was undertaken in Northern Ireland. Castles of native princes have more recently been subjected to excavation in Wales to

complement the already extensive studies of those built by the English. The changing interests and priorities of castle archaeology can be appreciated on a European level through *Château Gaillard*, the proceedings of the conference held every two years since the 1960s.

It was not until the beginning of the 1950s that rural medieval archaeology developed in

any significant way, and this interest was inspired by the development of open-area settlement excavation in Denmark by Hatt and Steensberg. In England, the fieldwork identifying medieval villages as earthworks by Maurice Beresford was a vital step, and it was consolidated by a long-term research project at Wharram Percy by Beresford and John Hurst. Partly because of this work, the Medieval Village Research Group was established, and it was followed by the Moated Sites Research Group. The recognition of other forms of medieval settlement in the countryside led to the eventual merger of the two groups to form the Medieval Settlement Group.

From a British origin, such special interest groups have taken on a wider European dimension, and their annual reports have included frequent short reports and some longer papers on Continental material. One of the landmarks of medieval archaeology was the establishment of the Society for Medieval Archaeology in England in 1956 and the publication of the first volume of its journal, *Medieval Archaeology*, the following year. The European scale of medieval archaeology was indicated by a conference held at Rotterdam in the Netherlands in 1966, and a review of urban archaeology was later distilled at an Oxford, England, conference in 1975; the proceedings of both conferences were subsequently published and had considerable impact.

Early medieval studies continued have an ethnic basis, but social questions began to be considered and grave goods were used to establish patterns of ranking. The use of documentary sources to provide a social structure expected in the burial finds was widespread. An early example was W. Veeck in the 1930s, but most studies were undertaken in the 1960s and 1970s by R. Christlein and H. Steuer in Germany and J. Shepherd and C. Arnold in England. In eastern Europe, the role of the Slavs was a major early medieval theme, one that combined both burial and settlement archaeology. The International Union of Slavonic Archaeology was established in 1965 at Warsaw, and subsequent conferences have been held every five years in other cities in eastern Europe.

Typological studies continued for the early medieval material, with examples including the K. Böhner refining chronologies for the Trier region in Germany and sir john myres's extensive studies of Anglo-Saxon cremation urns. Early medieval cemetery studies have also developed with greater care and consideration being given to skeletal remains, other evidence from the graves and their fills, and structural features around the graves. Cremation cemeteries have also been studied with regard to cremation pyres and the cremated remains within the vessels. Several major rich burial sites were excavated during the twentieth century under high-quality archaeological conditions. Two Frankish graves were recovered from under Cologne Cathedral in Germany and one from Saint-Denis in France, all in 1959. The boat burial and impressive assemblage of artifacts from Mound 1 at sutton hoo were recovered in 1939, and there were further archaeologically significant but less spectacular findings at the site in the 1980s and 1990s.

Recent Developments

Medieval archaeology has continued to expand across Europe, although the amount of rescue excavation has often declined as planning procedures have reduced the amount of destruction. Moreover, a reduction of state funding, replaced by developer funding, has meant that mitigating strategies are often favored by developers. A trend for conservation that started in Britain has now spread to Scandinavia and is becoming increasingly favored in other areas. In contrast, the study of standing remains in a fully archaeological sense has become far more important.

The application of scientific methods in medieval archaeology has been rapid in recent decades. For some early medieval archaeological sites radiocarbon dating offers some potential, although in most situations its precision is too crude to improve on artifactual dating. More success has been obtained

with archaeomagnetic dating, and dendrochronology has been of particular importance. The latter has been applied to structural timbers in standing buildings and in waterlogged situations such as wrecks and waterfronts, and the method has provided dates similar in precision to those in

documented sources across much of northern and western Europe. In ceramics, the use of thin sections has been effective in identifying clay sources and trade patterns, and x-ray florescence and other analytical techniques have also been applied.

In some regions and countries, medieval archaeology has only developed as an activity with a separate identity in recent decades. A good example of this is Italy, where apart from nineteenth-century interests associated with major ruins, the Roman past was the dominant concern. The full development of medieval archaeology there has come about through a few significant academics and opportunities for rescue archaeology, and the publication of the national periodical *Archeologia Medievale* since 1974 has provided a vehicle for much innovative and important work. An even later start can be identified in Spain. Although some aspects were developed in the early part of the century, it was the foundation of the Spanish Association of Medieval Archaeology in 1980 that defined the subject, with *Acta Medievalia* being published from that year. Since 1985, a biennial conference has been held in Spain, and *Boletin de Arqueologia Medieval* has appeared since 1987.

The increasing European identity of medieval archaeology, confidence in its intellectual integrity, and the development of wide-ranging research themes have been manifested by several relatively recent developments. One initiative was the establishment of the European Symposium for Teachers of Medieval Archaeology, first held in Lund, Sweden, in 1990 and held regularly since. Another was the innovative international conference Medieval Europe held in york, England, in 1992. With a series of seven parallel thematic sessions, each headed by keynote papers, case studies and overviews were offered from all over Europe. A subsequent medieval Europe conference was held in Bruges, Belgium, again with major thematic strands, and it demonstrated the expanding and increasingly sophisticated nature of medieval archaeology.

As yet there is no substantial Europe-wide synthesis of early or late medieval archaeology, and even national syntheses have only recently appeared in a few countries. Medieval archaeology is a young aspect of archaeology in its present form, and a great deal was achieved in the last half on the twentieth century, but it is in the twenty-first century that it will mature into a coherent and fully confident section of the discipline.

Mercati, Michele

(1541-1593)

Although Greek and Roman writers had been aware that some people had made and used stone tools, this knowledge was lost during the Dark Ages after the fall of Rome. It was rediscovered during the Renaissance as scholars began to have access to ancient documents and to question medieval oral and written knowledge.

Michele Mercati was superintendent of the Vatican Botanical Gardens in Rome and physician to Pope Clement VII. He also created one of the first mineralogical collections in Europe, which distinguished between minerals and metals in its display. A contemporary of the antiquarians william camden, johan bure, and ole worm, Mercati was interested in new interpretations of evidence rather than the acceptance of traditional explanations of it. And like them, too, he was interested in chorology and geography.

In 1570, Mercati wrote *Metallotheca Vaticana, opus posthumum,* in which he argued that before the use of iron, stone tools might have been made out of flint to be used "in the madness of war." Mercati believed that fossils were organic in origin and that many of the flints called *ceraunia,* or "thunderstones," had been fashioned by hand and not by natural forces such as lightning. He cited biblical and classical sources, such as Lucretius, for the use of stone tools. In making these arguments he would have been familiar with the ethnographic specimens from the New World sent as presents to the vatican.

Mercati's ideas were not accepted by the learned world, and his book was not published until over 100 years after his death. Its appearance prompted the French scholar Antoine de Jussieu to write a paper to the Académie des Sciences on the possible human origins of stone tools and ethnographic comparisons in 1723. Mercati's ideas were echoed by English aniquarians william dugdale in the seventeenth century and john frere in the late eighteenth century.

Mesoamerica

Coined in 1943 by the scholar Paul Kirchoff, the name *Mesoamerica* is used to describe the culture area of the ancient civilizations of central and southern mexico and northern Central America. The name was partly based on analogy with the term *mesopotamia*, since the geographic region involved lies between the great landmasses of North and South America.

Mesoamerican Archaeological Sites

More than a geographic entity, however, Mesoamerica was a cultural entity. The peoples inhabiting the area shared a great many cultural traits that very clearly separated them from the peoples to their north and south. These traits included subsistence based on agriculture (the Mesoamerican cultigens maize, beans, and squash being the most important crops); cities with ceremonial precincts containing temple-pyramids; a fatalistic religion with a largely shared cosmology and pantheon of gods; the practice of human sacrifice; a ritual calendar of 260 days; and a ballgame played with a solid rubber ball.

Although Mesoamerican cultures shared many cultural traits, there were also differences among them. First and foremost of these differences was language: dozens of different languages were spoken by the various peoples of Mesoamerica, including Nahuatl (the language

of the aztecs), about thirty different Mayan languages, the Zapotec and Mixtec languages of Oaxaca, and the Tarascan or Purépecha spoken in western Mexico.

The olmecs, who flourished between about 1200 and 400 b.c., are considered to have had the first complex society in the area, and it appears that they developed many of the cultural patterns that later became the hallmarks of Mesoamerican civilization. Other Mesoamerican groups adopted these patterns, adding their own distinctive characteristics.

Mesopotamia

History of Excavation

The origins of Mesopotamian archaeology lie in nineteenth-century adventurism, tempered by the practical intelligence and broad learning that was the Victorians' defining hallmark. A handful of intrepid travelers (notably Pietro della Valle, L'Abbé de Beauchamp, and Karsten Niebuhr) had ventured through Mesopotamia in earlier centuries, stopping at nineveh, Babylon, and other sites whose identification survived in local folklore. Some brought back occasional inscriptions and other artifacts but, despite legends of buried treasure, none attempted any significant excavations.

A major turning point came in the first decades of the nineteenth century when Babylon, Nineveh, and a number of other Mesopotamian sites were systematically inspected and surveyed by Claudius Rich, a talented linguist who was the East India Company's resident in Baghdad (in what is now Iraq). Rich's accounts of his discoveries (1813, 1818, 1836, and 1839), and the collection of his finds bought by the british museum in 1825, inspired the first generation of Mesopotamian explorers. First in the field were the French, under paul-émile botta, who after brief soundings at Nineveh in December 1842 spent two seasons (1843-1844) excavating the Palace of Sargon II at Khorsabad (ancient Dur Sharrukin), the third of four Assyrian capitals (the others being Ashur, Kalhu [nimrud], and Nineveh). Botta was relatively well financed by the louvre Museum and approached his task with the discipline of a trained surgeon and naturalist, although not yet with any understanding of the principles of stratigraphy. Botta was succeeded by Victor Place, who led from 1852 to 1854.

The first British excavations were made by austen henry layard, who had set out overland from England in 1839 intending to reach Ceylon, but having been captivated by the Assyrian sites resolved to stay and dig. Eventually gaining the financial support of the British ambassador in Istanbul, Sir Stratford Canning, Layard, aged only 28, began excavating at Nimrud (ancient Kalhu, which he believed to be Nineveh) in November 1845. There he immediately came upon the palace of the ninth-century b.c. Assyrian King Ashurnasirpal II. During the next eight years Layard and his assistant Hormuzd Rassam uncovered no less than eight royal palaces, as well as temples and other imposing structures, whose sculpted bas-reliefs, ivory carvings, and cuneiform tablets (written in the then-still-undeciphered Assyrian language) were a revelation to Victorian Britain, whither the major finds were shipped.

Layard's priorities, as prescribed by the British Museum, were “to obtain the largest possible number of

well-preserved objects at the least possible outlay of time and money." His method was equally direct: he dug trenches along the sides of the palace rooms to expose the whole of the carved stone slabs without removing the earth from the center. Consequently few of the chambers were fully explored and many small objects and other evidence were left or lost. There was no recognition in this method of the stratigraphic principles-rudimentary as they still were-now beginning to be observed in the excavation of European prehistoric sites. It did however provide enough trophies of art (including some three kilometers of sculpted wall reliefs), architecture, and inscriptions to sustain the British Museum's grudging and inadequate support.

Layard's priorities, as prescribed by the British Museum, were “to obtain the largest possible number of

well-preserved objects at the least possible outlay of time and money." His method was equally direct: he dug trenches along the sides of the palace rooms to expose the whole of the carved stone slabs without removing the earth from the center. Consequently few of the chambers were fully explored and many small objects and other evidence were left or lost. There was no recognition in this method of the stratigraphic principles-rudimentary as they still were-now beginning to be observed in the excavation of European prehistoric sites. It did however provide enough trophies of art (including some three kilometers of sculpted wall reliefs), architecture, and inscriptions to sustain the British Museum's grudging and inadequate support.

The initial phase of Assyrian excavation by

of Babylon's earlier grandeur, when it was the capital of the dynasty of Hammurabi in the eighteenth and seventeenth centuries b.c.

After an exploratory season in 1884, the first major American excavations began under H.V. Hilprecht, J.P. Peters, and J.H. Haynes at the Sumerian cult center of Nippur in 1887 and continued intermittently up until the 1980s. The thousands of texts from this site, mostly school exercises in Sumerian, form the backbone of our knowledge of Sumerian literature. Four Sumerian and Akkadian sites of the third and second millennia b.c. were excavated in the Diyala region in the 1930s by a Chicago expedition under henri frankfort, whose close analysis of the ceramic typology and glyptic and sculptural art found formed the basis of the first systematic periodisation of third-millennium Mesopotamia (1929, 1931).

A hiatus in excavation during World War I was followed by the creation of the nation of Iraq and the establishment of a department of antiquities under gertrude bell. Expeditions returned to earlier Assyrian (Khorsabad, Nineveh) and Sumerian (Tello, Kish, Jemdet Nasr, Fara) excavations, and started at many new sites. The most important of these was the joint U.S.-British expedition (1922-1934) under c. leonard woolley to the Sumerian city of Ur. This was the first British expedition to emulate the care and precision of the Germans, to which Woolley added his own talent for inspired improvisation (as in his use of plaster to recover the forms of perished wooden objects). Woolley recovered important remains of Neo-Babylonian and Isin-Larsa period housing, and established a deep stratigraphical sequence for early Sumer, but the most celebrated finds then and since were the richly furnished “Royal” Tombs of ca. 2600 b.c. (in fact probably priestly burials). This was the first and only time Mesopotamia has yielded “treasure” that ranks in the popular conception with the finds of Bronze-Age Greece and Egypt. Woolley's excavations at nearby al-Ubaid (1923- 1924) recovered evidence of the earliest (fifth millennium b.c.) settled presence in the alluvium, known since as the Ubaid culture.

The period up to World War II also saw an expansion of activity in the hilly uplands surrounding the Tigris-Euphrates valleys at sites like Tepe Gawra, Tell Brak, Arpachiyeh, hassuna, Samarra, and Tell Halaf, where rain-fed agriculture had supported pre-Ubaid village communities. Continuing discoveries in this “fertile crescent” (extending beyond Mesopotamia from Palestine through Syria and Turkey and down western Iran), especially by American archaeologist robert braidwood in the 1950s at jarmo, have documented this region's crucial role in the early domestication of plants and animals, and, at some Samarran sites, early irrigation. Evidence of Paleolithic activity in the Kurdish mountains was found in the 1920s by English archaeologist dorothy garrod.

The broad chronological and cultural outlines of Mesopotamian archaeology having now been defined, the period after World War II saw a proliferation of excavation at sites of nearly all periods and regions, some continuing long-established expeditions (Uruk, Nippur), others recommencing at earlier excavations (Tell Brak, Nimrud, Sippar, Babylon), and others starting on new sites. In the 1970s and 1980s a large number of rescue excavations were undertaken in areas designated for flooding by the Hamrin, Haditha, and Eski Mosul dams in Iraq (and for dams in Syria and Turkey), some with startling results. The German and Dutch excavations at Habbuba Kabbira and Jebel Aruda in Syria uncovered hitherto-unsuspected outposts of early Sumerian culture (“colonies”) along the Upper Euphrates. Survey and limited excavation along the Arabian side of the Gulf from the 1950s on has indicated an Ubaid-period Mesopotamian presence (fifth millennium b.c.) along this littoral, a prelude to the well-documented Gulf trade with Meluhha (Indus Valley) of the third through the second millennia b.c. A number of area surveys of Babylonia by American archaeologist robert mccormick adams in the 1960s and 1970s illuminated demographic patterns that have had a significant impact on models of early state development.

Intellectual History

The great popular and scholarly interest in Mesopotamian archaeology in the nineteenth century was sustained both by the historical-scientific

impact on the field. More inhibiting have been a variety of internal factors, in particular ignorance of key aspects of how art was conceived and made in Mesopotamia: the lack of virtually any basis for attributing works to individual hands or names, which has forced the reconstruction of broader styles, schools, and traditions; ignorance of the functional priorities of the artist (ritual, propagandistic, apotropaic, etc.) vis-à-vis any artistic/aesthetic ambitions; ignorance of the degree of artistic latitude allowed to artists (minimal?); ignorance of the aesthetic and other categories in which they conceived the success or failure of a work of art (an area now being profitably investigated by I. Winter); and, perhaps most compromising of all, an inability in most contexts to define criteria for distinguishing conscious difference of style from unintentional difference of quality (or conception or execution). This leads to arbitrary and subjective value judgments, as in the common postulate of "crude" or "schematic" styles, when it is not clear that style is involved at all, but rather competence.

Gold helmet, Mesopotamia, ca. 2500 B.C.

(Image Select)

Most of what goes under the name of art history in Mesopotamian studies has been in the nature of iconographical and typological analysis, often with a view to defining period, cultural, ethnic, or regional styles, and thence to tracing patterns of influence and diffusion. Under the circumstances this is often all that can be done, and it has yielded many significant results. But it is considerably coarser-grained and often more speculative than art history in the sense that this discipline is generally understood.

Mexico

Archaeological research in Mexico has a long, complex history covering over 150 years and the careers of hundreds of archaeologists. Part of this history has been summarized in fairly recent surveys (Bernal 1979; García Mora et al. 1987-1989; Willey and Sabloff 1980), but much of it remains to be written. This article examines some of the central developments in Mexican archaeology with an emphasis on the work since 1940 when the quantity and types of investigations increased at an accelerated pace.

The evolution of Mexican archaeology as a scientific discipline generally has been closely

PREV NEXT

connected with the development of archaeology and anthropology in the rest of the world and with specific processes in the historical, political, and social configuration of Mexico. During the twentieth century, archaeology related directly to the political and ideological needs of the Mexican national state. Starting with the dictatorship of Porfirio Díaz, which was ended by a revolution in 1911, and continued by subsequent postrevolutionary movements, the monuments of the pre-Hispanic peoples have been utilized as an ideological base for an ethnic and cultural identity to fortify the growing nationalist sentiments needed by the new groups in power. Since the nineteenth century, Mexican nationalist governments have promoted a series of laws and regulations to conserve and protect historical and archaeological patrimony, and these laws and regulations were truly advanced for the time. The first of these, a law prohibiting the export of antiquities, dates to 1827, shortly after Mexico's independence from Spain.

Nationalist movements have largely determined and defined one of the major traditions of archaeological research in Mexico: archaeology centered on the exploration, restoration, and reconstruction of ancient buildings and monumental sites or "zones." This tradition started at the end of the nineteenth century, and although there have been changes in key concepts, techniques, and goals, it is still the major type of archaeology today, stimulated and maintained by the state because of the political and ideological functions of archaeological monuments.

The Beginnings of Archaeology in Mexico

The beginning of archaeology in Mexico can be divided into two periods: the first starting around 1840 and ending in 1880; the second extending between 1880 and 1910, during which time there was a notable increase in the number of scholars interested in the pre-Hispanic cultures of Mexico.

The most influential scholarly work that mentioned ancient Mexico and was published before the first initial period were the studies of the naturalist and philosopher Alexander von Humboldt (1814). Other important contributions were the books recording visits to maya ruins written by john l. stephens (1841) and illustrated by frederick catherwood. These do not indulge in speculations typical of the time proposing migrations of peoples from the Old World to explain the origins of American civilizations. Both Stephens and Catherwood attributed the ruins of Yucatán, Chiapas, and Central America to the ancestors of the contemporary Maya, and this conclusion helped change the interpretations of many scholars in the Americas and Europe concerning the cultures of pre-Hispanic Mexico.

Between 1840 and 1870, the French priest Abbé Brasseur de Bourbourg established himself as the first general Mesoamericanist. His contributions were mainly in linguistics and ethnohistory, but he also advanced archaeological knowledge considerably through his effort to establish ties between contemporary indigenous peoples and pre-Hispanic cultures using Spanish colonial documents and native histories from the sixteenth century. He learned several Maya languages, made some of the first attempts to translate Maya hieroglyphs, and edited the first published edition of the *Popol Vuh* (the most important surviving Maya epic cycle). He also discovered and edited an encyclopedic sixteenth-century account by Bishop Landa of Maya culture in Yucatán at the time of the Spanish conquest. The Landa manuscript contains descriptions of some of the hieroglyphs that eventually made possible the first successful phonetic translations of ancient Maya writing.

During the same period, early syntheses of ancient highland Mexican history were made by Garcia Icazbalceta and Orozco y Berra. Their work is especially important because, in some cases, it is based on native codices and other original manuscripts that have since disappeared. In 1858, the geographer García Cubas published a geographical and statistical atlas of Mexico that included a number of archaeological sites, and in the 1870s, he produced important descriptions of teotihuacán and Tula.

The French archaeologist-explorer Désiré Charnay arrived in Mexico in 1858 and continued his investigations there until the 1880s. His contributions include the introduction of photography to record monuments in the Maya area

PREV NEXT

of codices, religions, and calendars are classics (Coe 1993). Seler made numerous field trips to Mexico and Central America and published descriptions of sites and monuments in regions as diverse as guatemala, Chiapas, Oaxaca, Los Tuxtlas (Veracruz), and Zacatecas, among others. His study of the areas influenced by the major city of Teotihuacán, based mainly on the analysis of museum collections, was the direct precursor for the concepts of cultural unity that would be used to define Mesoamerica (Bernal 1979, 142). Seler knew several of the major pre-Hispanic languages and also made key contributions in ethnology and ethnohistory.

The Expansion of Mexican Archaeology

In 1911, at the beginning of the armed conflicts of the Mexican Revolution, the Escuela Internacional de Arqueología y Etnografía Americana (International School of American Archaeology and Ethnography) was founded in Mexico City. On the basis of agreements between the Mexican government and universities and museums in Germany, France, and the United States, the school functioned as a research institute. Even though it existed formally only until 1920, the institute's activities were of such importance that its foundation clearly marked a new period in the development of Mexican archaeology. Directors included some of the greatest anthropologists in the Americas-Eduard Seler, Franz Boas, Alfred Tozzer, and manuel gamio-and the programs were truly anthropological, with important studies in ethnology and linguistics in various regions of Mexico, despite the violence of the revolution (Rivermar 1987). Heroic linguistic investigation was done by Boas (1917) in studying speakers of archaic Nahuatl (the language spoken by the Aztecs) in the remote Oaxaca coastal town of Pochutla, but such work may have been routine for a man who was studying the Eskimos of central Greenland in the 1880s.

The school's central contribution to archaeology was the introduction of stratigraphic excavations in Mexico. In 1912, Gamio conducted a series of stratigraphic excavations at San Miguel Amantla (Azcapotzalco), which provided the basis for the first ancient culture sequence in the basin of Mexico. Boas and Gamio also extensively studied the collections of the national museum from sites in the basin of Mexico and published a catalog based on this work. Tozzer excavated Teotihuacán-period residences at Santiago Ahuizotla in the west-central basin near Azcapotzalco and identified a new ceramic complex called Coyotlatelco. It was eventually shown that this complex was part of a cultural tradition that appeared between the collapse of the Teotihuacán state and the rise of the Tula.

The sequence for the basin of Mexico proposed by the members of the International School consisted of three different cultures: archaic (which is now called formative), Toltec (related to the culture of Teotihuacán), and aztec. This chronological framework was partially modified by Alfred Kroeber in 1925, and in 1938, George Vaillant, on the basis of numerous stratigraphic excavations, published a more detailed chronology. The cultural sequence for the basin that is currently used was formulated by Pedro Armillas in 1950 on the basis of excavations at Teotihuacán along with the investigations of Vaillant and Sigvald Linne and the work of Acosta at Tula. Despite these modifications, it is fair to state that the investigations of the International School correctly identified the principal cultures of the basin of Mexico in the proper chronological order.

The outstanding figure in Mexican archaeology during the revolution and the decade of the 1920s was Manuel Gamio (González Gamio 1987), who had been one of Boas's students at Columbia University in 1910-1911. Gamio was the last director of the International School, and between 1917 and 1922, supported by funds from the Mexican government, he planned and directed the first multidisciplinary anthropological project in the Americas on the population of the Teotihuacán Valley. The program comprised archaeology, ethnography, demography, geology, and environmental and agricultural studies and investigated the people of the Teotihuacán Valley from pre-Hispanic times to the twentieth century. The project's findings were published in five volumes, and it was one of the most successful large-scale

anthropological projects ever attempted, with a very advanced level of research for its time. The project's most important

dates established the first absolute chronology in Mesoamerica, and the projects of Maudslay, Maler, Morley, and others who discovered and recorded a preliminary corpus of Maya inscriptions made possible the subsequent breakthroughs in the deciphering of this writing system.

Consolidation

In some ways, the 1940s constituted a period of consolidation and critical reviews of previous investigations in Mexico. During the second half of the decade, however, a series of projects began that had new kinds of objectives and new fields of study.

In 1940, the social anthropologist Clyde Kluckhohn published a severe criticism of archaeological investigation in Mexico and Central America. He was especially critical of the tendency of archaeologists to study pre-Hispanic cultures in terms of isolated elements such as architecture, ceramics, and inscriptions, and he argued that there was little commitment to produce syntheses concerning the totality of a culture similar to the analyses that ethnologists were making of living peoples. These criticisms were expanded and essentially codified by his archaeologist student walter taylor (1948), whose work was a forerunner of some of the concepts "the new archaeology" of the 1960s. Pedro Armillas similarly criticized traditional Mesoamerican archaeology in Mexico during the same period.

The 1940s began with debates among archaeologists concerning two poorly understood cultures: the Toltecs and the Olmec. The Toltecs were mentioned in many pre-Hispanic chronicles as the ancestors of the Aztecs and some other peoples. Their empire, which was said to have reached its apogee during the tenth or eleventh century a.d., had its capital city called Tula, or Tollan, somewhere in the central highlands. Charnay (1885) and others had proposed that the center called Tula in the state of Hidalgo was the legendary Tollan, but many early-twentieth-century archaeologists, including Gamio and Vaillant, thought that Teotihuacán was the Toltec capital.

In 1941, the distinguished ethnohistorian Jiménez Moreno had analyzed the place-names and geographical regions mentioned in the chronicles concerning the location of ancient Tollan and had showed that most of the places were clearly identified with the area of Tula, Hidalgo. In 1940, with the support of the newly founded National Institute of Anthropology and History, Jorge R. Acosta began the first of nearly twenty archaeological field seasons at Tula, and the first roundtable conference of the Mexican Society of Anthropology was organized the next year with Tula and the Toltecs as its theme. Over thirty archaeologists discussed the significance of the findings of Jiménez Moreno and Acosta and concluded that Tula, Hidalgo, was the Tollan described in the chronicles of central Mexico.

The Olmec were the subject of the second roundtable conference of the Mexican Society of Anthropology, held in 1942 with Caso, M. Stirling, M. Covarrubias, and Jiménez Moreno as key participants. Discussions centered on Stirling's recent investigations of Olmec centers in Veracruz and Tabasco, especially his discovery of Stela C at Tres Zapotes, Veracruz, which had an inscribed date corresponding to 32 b.c. The iconographic studies of Caso and Covarrubias, and the ethnohistorical syntheses of Jiménez Moreno, all presented cases for the great antiquity of the Olmec. On the basis of these investigations, the majority of the roundtable participants concluded that, as Caso had proposed, the Olmec were "the mother culture" of Mesoamerican civilizations such as the classic Maya, Teotihuacán, and Zapotecs of Monte Alban. The chronological placement of the Olmec was debated until the 1950s when radiocarbon dating showed that this culture existed at least as early as 1000 b.c., during the formative period.

During the 1940s, many Mayanists, including Morley and Thompson, did not accept that the Olmec were older than the Maya of the classic period (a.d. 300-900). In 1941, Thompson published a

complex analysis that tried to demonstrate that the Olmec were a postclassic culture of the fourteenth or fifteenth century a.d. Stirling continued excavating Olmec sites during the 1940s at La Venta, Tres Zapotes, and San Lorenzo, and Covarrubias (1943, 1946a, 1946, 1949) excavated Tlatilco in the basin of Mexico where he found evidence for the early

without much historical content. The importance of Knorosov's phonetic analyses was not fully accepted until nearly twenty years later.

Major projects along the Gulf coast of Veracruz and Tabasco included García Payón's excavations at El Tajin and Zempoala and his surveys in various regions (1954, 1955). Medellín Zenil established ceramic sequences in the Totonicapán and other areas of south-central Veracruz (1953, 1960), and in extensive excavation at La Venta, Tabasco, by Drucker, Heizer, and Squier 1959) many offering and monuments were uncovered. This work obtained the first radiocarbon dates for the Olmec culture, placing it tentatively between 1000-400 b.c., thus confirming the Olmec chronology proposed by Caso and Covarrubias.

In the Valley of Oaxaca, Bernal and Paddock excavated various centers as part of the investigation program for the newly founded Universidad de las Americas, and in the basin of Mexico, Piña Chan excavated formative sites while investigating some of the problems relating to early cultures there that had previously been defined by Vaillant, Noguera, and Covarrubias. In surveying the northern basin, Tolstoy (1958) refined ceramic typologies for some phases of the classic and postclassic periods, and Sejourné (1959) made controversial nonstratigraphic excavations in Teotihuacán that uncovered many murals and provided information concerning the planning and internal structure of residential buildings.

Richard MacNeish's (1958) project in Tamaulipas in northeastern Mexico was significant because it attempted to investigate the early domestication processes for basic food plants such as maize and beans, a problem MacNeish would study more thoroughly later in his multidisciplinary project in the Tehuacán Valley.

The 1950s produced some ambitious general syntheses of Mesoamerican archaeology. In Marquina's (1951) encyclopedic study of pre-Hispanic architecture, still an indispensable work in Mesoamerican studies, he cited and analyzed numerous unpublished reports from the archives of the Department of Pre-Hispanic Monuments in enriching his coverage of poorly known cultures and regions. Two book-length essays on cultural definitions of Mesoamerica were published by Olivé (1958) and Piña Chan (1960).

Contemporary Mexican Archaeology

Most of the concepts and theories currently in use by Mesoamerican archaeologists emerged, close to their present form, during the 1960s and 1970s. In some cases, the theoretical and methodological goals of new projects are so ambitious that there are lapses of as much as ten to twenty years between the beginning of fieldwork and the publication of the detailed “final reports.”

Mexican archaeology experienced some radical changes during the 1960s with numerous debates concerning the validity of the theory, methods, and objectives of traditional archaeology. Some of the debates were influenced by the development of “the new archaeology” in the United States, especially by the ideas and theories of lewis binford. Among younger Mexican archaeologists there was an even stronger interest in Marxism and the use of historical materialism to study social process and attempt to discover general “laws” of social development. This shift toward Marxism was part of a much larger intellectual and political process that eventually resulted in the student movement of 1968 that changed key aspects of the contemporary Mexican political system. So far, the best Marxist analyses have been produced by social anthropologists such as Bonfil and Olivera, and although numerous archaeological projects have used Marxist interpretive frameworks, no rigorous materialist syntheses have appeared similar to the ones that Childe produced for ancient peoples in the Old World. Some of the best materialist studies using archaeological and ethnohistorical data concern the development of social

stratification and state-level societies (Batra 1969; Carrasco, ed., 1976; Carrasco and Broda 1978).

Starting in the 1960s, the National Institute of Anthropology and History steadily grew and diversified, and there was a considerable increase in the number of archaeologists on its staff. Laboratories for geological, biological, and ecological analyses were set up in the Department of Prehistory, and the Departments of Salvage Archaeology and Subaquatic Archaeology

Moche

Moche is the name of the dominant culture on the north coast of peru from the first to the seventh centuries a.d., known as the early intermediate period. The culture was first identified in the Moche Valley and was centered on the

large pyramid sites of huaca del sol and Huaca de la Luna. During the course of Moche history, a distinctive pottery style developed, one that emphasized accurate observation of everyday life. Moche culture was also rich in other areas of the decorative arts.

A typical Mochica pottery effigy jar picturing a mother and child

(Burstein Collection/Corbis)

Uncertainty still surrounds the political organization of the Moche culture, which appears to have been based around social stratification. The erection of large pyramids, first at Huaca del Sol and later at Galindo and Pampa Grande, indicates that although the core territory of the Moche culture may have retreated from the coast in the early seventh century a.d., some continuity in forms of political organization may have continued. The cause of the downfall of the Moche is also widely debated. It has been argued that adverse weather patterns generated by the El Niño current attacked the fundamentals of the Moche economy; other people have suggested that Moche was adversely affected by the rise of the Huari state. Whatever the reason or reasons, it is clear that the Moche culture had been influenced by the earlier Chavín cultural forms and that it in turn influenced the Chimú and other cultures that followed it.

Monte Albán

A major site and center of Zapotec civilization in southern mexico, Monte Albán is a huge hilltop site adjacent to the modern city of Oaxaca. Monte Albán is located in the center of the three major arms of the Valley of Oaxaca and is surrounded by rugged mountains. The Zapotecs are members of an ethnic group that is still widespread in Oaxaca today, and there is no doubt that their ancestors built Monte Albán.

Prior to 500 b.c., the Valley of Oaxaca had seen a long period of cultural development that had given rise to a number of chiefdoms, each containing a central town with several hundred inhabitants and public ceremonial buildings surrounded by smaller agricultural villages. The settlement and demography of the valley changed radically in 500 b.c., however. Monte Albán was founded on top of a 400-meter-high hill on what had previously been bare land. The hill was leveled, and settlement began in three discrete localities on the hilltop. From this fact some scholars have argued that Monte Albán represents the coming together in a central place by the people of the three arms of the valley, and certainly, the valley and its preexisting towns and villages saw a temporary reduction in population after

the founding of Monte Albán.

Over the following centuries, Monte Albán grew enormously in population and power, and it came to dominate the entire Valley of Oaxaca as well as lands beyond. There are some indications

Monte Albán

A major site and center of Zapotec civilization in southern mexico, Monte Albán is a huge hilltop site adjacent to the modern city of Oaxaca. Monte Albán is located in the center of the three major arms of the Valley of Oaxaca and is surrounded by rugged mountains. The Zapotecs are members of an ethnic group that is still widespread in Oaxaca today, and there is no doubt that their ancestors built Monte Albán.

Prior to 500 b.c., the Valley of Oaxaca had seen a long period of cultural development that had given rise to a number of chiefdoms, each containing a central town with several hundred inhabitants and public ceremonial buildings surrounded by smaller agricultural villages. The settlement and demography of the valley changed radically in 500 b.c., however. Monte Albán was founded on top of a 400-meter-high hill on what had previously been bare land. The hill was leveled, and settlement began in three discrete localities on the hilltop. From this fact some scholars have argued that Monte Albán represents the coming together in a central place by the people of the three arms of the valley, and certainly, the valley and its preexisting towns and villages saw a temporary reduction in population after

the founding of Monte Albán.

Over the following centuries, Monte Albán grew enormously in population and power, and it came to dominate the entire Valley of Oaxaca as well as lands beyond. There are some indications

by a.d. 900 Monte Albán was declining into ruin. Perhaps as many as 4,000 people were still living on the flanks of the hill, but the great palaces and temples were in disrepair. When Mixtec peoples invaded the Valley of Oaxaca during the fourteenth century, they settled at the base of the hill. They did find and use some of the earlier Zapotec tombs, scooping the old Zapotec inhabitants to one side and burying their own elite members there. One such tomb, with the prosaic designation Tomb 7, was particularly rich. The burial was that of a fourteenth-century Mixtec prince, and he was accompanied by several sacrificed servants as well as magnificent works of art in gold, silver, and precious stones.

Montelius, Gustaf Oscar Augustin

(1843-1921)

Born in Stockholm, sweden, and educated at Uppsala University, Montelius finished his Ph.D. in 1869. From 1863 to 1880 he worked at the Museum of National Antiquities in Stockholm in various capacities, and finally as senior executive officer. From 1907 to 1913 he was state antiquarian, head of the Central Board of Antiquities and the Museum of National Antiquities. Montelius was a fellow of the Swedish Academy and a member of its Nobel Prize Committee.

When Montelius started as a prehistorian in the mid-1860s knowledge of chronological details in European archaeology was almost nonexistent. In spite of a long research tradition, Scandinavian archaeology had not yet advanced beyond a division of the Stone Age into an earlier (Mesolithic) and a later (Neolithic) phase. There was a similar division of the Bronze Age into two stages, and a division of the Iron Age into three periods. In most other parts of Europe, prehistoric research had not even reached that level of chronological understanding. Consequently archaeologists were limited in their ability to interpret prehistoric life and society in any depth. Montelius clearly recognized this problem and throughout his career as an archaeologist he was engaged in creating reliable time scales for prehistoric Europe. No other single researcher did so much to develop traditional archaeological dating methods as Montelius. Largely because of his efforts and methodological examples, prehistoric archaeology in northern Europe by the end of the century had access to a fairly detailed and reliable chronology, both in relative and absolute terms. In fact, Montelius's work left its mark on the development of prehistoric chronology in other parts of Europe as well as in the Near East.

As a prehistorian, Montelius did not have much interest in theory. He was primarily an empiricist and his strength lay in his supreme ability to collect information; to systematize, digest, and generalize great quantities of archaeological data; and to present his results in a clear and convincing way. Given his systematic nature, energy, and curiosity, it is remarkable that Montelius did not become a prominent excavator.

Aside from chronologies, Montelius was also interested in issues of prehistoric culture. He was an energetic popularizer. Many of his scientific works were edited for the general public, with less emphasis

on chronological problems and more discussion of general cultural and social perspectives. He became a central figure in European archaeology. Many of his works were published in major European languages, and his extensive international network of contacts was facilitated by his proficiency in German, French, Italian, and English.

Montfaucon, Bernard de

(1655-1741)

De Montfaucon was a French Benedictine monk, paleographer, philologist, and antiquary, who published several histories and

by a.d. 900 Monte Albán was declining into ruin. Perhaps as many as 4,000 people were still living on the flanks of the hill, but the great palaces and temples were in disrepair. When Mixtec peoples invaded the Valley of Oaxaca during the fourteenth century, they settled at the base of the hill. They did find and use some of the earlier Zapotec tombs, scooping the old Zapotec inhabitants to one side and burying their own elite members there. One such tomb, with the prosaic designation Tomb 7, was particularly rich. The burial was that of a fourteenth-century Mixtec prince, and he was accompanied by several sacrificed servants as well as magnificent works of art in gold, silver, and precious stones.

Montelius, Gustaf Oscar Augustin

(1843-1921)

Born in Stockholm, sweden, and educated at Uppsala University, Montelius finished his Ph.D. in 1869. From 1863 to 1880 he worked at the Museum of National Antiquities in Stockholm in various capacities, and finally as senior executive officer. From 1907 to 1913 he was state antiquarian, head of the Central Board of Antiquities and the Museum of National Antiquities. Montelius was a fellow of the Swedish Academy and a member of its Nobel Prize Committee.

When Montelius started as a prehistorian in the mid-1860s knowledge of chronological details in European archaeology was almost nonexistent. In spite of a long research tradition, Scandinavian archaeology had not yet advanced beyond a division of the Stone Age into an earlier (Mesolithic) and a later (Neolithic) phase. There was a similar division of the Bronze Age into two stages, and a division of the Iron Age into three periods. In most other parts of Europe, prehistoric research had not even reached that level of chronological understanding. Consequently archaeologists were limited in their ability to interpret prehistoric life and society in any depth. Montelius clearly recognized this problem and throughout his career as an archaeologist he was engaged in creating reliable time scales for prehistoric Europe. No other single researcher did so much to develop traditional archaeological dating methods as Montelius. Largely because of his efforts and methodological examples, prehistoric archaeology in northern Europe by the end of the century had access to a fairly detailed and reliable chronology, both in relative and absolute terms. In fact, Montelius's work left its mark on the development of prehistoric chronology in other parts of Europe as well as in the Near East.

As a prehistorian, Montelius did not have much interest in theory. He was primarily an empiricist and his strength lay in his supreme ability to collect information; to systematize, digest, and generalize great quantities of archaeological data; and to present his results in a clear and convincing way. Given his systematic nature, energy, and curiosity, it is remarkable that Montelius did not become a prominent excavator.

Aside from chronologies, Montelius was also interested in issues of prehistoric culture. He was an energetic popularizer. Many of his scientific works were edited for the general public, with less emphasis

on chronological problems and more discussion of general cultural and social perspectives. He became a central figure in European archaeology. Many of his works were published in major European languages, and his extensive international network of contacts was facilitated by his proficiency in German, French, Italian, and English.

Montfaucon, Bernard de

(1655-1741)

De Montfaucon was a French Benedictine monk, paleographer, philologist, and antiquary, who published several histories and

translations from Greek. In 1685 de Montfaucon published an account of the excavation of a megalithic stone tomb at Cocherel that contained polished stone axes. He ascribed the tombs to a people who had no knowledge of iron, and in passing referred to the possibility of a three-age sequence-stone, copper, and iron-of human development. In reaching this conclusion he was undoubtedly influenced by contemporary archaeological research in England and Scandinavia.

From 1698-1701 de Montfaucon worked in the Vatican Library in Rome, publishing his travels and experiences in *Diarium Italicum.* For the next twenty years he prepared his monumental fifteen-volume *L'antiquité expliquée et representée en figures* (1722-1724), comprising an enormous amount of source material and iconographical data from the ancient world. His aim was to illustrate and describe the monuments of antiquity in order to explain them and attempt to reconstruct the past. It was both a scientific and an educational work-and de Montfaucon suggested that a serious student could take up to two years to do it justice. His work was to have an enormous impact on subsequent antiquarian studies and the beginnings of an archaeology based on illustration and interpretation.

Morgan, Lewis Henry

(1818-1881)

Born in New York State, Lewis Henry Morgan studied law at Union College in Schenectady and moved to Rochester in 1844. He became wealthy through investments in railways and iron smelting and was thus able to devote all of his time to his scholarly interests after 1860. Morgan took part in the literary and scientific societies of his day, joining the American Association for the Advancement of Science in 1856, presiding over the newly created anthropology section in 1873, and becoming the association's president in 1879. He was made a member of the National Academy of Sciences in 1875.

Morgan's passion was for Native American Indian ethnology, and his first book, *League of the Iroquois* (1851), is still the best ethnography on the subject. He undertook fieldwork among the Ojibwa in Michigan, out of which grew modern kinship studies such as those outlined in *Systems of Consanguinity and Affinity* (1871). In *Ancient Society, or Researches in the Line of Human Progress from Savagery through Barbarism to Civilization* (1877), the influence of the evidence of human antiquity recently discovered in Europe moved Morgan in the direction of evolutionism.

The impact of his work was enormous-Karl Marx, Frederick Engels, John Lubbock, and Charles Darwin all read and considered it, and in the next generation, Lorimer Fison, the Australasianist; Adolph Bandelier, Mesoamerican and southwestern archaeologist and historian; and john wesley powell, head of the Bureau of American Ethnology and leading classifier of Native American languages in his day, were all Morgan's students and successors. He was also a major influence on the outstanding anthropologists W.H.R. Rivers, A.R. Radcliffe-Brown, and Claude Lévi-Strauss.

Morley, Sylvanus Griswold

(1883-1948)

The son of a former military academician and mine owner, Sylvanus Morley corresponded with frederic ward putnam of Harvard University's peabody museum from the age of fifteen. To please his father, Morley first studied to be a civil engineer but then began studying anthropology at Harvard. His earlier fascination with Egypt gave way, under Putnam and Alfred Tozzer's encouragement, to an abiding interest in the Maya of Central America.

After his graduation from Harvard Morley was sent by the archaeological institute of america to the Yucatán in mexico to study linguistics. There he met Mesoamerican archaeologist Edward Thompson at the site of chichén Itzá.

PREV NEXT

Other travels through the Yucatán convinced Morley to abandon linguistics for a career in archaeology. Back at Harvard in 1905 he studied anthropology under Tozzer and read Daniel Brinton's *Primer of Maya Hieroglyphics*-his first exposure to a subject that would become his lifelong forte.

In 1907 Morley participated in edgar lee hewett's field-methods school in archaeology in the Southwest, along with alfred v. kidder. His engineering training in areal survey proved to be invaluable, and he continued to work for Hewett until 1915, when he was hired by the Carnegie Institution's new Department of Central American Archaeology. His first book, *Introduction to the Study of the Maya Hieroglyphs,* a synthesis of what was then known about maya epigraphy, was published in the same year. In the *Supplementary Series in the Maya Inscriptions* (1916) Morley brought together drawings of all lunar glyphs, thereby allowing John Edward Teeple to solve the riddle of the lunar count.

Over the next decade Morley searched and surveyed some of the most inaccessible parts of Mayan territory. Traveling by mule and camping with few creature comforts, surrounded by jungle, suffering from malaria, and surviving Mexican bandits, Morley visited Copan, Tulum, and Uaxactun. The artist william henry holmes and archaeologist Samuel Lothrop were part of his field team. From 1917 to 1919 he worked for U.S. naval intelligence in Washington, D.C., before returning to the field in 1919. Until 1922 Morley spent most of his time in the Petén looking for Mayan date inscriptions, and he visited costa rica and guatemala to study Mayan influences there. In 1920 he completed the *Inscriptions of Copán,* the first book to discuss in detail all the texts of a single site.

Morley's available time for deciphering glyphs was seriously eroded by the constraints of field trips and lecture tours for the Carnegie Institution. He still managed to provide a number of the meanings for glyphs and demonstrated that almost every Mayan monument was erected to "mark the close of a katun (a period of time in the Mayan calendar) or one of its quarters." Perhaps as important to Mayan archaeology as his scholarly work was his insistence that the public become aware of the achievements of the Maya. He delivered lectures throughout the United States and wrote popular articles on the maya civilization.

Morley's plan of making a thorough study of the Maya at Chichén Itzá, which was why the Carnegie Institution had employed him, was never realized, for it was overtaken by his desire to find and decipher Mayan glyphs. As early as 1925 the institution began to consider a leadership change and a reorganization. Kidder was appointed as director of the new Division of Historical Research in an attempt to introduce a multidisciplinary strategy to the Mayan project. Morley continued his pioneering work on Mayan glyphs until 1947, when he became director of the Museum of New Mexico in Santa Fe.

Mortillet, Gabriel de

(1821-1898)

Gabriel de Mortillet studied to be a priest in Grenoble and then went to Paris to study engineering. His fascination with geology and conchology (the study of shells) soon eclipsed his interest in engineering, and his radical socialist political beliefs led to his exile to Savoy, italy, in 1848. Four years later Mortillet cataloged the geological collections at the museum in Geneva, and in 1854 he moved back to Savoy to look after the museum in Annecy, until the province was annexed by france in 1857. From 1858 until 1863 Mortillet worked in Italy for the Lombard-Venetian Railway Company and began his research into prehistory, prompted by his interest in the discovery of Neolithic settlements in the lakes of switzerland.

In 1864 Mortillet returned to Paris and founded the prehistory review *Les Materiaux pour l'Histoire Positive et Philosophique de l'Homme,* becoming

a conservator at the Musée des Antiquités Nationales at Saint-Germain-en-Laye in 1868. There, he drew up the classification of stone-tool technology whose denominations have remained standard until the present day; this work represents his major contribution to the science of prehistory in the nineteenth century. Mortillet argued against édouard lartet's classification of Paleolithic material based on faunal assemblages and argued for classification based on stone-tool types.

From 1880 onward Mortillet was one of the prime movers of a group of scientists, mostly anthropologists, who called themselves "scientific materialists," and between 1884 and 1887 he founded and ran the review *L'Homme,* in which their arguments and positions were promulgated. Mortillet became anticlerical and denounced the Catholic Church for its interpretations of scientific data, arguing for the separation of science and religion that became a political struggle for the separation of church and state. After 1870 and the defeat of France by the Prussians, his arguments took on a nationalist tone.

Mortillet also participated in the debate over the existence of an intelligent human ancestor in the Tertiary period, provoked by the discovery of incised bones and apparently worked flints in Tertiary soils. Some prehistorians, such as jean louis armand de quatrefages, argued for an intelligent human being created by God in the beginning. Mortillet, faithful to his concept of evolution, deduced from the flints the existence of a transitional creature between man and ape-the missing link, which he called *anthropopithecus* and to whom he devoted many pages in his book *Le préhistorique* (1883). His creation was replaced by eugene dubois's *Pithecanthropus erectus,* discovered in Java in 1894, which destroyed the concept of evolution promulagated by Mortillet, suggesting that the transformation of species was neither as linear nor as simple as the French prehistorian had thought.

Mortillet's philosophical beliefs also had a strong impact on the debate about prehistoric art and religion. He was certain that Paleolithic peoples were primitive and, as savages, on a lower rung of the ladder of biological and cultural development, far removed from modern people. However, discoveries of art objects, funeral practices, and cave-art galleries inevitably raised a few problems for a priori ideas about primitive beings. Mortillet refused to see any symbolic value in Paleolithic art and denied the existence of anything abstract. Eventually, as the evidence accumulated, Paleolithic art was recognized by other prehistorians such as emile cartailhac, breaking down the equation of the primitive with the barbarian.

In key academic positions for half a century, Mortillet was both a great theoretician and the leader of a school. A controlling influence, he helped to train, through his writing and teaching, a large proportion of the French prehistorians of the second generation and significantly assisted in establishing the discipline of prehistory in France.

Most na Soči

Most na Soči, also known as Sveta Lucija or Santa Lucia, is an early-Iron Age site in the subalpine area of western slovenia at the confluence of the rivers Soča (Isonzo), Idrijca, and Baca. The cemetery was extensively excavated between 1884 and 1902 by Carlo Marchesetti, the curator of the Trieste City Museum, and by Joseph Szombathy, the curator of the Naturhistorisches Museum in Vienna.

More than 6,400 graves were discovered during the excavations, making Most na Soči one of the

largest prehistoric cemeteries in this part of Europe. The burial rite was almost exclusively cremation in a flat grave; only 10 percent of the cremation graves were deposited in urns. Grave goods comprised personal ornaments (fibulae, pins, bracelets, pendants, necklaces, etc.).

The cemetery is divided chronologically into six phases between the eighth and fourth centuries b.c. Weapons (spearheads and axes) were absent throughout most of this period, only appearing in the last phase, i.e., in the fourth century.

PREV NEXT

Culturally, the community living in Most na Soči had strong ties with Paleovenetic groups in northeastern italy (especially with the Este group) and with the Dolenjska (lower Carniola) group in Slovenia.

The settlement was partially excavated between 1971 and 1982 by Drago Svoljsak, the curator of the Regional Museum in Nova Gorica. These excavations revealed thirty early-Iron Age houses as well as some later structures. In the early Iron Age, Most na Soči was an open settlement-which means that no defensive structures were recorded-divided into dwelling and craft sections (the latter including metallurgical activities).

Moulin Quignon

Second only to the piltdown forgery, Moulin Quignon is one of the most celebrated frauds of prehistoric archaeology. By the end of 1859, the argument about whether human beings had a high antiquity (certainly extending back to the time of extinct animals) had been won by jacques boucher de perthes, hugh falconer, and others through the patient excavation of sites such as brixham cave and the reexamination of the English sites of kent's cavern and Hoxne and the Somme River gravels in france. However, at none of those sites had the excavators been able to locate the bones of the oldest humans, and they based their arguments on the presence of artifacts in very old deposits.

Boucher de Perthes sought to solve this problem by offering his workmen the sum of 200 francs or the first human bones to be retrieved from his sites. On 23 March 1863, one of his workmen recovered a human tooth (in association with two axes). A week later, Boucher de Perthes's joy knew no bounds when another tooth and the right half of a human lower jaw were retrieved from the same deposit.

Many of the scientists most directly concerned with the debate about high human antiquity flocked to the site, in particular armand de quatrefages, Falconer, john evans, and joseph prestwich. Early conviction that Boucher de Perthes had made a significant discovery was (on the English side at least) replaced by skepticism when Prestwich and Evans announced that some of the stone artifacts recovered from the site were fakes.

Falconer reexamined the tooth and the jaw and pronounced them modern, a conclusion that sparked a storm of controversy. In an attempt to resolve the dispute, édouard lartet proposed a committee of inquiry that would provide each side with the opportunity to state its case in open discussion. This event took place on 9 May 1863 and was attended by most of the disputants (with the exception of Boucher de Perthes). Argument raged about whether the stone tools were fakes (resolved in the negative after the committee visited the site on the 13 May and observed the excavation of more artifacts that Prestwich thought were genuine) and about whether the jaw was modern and had been introduced to the deposit (the argument favored by Falconer but not endorsed by the committee).

The matter did not end there. Returning to England, Falconer urged Prestwich and Evans to return to the site and excavate under controlled conditions. Evans arranged for Henry Keeping (the excavator of Brixham Cave) to visit the site (between 3 June and 6 June), and his assessment, reported by Evans and supported by Evans's continued analysis of the previously excavated tools, was highly negative. Evans closed the circle by making a strong case that the jaw had been taken from the nearby site of Mesnières, which had been visited by one of the workmen from Moulin Quignon.

There was never any admission (certainly not by Boucher de Perthes) that there had been any fraud. Nonetheless, the evidence mounted by Falconer, Evans, and Prestwich about the jaw and the associated artifacts effectively consigned the remains to obscurity in the store of the

Musée de l'Homme in Paris. Interesting questions continue to be unanswered. Who was to have profited from the fraud? Was it the workmen to get their 200 francs, Boucher de Perthes to obtain a crowning achievement and recognition, or Quatrefages (an opponent of Darwin), who could now demonstrate that from the time of earliest human occupation of the earth the physical form of human beings had hardly changed? Perhaps it was simply that both Boucher de Perthes and de Quatrefages seized an opportunity provided by the quarry workers, nothing more.

Moundville

Moundville, a site comprising twenty large mounds distributed around a central plaza, is located in Alabama. Considered by many people to be among the largest of such sites in the Mississippian culture, Moundville has been explored by antiquarians and archaeologists since the late 1860s. The first extensive excavations, undertaken by U.S. archaeologist Clarence B. Moore, occurred in 1905 and 1906.

The Great Mound at Moundville in Alabama

(Hulton Getty)

The site has proved to be exceptionally rich in material culture and in food remains, and these have, in conjunction with evidence of house plans and site layout, allowed archaeologists to construct a viable site history. Moundville was first occupied around a.d. 1050 and gradually grew in size, complexity, and importance over the next 350 to 400 years. The site is thought to have been abandoned around a.d. 1550, and it is now interpreted as being the most important residential, religious, and political center of the surrounding region.

Müller, Sophus Otto

(1846-1934)

Sophus Müller was born in Copenhagen, denmark, the son of a numismatist and museum director. Enrolling at Copenhagen University in 1864 to study classics, he attended jens jacob worsaae's lectures on archaeology and read the work of English geologist charles lyell. After graduating in 1871 Müller worked as a teacher, but he gradually became associated with the collections in Copenhagen and with Worsaae, the curator of the Royal Museum of Nordic Antiquities (after 1892 the National Museum).

Müller begun to publish articles on the Danish Iron and Bronze Ages and traveled to the major museums and collections in central, western, and northern Europe. In 1878 he was employed as a scientific assistant to his father in the Department of Numismatics at the museum. He kept in contact with Worsaae and his group and participated in the activities of the museum. He also began publishing the *Nordic Journal* in Stockholm. In 1880 he received a Danish doctoral degree for his dissertation on animal ornamentation in Scandinavia.

In 1885 he became a curator at the Royal Museum and seven years later was named codirector of the new National Museum, with responsibility for prehistoric, ethnographic, and classical collections. During his tenure the National Museum assumed all the main tasks arising from archaeology's emergence as a discipline: publications, the preparation of finds for exhibition or storage, excavations, inspections, conservation, and the training of the next generation of archaeologists. The teaching of archaeology disappeared from the university and was taken over the by National Museum. Remaining at the museum until his retirement in 1921, he effectively dictated and controlled Danish archaeology during this period.

Müller also had extensive excavation experience, and the context of the finds he worked on always played a paramount role in his analysis and interpretations. He was at times a publicist, and he was also well traveled. He was therefore familiar with much of the prehistoric material then known and housed in the main European museums and collections. From 1881 on he was secretary of the Royal Nordic Antiquaries Society and editor of its journal, *Yearbook for Nordic Archaeology*.

Müller is one of the key figures in the nineteenth-century development of the methods and theories of archaeology. His dispute with oscar montelius about typology has been characterized as the first methodological debate on such issues-an illustration opposing an essentially objective and subjective methodology and how each methodology could affect the discipline. Müller also defined several significant cultural sequences in Danish prehistory and laid a solid foundation for future studies. His works include various illustrated manuals, such as *The Arrangement of Denmark's Prehistoric Object*s (1888-1895). Much of this work still constitutes the backbone of the discipline in Denmark, and researchers actively draw upon it today. Müller can be credited with establishing the fundamental themes of Danish archaeology-wide-ranging research, penetrating analysis, and a profound respect for source material.

Müller, Sophus Otto

(1846-1934)

Sophus Müller was born in Copenhagen, denmark, the son of a numismatist and museum director. Enrolling at Copenhagen University in 1864 to study classics, he attended jens jacob worsaae's lectures on archaeology and read the work of English geologist charles lyell. After graduating in 1871 Müller worked as a teacher, but he gradually became associated with the collections in Copenhagen and with Worsaae, the curator of the Royal Museum of Nordic Antiquities (after 1892 the National Museum).

Müller begun to publish articles on the Danish Iron and Bronze Ages and traveled to the major museums and collections in central, western, and northern Europe. In 1878 he was employed as a scientific assistant to his father in the Department of Numismatics at the museum. He kept in contact with Worsaae and his group and participated in the activities of the museum. He also began publishing the *Nordic Journal* in Stockholm. In 1880 he received a Danish doctoral degree for his dissertation on animal ornamentation in Scandinavia.

In 1885 he became a curator at the Royal Museum and seven years later was named codirector of the new National Museum, with responsibility for prehistoric, ethnographic, and classical collections. During his tenure the National Museum assumed all the main tasks arising from archaeology's emergence as a discipline: publications, the preparation of finds for exhibition or storage, excavations, inspections, conservation, and the training of the next generation of archaeologists. The teaching of archaeology disappeared from the university and was taken over the by National Museum. Remaining at the museum until his retirement in 1921, he effectively dictated and controlled Danish archaeology during this period.

Müller also had extensive excavation experience, and the context of the finds he worked on always played a paramount role in his analysis and interpretations. He was at times a publicist, and he was also well traveled. He was therefore familiar with much of the prehistoric material then known and housed in the main European museums and collections. From 1881 on he was secretary of the Royal Nordic Antiquaries Society and editor of its journal, *Yearbook for Nordic Archaeology*.

Müller is one of the key figures in the nineteenth-century development of the methods and theories of archaeology. His dispute with oscar montelius about typology has been characterized as the first methodological debate on such issues-an illustration opposing an essentially objective and subjective methodology and how each methodology could affect the discipline. Müller also defined several significant cultural sequences in Danish prehistory and laid a solid foundation for future studies. His works include various illustrated manuals, such as *The Arrangement of Denmark's Prehistoric Object*s (1888-1895). Much of this work still constitutes the backbone of the discipline in Denmark, and researchers actively draw upon it today. Müller can be credited with establishing the fundamental themes of Danish archaeology-wide-ranging research, penetrating analysis, and a profound respect for source material.

Mulvaney, John

(1925-)

John Mulvaney is an Australian archaeologist who trained at Cambridge University after completing a history degree at the University of Melbourne. On his return to Australia Mulvaney followed the pioneering work of norman tindale and fred mccarthy at Fromm's Landing and Kenniff Cave (among other sites). He noted that there was clear evidence for cultural change in prehistoric Australia, and his work at Kenniff Cave revealed conclusive evidence (through radiocarbon dating) of the Pleistocene occupation of Australia.

Apart from this demonstration of high human antiquity in Australia, Mulvaney forged much of the agenda of Australian prehistoric archaeology in the 1970s with the publication of his *Prehistory of Australia* in 1969 (now in its third edition). Specifically interested in Australian prehistory as a central element in the story of Aboriginal Australia, Mulvaney championed the notion of archaeology and anthropology working together to enlighten non-Aboriginal Australians about the richness and variety of pre- (and post-) European life in Australia. Of equal importance was Mulvaney's service to his profession through his membership in key government committees and investigations, his advocacy of the cause of preserving the human heritage of Australia, and his defense of the principles of liberal inquiry.

Myres, Sir John Linton

(1869-1954)

John L. Myres attended Winchester School and then New College, Oxford. After completing his undergraduate degree he became a fellow of Magdalen College, Oxford, and visited the Mediterranean in 1892, where he worked with sir john evans on Crete. By comparing Cretan vases with vase fragments found by sir william matthew flinders petrie in Egypt, Myres was able to argue for trade links between the ancient civilizations of Crete and Egypt. He joined the British School's excavation of Palakastro and Petsofa on Crete and published his finds.

In 1894 Myres began excavating on cyprus at Kition, and with a German colleague, he wrote the catalog of the Cyprus Museum. In 1907 he became a professor of Greek and a lecturer in ancient geography at Liverpool University, but three years later he returned to Oxford as the new Wykeham Professor of Ancient History, a position he held until 1939. He wrote the popular study *The Dawn of History* in 1911 and contributed several chapters to the Cambridge Ancient History. During World War I his detailed knowledge of the geography and people of the eastern Mediterranean was put to use when he led raiding operations from a former royal yacht onto the coast of turkey. He was made a commander of the Royal Navy and was awarded the Order of the British Empire and the Greek Order of George I.

In 1927 on the death of sir arthur evans, Myres took on the task of completing the editing and publishing of the Linear B tablets from knossos, and he was pleased that when Michael Ventris deciphered it in 1952, Linear B proved to be Greek. In 1930 Myres's best-known work-*Who Were the Greeks?*-was published, followed by *Herodotus, Father of History* and *Geographical History in Greek Lands* in 1953. In all these works he used not only the classics but also a multidisciplinary approach, combining ancient history, archaeology, geography, and anthropology. He was knighted in 1943 and won the Victoria Medal of the Royal Geographic Society in 1953. During World War II, once again using his great geographic knowledge of the eastern Mediterranean, he edited handbooks for naval intelligence. He was president of the Royal Anthroplogical Institute from 1928 to 1931, president of the Hellenic Society from 1935 to 1938, and chairman of the British School at Athens from 1934 to 1947.

National Geographic Society

Founded in Washington, D.C., in 1888 with the object of fostering the development and dissemination of geographic knowledge, the National Geographic Society has made a significant contribution to archaeology through its publications and its Committee of Research and Exploration. Between 1912 and 1915 the society funded the work of Hiram Bingham at machu picchu, and between 1938 and 1946 it supported eight expeditions by Matthew Stirling that culminated with his excavation of the olmec site of la venta. Other highlights have been the work it supported at chichén itzá, the exploration of pueblo bonito by Neil Judd beginning in 1921, and the excavation of the Hellenistic site of Aphrodisias in turkey by Kenan Erim.

Notwithstanding its strong support of the archaeology of more recent periods, the society has made its greatest impact in the field of paleoanthropology. The most famous recipients of society funding since 1959 were louis leakey and mary leakey and, through Louis Leakey's influence, the primatologists Jane Goodall and Diane Fossey.

National Geographic magazine and other society publications have also played an important role in reporting archaeological research to the public. As the society rightly acknowledges, the act of disseminating geographic knowledge has the capacity to make some archaeologists internationally famous. However, the magazine's greatest impact on archaeology may well derive from the ways in which its staff writers and artists have sought to communicate the sense of archaeological research to nonspecialist audiences.

The museum has been called by its present name, Narodni Muzej Slovenije (National Museum of Slovenia) since 1997.

The museum was to be the central cultural and scientific institution in the province of Carniola, so it

therefore embraced several functions: museum, exhibition place, research center, public library, gallery, public archive. It was meant to cover all the major fields representative of the province of Carniola: natural history,

stane gabrovec, head of the Archaeological Department at the National Museum (1948-1988) and an eminent prehistorian, began to research late-Bronze and Iron Age sites in Slovenia in the late 1940s. He also initiated a large-scale program, documenting numbers of Slovenian sites excavated during the Austro-Hungarian period and deposited in foreign museums. In less than two decades, Gabrovec succeeded in developing the chronology and cultural-history synthesis of the Bronze and Iron Ages of Slovenia and neighboring lands, and the prehistoric collection, once again, became the pride of the museum.

Developments after 1950s reflect a gradual rise in the complexity of the museum. Its rich archaeological collections were divided into prehistoric, Roman, and early mediaeval units, with each unit having specialized curators. Peter Petru, director of the National Museum from 1970 to 1983, continued and completed the organizational structure of the museum and also contributed much to the development of Roman archaeology in the museum. In the last decades of the twentieth century, the numismatic cabinet developed into one of the major regional reference centers for Celtic and Roman coinage.

Nautical Archaeology

The term *nautical archaeology,* as in the archaeology of ships, comes from the Greek word for ship (naos) and is used in preference to the terms marine or underwater archaeology.

Beginnings

Interest in ships of earlier times began at least as far back as the classical period when Jason's famed Argo was supposedly preserved and displayed at a sanctuary of Poseidon in what is now Greece near the Isthmus of Corinth. Then, as today with the *U.S.S. Constitution* (“Old Ironsides”) in Boston and other historic vessels, there was the philosophical question of how much wood could be replaced before the ship would no longer be considered to be its original self. Also in the classical period, an old-fashioned vessel said to be similar to the one that had carried Theseus to Crete to slay the Minotaur was sailed annually from Athens to Delos for a religious festival. In the sixth century a.d., Procopius of Caesarea recorded a description of the ship of Aeneas, founder of Rome, that was said to be on display in a specially built shed on the bank of the Tiber River in the middle of the city. A fresco of a naval procession dating from around the middle of the second millennium b.c. that was uncovered on the Aegean island of Thera shows, according to some scholars, the practice of depicting or replicating watercraft from the still more distant past.

The conservation and replication of old ships are still elements of nautical archaeology, but the actual surveying for and excavation of ships of prior ages may have begun in the Renaissance. Traditional reports of two ancient vessels in Lake Nemi, seventeen miles southeast of Rome, led to salvage attempts by the architect Leon Battista Alberti in 1446. After having the wrecks examined by breath-holding Genoese divers, Alberti tried to raise and tow one of the hulks ashore with hooks lowered from a raft of

barrels. Although the attempt was unsuccessful, he did recover a statue from one wreck. His failed salvage effort was followed in 1535 by more-detailed observations and measurements made by Francesco Demarchi, who dived in perhaps the earliest recorded diving suit to take samples of the ship's wood while wearing a wooden helmet outfitted with a small crystal viewing plate.

Nineteenth Century

Three centuries later, in 1827, the engineer Annesio Fusconi, working from an eight-seat diving bell, raised artifacts from the Lake Nemi wrecks that eventually were acquired by the Vatican Museum. However, Fusconi, too, failed to raise either of the hulls.

PREV NEXT

Early inventors of diving equipment in England soon became involved in nautical archaeology. In 1836, John Deane and William Edwards found the remains of Henry VIII's warship *Mary Rose,* which sunk in 1545 off Portsmouth, England. During the next four years, they salvaged numerous artifacts, including a variety of armaments and some wooden hull remnants, many of which they recorded in exquisite watercolors.

Not all early nautical archaeology required diving. Remains of an earlier battleship, Henry V's *Grace Dieu,* which had been launched in 1419, were reported in the mud of the Hamble River in Harold J. Osborne White's *1859 Hampshire and Isle of Wight Directory* but were not properly identified before the twentieth century. After an amateur's crude excavation of the site in the 1870s, perhaps with explosives, the Hampshire Field Club in the last year of the nineteenth century removed some of the ship's timbers to a museum in Winchester, England, where they were displayed as being from a "Danish galley."

Other European discoveries followed that of the *Grace Dieu.* In 1864, part of a Roman hull of the second or third century a.d. was salvaged from the harbor in Marseille and fancifully named "Caesar's galley." Other parts of the hull, raised in the 1950s, showed its planks to be fastened edge-to-edge by mortise-and-tenon joints in the shell-first kind of construction now known to have been in fashion in the Mediterranean from at least the fourteenth century b.c. until around the eleventh century a.d. Most modern wooden hulls are built in the frame-first manner, in which planks are simply nailed to a pre-erected framework of keel, stem, sternpost, and frames (ribs).

A different tradition of shell-first hull construction existed in Northern Europe, and a great deal of research was conducted there in the nineteenth century. Instead of being joined edge to edge, the planks of these hulls overlapped one another like shingles, and in this case were fastened together by long metal nails driven through them from the outside and clenched over inside, coining the term *clinker built.*

The clinker-built hull of a great open war vessel from the second half of the fourth century a.d., deposited as an offering to the gods in a bog at Nydam in Schleswig, germany, was, in 1864, the first ancient ship excavated by an archaeologist. Less than two decades later, in 1880, a clinker-built, ninth-century ship found at Gokstad became the first of a number of Viking ships recovered from royal burials in Norway, where the clay soil remarkably preserves wood and iron. A replica of this ship crossed the Atlantic in 1893, an early example of experimental archaeology.

Far away in Africa, hot desert sands preserved hull timbers equally well. Five funerary boats from about 1,850 b.c., intentionally buried near the pyramid of Sesostris III at Dashur, were discovered in 1894 by the French archaeologist Jacques De Morgan. The planks of the ten-meter hulls were held together by mortise-and-tenon joints. Two of the hulls are now in the Cairo Museum, one is in the Field Museum in Chicago, and one is in the Carnegie Museum in Pittsburgh; one is missing, perhaps reburied at Dashur.

1900-1960

The first half of the twentieth century saw a dramatic increase in salvage by helmet divers. Although a Roman wreck found in 1900 by Greek sponge divers off the Aegean island of Antikythera gained notoriety mainly because of spectacular discoveries of bronze and marble Greek statues, and a unique astronomical instrument, a few planks were raised that showed mortise-and-tenon joinery. Concentration on statuary and pottery rather than hulls continued in the salvage of artifacts by Greek and Turkish sponge divers from another Roman wreck, at Mahdia off the coast of Tunisia, in the six years following its discovery in 1907. Although fragments of wood were raised in 1928 by the Greek sponge divers who salvaged famed bronze statues of Zeus or Poseidon and a jockey and horse off Cape

Artemision, they were never properly studied. Nor were the fragments of wood netted by a fisherman three years earlier along with the bronze statue of a nude youth in the Bay of Marathon in the Aegean.

Detailed records of a hull of the Roman period had already been made at this early date,

Perfection of a self-contained underwater breathing apparatus (scuba) by Jacques-Yves Cousteau and Emile Gagnan in france in the 1940s revolutionized the study of ancient and historic shipwrecks by providing divers with the mobility they needed for the careful excavation of delicate ships' hulls. A number of pioneering efforts conducted in the 1950s along the coasts of France and Italy introduced the regular use of airlifts (suction pipes) for removing overburden, air-filled lifting balloons for raising heavy objects to the surface, underwater photography, and even underwater television. In 1958, to aid in photographic mapping, Gianni Roghi, working with Nino Lamboglia, laid a tape grid over a Roman wreck at Spargi, a small island north of Sardinia; the tape was replaced in 1959 by rigid pipes.

Mistakes were unavoidably made along the way. Because careful archaeological plans were not kept, the site at Grand Congloué near Marseilles in France was thought to be that of a single Roman wreck whereas it is now recognized that it is instead one Roman wreck lying atop another of earlier date. Philippe Taillez, after his exemplary excavation of a Roman wreck near Le Titan in the same region, bemoaned the fact that diving archaeologists were not part of such excavations. Nevertheless, the nondiving archaeologists, especially Lamboglia in Italy and Fernand Benoit in France, who received finds and assessed information from the professional and amateur divers under their direction, began to pay close attention to the construction techniques of ancient ships. It became accepted that Roman ships were generally edge-joined with mortise-and-tenon joints and that hulls frequently were sheathed in lead.

Salvage mistakes were also made in North America. In 1956, the historian Edwin C. Bearss and colleagues, using a simple magnetic compass to detect a mass of iron, located the American Civil War ironclad *Cairo* in the Yazoo River, Mississippi, where it had lain in perfect condition since becoming, in 1862, the first vessel ever sunk by an electrically detonated mine. Beautifully preserved artifacts and what is left of the hull, which was mostly destroyed by misguided salvage methods in 1965 and a lack of prompt conservation, are displayed in the Vicksburg National Military Park.

Other wrecks, like those in the York River, were found by dragging. The Swedish engineer Anders Franzén, knowing that the Baltic Sea does not support ship worms, dragged the bottom of Stockholm's harbor from 1953 until 1956 in a successful search for what he rightly guessed would be a perfectly preserved warship, the *Vasa,* which sank on its maiden voyage in 1627.

1960s

After 1960, the field of nautical archaeology expanded rapidly in a number of new directions. “Whitewater archaeology” began in Minnesota and canada when amateur divers found goods lost by fur traders who had unsuccessfully tried to shoot rapids in their canoes. These finds led to a long-term survey for other such goods by Robert C. Wheeler of the Minnesota Historical Society and Walter A. Kenyon of the Royal Ontario Museum.

Archaeologists explore an ancient shipwreck in the Mediterranean, June 1969.

(Hulton Getty)

At the end of the 1960s, Michael and Susan Katzev from the University of Pennsylvania Museum team located and excavated a fourth-century classical Greek ship off Kyrenia, cyprus. They advanced the field of nautical archaeology by raising and preserving, for the first time in the Mediterranean, the ship's hull, its planks fastened with pegged mortise-and-tenon joints. The hull was then reassembled for display and study by Richard Steffy, a task that lasted into the early 1970s.

Waterlogged wood, unless properly treated, will shrink and warp out of recognition when exposed to air. The Kyrenia ship was conserved with polyethylene glycol, as had been the restored Viking ships from Roskilde Fjord, the *Vasa* in Sweden, and three colonial bateaux raised at the beginning of the decade from Lake George, New York.

Survey techniques also improved. Many shipwrecks in the Mediterranean were initially spotted by local sponge divers, but in 1967, sonar and underwater television were used successfully for the first time to locate an ancient wreck, later examined from the submersible *Asherah*, eighty-five meters deep off the coast of Turkey. In England, Alexander McKee, working with Harold Edgerton's subbottom sonar, relocated the *Mary Rose*, its position having been lost after the nineteenth-century salvage of some of its cannons. Magnetometers, which detect iron, proved equally successful in searches for more modern ships, which, even if built of wood, often carried large iron objects such as cannons and anchors. Unfortunately, scuba equipment and better search techniques also caused an increase in underwater treasure hunting and the looting of wrecks in the 1960s, especially in the waters around florida and the caribbean islands.

1970s

In the 1970s, surveys and excavations of high quality were conducted around the globe, starting in 1970 in England with the discovery and excavation of a clinker-built boat of around a.d. 950 at Graveney in Kent. Beginning in 1972, archaeologists from the Western Australian Museum, led by Jeremy Greene, not only excavated, published, and restored Dutch East Indiamen from their own waters, notably the *Vergulde Draeck* lost in 1656 and the *Batavia* in 1629, but traveled farther afield to study wrecks from Kenya to Thailand. Another Dutch East Indiaman, the *Amsterdam*, sunk deeply in sand in 1749 just off Hastings, England, was examined and sampled by Peter Marsden after its 1969 discovery-on those few days each year when it was revealed by exceptionally low tides.

The *San Esteban*, one of three ships driven aground on Padre Island, Texas, by a storm in 1554, was, between 1972 and 1976, the first Spanish treasure ship excavated archaeologically. One ship had already been destroyed by dredging operations in the 1940s, and another had been partly exploited by treasure hunters in 1967 before the Texas Antiquities Committee was formed to take on the job of excavating, under Carl Clausen, and conserving, under Donny Hamilton, what remained. These events led to a state law of protection for historic shipwrecks.

Veterans of the University of Pennsylvania team founded the Institute of Nautical Archaeology (INA) in 1972 and began projects on four continents. Excavation of a cargo of pottery lost around 1600 b.c. near Sheytan Deresi in Turkey was followed by the excavation of a ship sunk in the natural harbor of Serçe Limanl on the southwestern Turkish coast around a.d. 1025. The latter ship produced the largest collection of medieval Islamic glass in the world and is the earliest known example of a seagoing hull built in the frame-first manner. Elsewhere in the Mediterranean, INA, with the assistance of Sub Sea Oil Services of Milan, conducted the first excavation using saturation diving of a Hellenistic wreck off the island of Lipari north of Sicily.

In North America, under the direction of David Switzer, INA undertook the excavation of two ships,

one American and the other British, sunk during the War of Independence. The American privateer *Defence* was excavated in Penobscot Bay, Maine, by Switzer in a joint project begun in 1975 with the Maine Maritime Academy and the Maine State Museum. An INA investigation in 1976 of a British ship scuttled by General Cornwallis at Yorktown led to the proposal that such ships should be excavated within coffer dams in which the murky water of

the York River could be clarified by industrial filters, an idea Norman Scott had earlier suggested for other sites with zero visibility.

Elsewhere in the United States, the famed "cheesebox on a raft," the Civil War ironclad *Monitor,* the first gunboat with a revolving turret, was located in 1973 seventy meters deep about seventeen miles off Cape Hatteras, North Carolina, by a Duke University team using sonar. Two years later, the archaeologists Gordon Watts, John Broadwater, and others visited the *Monitor* in the Harbor Branch Foundation's *Johnson-Sea-Link I,* a submersible from which they could be launched into open water to swim around and examine the site.

The 1968-1969 dryland excavation of the steamboat *Bertrand,* sunk in 1865 twenty-five miles north of Omaha, Nebraska, in the Missouri River (which had since changed course), was supervised by U.S. National Park Service archaeologists. The project yielded not only a well-preserved hull but nearly 2 million artifacts, including bottles with their paper labels intact.

In Canada, the amateur archaeologist Daniel A. Nelson, after searching with side-scanning sonar in an area narrowed by archival research to thirty-two square miles, in 1973 located two warships sunk during the War of 1812, the *Hamilton* and the *Scourge,* ninety meters deep in Lake Champlain. Inspected and recorded from a research submarine and by a remotely operated vehicle (ROV), the ships proved to be almost perfectly preserved with upright masts, figureheads in place, and skeletons of the crew on the decks.

Pioneering work on ships in the Far East was conducted both on land and under water in the 1970s. At the port city of Quanzhou, china, a thirty-four-meter ship of the thirteenth century a.d. was discovered and excavated in 1973, and a fourteenth-century wreck with an immense collection of Chinese ceramics was excavated by the Korean navy after the ship was discovered near Shinan, Korea, by a fisherman in 1975. Both ships offered the surprise of V-shaped hulls from a time when scholars assumed that all Chinese ships were flat-bottomed.

In Mombasa, Kenya, Robin Piercy of INA began, in 1977, the first full-scale shipwreck excavation in East Africa on the remains of the *Santo Antonio de Tanna,* a Portuguese ship built at Goa and sunk in 1696 while trying to help relieve a siege of the Portuguese fort, Fort Jesus, by Omani Arabs. During the same period, Colin Martin continued excavating two Spanish ships-*El Gran Grifón* and *La Trinidad Valencera*-that had fled north around Scotland and Ireland following the defeat of the Spanish Armada in 1588.

1980s

A number of projects in the 1980s proved that wrecks could be found and at least partly recovered from any depth and at any temperature. In the first year of the decade, using sonar, a team led by Joe MacInnis discovered the well-preserved *Breadalbane* under two meters of surface ice at a depth of a hundred meters in Canada's Northwest Passage. The British bark had been sunk by ice in 1853 while on a rescue mission for the ill-fated Franklin expedition of 1846. MacInnis's team was able to explore the site in a one-person submersible, the *WASP*, lowered through a hole in the ice.

In 1985, a French-American team, searching an area of the North Atlantic 350 miles southeast of Newfoundland and 150 miles square, was able to locate and examine, at a depth of 4,000 meters, the "unsinkable" *Titanic,* a ship sunk by an iceberg on its maiden voyage in 1912 with a loss of 1,522 lives. Preliminary images of the wreck were seen via television from ROV, and in 1986, Robert Ballard of the Woods Hole Oceanographic Institute visually inspected the site from the submarine *Alvin.* After the discovery, amid some controversy, artifacts were raised from the ship by a French group for display.

Equally impressive was the discovery in 1987 of the SS *Central American,* lost 200 miles off Charleston, South Carolina, in 1857 in water a mile and a half deep. The Columbus-America Discovery Group, admittedly after the gold bullion the ship was known to be carrying, surveyed 1,400 square miles of ocean floor with sonar to locate the vessel and then retrieved much of the cargo and other artifacts with advanced robots. In the muddy York River, John Broadwater of the Virginia Department of Conservation and Historic Resources showed that

PREV NEXT

archaeologists could work with excellent visibility by building a coffer dam around another of Cornwallis's scuttled ships and filtering the water inside.

These spectacular tours de force did not mean that controlled excavations at lesser depths did not continue. In Red Bay, Labrador, Robert Grenier of Parks Canada directed the excavation, between 1980 and 1984, of the sixteenth-century Basque whaler *San Juan* and several small boats, including one of the ship's whaleboats, probably the oldest and best specimen of an early boat used to hunt whales. To the south, Kevin Crisman and Arthur Cohen created a specialty of studying ships sunk during the War of 1812 in Lake Ontario and in Lake Champlain for the Champlain Maritime Society and the Vermont Division for Historic Preservation.

Anders Franzén returned to nautical archaeology in 1980 with the discovery of another well-preserved seventeenth-century Swedish warship, the Kronan. The *Mary Rose,* carefully excavated under the direction of Margaret Rule since 1979, was finally raised in 1982 but must undergo decades of chemical conservation before the remains of the hull are fully restored for public viewing. In the meantime, a stunning array of artifacts, including rare examples of English longbows, have already been conserved and are on display in Portsmouth, England; many have also been shown around the world in a traveling exhibit.

The most careful underwater excavation in the Caribbean was begun in 1982 when Donald H. Keith of the Institute of Nautical Archaeology undertook the excavation and conservation of what was then the oldest wreck known in the New World, presumably a Spanish vessel of the early fifteenth century, at Molasses Reef in the Turks and Caicos Islands. Keith explored other fifteenth-century wrecks in the Caribbean for INA before forming his own group, Ships of Discovery, which has established a museum for the Molasses Reef wreck on Grand Turk Island.

Also in 1982, Mensun Bound of MARE at Oxford University excavated a probable Etruscan wreck of around 600 b.c. at Giglio, an island off the southwestern coast of Tuscany in central Italy. In Turkey, the Institute of Nautical Archaeology, in a project that continued from 1983 into the 1990s, surveyed and excavated a fourteenth-century b.c. wreck that has produced fifteen tons of raw goods. These include the oldest known tin ingots, glass ingots, a wooden writing tablet, ebony logs, a fragmentary seagoing hull, ten tons of copper ingots, a unique gold scarab that once belonged to Egypt's Queen Nefertiti, and pottery, seals, jewelry, and stone objects from half a dozen ancient civilizations. Twenty-four stone anchors were carried in the fifteen-meter hull made of fir planks fastened with pegged mortise-and-tenon joints. Lying between forty-four and sixty-one meters deep off Uluburun, near Ka in Turkey, it is the deepest site yet excavated by scuba divers.

Israeli archaeologists and divers had long been finding and mapping artifacts from the Bronze Age onward in the Mediterranean, including the bronze ram of a Hellenistic warship off Atlit on the coast of israel. A severe drought in 1985 lowered the level of the Sea of Galilee sufficiently to expose a fishing boat from the time of Christ. It was removed for conservation and study in early 1986 by Shelley Wachsmann.

In Egypt, a covered pit next to the great pyramid of Cheops was opened to reveal a second dismantled boat. And in 1987, the Abandoned Shipwreck Act, which was signed into law in the United States, removed historic shipwrecks in states' waters from the jurisdiction of admiralty salvage law.

1990s

By the last decade of the twentieth century, nautical archaeology had become a respected subdiscipline of archaeology, and there were graduate programs devoted to training future specialists at St. Andrews

University in Scotland; Texas A&M University, with which INA affiliated in 1976; East Carolina University in North Carolina, studying not only local wrecks but wrecks in Bermuda; Haifa University in Israel; the University of Copenhagen; and Bilkent University in Ankara, Turkey. Courses in nautical archaeology were also being offered from Australia to Oxford to the University of Texas.

Proceedings of conferences and journals devoted to the field have become commonplace.

Laws to protect ancient and historic wrecks have been passed by an increasing number of states and nations, and an increasing number of state and national programs have been developed around the globe.

Splendid museums of nautical archaeology attract an increasing number of visitors. Noteworthy are those devoted to single ships (such as the *Vasa*, the *Mary Rose*, the Bremen cog, and the Molasses Reef Wreck) or groups of ships (for instance, in the Roskilde Museum in Denmark, the Bodrum Museum of Underwater Archaeology in Turkey, the Viking Ship Museum in Oslo, and the National Maritime Museum in Greenwich, England).

Results of fieldwork in progress were eagerly awaited from projects such as the Greek excavations of a Bronze Age wreck at Iria and an unexpectedly large fifth-century b.c. amphora carrier in the Northern Sporades in the Aegean Sea. There was also ongoing work on dozens of vessels revealed through land reclamation in the Netherlands, the excavation of early dynastic Egyptian boats found by the University of Pennsylvania in the sands at abydos, the conservation with sugar rather than polyethylene glycol of an early Spanish hull excavated in Cuba, and surveys conducted by INA from the Red Sea to the Persian Gulf to the Black Sea and by the Western Australian Museum throughout the Far East.

Naville, Henri Edouard

(1844-1926)

Born in Geneva, switzerland, and educated at the University of Geneva; King's College, London; and the universities of Bonn, Paris, and Berlin, Henri Edward Naville was a biblical scholar and philologist who studied under the great Egyptologist karl richard lepsius. Naville first visited Egypt in 1865 and copied the Horus texts at Edfu, a site in Upper Egypt. He later worked on the Solar texts and published four volumes of the Book of the Dead. The decipherment of these ancient texts and inscriptions enabled a chronology and history of ancient Egypt to be devised.

Naville was the first archaeologist to be employed by the egyptian exploration society (at that time the Egypt Exploration Fund), and he excavated at Tell el-Makhuta in 1883 and the Wadi Tumilat in 1885-1886, the western end of which was identified as the biblical land of Goshen. Between 1886 and 1889, Naville excavated at Bubastis on the southeastern Nile Delta and brought back many artifacts from there to the british museum, including a huge granite head of the pharaoh Amenemhat III. He then excavated another ten sites in the Nile Delta, including Herakleopolis, Mendes, and Tell Mukdam.

From 1893 to 1896, Naville worked in Upper Egypt finishing the excavation of Hatshepsut's mortuary temple at Deir el-Bahari begun by auguste mariette, and his field assistants there included david hogarth and howard carter. In 1903, Naville returned to excavate the temple's mounds, discovering tombs and

the temple of King Menthuhotep II from the eleventh dynasty. Naville was the successor of earlier archaeologists such as heinrich schliemann, Mariette, and Gaston Maspero, who were interested in architectural ruins and large monuments, not in the smaller details or the kind of painstaking work of the younger generation of archaeologists in Egypt such as sir william matthew flinders petrie. Naville's last excavation was at abydos in 1909, where he cleared the Osireion, which had been discovered by Petrie in 1902.

Naville was awarded many honors and distinctions from most European countries including his own, Switzerland, and he published many articles, reviews, and books on his work in Egypt.

Netherlands

According to Dutch archaeological lore, archaeology became a scientific endeavor in the early years of the twentieth century when a young zoology graduate, albert egges van giffen, studied faunal remains unearthed during a study of *terpen* as indicators of prehistoric economies. *Terpen* (“terps”) are artificial mounds on the coastal wetlands of the Netherlands on which Iron Age and early medieval villages were built, and after the area was diked after a.d. 1000, they were exploited as sources of manure.

At the time, the only archaeological institution in the country was the State Museum of Antiquities in Leiden where the traditionalist Jan Hendrik Holwerda dominated Dutch archaeology. Inevitably, he and Van Giffen became enemies, and after some years of struggle, Holwerda and his museum faded away to be superseded by Van Giffen and the archaeological institute he had founded at the University of Groningen in the north of the country, right in the middle of terp-land. Because of Van Giffen, Dutch archaeology won international status, especially because of its meticulous excavation techniques, use of auxiliary sciences (botany, zoology, geology), and settlement excavations. Later, Van Giffen's students ran archaeological institutes at every university in the country as well as staffing the State Archaeological Service. Today, almost all archaeological research in the Netherlands is directly or indirectly related to Van Giffen's exploits.

In the late 1990s, that was still the majority view of the modernization of Dutch archaeology (e.g., Slofstra 1994), because when Van Giffen's students became dominant in the late 1940s and early 1950s, their view of the discipline's history became the founding myth of Dutch archaeology. However, the myth is mainly a repeat of Van Giffen's arguments that he used in his attempt to bypass Holwerda between 1910 and 1915-a construct used in the battle for academic positions. Van Giffen and his students have retired or died now, so perhaps it is time to sketch a different picture.

Historians distinguish three periods of nation building in the Netherlands: the sixteenth and

the temple of King Menthuhotep II from the eleventh dynasty. At the universities, the number of students started to increase rapidly in the 1950s with growing participation of middle-class groups after 1960. At first, that swell generated new academic jobs and ever more participation, but after 1970-1975, academic job opportunities tended to decrease, resulting in misemployment first and later substantial underemployment of later university trainees. The number of archaeological jobs closely followed suit, as did the number of academic and nonacademic archaeological institutes. Presently, heritage and rescue archaeology fare much better than academic archaeology in this respect.

An Institutional History

The State Museum of Antiquities in Leiden (Rijksmuseum van Oudheden, hereafter RMO) was the first public archaeological institution in the Netherlands, and its foundation in 1818 marked a shift from traditional to positivist thinking about the past. The museum has been and is active as a collector of antiquities from the Old World and in fieldwork in the Netherlands and abroad. The first director of the RMO, Caspar J.C. Reuvens, was also appointed professor of archaeology at Leiden State University in 1818, but that appointment was not a recognition of the subject in the Netherlands. “[Archaeology is] not so much a distinct, useful science, as it is a pleasant pastime… when not useless, then not really necessary” as one obituary of Reuven put it after his untimely death in 1835 (Byvanck-Quaries van Ufford 1984).

By and large, that was the dominant attitude toward archaeology in the Netherlands until well into the twentieth century. Accordingly, the chair was left vacant until A.E.J. Holwerda (1845-1923) was appointed to the chair of Archaeology, Ancient History, and Greek Antiquities. Later, Holwerda also became director of the RMO (1903-1919), and from there, he revived contact with the university. In 1907, Holwerda founded the *Oudheidkundige Mededelingen van het Rijksmuseum van Oudheden* as an outlet for the publications of the museum's investigations, but even then, there was no continuity, and Holwerda's successor at the university was an ancient historian who had no use for archaeology except as an illustrator of early events. In 1922, Alexander Byvanck, who had studied with Holwerda, succeeded to this chair. Byvanck pushed the appointment of assistants whose major interests were in classical archaeology, and that subject rapidly became well entrenched at Leiden University. In 1921, archaeology had been legally acknowledged as a separate discipline, and only then could a degree in archaeology be obtained.

Meanwhile, at the University of Utrecht, two classical philologists had been lecturing on archaeology. One of them, G. van Hoom, also lectured at Groningen from 1919 onward, thus paving the way for a chair of classical archaeology at that university in 1951. C.W. Vollgraff, the other Utrecht philologist, excavated the acropolis of Argos from 1903 until 1930 in a joint project with the French Archaeological School at Athens. He also participated in excavations of the Roman core of the city of Utrecht led by Van Giffen between 1934 and 1938. One of Vollgraff's students, H.G. Beyen, became the first professor of classical archaeology at the University of Groningen.

When Leiden University was reopened in 1945 after its forced closure by the Germans in 1941, a separate chair of classical archaeology was finally established, and it was held by Byvanck until 1954. There were good and varied relations with the chair of art history (which is still named Art History and Archaeology) at the same university, and contact with the material products of the ancient world was maintained through yearly student excursions to the Mediterranean's monumental sites. Only when H.A. A.P. Geertman was appointed in 1979 did interest in fieldwork reemerge.

At the University of Groningen, Van Giffen founded the Biological Archaeological Institute (hereafter BAI) in 1920. He also became an active consultant of local antiquarian committees and exercised great

influence in the archaeological field in the northern Netherlands. Van Giffen was appointed professor of prehistory and Germanic archaeology in 1939, and in the 1950s he convinced the Groningen physicist and

by the museum, and articles range from Dutch prehistoric excavations to discussions on Coptic grammar. Van Giffen's BAI also began issuing an archaeological journal, *Palaeohistoria,* in 1953. It contains research reports on activities by the staff of that institute, both in the Netherlands and abroad-for example, in the Middle East and indonesia.

An important backbone of classical archaeology has been the Vereeniging tot Bevordering der Kennis van de Antieke Beschaving (Society for the Furtherance of Knowledge of Antique Civilization). From 1925 onward, the *Bulletin* of this society (presently called *Bulletin Antieke Beschaving,* or *BABesch*) has appeared yearly and is the major journal of Mediterranean archaeology in the Netherlands. There are more archaeological journals with a Dutch background, the larger ones being *Berichten ROB* (which reports on the research by the ROB), *Helinivm* (which caters to Dutch and Belgian audiences, mainly prehistory), *Iranica Antiqua, Persica, Anatolica,* and *Bibliotheca Orientalis* (concerned with Middle Eastern philology and archaeology), and *Tijdschrift voor Mediterrane Archeologie* (archaeology in the Mediterranean). Of the others, *Analecta Praehistorica Leidensia* (which appears irregularly) and *Archaeological Dialogues* (which has a theoretical orientation) should be mentioned.

Major Collections and the Archaeological Record

The major archaeological collection of the Netherlands is in the RMO. The origin of this collection lies in the first systematic display of antiquities in the Netherlands, begun in the early years of the sixteenth century, when the Baron of Wassenaar looted the Roman fortress of Brittenburg, which had emerged at the ancient mouth of the Rhine owing to natural excavations by the North Sea. In a contemporary chronicle, the Wassenaar lineage was said to have descended from the fortress's Roman lord (Aurelius 1517), and almost two centuries later, that attribution was echoed and extended (Pars 1697). To further substantiate his claims, the baron also bought Roman artifacts from other places. The Wassenaar collection remained in the family's Duivenvoorde Castle in Voorschoten (south of Leiden) and was enlarged over later centuries. Part of it is still there, but another part is now in the RMO in Leiden.

The antecedents of Batavian (the native Germanic dialect) were eagerly sought after the sixteenth and seventeenth centuries. The years of insurrection against the Hapsburg's centralism and taxation resulted in the foundation of the Republic of the United Provinces of the Netherlands, and territorial claims were bolstered by reference to a mythical past. Reconstructions of Batavian society were published or painted, and the collection of antiquities kept pace with the political situation, tacitly forgoing local, native remains for objects from classical civilization that exemplified humanist and Renaissance ideas. One example among many stems from the early-seventeenth-century Antwerp painter Peter Paul Rubens who assembled classical statuary, which, after a detour to the collection of the Duke of Buckingham in London, was obtained by the Rotterdam brewer Reiner van der Wolff in 1660; today, part of the collection is in the RMO. In 1647, the Nehalennia sanctuary-the temple of a Romanized local goddess near the mouth of the river Scheidt-was exposed by the sea, and several altars were found on the beach. Ultimately, they ended up in the RMO.

Dutch collectors were also active in classical countries: a set of antique statues ultimately attributable to a Venice collector was bought by the Council of Holland in 1660, and early in the following century, an important collection of 150 classical *marmora* was bought by Gerard van Papenbroek at auction and bequeathed to Leiden University in 1743. This “cabinet of antiquities” was put on display in a specially constructed pavilion in that university's Botanical Gardens, probably the first public exhibition of antiquities in the United Provinces. The Papenbroek collection is remarkable for its relatively complete documentation, and it, too, is now in the RMO. In the same period, another important collection was begun when the Duke of Thoms, a Dutch diplomat in Italy, published an extensive catalog of his large collection of gems and coins in 1740. This collection was purchased by the Prince of Orange in 1751,

who passed it on to his heirs. Looted by the French in 1795 and later

repatriated to the Netherlands, it constitutes the core of the collection of the newly founded Royal Numismatic Cabinet in the Hague.

There have been more private and public collections of classical artifacts, and most of them have found their way to the RMO or to local museums. Some of the Dutch merchant dynasties amassed extensive private collections of ancient and contemporary art, which are still kept in their city palaces. Occasionally, such collections are put into public trust, most notably the collections of Allard Pierson and Lunsingh Scheurleer, which have been handed over to the archaeological museum of the University of Amsterdam (now the Allard Pierson Museum), and the important Van Beuningen collection of medieval pottery, which has been donated to the Van Beuningen Museum in Rotterdam.

A few examples of the forgery and fraud that have existed throughout the history of archaeology in the Netherlands are in order. For instance, the reason for the collection of the sixteenth-century finds from the Brittenburg fortress was to construct a Roman pedigree for an aristocratic lineage, a fraudulent enterprise. In the 1840s, Janssen of the RMO excavated a "Neolithic" pit village near Hilversum, and it took a century for the finds to be recognized for what they were, nineteenth-century forgeries, perhaps by one of Janssen's laborers. Famous among prehistoric fraud is Holwerda's misidentification of late Bronze Age tree coffins as the wall blocks of wooden "dome graves," based on a supposed analogy with Mycenaean *tholoi* (chamber tombs).

Several World War II finds that were later identified as probable forgeries by a Nazi bureau active in the Netherlands include "the Viking treasure" of Winsum (Elzinga 1975; Maarleveld and Pieper 1983). In the 1970s, news media ran stories about "the Vermaning hoax"-the Drenthe museum at Assen had for years been buying Paleolithic tools from the amateur archaeologist Tjerk Vermaning that were later recognized as forged. It was rumored that Vermaning was acting in good faith and that a conspiracy against official archaeology was behind the affair.

In the Netherlands-as elsewhere-interest in the archaeological record has never been very extensive. As Johan Picardt wrote (1660): "In the investigation of these antiquities of our home country, I do not find our compatriots very curious. They used to heed foreign, and external, more than indigenous histories. Yet I cannot understand or perceive that there are rarities or particularities in external histories, which we would not have, too, within our own country." Indeed, both the general public and the government have been rather unconcerned. Only megalith graves have been protected since 1734, as a result of a provincial law to prevent their destruction during the construction of roads and dikes, and grave barrows, Celtic fields (late Bronze Age-early Iron Age field systems), and other early sites have been destroyed in agricultural reallotment schemes. The legacy of the Middle Ages-such as city houses and in places whole city quarters, sixteenth- and seventeenth-century city defenses, and even old windmills and dikes-have only recently been or are still threatened by city construction. Only the Monuments Act of 1961 provides a means to preserve selected parts of the archaeological record.

A Gallery of Dutch Archaeologists

Dutch names are mentioned in few of the overviews of archaeological history (for example, Hodder 1991; Trigger 1989), a reflection of the importance that Dutch archaeology has been accorded by the world. Nevertheless, from this local archaeology some names can be proposed as worthy of international stature, if only because of their impact, long after their death, on Dutch archaeology. Of particular importance are Caspar Reuvens, Jan Hendrik Holwerda, Albert Egges van Giffen, and Hendrik Beyen, but some lesser figures have played important roles as well.

Casper J.C. Reuvens (1793-1835) studied law and defended his dissertation at the University of Paris in

1813. A professor of classical art at the (now closed) college of Harderwijk, in 1818 he became the first director of the RMO and also the first professor of archaeology at Leiden University. His first excavations (1826-1834) were at Arentsburg near Voorburg on an estate bought by the government especially

PREV NEXT

between prehistorians and art historical archaeologists increased. The former considered themselves to be the "real" scientific archaeologists while the art historical archaeologists regarded the prehistorians as newcomers who threatened funds and opportunities. The foundation of ARCHON, a government subsidizing agency (one of the suboffices of the Netherlands Organization for the Advancement of Pure Scientific Research), in 1981 was a major step toward easing these tensions. Classical, prehistoric, and other archaeologists met on commissions where research proposals were judged, and this work fostered a mutual understanding. The economic slump of 1980s set ceilings on university budgets, and this fact also resulted in closer cooperation as the various groups shared the burdens of student training.

A History of Dutch Archaeological Discussion

Most archaeologists are rather provincial in outlook, with little knowledge of problems elsewhere, and it is possible that nowhere has the universal ideology of positivism been achieved. Dutch archaeology is no exception, and historic-humanitarian ("culture historical") rather than scientific leanings have been dominant. In the Netherlands, the study of the relation of material culture to society has involved a study of the relation of the Dutch archaeological record with previous Dutch cultures, and those Dutch archaeologists who worked elsewhere (Middle or Far East, Mediterranean) have related to their particular problems elsewhere in the same way. This situation held true until at least the 1970s.

In addition to the general provincialism of Dutch archaeology, there is the scientific influence of politically dominant neighbors. Thus, when France was dominant during much of the nineteenth century, references to French archaeology were frequent, and texts were written in French. With Germany in the political ascendancy, references (if any to non-Dutch texts) were to German writings, German congresses and training programs were attended, German ideas were copied, dedications were to German scholars, and texts were sometimes published in the German language. After World War II, when England and then the United States dominated the political scene, former German references were gradually replaced by English ones, and the general orientation, especially in prehistoric texts, became Anglo-Saxon and there was an almost complete ignorance of other-for example, French, Italian, or Russian-developments.

In Dutch classical archaeology, with its art history orientation, the same trend is present although slightly attenuated. The number of English references surpassed that of German texts only in 1980, and in prehistoric archaeology that index changed around 1970. Perhaps the languages in which the Dutch research is reported is even more eloquent. Before World War II, more than 90 percent of articles were in Dutch; during the war, only Dutch texts were offered; after the war, the percentage dropped from 60 percent in the 1950s to 15 percent in the 1990s, and in the same years, German texts decreased from 25 percent to 5 percent, and English texts rose from 10 percent to over 60 percent.

Whenever ideas of non-Anglo-Saxon scholars are discussed in the Netherlands, they have been introduced through English translations, even though the study of at least two foreign languages is compulsory in the universities. Thus, Italian archaeologist Bianchi-Bandinelli's ideas are understood by only a handful of classical archaeologists, and French archaeologist andré leroi-gourhan and philosophers Foucault, Derrida, and Bourdieu only became known to prehistoric archaeologists when they were translated into English. The Russian archaeologist Leo Klejn is referenced only for his *Current Anthropology* contributions. Postmodernism is understood in its U.S./U.K. variant, with Ian Hodder and Michael Shanks as major leaders; Marxist (and other nondominant) archaeology are referenced rarely, if at all.

In Dutch mainstream prehistoric archaeology after the 1960s, the old (Childean) normative paradigm of archaeological culture as a recurrent set of archaeological traits was gradually replaced by a more anthropologically informed model of a systematically networked set of organizing subsystems of

archaeological attributes (Bloemers and Van Dorp 1991; Slofstra 1994). A

repertory. It remained in vogue in Dutch archaeology for many years, even with different epistemological props. In these larger ventures, ever more diverse phenomena were incorporated (ecology, locational analysis, historical traditions), and discussion thus moved on to more abstract levels.

In the 1970s, several young archaeologists produced less narrow texts: Bloemers and Willems and their work on Romanization have already been mentioned; Sander Van der Leeuw did comparative work on pottery production (Van der Leeuw and Pritchard 1984); and Jan Slofstra (1994) and Van de Velde argued for a social archaeology, the former with an evolutionist/functionalist emphasis (e.g., Brandt and Slofstra 1983), the latter being more structuralist (e.g., Van de Velde 1979). Later, two task groups ("pioneer programs") were set up, one to work on political developments in the Iron Age, Roman, and early medieval periods as a historical anthropological exercise, the other to attempt to integrate earth sciences with anthropological notions of the Paleolithic period of northern Europe.

No matter whether there were written records or not, archaeology has probably always been understood as ancient history in the Netherlands. Views regarding the means to write that history have varied as have the understandings of how such a history should read. A kings-and-battles approach is not feasible, as was clear even to Reuvens; however, a bourgeois emphasis on "high culture" (art, literature) has hampered Dutch archaeological discussion. A more general approach has recently been gaining ground. The means to read ancient history through archaeology have also varied considerably, with emphasis swinging repeatedly from objects toward context and back, and from observation to inferences-the increasing efficiency of soil removal (in the early years by crofters, in the twentieth century by vast numbers of unemployed people and later by mechanical equipment and technicians), which resulted in an ever-larger scale of field operations, has been utilized primarily by the empirically minded.

Finally, a word or two should be said about present archaeological practice in the Netherlands. Theorizing (or general critical discussion) began when it became clear that there was no simple one-to-one correspondence between Dutch archaeological data and Dutch archaeological history-as was still assumed tacitly or openly in the major field projects of the 1970s and 1980s. Probably, it was a matter of reflexivity emerging from repression: the implications of fieldwork had been authoritatively taught to be straightforward ("This is no archaeology," a comment by an archaeologist working on david l. clarke's *Analytical Archaeology,* may be considered typical for much of Dutch archaeology until recently). In its turn, the self-perceived peripheral nature of Dutch archaeology can be invoked. Archaeology was considered either a handmaiden of ancient history, a collector of objects for art history, or a consumer of the advances in ecological research, in each of which the numbers of scholars were many times larger than all the archaeologists combined.

In other words, the referent groups, or the intellectual debates to which Dutch archaeologists used to refer to, were external to the discipline. The archaeologists were not in a position to contribute substantially to the core debates nor were they in a position to establish a general discussion of their own. Only when the number of archaeologists had crossed a quantitative threshold (Van der Leeuw 1994), could internal discussion become effective: first, through the full implementation of a complete archaeological training program in 1986; second, when in archaeological academia distinction could be obtained by the additional deployment of a perceptibly different outlook; and third, through the fierce competition for junior jobs when too many students to be employed archaeologically took their degrees in the period after 1975. The discussion has been channeled through a yearly congress on theoretical archaeology and communicated to a wider audience through a semiannual journal, *Archaeological Dialogues,* which was first issued in 1994.

Some Other Dutch Archaeological Enterprises

Apart from provincial Roman, classical, and prehistoric archaeologists, there were others interested

in other periods and other regions: Mesopotamia, Egypt, and, of course, the Dutch colonies in Southeast Asia and the Caribbean. Many of these scholars continued philological pursuits and were hardly interested in field archaeology, but several philologists have been and are active in excavation and survey programs.

In the Dutch East Indies (present-day Indonesia), an early pioneer was eugene dubois (1858- 1940), a physician and paleontologist who discovered the remains of *Homo erectus* (Pithecanthropus) on Java in 1891. Although work on these protohumans continues (by C. ter Haar, G.H.R. von Koenigswald, H.R. van Heekeren, and G.-J. Bartstra), the main interest of colonial archaeologists has been in the monumental remains of the classical Hindu period, most of them on Java (the Borobudur complex, the temples at Prambanan, etc.). These scholars came up with remarkably modern ideas on restoration as early as the 1910s and 1920s (especially N.J. Krom and Th. Van Erp; Bernet Kempers 1978). Some members of the Colonial Antiquities Service were sent to the Netherlands to be trained by Van Giffen (notably W.J.A. Willems and P.V. van Stein Callenfels), and they almost inevitably returned with prehistoric interests: for example, megaliths and the Hoabinh shell heaps. The Dutch did not set up a training program for prospective indigenous archaeologists.

After World War II and after Indonesian independence in 1949, the Archaeological Service of the Indonesian Republic was run by a Dutch planter and amateur archaeologist, H.R. van Heekeren, and he was succeeded by his Indonesian assistant and trainee, R.P. Soejono. Dutch interest in the archaeology of Indonesia has never been great. Bartstra of the University of Groningen has taken over the Paleolithic interests of Van Heekeren and has been cooperating with Soejono on the Pleistocene hominids in the archipelago since the 1970s.

In the Caribbean, the ethnologist J.P.B. de Josselin de Jong worked on Amerindian prehistory and did some small excavations on the islands of Aruba and Curaçao. Since the 1970s, was a more regular interest in the past of these Dutch colonies (including Surinam) on the part of archaeologists from Leiden University-E. Boerstra, A.H. Versteeg, C. Hofman, M. Hoogiand, each having had appropriate field training by Modderman.

Of the Dutch archaeologists who have been active in the Middle East, the best known is perhaps henri frankfort (1897-1954), an international figure who was born in Amsterdam. He worked with sir william matthew flinders petrie at the British School in Athens and with J.H. Breasted at the Chicago oriental institute, where he organized the multidisciplinary Diyala project in Iraq while simultaneously holding a professorship of Middle Eastern archaeology at the University of Amsterdam (1932-1939). Later, Frankfort went to the Warburg Institute in London to become professor of the history of preclassical antiquity at London University.

Another well-known name in Mesopotamian archaeology is M.N. van Loon, who also worked in the Chicago Oriental Institute before he was appointed professor in Amsterdam (1972-1987). Excavations at Tell Hammam in Syria are continued by D.J.W. Meijer, who presently works at Leiden. H.J. Franken, a theologian turned archaeologist, worked in Palestine at Deir Alla (where work is now carried on by G. van der Kooij). Franken also collaborated with kathleen kenyon at Jericho and Jerusalem and contributed to both the recording and the interpretation of tell stratigraphy and pottery studies by employing artisan potters in his institute. The Groningen BAI has also conducted investigations in this region (H. T. Waterbolk at Bouqras in Syria), as has the RMO (P. M.M.G. Akkermans at Tell Sabi Abyad in Syria; H. Schneider in Egypt).

Conclusions

This account has made it clear that Dutch archaeology is not primarily the development of Van Giffen's ideas but, rather, that he was part of an important phase of an ongoing tradition. From the very beginning of academic archaeology, even from the first recorded excavation in the Netherlands (Titia Brongersma and Ludolf Smids at the Borger megalith grave in 1685), auxiliary sciences have systematically been called on to aid in or back up interpretation.

New Zealand: Historical Archaeology

Culture contact, extractive industry, and urban domesticity are themes that dominate the archaeological history of New Zealand since 1769 when European exploration brought New Zealand into the historic era. Originating in the 1920s, public and academic interest in the field of historical archaeology in New Zealand has grown dramatically since the mid-1970s.

Archaeological interest in the prehistoric Maori occupants of the country developed within a few decades of the founding of the first European settlement in 1792, but it was almost 120 years before attention turned to the postcontact period. The earliest work focused on sites from the mid-nineteenth-century wars between the Maori and the colonists, the most important being Elsdon Best's description of European redoubts, stockades, and blockhouses in the Wellington district (Best 1921) and his analysis of the manner in which Maori *pa* (earthwork fortifications) adapted to the introduction of muskets and artillery bombardment (Best 1927). These and other early works (*see* Smith 1990) concentrated on the description of surface features and reconstruction from historical sources rather than excavation. These works were also driven by the enthusiasm of individual scholars rather than by an institutionally based concern for the sites or the material culture of the historic period. Once the attention of those scholars turned elsewhere, historical archaeology in New Zealand became dormant.

The first excavation of a historic period site took place in 1959 at Orongo Bay, Gisborne, and was of a nineteenth-century Maori occupation

New Zealand: Prehistoric Archaeology

Early Problems: 1769-1950

Natural History: 1769-1892

Initial research into the presence of the Maori in New Zealand was carried out by historians, philosophers, and scientists who studied aboriginal peoples as an aspect of natural history. In 1770, English explorer Captain James Cook and English botanist Joseph Banks noted similarities between the New Zealand Maori and the inhabitants of other South Seas Islands and concluded that both had a common origin to the west (Beaglehole 1962). By the time of his third voyage in 1777, Cook was able to discuss the distinctive features of Maori material culture (fortified villages, carved canoes, weapons, and ornaments) and the dissimilarities between Maori and eastern Polynesian cultures, such as the absence of the monumental stone *marae* (temples comprising a rectangular enclosure with a stone platform) he had seen in Tahiti (Reed and Reed 1969).

The presence of the giant ratite *Dinornithiformes*, or moa, in New Zealand was demonstrated by Richard Owen on the eve of the signing of the Treaty of Waitangi (Owen 1839), and knowledge that the extinct moa occurred in human habitation sites followed shortly after. Scientific demonstration of the association of moa and human remains came from the work of the German-trained geologist Julius von Haast (1872), though other scientists such as Walter Mantell and James Hector were also active at the same time.

Through the works of English geologist sir charles lyell (1869), Haast was influenced by John Lubbock's (1865) division of human cultural development into the Paleolithic period, characterized by crudely chipped stone artifacts and extinct mammals such as the mastodon, and the more recent Neolithic period, containing polished stone implements. Haast assumed that the moa remains from human encampments in the South Island were of Pleistocene age and that the moas had been finally exterminated by a Paleolithic race who used only chipped stone implements. He initially identified this race with the Australian Aborigines but later accepted that its members were of Polynesian origin. He denied that these moa hunters were the ancestors of the Neolithic Maori, as the latter manufactured polished stone implements and used nephrite (greenstone), indicating that they had reached a higher state of civilization.

Haast's views were challenged by Alexander McKay, whom Haast had employed to excavate Moabone Point Cave near Christchurch, New Zealand. McKay (1874) noted that moa bones and polished stone adzes occurred together and argued that this was proof that the moa hunters had a technology similar to that of the Maori. He concluded that whether or not the Maori had been responsible for the extinction of the moas depended on how old the sites were as well as on the date of first arrival of the Maori. Basing his estimate on the length of time required to produce the Maori population present in 1769, McKay suggested the Maori had probably been in New Zealand for about 1,350 years and furthermore that their first impact on the country was the extermination of the moa.

Traditional History: 1892-1950

The polynesian society was created in New Zealand in 1892, and its formation marked a split between the humanities and the natural sciences following the reorganization of science into specialized disciplines. Most of the research at the end of the nineteenth century and in the first half of the twentieth was carried out by a small number of professionals in museums or else was done on a part-time basis by interested individuals working for private firms or in public service. Although the Polynesian colonization of the Pacific archipelago was diffusionist by necessity, the study of Maori origins retained other aspects of the

older natural history approach. In particular, changes in culture were invariably interpreted as the result of racial replacement. Innovative peoples were seen as emanating from a center as waves that left isolated peoples on the margins as the embodiment of these primordial events.

Through the works of English geologist sir charles lyell (1869), Haast was influenced by John Lubbock's (1865) division of human cultural development into the Paleolithic period, characterized by crudely chipped stone artifacts and extinct mammals such as the mastodon, and the more recent Neolithic period, containing polished stone implements. Haast assumed that the moa remains from human encampments in the South Island were of Pleistocene age and that the moas had been finally exterminated by a Paleolithic race who used only chipped stone implements. He initially identified this race with the Australian Aborigines but later accepted that its members were of Polynesian origin. He denied that these moa hunters were the ancestors of the Neolithic Maori, as the latter manufactured polished stone implements and used nephrite (greenstone), indicating that they had reached a higher state of civilization.

Haast's views were challenged by Alexander McKay, whom Haast had employed to excavate Moabone Point Cave near Christchurch, New Zealand. McKay (1874) noted that moa bones and polished stone adzes occurred together and argued that this was proof that the moa hunters had a technology similar to that of the Maori. He concluded that whether or not the Maori had been responsible for the extinction of the moas depended on how old the sites were as well as on the date of first arrival of the Maori. Basing his estimate on the length of time required to produce the Maori population present in 1769, McKay suggested the Maori had probably been in New Zealand for about 1,350 years and furthermore that their first impact on the country was the extermination of the moa.

Traditional History: 1892-1950

The polynesian society was created in New Zealand in 1892, and its formation marked a split between the humanities and the natural sciences following the reorganization of science into specialized disciplines. Most of the research at the end of the nineteenth century and in the first half of the twentieth was carried out by a small number of professionals in museums or else was done on a part-time basis by interested individuals working for private firms or in public service. Although the Polynesian colonization of the Pacific archipelago was diffusionist by necessity, the study of Maori origins retained other aspects of the

older natural history approach. In particular, changes in culture were invariably interpreted as the result of racial replacement. Innovative peoples were seen as emanating from a center as waves that left isolated peoples on the margins as the embodiment of these primordial events.

New Zealand: Prehistoric Archaeology

Early Problems: 1769-1950

Natural History: 1769-1892

Initial research into the presence of the Maori in New Zealand was carried out by historians, philosophers, and scientists who studied aboriginal peoples as an aspect of natural history. In 1770, English explorer Captain James Cook and English botanist Joseph Banks noted similarities between the New Zealand Maori and the inhabitants of other South Seas Islands and concluded that both had a common origin to the west (Beaglehole 1962). By the time of his third voyage in 1777, Cook was able to discuss the distinctive features of Maori material culture (fortified villages, carved canoes, weapons, and ornaments) and the dissimilarities between Maori and eastern Polynesian cultures, such as the absence of the monumental stone *marae* (temples comprising a rectangular enclosure with a stone platform) he had seen in Tahiti (Reed and Reed 1969).

The presence of the giant ratite *Dinornithiformes*, or moa, in New Zealand was demonstrated by Richard Owen on the eve of the signing of the Treaty of Waitangi (Owen 1839), and knowledge that the extinct moa occurred in human habitation sites followed shortly after. Scientific demonstration of the association of moa and human remains came from the work of the German-trained geologist Julius von Haast (1872), though other scientists such as Walter Mantell and James Hector were also active at the same time.

Through the works of English geologist sir charles lyell (1869), Haast was influenced by John Lubbock's (1865) division of human cultural development into the Paleolithic period, characterized by crudely chipped stone artifacts and extinct mammals such as the mastodon, and the more recent Neolithic period, containing polished stone implements. Haast assumed that the moa remains from human encampments in the South Island were of Pleistocene age and that the moas had been finally exterminated by a Paleolithic race who used only chipped stone implements. He initially identified this race with the Australian Aborigines but later accepted that its members were of Polynesian origin. He denied that these moa hunters were the ancestors of the Neolithic Maori, as the latter manufactured polished stone implements and used nephrite (greenstone), indicating that they had reached a higher state of civilization.

Haast's views were challenged by Alexander McKay, whom Haast had employed to excavate Moabone Point Cave near Christchurch, New Zealand. McKay (1874) noted that moa bones and polished stone adzes occurred together and argued that this was proof that the moa hunters had a technology similar to that of the Maori. He concluded that whether or not the Maori had been responsible for the extinction of the moas depended on how old the sites were as well as on the date of first arrival of the Maori. Basing his estimate on the length of time required to produce the Maori population present in 1769, McKay suggested the Maori had probably been in New Zealand for about 1,350 years and furthermore that their first impact on the country was the extermination of the moa.

Traditional History: 1892-1950

The polynesian society was created in New Zealand in 1892, and its formation marked a split between the humanities and the natural sciences following the reorganization of science into specialized disciplines. Most of the research at the end of the nineteenth century and in the first half of the twentieth was carried out by a small number of professionals in museums or else was done on a part-time basis by interested individuals working for private firms or in public service. Although the Polynesian colonization of the Pacific archipelago was diffusionist by necessity, the study of Maori origins retained other aspects of the

older natural history approach. In particular, changes in culture were invariably interpreted as the result of racial replacement. Innovative peoples were seen as emanating from a center as waves that left isolated peoples on the margins as the embodiment of these primordial events.

central and eastern Polynesia (Skinner 1921). Subsequently, Skinner maintained the Polynesian identity of all the prehistoric inhabitants of New Zealand. In 1924, Skinner drew attention to the presence of tanged adzes in New Zealand, the Chatham Islands, and Polynesia and also in those areas of Southeast Asia where Austronesian languages are spoken. In so doing, he substantiated his conclusions of the previous year (Skinner 1923) that the closest relationship of the Moriori culture (Chatham Islands) and the southern culture of the Maori was with eastern Polynesia.

Skinner's insights were confirmed by ethnographer Edwin G. Burrows's (1938) differentiation of Polynesia into a western cultural block (Samoa, Tonga, and neighboring islands) and eastern Polynesia, which joined the Society Islands with Hawaii, the Marquesas Islands, Easter Island, and New Zealand. Skinner employed the untrained but enthusiastic David Teviotdale as his archaeological collaborator, and Teviotdale's collections of tanged adzes, fishhooks, bone and stone ornaments, and greenstone artifacts clearly demonstrated the association of Maori artifacts with moas at sites such as Waitaki, Shag River, and Little Papanui (Teviotdale 1932).

Culture-Historical Studies: 1950-1965

The excavation of thirty-six human burials at Wairau Bar, near Blenheim on the South Island, between 1939 and 1952 represents the introduction of culture-historical archaeology to New Zealand. Accompanying the human remains were grave goods, including parts of moa skeletons, moa egg "waterbottles," tanged adzes, fishhooks, and necklaces of whale ivory "reels" and imitation whale teeth. The site also incorporated housing, areas for stone working, and cooking and midden dumping areas.

roger duff (1950) reformulated the ideas of Haast, Smith, Buck, and Skinner to argue that New Zealand's prehistory could be divided into an early, or moa hunter, period of Maori culture, and a later period of Maori culture. Duff defined Maori culture in terms of the observations of Cook and the earliest ethnographers. He was, however, unable to accurately date the Wairau Bar burials or to demonstrate the chronological and stratigraphical relationships between his two culture periods. Consequently, Duff made use of the presence of tanged adzes and the age-area concepts of centers of innovation and marginal survival to argue that Wairau Bar dated from the earliest period of Hawaiki dispersals. Second, he used Smith's chronology of the discovery of New Zealand in a.d. 950 and the arrival of the domestic plants *kumara*, taro, yams, and gourds with the great fleet in a.d. 1350 to both date and explain the development of the later Maori culture.

In 1955, Duff was able to announce a C-14 date of a.d. 1150 for Wairau Bar (Duff 1956). His predictions regarding the nature of the early period of eastern Polynesian culture were confirmed by Kenneth Emory and Yosihiko Sinoto of Hawaii's Bishop Museum, who in 1964 discovered human burials at Maupiti in the Society Islands, which were associated with whale tooth pendants, fish lure shanks, and tanged adzes, items almost identical to those recovered in New Zealand.

Ideas of adaptation to the temperate New Zealand environment continued to run alongside ideas of migrations and racial or economic replacement as explanations for the development of the distinctive Maori material culture. Cook thought that the Maori houses reflected the cool New Zealand environment while Skinner (1924) explained divergences between Maori and eastern Polynesian art and culture as a response to the move from the tropics. Buck (1949) similarly maintained that local developments were responsible for the most distinctive Maori cultural items, including warm houses, clothing, and *kumara* storage pits. The use of large canoes and carved houses was stimulated by the availability of large trees while fortified pa, warfare, and curvilinear art forms were a response to the tribal rivalry and competition that took place after the arrival of the great fleet. Finally, Duff (1947) explained the terraced pa, the tangless rounded 2B adze, and greenstone ornaments, which he used to

define his Maori period in terms of population growth and the innovative use of local materials.

The arrival of jack golson at Auckland University

most particularly Green (1963), advocated the use of nonartifactual evidence to establish the space and time coordinates of sites and prehistoric social entities. In quick succession, flaked stone artifacts (Shawcross 1964b), storage pits (Parker 1962; Shawcross 1964a), and shell middens (Davidson 1967) were tested and found to be poor indicators of either chronological periods or regional styles.

Additional attention was given to archaeological sites where artifacts might be better preserved, in particular swamp sites-such as Ngaroto (Shawcross 1968), Kauri Point (Shawcross (1976), Mangakaware (Bellwood 1978), and Kohika (Irwin 1975)-or artificial pa constructed out of shell in low-lying areas such as Oruarangi on the Hauraki Plains (Shawcross and Terrell 1966). The artifacts from these sites have contributed to the knowledge of artifact and carving styles, and they have proved to have an antiquity that has undercut many of Groube's prescriptions for the classic phase. However, the specialized and rare nature of these sites has precluded the extension of these findings to other areas (Furey 1996).

Much attention has also been given to purifying the ethnographic and archaeological record of European influences in order to define a pristine classic Maori culture, an approach criticized by Stuart Bedford (1996). Artifact collections and observations made by the earliest visitors to New Zealand have been studied in detail (Salmond 1991; Shawcross 1970a), and some research has concentrated on archaeological sites known to have been occupied at the time of first contact such as Paeroa pa, which was mapped by Marion du Fresne in 1772 and destroyed by his men after du Fresne's death. In almost every case, either the historically documented phase could not be identified or else it had been destroyed by subsequent occupation (Groube 1965).

Studies of Process: 1965-1999

Because of the short time depth of New Zealand prehistory, culture-historical archaeology in New Zealand has always included some study of the processes of change. After 1965, the lack of success in defining culture periods culminated in an explicit shift to the study of processes.

Regional and Thematic Studies

The appointment of English archaeologist Charles Higham and other archaeological staff members at Otago University in the 1960s initiated a fruitful period of regional studies. These began with Australian archaeologist Peter Coutt's study of contact between Europeans and Maori in the Foveaux Straits region (Coutts 1969).

The Wairarapa Research Programme, initiated by Foss Leach and Helen Leach in 1969, marked a further stage in the development of a regional approach as a viable alternative to the definition of cultural periods (Leach 1976). This program, carried out at Palliser Bay in the Wairarapa, a marginal area for Maori agriculture on the northern side of Cook Strait, brought together studies of site distribution, settlement types, agriculture, house forms, shell midden content, stone artifacts, and traditional history (Leach and Leach 1979). It provided a model for similar regional studies that have been carried out for the Chatham Islands (Sutton 1982), Auckland (Davidson 1978; Irwin 1985), Northland (Sutton 1990), the Hauraki Plains (Phillips 2000), and the South Island (Anderson 1998). Such regional studies have not always escaped presenting their evidence within the culture-historical framework (see Prickett 1982), but for the most part, they have documented increases or decreases in the magnitude of human populations or changes in the complexity of regional, economic, or social organization for which the division of New Zealand prehistory into archaic or classic periods is largely irrelevant.

A number of studies, however, have continued to rely on adaptational or environmental explanations. Doug Sutton and Yvonne Marshall's (1980) use of convergent adaptation to explain similarities between

the Chatham Island Moriori, southern South Island Maori, and other southern foragers such as the Tasmanians is an example (see Anderson 1981). In a more recent study of the emergence of a northern Maori chiefdom, Sutton (1990) modified this stance by also considering sociopolitical and ideological factors. On the other hand, Atholl Anderson (1991) has returned to modeling the initial colonization of New Zealand in terms of the arrival

Studies of Process: 1965-1999

Because of the short time depth of New Zealand prehistory, culture-historical archaeology in New Zealand has always included some study of the processes of change. After 1965, the lack of success in defining culture periods culminated in an explicit shift to the study of processes.

Regional and Thematic Studies

The appointment of English archaeologist Charles Higham and other archaeological staff members at Otago University in the 1960s initiated a fruitful period of regional studies. These began with Australian archaeologist Peter Coutt's study of contact between Europeans and Maori in the Foveaux Straits region (Coutts 1969).

The Wairarapa Research Programme, initiated by Foss Leach and Helen Leach in 1969, marked a further stage in the development of a regional approach as a viable alternative to the definition of cultural periods (Leach 1976). This program, carried out at Palliser Bay in the Wairarapa, a marginal area for Maori agriculture on the northern side of Cook Strait, brought together studies of site distribution, settlement types, agriculture, house forms, shell midden content, stone artifacts, and traditional history (Leach and Leach 1979). It provided a model for similar regional studies that have been carried out for the Chatham Islands (Sutton 1982), Auckland (Davidson 1978; Irwin 1985), Northland (Sutton 1990), the Hauraki Plains (Phillips 2000), and the South Island (Anderson 1998). Such regional studies have not always escaped presenting their evidence within the culture-historical framework (see Prickett 1982), but for the most part, they have documented increases or decreases in the magnitude of human populations or changes in the complexity of regional, economic, or social organization for which the division of New Zealand prehistory into archaic or classic periods is largely irrelevant.

A number of studies, however, have continued to rely on adaptational or environmental explanations. Doug Sutton and Yvonne Marshall's (1980) use of convergent adaptation to explain similarities between

the Chatham Island Moriori, southern South Island Maori, and other southern foragers such as the Tasmanians is an example (see Anderson 1981). In a more recent study of the emergence of a northern Maori chiefdom, Sutton (1990) modified this stance by also considering sociopolitical and ideological factors. On the other hand, Atholl Anderson (1991) has returned to modeling the initial colonization of New Zealand in terms of the arrival

of a small and highly mobile population that was stimulated by the rich environment to live more by hunting than by swidden agriculture, which involved effort in field preparation through cutting down and burning trees.

A major investigation of the various traits used by Duff, Golson, and Green to define their culture periods-e.g., material culture (including fishing gear, ornaments, adzes, and other stone artifacts), subsistence and technology, house and settlement forms, burials, warfare and pa design, and art styles-led New Zealand archaeologist Janet Davidson (1984) to conclude that changes in these traits took place at different times and in different places in response to quite different stimuli. Arguing that classic Maori culture could not have had a single point of origin, Davidson stressed that the polarization of New Zealand prehistory into the archaic and classic periods created insuperable difficulties for the explanation of the changes she had documented.

Thematic and regional projects in historical archaeology have been well documented by Ian Smith. Apart from Groube's (1965) study of proto-historic settlement patterns in the Bay of Islands, major projects have included the excavation of sites affected by the central North Island Tongariro power scheme carried out by Hoskins, a study of culture contact sites in Fiordland (Coutts 1969), Prickett's study of historic sites of the Taranaki wars (between Maori and the Crown), Neville Ritchie's explorations of the Otago goldfields affected by the Clutha dam development project, and, finally, a program on sites affected by urban development in the Auckland region led by Bulmer and others (see I. Smith 1990).

The last two projects were initiated under the Historic Places Amendment Act of 1975, a monument to the work of Green that gave the New Zealand Historic Places Trust control of the destruction of archaeological sites. Since 1975, the number of archaeologists employed by public and private agencies has matched the combined total of archaeologists in the universities and museums (about eighteen). Salvage archaeological projects have resulted in new surveys of remote or forested areas and the detailed archaeological investigation of the layout of fortified, residential, agricultural, and colonial industrial sites (Clough 1990).

Economic and Ecological Archaeology

In an innovative series of studies of North Island shell middens, Wilfred Shawcross combined grahame clark's economic approach with that of the Californian school of midden analysis (Heizer and Cook 1956). Using the interrelationships among site size, population, and the energy content of shell middens, Shawcross's work ranged from a study of the length of time a small group might have occupied a site (Shawcross 1967b) to the potential of harbor shellfish resources to support a human population (Shawcross 1967a) to the carrying capacity of both the North and South Islands based on seaboard productivity (Shawcross 1970b) and, finally, to the use of shell middens to construct a thermodynamic model that would allow a comparison of an early and late period midden in terms of work and efficiency (Shawcross 1972).

Detailed investigations of midden content and shellfish gathering practices have also been carried out by Reg Nichol (1988) and Atholl Anderson (1973). Anderson's study of prehistoric shellfish gathering behavior at Black Rocks, Palliser Bay, represents an early and probably independent use of ecological niche and optimal foraging models in New Zealand archaeology. Since 1978, Anderson has pursued the interaction of the prehistoric human population and moas in New Zealand. The results of this taphonomic and chronological study are correlated with the ecology of the moa and the distribution and contents of early archaeological sites to show the rapid extinction of the moa through hunting between 900 and 400 b.p. (Anderson 1989; Anderson, Allingham, and Smith 1996). Anderson and Smith (1996) argue that the early period of base settlements (villages), supported by localities rich in moas and seals, was a

short-lived phenomenon and an unsustainable colonizing strategy. Villages reemerged on the southern part of the South Island in the later part of its prehistory as the result of an intrusion of peoples from the North Island who were equipped with a more highly organized

exploitation strategy based upon stored foods and exchanges, including the payment of tribute to chiefs.

Chronological and Demographic Studies

In research on fortified pa, Groube (1964, 1970) plotted the regional distribution of chronological types based on their evolution from large, open-terraced pa to small pa that were heavily defended by multiple ditches, banks, and palisade posts. Initially, Groube explained this change in social terms as reflecting the breakdown of large tribal entities (and chieftainships?) into small, highly competitive descent groups. Chronology, demography, and resource stress were also included as factors. Groube argued that it would take 200 years or more for the population of a small group of colonists arriving in a.d. 1000 to reach about 25,000. After that, however, even moderate growth would take the population up to 100,000 by a.d. 1700. The thousands of fortified pa sites that dot the North Island landscape were the outcome of increasing competition for good-quality agricultural land within the zone of favorable climate. This was a form of resource stress through overpopulation that only had major effects during the final 200 years of New Zealand's prehistory.

It was many years before the information on pa distribution and chronology would allow the testing of Groube's hypotheses. Matt Schmidt (1996), using Anderson's (1991) suggestions for chronometrical reliability, derived 72 robust dates from a series of 221 radiocarbon dates from ninety-six pa. These dates suggested, first, that pa sites appeared rather suddenly at about a.d. 1500 and, second, that Groube's different classes of pa were spatially and chronologically coterminous. These conclusions repeated those of Geoffrey Irwin's (1985) study of spatial and hierarchical relationships of the pa of Kaipara Harbor and elsewhere. Irwin found that there was evidence that the settlement system (of Pouto) went through a stress threshold during the late prehistoric period that resulted in a spate of pa building. Multiple small pa and a few massive ones indicative of a higher order of organization suggested that the pa building was a response to both internal division and external threat.

Anderson (1991), in an extensive review of the time of initial settlement of New Zealand based on radiocarbon dates, found little evidence for settlement earlier than a.d. 1200. He added that the possibility of a planned immigration by some hundreds of people could not be ruled out. Sutton (1987, 1994), by contrast, used indications of fire disturbance in New Zealand pollen cores to claim that initial settlement was substantially earlier than a.d. 800. Part of Sutton's argument for an early date of colonization is based on life expectancy data and the implications of fertility and diet for population growth (Brewis, Malloy, and Sutton 1990).

Questions regarding the chronology of settlement and population growth in prehistoric New Zealand directly concern the time available for cultural processes. At present, the short chronology supports the idea of multiple settlement episodes and rapid and possibly intrusive changes in population, technology, and settlement patterns. The longer chronology supports arguments for the internal development of Pacific societies through evolutionary processes that led to the development of chiefly societies as a result of population increase, resource stress, agricultural intensification, or competition (Kirch and Green 1987).

Groube (1970) allied his model of population growth and resource stress with David Simmons's attempt (Simmons 1976) to reinstate the status of Maori canoe traditions by shifting their location to voyages around and between the islands of New Zealand (see Orbell 1985). Linking the distribution of the highly defended “ring ditch” pa with the historic movements of the “Awa” peoples enabled Groube to claim that the exile and forced migration of this group followed a standard Polynesian response to overpopulation. Computer simulations (Levison, Ward, Webb 1973), experimental voyages (Finney 1977), and increased knowledge of Pacific archaeology and Polynesian sailing techniques (Irwin 1992)

have led to a reassessment of Andrew Sharp's pessimistic views. His model has now been replaced by the possibility of planned voyages, multiple episodes of discovery and colonization,

Nilsson, Sven

(1787-1883)

The son of a farmer who was taught to read and write by his father, Sven Nilsson enrolled at Lund University in sweden in 1806 with the intention of becoming a priest. He finished a degree in theology but then studied philology, natural history, and philosophy. In 1812, Nilsson was offered a position at Lund's natural history cabinet (or premuseum collection) as well as an associate professorship in natural history.

Through his work of classifying donations to the cabinet Nilsson became interested in fossil remains and research. He was elected to the Royal Swedish Academy of Sciences in 1812 and drew up plans for the academy's transformation into the Swedish Museum of Natural History, where he was eventually a curator.

While he was working in the museum, Nilsson continued to study zoology, geology, and anatomy and finished a medical degree in 1818. In 1832, he returned to the University of Lund as a professor of zoology, and the natural history museum at Lund became the center for Swedish zoology. In Nilsson's view, all natural-scientific research rested ultimately on careful comparisons, which made collecting decisive for the development of the sciences. He became a central figure in nineteenth-century Swedish zoology through his forty-year career as a university teacher and through the popularization of his scientific interests via lectures and publications. He was also one of the pioneers of the embryonic discipline of quaternary geology, linking geology, zoology, and archaeology to create a

Nilsson, Sven

(1787-1883)

The son of a farmer who was taught to read and write by his father, Sven Nilsson enrolled at Lund University in sweden in 1806 with the intention of becoming a priest. He finished a degree in theology but then studied philology, natural history, and philosophy. In 1812, Nilsson was offered a position at Lund's natural history cabinet (or premuseum collection) as well as an associate professorship in natural history.

Through his work of classifying donations to the cabinet Nilsson became interested in fossil remains and research. He was elected to the Royal Swedish Academy of Sciences in 1812 and drew up plans for the academy's transformation into the Swedish Museum of Natural History, where he was eventually a curator.

While he was working in the museum, Nilsson continued to study zoology, geology, and anatomy and finished a medical degree in 1818. In 1832, he returned to the University of Lund as a professor of zoology, and the natural history museum at Lund became the center for Swedish zoology. In Nilsson's view, all natural-scientific research rested ultimately on careful comparisons, which made collecting decisive for the development of the sciences. He became a central figure in nineteenth-century Swedish zoology through his forty-year career as a university teacher and through the popularization of his scientific interests via lectures and publications. He was also one of the pioneers of the embryonic discipline of quaternary geology, linking geology, zoology, and archaeology to create a

PREV NEXT

picture of the environment and living conditions in Sweden over long periods of time-the beginning of late-quaternary research.

Although Nilsson had collected archaeological artifacts since the 1820s and had participated in archaeological excavations as early as 1819, it was not until later in his career that he began to devote much of his time to archaeology, when he endeavored to translate a natural-science approach into a complex model of cultural development that could be measured empirically through technological change. Nilsson was the first to use comparative ethnography to elucidate cultural history-and thus he exercised great influence on the development of modern anthropology, particularly on American anthropologist lewis h. morgan and English ethnographer e. b. tylor. oscar montelius, who was critical of Nilsson in other contexts, believed that his cultural-evolutionary scheme and his comparative method had elevated antiquarian research into a science.

Nilsson began to lose prestige within the archaeological establishment mainly because his attempts to determine the origin of the Swedish Bronze Age led to chronological misjudgments. But his contributions were considerable: he provided a picture of prehistory that was more complex than any other; he clarified how flint tools were made, both through the use of experiments as well as through ethnographical and ethnological analogies; and he helped confirm and develop the three-age system. Perhaps most significant of all, however, was the fact that he showed how Stone Age societies had probably lived and demonstrated that the three-age system applied to Sweden as well as to denmark.

Nimrud

Also known as Kalhu, Nimrud was an Assyrian city on the banks of the Tigris River quite close to nineveh. Made famous as a result of its excavation, initially by austen henry layard beginning in 1845 and later by sir max mallowan in 1954, Nimrud suffered fluctuating fortunes during its history. First established in the late second millennium b.c., the city was designated an imperial Assyrian city around 883 b.c. but shortly afterward lost that status to Khorsabad.

(Image Select)

But there had been time enough to produce the palaces, major sculptures (such as the winged bulls), and hundreds of cuneiform texts that were so enthusiastically excavated by Layard. The public exhibition of the results of his excavations in England after 1849 created a high level of public interest, which can in part be explained by the lure of spectacular objects. By the same token, Layard was quite aware of the powerful attraction of archaeological “proofs” of stories from the Old Testament (even though he managed to confuse Nimrud with the biblical Nineveh). In 1954, the site was systematically reexcavated

in a somewhat less bravura manner by Mallowan, who had signal successes of his own, particularly in the recovery of the famous Nimrud ivories.

Nineveh

Nineveh, the great capital of the Assyrians on the river Tigris, became prominent around 700 b.c. during the reign of Sennacherib, who moved his capital there. Notwithstanding its great size and the magnificence of its architecture, Nineveh was sacked by the Medes and the Babylonians in 612 b.c.

First excavated by paul emile botta in 1842, the site is most famously associated with sir austen henry layard, who began excavating at Sennacherib's Palace in 1846. Layard was fortunate in his assistant Hormuzd Rassam, and the latter developed into an excavator of skill and vigor and took over the excavations after Layard's return to England in 1851. Between 1846 and 1851, during two major expeditions, spectacular examples of Neo-Assyrian art such as winged bulls and stone wall relief carvings were recovered and sent back to the british museum-which was the major sponsor of the work. Rassam later excavated the famous relief carvings of the royal lion hunt, which also grace that museum.

Of equal importance to the architecture and art works were the numerous cuneiform tablets that made up the Assyrian royal archives in the seventh century b.c., which have since been deciphered. Given the significance of the site, it is hardly surprising that it has attracted constant attention, including the valuable and technically excellent excavations undertaken by sir max mallowan in 1931 and 1932 and the postwar work of Iraqi archaelogists such as Manhal Jabr and the short tenure of the University of California, Berkeley, team under the direction of David Stronach (1987-1990).

individual households, including the homes of artists, craftspeople, nobles, and slaves (Rybina 2001).

A most interesting feature of medieval Novgorod was the existence of thousands of documents scratched onto birchbark pages (*beresty*), of which almost 1,000 have been recovered. These deal with a wide range of subjects and include peasant complaints, financial records, school exercises, notes on literature, and love letters. Other preserved objects include tools, weapons, musical instruments, toys, jewelry, clothes, and craft materials.

Novo Mesto

A late prehistoric settlement and complex of burial sites in Dolenjska (lower Carniola) in slovenia, Novo Mesto is characterized by a number of cemeteries dated from the whole first millennium b.c. The settlement is located on the Marof and was probably occupied from the late-Bronze Age to Roman times. The first excavations of the cemeteries began at the end of the nineteenth century (by the Naturhistorisches Museum, Vienna, and the National Museum, Ljubljana). However, more intensive research was initiated by the Dolenjski Muzej (lower Carniola museum) in Novo Mesto from 1967 onward.

The Novo Mesto cemeteries date to three main periods: late-Bronze Age (ninth-eighth centuries b.c.), early-Iron Age (eighth-fourth centuries b.c.), and the late-Iron Age to the Roman period (third century b.c.-second century a.d). From the first period, the sites of Mestne njive, Kapiteljska njiva, and Brsljin contain some 400 urned cremation graves and were part of the Ljubljana Urnfield group. Grave goods consisted mostly of dress ornaments (fibulae, bracelets, pins) and ceramic vessels. Only a few graves contained weapons (axes, spearheads), razors, necklaces, knives, or glass beads.

The early-Iron Age sites of Kapiteljske njive and Kandija are made up of some twenty earthen barrows.

The burial rite was inhumation (from few to seventy graves per barrow). Some rich princely graves of this period were recorded containing body armor, tripod, various helmet types, weapons, and decorated bronze vessels together with numerous warrior graves and graves with standard personal ornaments and ceramic vessels. In the early-Iron Age period, Novo Mesto was one of the most important centers of the Dolenjska (lower Carniola) group of the Hallstatt culture.

The late-Iron Age sites of Kapiteljske njive, Kandija, and Beletov vrt are characterized by cremation burials in flat cemeteries. Graves contain mostly middle and late la tène artifact types (swords with scabbards, shields, knives,

belt pieces, fibulae, necklaces, bracelets, and pottery) and early Roman provincial objects.

Nubia

Nubia is the name that has been given in modern times to a region that was known to ancient Egyptians and their neighbors as Kush (or Cush) and to Greeks and Romans as Aethiopia. Today, it comprises the most southerly part of Egypt and the adjoining northern part of the Republic of Sudan. Historically, however, the region has usually been both culturally and politically autonomous, neither wholly Egyptian nor wholly Sudanese. Its peoples speak languages of the African eastern Sudanic family and exhibit both racial and cultural characteristics that connect them with peoples further to the south in Africa as well as with their Egyptian neighbors. Nubia was the seat of the ancient Empire of Kush and later of medieval Christian kingdoms that successfully resisted the incursion of Islamic Egypt for a thousand years.

The northern boundary of Nubia since time immemorial has been at the First Cataract of the Nile, just upriver from the town of Aswan in Egypt. The peoples to the south of that point have always been and remain ethnically and linguistically different from the Egyptians. The southern limit of Nubia is more difficult to specify, for it has varied at different times in history. However, in the usage of archaeologists and culture historians, the term is generally synonymous with ancient Kush and Aethiopia; it designates that portion of the Nile Valley, upriver from Egypt, that was strongly affected by cultural and political currents from Egypt and the Mediterranean world. In that sense, the historic southern limit of Nubia should be placed somewhere to the south of modern Khartoum at the confluence of the Blue and White Nile Rivers.

The Nubian environment resembles that of Egypt in that the fertile Nile Valley is flanked, for most of its length, by totally lifeless deserts. Instead of a broad and continuous floodplain, however, the valley in Nubia contains only limited and disconnected patches of alluvium while elsewhere, bare granite or sandstone outcrops come right to the water's edge. In most of the region, moreover, the Nile did not annually overflow its banks, and irrigation required the use of man-made lifting devices. The agricultural potential was, as a result, very much less than that of Egypt, and the population was proportionately smaller. The prosperity of ancient and medieval Nubian civilizations did not depend on agricultural fertility, as in the case of Egypt, but on the country's position astride one of the world's oldest and richest trade routes. Before the development of trans-Saharan caravan trade in the first century a.d., the Nile Valley represented the only secure corridor across the Sahara through which gold, ivory, slaves, and other coveted goods from the African interior could reach the Mediterranean Basin.

A Resume of Cultural History

The late Palaeolithic and early Neolithic cultures of Nubia conformed to a general pattern that has been observed all over the eastern Sahara. Although pottery made its appearance surprisingly early, other

aspects of Neolithic cultural development lagged far behind contemporary developments in the Near East. As the Sahara gradually became drier and wild animal and bird life retreated to the Nile corridor, the abundance of aquatic and game resources seems to have actually retarded any heavy reliance on agriculture until near the end of the Neolithic period; similarly, the warm climate retarded the development of permanent housing. It was only during the time of “the copper age,” more or less contemporary with the beginnings of dynastic civilization in Egypt, that advanced Neolithic cultures made their appearance in Nubia.

The distinctive late Neolithic cultures of Nubia were first discovered as a result of excavations near Aswan in 1907. Because the finds corresponded to nothing previously known from Egypt, they were designated by the discoverer

belt pieces, fibulae, necklaces, bracelets, and pottery) and early Roman provincial objects.

Early Archaeology in Nubia

Because of its historical connection with Egypt, Nubia has always been regarded by Egyptologists as part of "their" rightful domain. However, chaotic political conditions prevented any actual exploration in the country until the early nineteenth century when Nubia was once again annexed as an Egyptian colony. The Swiss explorer J.L. Burckhardt made the first full traverse of the country by any European in 1813, noting along the way a number of ruined Egyptian temples, including the huge rock-cut colossi of abu simbel. He was followed over the next three decades by several other explorer observers who left descriptions and sometimes woodcut illustrations of the major Nubian antiquities. Systematic and scientific investigation began, however, with the monumental work of karl richard lepsius, who between 1842 and 1845 copied all of the then-visible hieroglyphic inscriptions and reliefs on all of the ancient monuments both in Egypt and in Nubia as far south as the ruins of Meroe. His resulting five-volume *Denkmaler aus Agypten und Athiopien* (1849) remains today as the sole authoritative source for a great many monuments that have since been destroyed.

In the later nineteenth century, political conditions were again disturbed as a result of the Mahdist rebellion in the Sudan, and field investigation did not resume until after the Anglo-Egyptian reconquest in 1898. The highly publicized military campaign in the Sudan aroused a great deal of interest not only among the general public but among archaeologists, and within a decade of the reconquest, no fewer than nine expeditions took the field in the Egyptian and Sudanese portions of Nubia. In the years immediately following the reconquest, Wallis Budge of the british museum carried out a series of rather desultory excavations at several places in northern Sudan while James Breasted and a team from the University of Chicago's oriental institute made photographic records of all the major temples and inscriptions in Nubia. A little later an expedition from the Vienna Academy of Sciences began work in the area just upstream from Aswan, and two expeditions, one from Oxford University and one from the university of pennsylvania museum, worked on sites in the Egyptian-Sudanese border area. Far to the south, a Liverpool University expedition began to excavate the royal palace compound at the city of Meroe, and an expedition privately financed by Sir Henry Wellcome, a pharmaceutical manufacturer, worked at Gebel Moya south of Khartoum. The architect Somers Clarke, also with private financing, undertook to record all of the medieval Christian remains of both Egypt and Nubia.

Although all the early expeditions, except that of Wellcome, were led by Egyptologists, it is noteworthy that they did not confine themselves to only the archaeological remains of the pharaonic periods. Several of them dug at sites of the Kushite period, and the Oxford and Pennsylvania groups, as well as Somers Clarke, also made major contributions to the study of medieval Nubian remains. There thus arose very early the idea that Nubian archaeology should be a unified study, embracing the whole history of the country, rather than being strictly divided between the Egyptologist and the medievalist, as was the case in Egypt. On the other hand, all of the early expeditions, except that of the Pennsylvania Museum, paid primary attention to monumental architectural remains, mainly of the pharaonic and Kushite periods, although several also did some excavation in cemeteries. There was a conspicuous neglect of townsites, which mostly appeared to be of medieval or later date and which, in any case, were not expected to yield attractive and intact objects for display.

The single most important turning point in the development of Nubian archaeology came about through an act of destruction. The Egyptian irrigation authorities had built a small dam on the Nile just above Aswan at the turn of the century, and in 1907, it was decided to enlarge it so as to create a lake almost 100 miles long. The region to be inundated included a substantial part of Lower Nubia and a number of its important temples as well an unknown, but presumably large, number of other sites. In advance of the destruction, the Egyptian Survey Department sponsored what was, in fact, the world's first

archaeological salvage program. It was called the Archaeological Survey of Nubia, although its

monumental structures-fortresses, temples, and palaces-from the pharaonic and Kushite periods and also on the excavation of graves from all periods that would yield objects for museum display. Typically, an expedition worked at the same site for four or five seasons in succession, with a small team of European supervisory personnel and a very large native labor force. The quality of architectural recording and mapping was generally very high, since this work was done by trained specialists, but excavation controls were likely to be lax and written documentation poor. A few scholars like Somers Clarke, F. Ll. Griffith, and Monneret de Villard took a special interest in the numerous ruined churches of Nubia, but in other respects the medieval period was neglected. The numerous and well-preserved Christian Nubian townsites were considered too recent to be of interest, and cemeteries were wholly avoided once it was discovered that Christian Nubian graves contained no objects.

World War II brought an end to all archaeological work in Nubia for more than a decade, but when work by European expeditions resumed in the middle 1950s, British, French, Italian, and German expeditions all began excavating some of the pharaonic and Kushite monumental sites that had been bypassed earlier. At the same time, Sudan's Government Antiquities Service made its first entry into the field and immediately enlarged the scope of Nubian archaeology by investigating both prehistoric (Paleolithic and Neolithic) remains and medieval townsites.

The High-Dam Campaign and After

At the end of the 1950s, the Egyptian government announced plans to build a new and much higher dam at Aswan, one that would back up the Nile waters for more than 100 miles into the territory of the Sudan and complete the final destruction of what had once been Lower Nubia. The new reservoir would not be emptied in the summer, as its predecessor was, and the sixteen major temples in Egyptian and Sudanese Nubia would therefore have to be either physically removed to higher ground or surrendered permanently to the lake's waters. Both the Egyptian government and the newly independent Sudanese government (independent of Anglo-Egyptian rule since 1956) chose the former alternative, and the International Campaign to Save the Monuments of Nubia was launched, with great fanfare, in 1960. The United Nations Educational, Scientific, and Cultural Organization (UNESCO), with headquarters in Paris, agreed to provide overall coordination and to serve as a fund-collecting agency for the campaign, and throughout the next decade it generated a steady flow of publicity that served to focus world attention on the archaeology and culture history of Nubia.

Throughout the 1960s, the tremendous engineering feats of temple removal and reconstruction engaged the world's attention, particularly in the case of the great rock-cut temple of abu simbel. It and most of the other Egyptian temples were taken apart and reassembled on higher ground along the lake shore, close to their original sites. The four temples of Sudanese Nubia were removed to the national capital at Khartoum, several hundred miles to the south of the lake area.

Although much less publicized, the Campaign to Save the Monuments of Nubia had also a purely archaeological component, which was and remains the largest coordinated body of archaeological work undertaken anywhere in the world. Between 1959 and 1970, when the new lake reached its full contour, no fewer than sixty expeditions, representing twenty-three different countries, took part in the effort to excavate the sites of Lower Nubia before their final destruction. The high-dam campaign, as it came to be known, in effect broke the monopoly of Egyptologists on the study of Nubian archaeology, for the new expeditions included a large number of European and American prehistorians as well as classicists, Africanists, and many other kinds of specialists. The newcomers brought new and often more-advanced excavation methods to the Nubian field as well as a new and more global cultural perspective.

The salvage campaigns were organized somewhat differently in Egypt and in the Sudan. In Egypt, the

territory to be flooded was divided into parcels of more or less equal size, and these

Nyerup, Rasmus

(1759-1829)

During the early-nineteenth century, Copenhagen was the administrative and intellectual center of the joint kingdom of denmark and Norway, and, as in the rest of Europe, there was growing concern about the destruction of ancient monuments and archaeological sites. A royal collection of artifacts, or a Kunstkammer, was located in Christianborg, but it was unordered and overflowing with material. sweden had already passed legislation for the protection of its monuments and artifacts, and groups in Denmark and Norway became interested in similar legislation.

Professor Rasmus Nyerup researched these issues and traveled throughout Europe to find the best solutions. In 1801, he visited the Museum of French Monuments in Paris, which had been set up under the new republic, and was most impressed. In 1806, he published the results of his research and recommendations: *Survey of the National Monuments of Antiquity Such as May Be Displayed in a Future National Museum,* the last volume of which outlined his ideas as to how prehistoric material and later remains from Denmark and Norway should be exhibited in a museum similar to the one in Paris.

The defeat of the Danish by the English in 1801 and 1807 stimulated national enthusiasm for past greatness now perceived to be circumscribed by contemporary politics, and by 1806, Nyerup was beginning to receive the first contributions of archaeological material for a future national museum. In 1807, the first legislation for the protection of monuments and archaeological finds was enacted, and it provided for the setting up of a commission to advise on the foundation of a state museum. Nyerup became secretary and member of this commission.

By 1816, the job had become too big for him, and a young numismatist, with a deep interest in antiquity, the right connections, and a talent for classification, christian jurgensen thomsen, replaced him as secretary. Although it was Thomsen who gradually brought the Danish national collection into working order, which involved developing a whole new system of classification, it was Nyerup's survey that helped Thomsen formulate the system. And it was Nyerup's passion for, and knowledge of, antiquities that helped found the Danish National Museum, whose collections and scholars greatly contributed to the elucidation of prehistory, not only in Scandinavia, but also in Europe as a whole.

(1877-1946)

Hugo Obermaier Grad was born into a traditional and cultured family fond of humanist studies and collecting. Between 1886 and 1895, Obermaier's training alternated between the study of the classics (Greek and Latin) and reading the work of the archaeologist heinrich schliemann, which, combined with familiarity with Roman Bavarian antiquities, awoke his interest in archaeology. He then studied philosophy and theology and was ordained as a Catholic priest in 1900.

At the University of Vienna, Obermaier studied geology with A. Penck, anatomy and anthropology with C. Toldt, and prehistoric archaeology with M. Hörnes. In 1904, he obtained his Ph.D. Between 1904 and 1906, he completed his training in Paris where he was in contact with the great French prehistorians Lapparent, Gaudry, marcellin boule, emile cartailhac, Commont, and Capitan and studied French Paleolithic sites, museums, and private collections. It was here and at this time that he began to work with the French prehistorian and priest henri breuil. Indeed, Obermaier and Breuil shared the secretariat position in sessions of the Congrès International d'Anthropologie de Monaco in 1905.

In 1909, Obermaier visited spain for the first time, and he subsequently spent summers participating in the excavations and study of the art of important Cantabrian Paleolithic sites in the caves of Castillo (1910-1914, with Breuil and H. Alcalde del Río), at altamira (1925 on), and in La Pasiega as well as in the Pileta Cave, Málaga, among other sites.

From 1909 to 1911, Obermaier taught a course on the Primitive History of Man at the University of Vienna without giving up his cooperative work with French researchers. In 1911, he went to Paris to work with Boule and Breuil, who were directors of the Institut de Paléontologie Humaine founded by Prince Albert I of Monaco in 1910.

In view of the great importance of his research in Spain, the Real Academia de la Historia (Royal Academy of History) made Obermaier an honorary member in Munich in 1913. His connection with the Institut de Paléontologie was interrupted by the outbreak of World War I, but the Junta para la Ampliación de Estudios e Investigaciones Científicas (Board for the Expansion of Study and Scientific Research) offered him the post of assistant lecturer in the Museo de Ciencias Naturales (Museum of Natural Sciences) in Madrid while the Duke of Alba took him into his household as chaplain. From then until 1938, Obermaier worked in Spain and became a Spanish citizen in 1924. In 1922, at the request of the Philosophy and Arts Faculty of the Universidad Central (Central University) in Madrid, the chair of Primitive History of Man was created for him, and he was head of the section of the Museo Antropológico in Madrid until 1936.

In 1926, he was admitted to the Royal Academy of History, and he was made an honorary doctor by the universities of Friburg, Oporto, and Lisbon as well as the Skandinaviska Släkt Tudie Samfundet (Germanitas Genealogiae Gothica). He belonged to the Academy of Sciences of Bavaria and the Pontificia of the Nuovi Lincei of Rome. He was a member of the deutsches archäologisches institut (German

In 1911, he went to Paris to work with Boule and Breuil, who were directors of the Institut de Paléontologie Humaine founded by Prince Albert I of Monaco in 1910.

In view of the great importance of his research in Spain, the Real Academia de la Historia (Royal Academy of History) made Obermaier an honorary member in Munich in 1913. His connection with the Institut de Paléontologie was interrupted by the outbreak of World War I, but the Junta para la Ampliación de Estudios e Investigaciones Científicas (Board for the Expansion of Study and Scientific Research) offered him the post of assistant lecturer in the Museo de Ciencias Naturales (Museum of Natural Sciences) in Madrid while the Duke of Alba took him into his household as chaplain. From then until 1938, Obermaier worked in Spain and became a Spanish citizen in 1924. In 1922, at the request of the Philosophy and Arts Faculty of the Universidad Central (Central University) in Madrid, the chair of Primitive History of Man was created for him, and he was head of the section of the Museo Antropológico in Madrid until 1936.

In 1926, he was admitted to the Royal Academy of History, and he was made an honorary doctor by the universities of Friburg, Oporto, and Lisbon as well as the Skandinaviska Släkt Tudie Samfundet (Germanitas Genealogiae Gothica). He belonged to the Academy of Sciences of Bavaria and the Pontificia of the Nuovi Lincei of Rome. He was a member of the deutsches archäologisches institut (German

Archaeological Institute) and a honorary member of the Prussian Academy of Sciences (both in Berlin), a honorary member of the Anthropological Society of Vienna, and a honorary fellow of the Royal Irish Academy.

In 1927, Obermaier founded, and directed until 1936, the monthly magazine *Investigación y Progreso* sponsored by the Center for Germano-Spanish Cultural Exchange, which published short papers on all fields of knowledge and research, mostly by German authors. Absent from Spain at the outbreak of the Civil War, he never resumed his academic career or residence there again. He was in Italy for a short time and then, in 1937, became a lecturer in prehistory at the Catholic University of Friburg in Germany, where he died.

Obermaier made important contributions to knowledge of Iberian prehistory in Europe, and to the development of the discipline of prehistory in Spain, through his teaching activity at the University of Madrid and through his research, which was primarily published in German and French. This research was concerned with Quaternary geology, the European Paleolithic period, Paleolithic rock art, and rock art during the postglacial period, both on the Iberian Peninsula and in Africa. He was responsible for the fundamental study of megalithic burial grounds, such as the dolmen of Matarrubilla (Seville) and the passage grave of Soto (Huelva).

Obermaier's first work of synthesis, *Der Mensch der Vorzeit* (1931), was translated into Russian a year later. The books *El hombre fósil* (1916) and *El hombre prehistórico y los orígenes de la humanidad* (1932) have been fundamental references for the study of the Paleolithic period in Spain for several decades.

In Spain, Obermaier's solid empirical training helped “to definitely overcome the distrust and prejudice which existed in academic circles with regard to Prehistory” (Peiro Martin and Pasamar Alzuria 1989-1990, 24). The introduction of Obermaier into these circles was additionally facilitated by his position as a Catholic author and by the sponsorship of the Duke of Alba. His most original contribution was his attempt to convert prehistory into paleoethnology by using ethnographic parallels. He was close to the historical-cultural school, but he did not consider it adequate for the study of the origins of human cultures (Obermaier 1926, 19). His paleoethnology was based on the community of ideas among peoples with the same degree of maturity, “how ever distant they were placed in space and in time” (Pairo Martin and Pasamar Alzuria 1989-1990, 27), and archaeological data. Some of the most important Spanish archaeologists were his pupils.

Okladnikov, Aleksei Pavlovich

(1908-)

The son of a village schoolteacher, Aleksei Pavlovich Okladnikov was born in Siberia and developed an interest in the history, traditions, and folklore of that region. Okladnikov finished school in 1925 and entered the teacher-training

became first director of the Institute of History, Philology, and Philosophy in Novosibirsk. During the 1960s and 1970s, Okladnikov edited and authored the *History of Siberia,* for which he received the USSR's State Award in 1973. He returned to work in Soviet Mongolia and put forward a general scheme of the evolution of the Paleolithic period there. He also studied petroglyphs, discovering and examining thousands of them and publishing his interpretations. He supervised over forty doctoral dissertations, and his students now work in positions in archaeology across the whole of russia. He was awarded the Gold Medal of the Hero of Labor in 1978, on his seventieth birthday.

Olduvai Gorge

Located near the Serengeti Plain in northern Tanzania, Olduvai Gorge is an erosional feature connected to the Rift Valley of Africa. Discovered as a fossil locality by the Germans before World War I (notably by Wilhelm Kattwinkel [1866-1935] and Hans Reck [1886-1937]), Olduvai Gorge was taken up as a research area by louis b. leakey when Reck revisted the area with him between 1931 and 1932. Leakey and his wife, mary leakey, conducted regular fieldwork in the gorge over the next thirty years, but it was not until 1959 (with Mary Leakey's discovery of the cranium of what Louis Leakey named *Zinjanthropus boisei*) that the spectacular discoveries which are synonymous with the place were made.

The landscape of the Olduvai Gorge

(Gallo Images/Corbis)

In many ways, Olduvai Gorge is an ideal fossil locality with a geological history spanning the last 2 million years and fossil-bearing sediments sandwiched by datable volcanic tuffs that have so far yielded australopithecines and early forms of the genus *Homo* (*Homo habilis* and *Homo erectus*). Notwithstanding its importance as a fossil locality, the sediments at Olduvai also contain a vitally important cross-sequence of early hominid stone technology. It is the type site of the Oldawan industry, the oldest yet discovered,

and archaeologists have been able to trace the development of that industry through three phases (A, B, and C) on the site, and there is clear evidence of the replacement of these industries by the Acheulean around 1.4 million years ago.

Skulls discovered in Olduvai Gorge

(Gamma)

Work continued in the Olduvai Gorge after the death of Louis Leakey and the retirement of Mary Leakey from a leadership role at the site. Apart from being one of the world's most significant localities for homind fossils, it is also one of the most important training grounds for the current leaders in paleoanthropology and Pleistocene archaeology.

Olmec Civilization

The Olmec civilization is often called the “mother culture” of mesoamerica. The first complex society of the area, the Olmecs developed and formalized many of the great hallmarks of Mesoamerican civilization.

The term *Olmec* means “people of the land of rubber.” The name was applied by the aztecs to the people living on the southern edge of the Gulf of Mexico-a low-lying, hot, and humid region where rubber trees are native. When archaeological sites with colossal heads carved in basalt were discovered in the area, archaeologists thought that they were relatively recent in date. A few scholars, however, argued for a greater antiquity. With the advent of more refined dating techniques such as radiocarbon dating, the debate was settled: the florescence of Olmec culture dated from about 1200 to 400 b.c.

Many of the most famous Olmec sites are in the steamy lowlands along the southern coast of the Gulf of Mexico, which is where the colossal heads were first found. This area has been called by many scholars the “Olmec heartland,” and sites such as San Lorenzo and la venta are two of the best-known and most excavated of all Olmec sites. Olmec San Lorenzo flourished between about 1200 and 900 b.c. The main part of the site was a huge, partly human-built earth mound some 1,200 meters long by 800 meters wide, on top of which were constructed ceremonial mounds, ritual pools, and a stone drainage system. The huge stone heads and other sculptures (carved from boulders dragged from about 60 kilometers away as the crow flies) were originally set in groups atop the large mound. Some were found to have been intentionally buried in large trenches; recently some heads have been discovered where they were apparently stored for recarving. About 900 b.c. many of the stone monuments at San Lorenzo were defaced (it was presumably at this time that some were buried in trenches), and the site was largely abandoned.

La Venta's florescence followed the decline of San Lorenzo and is dated from about 900 to 400 b.c. By that time the Olmecs had become master craftspeople in another medium, jade, which then became the most prized commodity throughout subsequent Mesoamerican cultures. La Venta suffered a fate similar to that of San Lorenzo: around 400 b.c. some of its monuments were smashed or defaced, and the site was abandoned.

The Olmec heartland was not the only place where the Olmec peoples flourished. Their presence in the highlands of central mexico is also attested at dozens of sites. Major highland Olmec sites included Chalcatzingo (ca. 1000-500 b.c.), just south of Mexico City, and another with the tongue-twister name of Teopantecuanitlan (ca. 900-600 b.c.). These

and many other Olmec sites were strategically located to control important resources and trade and communication routes. The large numbers and sheer volume of imported objects in many such sites clearly offer evidence of the Olmecs' ability to command resources from a wide area.

There are still many unanswered questions regarding the Olmecs. For example, was their widespread presence and influence based on political control, economic power, or the spread of an Olmec religion? All three possibilities have been proposed, but as yet there are no clear answers.

The Olmecs were wonderful artists and produced the first great art style of Mesoamerica. Their stone carvings great and small, their beautifully made and decorated ceramics, and their surviving paintings all are indicative of a mature and self-confident civilization. Many of their images are portraits of their gods, and major advances have been made in recent years in “deciphering” the Olmec pantheon. But other pieces are more personal, from the 20-ton portrait heads of their rulers to the smaller jade masks and other objects that have often been found in large numbers in caches.

What can be called classic Olmec civilization declined around 400 b.c., but the Olmec people survived. One of their achievements in later times was the development of a writing system. Traces indicating the first steps toward developing a script can be seen in monuments from La Venta, but evidence indicates that a full-fledged writing system was not used until near the time of Christ. This script, called epi-Olmec, has been brilliantly deciphered by two American scholars, John Justeson and Terrence Kaufman.

Olorgesailie

Although this Acheulean site south of Nairobi, in Kenya, was first discovered by louis leakey and mary leakey, it is most famously associated with the work of glyn isaac, who excavated there in the 1960s and early 1970s. The site originally aroused considerable interest because of the extensive record of hand-axe manufacture noted by Isaac and because he argued that he had identified clear evidence of butchery there. One part of the site also exhibited a large number of gelada baboon remains near a concentration of hand-axes, which gave rise to some speculation about whether these animals had been killed by hominids. Isaac's original interpretations of Olorgesaillie have been challenged on the basis that the sites are found in sandy stream channels, which at least makes it possible that the accumulations of stones and bones were not the direct result of hominid action.

Ozette Village

The Ozette Village is a Northwest North American coastal shell midden site on the Olympic Peninsula of Washington State. It was occupied for at least 2,000 years until the early-twentieth century, and a portion of the site was preserved intact by a catastrophic mudslide in protohistoric times.

The coastal shell middens of the Olympic Peninsula were first excavated in the early-twentieth century. Radiocarbon dates place the sites within the last 3,000 years. Like many of the coastal sites, Ozette is a shell midden, located at the top of Cape Alava, the westernmost tip of the continuous United States. The village was a multiseason and winter-use food processing site. The primary food resource was whale.

Although the site, composed of several locations between the mainland and the nearby offshore islands, may have been occupied for 2,000 years, a portion was covered in a catastrophic mudslide around 1500 a.d. A mudslide capped the site with a six- to ten-foot layer of clay, rendering a unique opportunity to study the native village on the Olympic Peninsula Pacific coast. Many food-processing remains were recovered at Ozette. Ozette is unique in the preservation resulting from the mudslide. Not only did the clay mud cover occur before contact with Europeans, but it also created a water-soaked environment for the contents of the houses it covered. The wet condition preserved materials such as fiber and wood, which would normally deteriorate very rapidly.

Scientists have been fascinated with the Northwest Coast cultures because of their elaborate development of a mostly sea animal- based subsistence that included hunting whales, sea lions, seals, and sea otters. As a result of the mudslide, Ozette provides a complete material record of village daily and seasonal life. Over 85 percent of the artifacts from Ozette were made of perishable materials that have not survived at other sites such as wood, plant fiber, and structural components.

Ozette was first test-excavated in 1967 by Richard D. Daugherty. Ozette was one of the five Makah Indian tribe villages on the Peninsula, located between a low ridge and a narrow beach facing the Bodeltah Islands. The Makah call themselves “people of the seagulls and rocks.” The area is rich in bird, fish, and mammal life. The Islands protect the shore and waters for canoeing and are part of the village site. Ozette has mainly sea mammal remains, including sea lions, harbor seals, and sea otters. Whale remains are the most abundant of all; over 75 percent of recovered faunal remains are from a few species of whale. The rich variety of sea life brought whales near the shore, where they were hunted from canoes by the Makah. Other abundant food and material resources included ducks, geese, shorebirds, and shellfish.

In the winter of 1947, Daugherty surveyed Ozette as part of an archaeological survey of the entire Pacific coast of Washington. Ethnographic studies were conducted in 1948 and 1949. In 1955 Stallard and Denman conducted a small test excavation at Ozette. In the summers of 1966 and 1967 Daugherty, Roald Fryxell, and Carl Gustafson tested all areas of the site; the earliest radiocarbon dates they received were 2010 +/- 190 years ago. In 1967 Area B, a recent longhouse area, was excavated on the sea bank edge. Normally perishable materials such as fiber matting, cordage, basketry, wooden wedges,

and boxes were found in the test excavations. In 1970, storms uncovered more perishable artifacts on the bank edge. At that time, the Makah Tribal Council asked Daughtery to return and salvage the materials. From that point on, excavations were continued year-round until 1981. After initial testing, a singular excavation project was conducted for over ten years, in cooperation with with the Makah Indian Nation.

The sheer volume of well-preserved fragile artifacts from the site is overwhelming. A special processing and exhibit center was constructed just for Ozette materials. The location required

P

Palenque

Palenque is a classic Maya site and kingdom in the southern state of Chiapas in mexico. Its florescence was during the late classic period, ca. a.d. 600-800, and after its decline and abandonment it became enveloped by dense forest until it was rediscovered in the late-eighteenth century. During the nineteenth century, the beauty of its architecture and art made the site famous, and during the twentieth century, excavations and mapping at the site have revealed an extensive city. The discovery in 1952 of a royal tomb beneath the Temple of the Inscriptions at Palenque was one of the greatest Maya archaeological finds.

Palenque's early history was not particularly stellar. A king list extending back to the early fifth century exists at the site, and some early remains have been found dating from Palenque's early years. Nevertheless, most of Palenque's archaeological remains excavated thus far date to the period after a.d. 600.

Shortly before and after that date, Palenque was devastated by a series of defeats in war. It appears that the capital itself was invaded, and a series of royal deaths around this time indicates that the kingdom was rocked to its foundations. The new king to emerge from this period of upheaval was a man called Hanab'-Pakal. He came to the throne in a.d. 615, at the age of twelve, and proceeded to guide his kingdom to a period of stability and power. By the time he died in 683, Palenque was one of the greatest kingdoms in the Maya area.

Hanab'-Pakal achieved that stability by consolidating the eastern frontier of his kingdom with military victories over his old enemies while a probable kinsman of his simultaneously extended the kingdom to the west. With his kingdom stabilized, Hanab'-Pakal turned his attention to his capital city and embarked on a major building program. Much of the palace at Palenque was his work, and he also began work on his most famous monument, the Temple of the Inscriptions. This temple pyramid, which contains the tomb of Hanab'-Pakal, has an interior stairway (filled in and covered in antiquity) leading to the temple above. Hanab'-Pakal was buried in a beautifully carved stone sarcophagus upon his death at the age of eighty.

Hanab'-Pakal was succeeded by his oldest son, Kan-Balam II, who extended his father's building program, building most notably the famous “Group of the Cross,” an arrangement of three temples that are widely considered to be among the most elegant of all Maya buildings.

Palenque's fortunes waxed and waned over the following decades, but by a.d. 800, the site was in decline. Late construction at Palenque consisted of such work as poorly built walls subdividing the elegant chambers of the palace-a sad conclusion to Palenque's great architectural tradition.

In addition to its beautiful architecture (which features the widest corbeled vaults in the Maya area), Palenque is famous for its elegant art. Many of the temples have beautiful scenes in modeled stucco adorning their outer facades. Stone carving at Palenque was mostly done using flat panels of finely grained limestone rather than the upright, free-standing stelae that typify other sites. These panels were carved and then set on walls in the interior of buildings, so for the most part they have been

With his kingdom stabilized, Hanab'-Pakal turned his attention to his capital city and embarked on a major building program. Much of the palace at Palenque was his work, and he also began work on his most famous monument, the Temple of the Inscriptions. This temple pyramid, which contains the tomb of Hanab'-Pakal, has an interior stairway (filled in and covered in antiquity) leading to the temple above. Hanab'-Pakal was buried in a beautifully carved stone sarcophagus upon his death at the age of eighty.

Hanab'-Pakal was succeeded by his oldest son, Kan-Balam II, who extended his father's building program, building most notably the famous “Group of the Cross,” an arrangement of three temples that are widely considered to be among the most elegant of all Maya buildings.

Palenque's fortunes waxed and waned over the following decades, but by a.d. 800, the site was in decline. Late construction at Palenque consisted of such work as poorly built walls subdividing the elegant chambers of the palace-a sad conclusion to Palenque's great architectural tradition.

In addition to its beautiful architecture (which features the widest corbeled vaults in the Maya area), Palenque is famous for its elegant art. Many of the temples have beautiful scenes in modeled stucco adorning their outer facades. Stone carving at Palenque was mostly done using flat panels of finely grained limestone rather than the upright, free-standing stelae that typify other sites. These panels were carved and then set on walls in the interior of buildings, so for the most part they have been

beautifully preserved. The Tablet of the Cross, for example, is one of the masterpieces of Maya sculptural art. The central scene shows an episode from the Maya creation epic and is flanked by King Kan-Balam II portrayed on his accession day. The hieroglyphic text that accompanies the scene tells about the Maya creation before presenting a list of the kings of Palenque.

Paleolithic Archaeology

Paleolithic archaeology was born in the decades between 1840 and 1860 by the interweaving of a number of intellectual threads that gave meaning to the material relics of the distant past. These included the antiquarian tradition (literally, an interest in artifacts manufactured in the past), a long-standing idea of progress and development as a general human characteristic, the establishment of human antiquity, and the idea of evolution (i.e., descent with modification).

The Discovery of the Archaeological Record

Individuals in many societies have, throughout history, expressed an interest in the human past and its visible antiquities, but much of this was philosophical speculation removed from the study of the remains themselves. It was the European Renaissance that provided the foundations for a material study of the past. The classical writers discussed the ancestors of the northern Europeans, which led some renaissance scholars to speculate on the origin of European antiquities (Daniel 1975, 17). Some sixteenth-century scholars were able to travel to greece and italy and see classical antiquities for themselves. During this time, however, the focus was on art and architecture, on visible standing monuments rather than on buried remains.

Paleolithic Archaeology

Paleolithic archaeology was born in the decades between 1840 and 1860 by the interweaving of a number of intellectual threads that gave meaning to the material relics of the distant past. These included the antiquarian tradition (literally, an interest in artifacts manufactured in the past), a long-standing idea of progress and development as a general human characteristic, the establishment of human antiquity, and the idea of evolution (i.e., descent with modification).

The Discovery of the Archaeological Record

Individuals in many societies have, throughout history, expressed an interest in the human past and its visible antiquities, but much of this was philosophical speculation removed from the study of the remains themselves. It was the European Renaissance that provided the foundations for a material study of the past. The classical writers discussed the ancestors of the northern Europeans, which led some renaissance scholars to speculate on the origin of European antiquities (Daniel 1975, 17). Some sixteenth-century scholars were able to travel to greece and italy and see classical antiquities for themselves. During this time, however, the focus was on art and architecture, on visible standing monuments rather than on buried remains.

edges, but such investigations did not begin in earnest until the second half of the nineteenth century. Gravel terraces were formed from water-laid sediments and contained a stratigraphic record of artifacts and animal bones, but this record was not as substantial as that found in caves (Sackett 2000).

A series of investigations in the late eighteenth and early nineteenth centuries reported the association of human remains or artifacts with the remains of extinct animals, but in each case doubts were cast on the stratigraphic integrity of the finds since they derived from limestone caves known to be affected by water movement. Thus, after French archaeologist Torunal discovered human bones associated with the bones of extinct animals at Grotte de Bize (a cave in southwest France) his colleague Serres claimed that both sets of bones were in the same state of preservation, but a committee led by Cuvier that evaluated the finds dismissed the suggestion. Belgian archaeologist philippe schmerling, excavating a number of caves near Liege in Belgium, uncovered human remains as well as many artifacts associated with rhinoceros and mammoth bones, but reports of these finds were not taken seriously by contemporary scholars (Daniel 1975, 33-35; Sackett 2000).

At kent's cavern in southern England, excavated by amateur archaeologist John MacEnery between 1825 and 1829, artifacts were discovered associated with rhinoceros remains beneath a stalagmite floor. At first MacEnery concluded that the associations were real, thereby demonstrating human antiquity, but after discussions with Buckland he became convinced that they were the result of postdepositional admixture (Grayson 1983, 75-76). Buckland himself sought an explanation for human remains from Goats' Hole Cave in Paviland (England) that would enable him to associate both the human remains and the artifacts he found with the Roman-British period (Daniel 1975, 37; Grayson 1983, 67).

The Establishment of High Human Antiquity

Although the number of discoveries of artifacts associated with bones of extinct animals continued to mount, the demonstration of high human antiquity required that the stratigraphic integrity of deposits be accepted. This first occurred at two locations: in the Somme gravel terraces in northern France and at brixham cave in England. From 1837 onward, inspired by the earlier studies of French archaeologist Picard, jacques boucher de perthes collected artifacts and the bones of extinct animals from the Somme River gravels. He published his findings in *Antiquités celtiques et antédiluviennes* in 1847, describing the stratigraphic position and integrity of his discoveries (Daniel 1975, 58; Grayson 1983, 119). However, intertwined with his stratigraphic observations were a range of speculative assertions that did little to further the acceptance of his views by his contemporaries. He assigned symbolic significance to many of the artifacts he discovered and interpreted them all according to a catastrophist theory that would have been more at home in the late eighteenth century than in the 1840s (Grayson 1983, 126; Sackett 2000).

In 1858, a grant was given to amateur geologist william pengelly to excavate the newly discovered cave at Brixham in search of paleontological samples. The project was supervised by a group of eminent British geologists: joseph prestwich, Lyell, hugh falconer, Richard Owen, and R. Godwin-Austen. Excavations revealed the bones of extinct animals, but unexpectedly, thirty-six artifacts were also recovered beneath a stalagmitic layer three to eight inches thick. Their discovery sparked a variety of explanations, but these were quickly unified as the result of a visit by Falconer to the sites of Boucher de Perthes in 1858. Impressed by what he saw at the Somme excavations, Falconer encouraged Lyell, Prestwich, and Godwin-Austin, together with the antiquarian Henry Flower and sir john evans, to also visit the sites of Boucher de Perthes. As a result of these visits, Prestwich and Evans were able to photograph a hand-axe *in situ*, associated with the bones of extinct animals at st. acheul in northern France (Daniel 1975, 58; Grayson 1983, 172-176; Sackett 2000).

In 1859, Prestwich read a paper to the Royal Society recalling Frere's work at Hoxne and describing how Pengelly's work at Brixham and

PREV NEXT

the discoveries of Boucher de Perthes in the Somme had convinced him of high human antiquity. Evans read a similar paper to the society of antiquaries of london (Daniel 1975, 58). A number of French scholars supported the British proposals. édouard lartet, for instance, almost immediately thereafter published the results of a study of cut marks on the bones of extinct animals that suggested the presence of humans in the remote past. The speed of his publication suggested that he had accepted high human antiquity sometime before the 1859 consensus (Sackett 2000).

The year 1859 also marked the publication of Charles Darwin's *Origin of Species,* but the two events were not connected. Darwin's theory of evolution to explain human ancestry was owing to Thomas Henry Huxley, who had published *Man's Place in Nature* in 1863 (Daniel 1975, 65), and Darwin's theory dealt with descent with modification, that is, successive generations of a species over time change in form, character, and behavior. The establishment of high human antiquity demonstrated that humans, like other animal species, had a long history on earth, which inevitably led to questions about the nature of human evolution.

The intellectual climate had changed considerably before 1859 as a result of debates between supporters of monogenesis and polygenesis. Those who supported a theory of monogenesis suggested that all humans belonged to a single species, and this was the prevailing view during the late eighteenth and early nineteenth centuries. However, after the 1840s, scholars who believed in multiple human species, or polygenesis, were able to use archaeological discoveries made in Egypt to argue that different human races were in existence as early as 2500 b.c. If a pre-1859 biblical chronology was accepted for the antiquity of humanity, there remained insufficient time for human racial differences to occur. Morton was able to use this evidence in support of the case of polygenesis (Grayson 1983, 158). In attempting to refute this position, monogenesists like Pickard were forced to abandon the biblical chronology to provide sufficient time for the development of racial differences. Therefore, well before 1859, many scholars were convinced that the Bible was inadequate as a source for determining human antiquity.

Early Years of the Discipline: 1860-1880

Three challenges dominated archaeological research following the acceptance of high human antiquity: establishing the validity of the three-age system; explaining progress in terms of economic, social, and political factors; and relating patterns of technological change in the archaeological record to human evolution.

French archaeologists proposed two ages of stone, the *période de la pierre taillée* (flaked-stone tools) and the *période de la pierre polie* (polished-stone tools), and these periods were adopted by Sir John Lubbock (lord avebury) in his book *Pre-historic Times* (1865*).* He applied the term Paleolithic to the period when artifacts were deposited with the remains of mammoths, cave bears, and rhinoceros, and the term Neolithic was applied to the period when polished stone artifacts were made. Such technological changes could be demonstrated through stratigraphic excavation and showed a pattern of increasing complexity through time-thus illustrating the universality of human progress.

By the 1860s, the twofold division had been increased to four based on the excavations of Lartet and henry christy in the Dordogne region of southern france (Lartet and Christy 1865-1875), where Lartet provided stratigraphic evidence for their existence based on associated animal remains. The cave period of the aurochs, or bison, was preceded by the reindeer period, the woolly mammoth and rhinoceros period, and finally the cave-bear period. To these Garrigou added earlier periods based on the presence of warm climate fauna. Finds from the Somme River gravel terraces associated with such fauna suggested that the people there lived mainly in open sites. The great bear and mammoth periods were

characterized by both rock-shelter and open-site deposits (Daniel 1975, 100).

In his use of paleontological categories as a basis for organizing archaeological materials, Lartet was well ahead of his time (Daniel 1975, 101). Indeed, the book by Lartet and Christy (1865-1875) on their Dordogne research reads

like an ambitious attempt at paleoethnology (Sackett 2000). However, it was not a direction that was followed for very long, and French archaeologist gabriel de mortillet reformulated Lartet's scheme, substituting archaeological names for the paleontological descriptions.

The hippopotamus age became the Chellean, later renamed the Abbevillian. Much of the great bear and mammoth age was classified as Mousterian, named after the site of le moustier in central France. De Mortillet identified the mammoth period with the site of Aurignac and called it Aurignacian. The reindeer age was divided into two, the earliest ultimately named the Solutrian after the site of solutré in eastern France, and the later named after la madeleine in central France (Daniel 1975, 103). However, even though site names had replaced the names of animals as labels, the scheme still owed much to paleontology. Each stage was thought of as an epoch, a vaguely defined temporal phase, rather than as an artifact complex (Sackett 1991). It was easy, therefore, to relate a unilinear succession of technological change to a unilinear theory of human evolution (Trigger 1989, 95-97).

The idea that all human groups passed through the same stages of cultural development, albeit not at the same time nor at the same rate, provided the rationale for using more-primitive living human groups to model the lifestyles of prehistoric groups with similar technologies. This analogy also provided an answer to the problem of explaining progress in terms of economic, social, and political factors. Huxley (1863) suggested that the Australian Aborigines could be used to flesh out reconstructions of the Neanderthals and their Middle Paleolithic tool kits (Trigger 1989, 113) while Lubbock (1865) applied descriptions of the Eskimo lifestyle to paint a picture of long-extinct Upper Paleolithic communities (Trigger 1989, 115).

By the 1880s, the Enlightenment ideal of universal human progress had been replaced by the idea that differences between cultural groups had deep-seated biological origins. As nationalism was encouraged, so was the search for the biological roots of those national characteristics, and racial factors replaced environmental ones as explanations for the different historical trajectories of different cultural groups (Trigger 1989, 111). Darwinian evolution seemed to equate with these ideas and helped to lay the foundations for a form of cultural evolutionism in which natural selection was invoked to explain both the differences between cultures and the biological capacity for culture. Thus, the sequence of stone artifact technologies described by Paleolithic archaeologists seemingly provided the tangible evidence needed to document the evolution of modern human societies (Sackett 1991).

Artifacts as Cultural Markers

Toward the end of the nineteenth century, a growing European nationalism fostered an interest in the history and archaeology of particular ethnic groups and focused attention on the archaeology of more recent time periods. By now, archaeologists had documented far more variation in material culture assemblages than could be accommodated comfortably within a unilinear evolutionary framework. In seeking to explain this variation, a resemblance was noted between the patterning of archaeological assemblages and differences in the material cultures of living peoples, with the diffusion of ideas contributing to the creation of distinct culture areas (Robertshaw 1990; Sackett 1981; Trigger 1989, 122).

Those observations laid the foundations for an explanatory model that was to dominate Neolithic, Bronze, and Iron Age archaeological research for much of the twentieth century. The model's development can be traced through the work of oscar montelius on typology and seriation (Trigger 1989, 158), gustaf kossinna on material remains used to track the history of ethnic groups (Trigger 1989, 163), and the late-nineteenth-century German ethnologists who established the association between material remains and ethnic groups, but it is perhaps best exemplified by the work of English archaeologist vere gordon childe (Childe 1925).

Childe sought to identify recurring sets of material remains whose spatial and temporal boundaries could be used to define the boundaries between prehistoric cultures. Those prehistoric cultures were considered analogous to

in the first half of the twentieth century, knowledge of North African prehistory was extended by the work of Sandford and Arkell (1929, 1933, 1939) in the Nile Valley, gertrude caton-thompson (1934) at Kharga Oasis in Egypt, and charles mcburney and R. W. Hey (1955) in Cyrenaica in what is now eastern Libya.

Initial work in the Near East was carried out by Godefroy Zumoffen between 1897 and 1900, and he was followed by Henry Neuville (1934, 1951) and Francis Turville-Petre (1932). However, the most significant excavations were by Neuville, Stékelis, and dorothy garrod (Garrod and Bate 1937) at Skhul, el-Wad, and et-Tabun in Israel.

In 1926, louis s. leakey began research in the Rift Valley of Africa for sites. In his *Stone Age Cultures of Kenya Colony* (1931) Leakey used European terminology to describe the African industries. Astley John Hilary Goodwin and Clarence Van Riet Lowe (1929) developed the first lasting African terminology based on their assessment of archaeological materials on the terraces of the Vaal River valley. They introduced the classic tripartite sequence of early, middle, and late Stone Age, which was applied widely in Africa during the 1930s and 1940s (Fagan 1981). However, Europe, not Africa, was seen as the source for new ideas. The Sahara acted as a significant barrier preventing movement from south to north and allowing only "higher" cultures to move north to south (Deacon 1990).

Parallel Phyla after World War II

Explanation for change according to the parallel phyla scheme was found in diffusion and migration, sometimes leading to quite dramatic explanations for supposed major changes in the artifact record. A species difference, for instance, was proposed to account for the change from the Mousterian to the initial Upper Paleolithic by both Burkitt in 1933 and Leakey in 1934 (Isaac 1972b).

After World War II, the French archaeologist françois bordes and his colleague Maurice Bourgon developed a new approach to the description, analysis, and interpretation of Lower and Middle Paleolithic artifact assemblages. This approach, which was to become enormously influential (Bordes 1950; Bordes and Bourgon 1951), separated the description of an artifact assemblage from the description of the artifacts it contained and distinguished the description of artifact forms from the description of the techniques involved in their production. The Bordes approach thus removed the circularity inherent in the work of Breuil and Peyrony, who had relied on certain diagnostic artifact types (type fossils) to simultaneously describe the content of an assemblage and assign it a position in an evolutionary scheme (Sackett 1981). Although developed initially to describe French Lower and Middle Paleolithic assemblages, Bordes's approach soon became the accepted method for characterizing assemblages from other parts of Europe as well as those from North Africa, the Middle East, and Asia.

Bordes used a common set of attributes to describe sixty-three different tool types that were recurring features of Middle Paleolithic assemblages. These attributes included the location of the retouched edges on the tool blank, the type of retouch applied to those edges, the number of retouched edges, and their shapes (Bordes 1961a, 1961b). The great majority of artifacts recovered from Lower and Middle Paleolithic sites could be classified using this typological scheme.

There are several reasons for the rapid and widespread acceptance of Bordes's methodology. First, the classificatory scheme on which it was based proved applicable to Lower and Middle Paleolithic artifact assemblages from many different contexts in many different regions. Second, artifact assemblages were not characterized solely on the basis of a few, apparently diagnostic, tool types. Third, the methodology facilitated comparisons between assemblages. Not only were they described using the same set of tool types, but Bordes introduced a simple statistical method for describing the composition of artifact

assemblages that showed how the percentage frequency of each tool type found in an assemblage altered in response to changes in the percentage frequencies. Fourth, because it provided a way of examining spatial and temporal variation in the co-occurrence of artifact

types, Bordes's method broadened the range of interpretative possibilities. Finally, the conclusion that variation in contemporaneous artifact assemblages reflected the existence of established cultural traditions brought Paleolithic archaeology closer to the explanatory frameworks being applied under the influence of Childe.

Functional Approaches

At the same time that Bordes was discussing cultural traditions, other archaeologists were exploring the possibility that recurring assemblage types might represent seasonal or functional differences in activities undertaken at different sites (e.g., Binford and Binford 1966; Clark 1959; Freeman 1966; McBurney 1950; Oakley 1952, 18). Of these, lewis binford's study became the best known because of a lively debate between Binford and Bordes (e.g., Binford 1973; Bordes 1973; Bordes and de Sonneville-Bordes 1970), a debate that arose from fundamentally different views about the type of behavioral information preserved in the archaeological record.

Bordes argued that variation in material remains reflected ethnic or cultural groupings. Binford argued that differences in the activities undertaken in different parts of the landscape, at different times of the year, were such pervasive features of hunter-gatherer societies that they must have been major influences on the composition of past material culture assemblages. At the heart of the debate lay the problem of disentangling the effects of functional and stylistic differences on the composition of artifact assemblages and of deciding which artifact attributes were stylistic or functional in origin.

Although the debate between Bordes and Binford dominated the literature for a time, there were archaeologists working on other time periods who were keen to explore the interpretative implications of new data being generated, not only by an expanding archaeological record but also by the incorporation of new techniques. For example, in a discussion of the implications of new dating techniques for the interpretation of the archaeological data, glyn isaac (1972a) noted that there are orders of magnitude of difference in the geographic and temporal distributions of Lower and Middle Paleolithic assemblages when compared with those recovered from the Upper Paleolithic record.

Isaac suggested that these differences could relate to the evolution of specific behavioral capacities and that different explanations for the existence of patterned variation in artifact assemblages might be sought for different portions of the record. For example, he postulated that while Upper Paleolithic artifacts may have served as cultural markers, this could not be considered an appropriate explanation for the similarities and differences exhibited, for example, by Acheulean artifact assemblages, simply on the basis of the spatial and temporal scale of the documented pattern of variation. This observation, coupled with the long-standing suggestion that the Upper Paleolithic record marked the establishment of modern human populations and a unique set of behavioral traits (e.g., Burkitt 1955, 143-161; McBurney 1950), was reinforced by studies of many different components of that record (e.g., Binford 1973; Mellars 1989).

From the 1960s to the Present

In the last four decades of the twentieth century, another shift occurred in the way Paleolithic archaeologists ascribed meaning to the succession of stone technologies first documented in the late nineteenth century. Even during the 1950s, a number of archaeologists working with the earliest Paleolithic record had expressed dissatisfaction with the multiple phyla concept (Isaac 1972b), opting instead for an explanation that involved relating assemblage differences to different activities between sites (e.g., Clark 1950, 1959; Howell and Clark 1963; Kleindienst 1961). Following this lead, archaeologists once again became interested in the comparative method as a means for learning about

human evolutionary history.

During the late nineteenth century, evolutionists like Darwin, Huxley, and Haeckel had begun to ask questions about the kind of ancestor that had given rise to humans. In trying to answer the question, they attempted to identify the closest living relatives to humans and drew up a list of human-versus-ape characteristics.

types, Bordes's method broadened the range of interpretative possibilities. Finally, the conclusion that variation in contemporaneous artifact assemblages reflected the existence of established cultural traditions brought Paleolithic archaeology closer to the explanatory frameworks being applied under the influence of Childe.

Functional Approaches

At the same time that Bordes was discussing cultural traditions, other archaeologists were exploring the possibility that recurring assemblage types might represent seasonal or functional differences in activities undertaken at different sites (e.g., Binford and Binford 1966; Clark 1959; Freeman 1966; McBurney 1950; Oakley 1952, 18). Of these, lewis binford's study became the best known because of a lively debate between Binford and Bordes (e.g., Binford 1973; Bordes 1973; Bordes and de Sonneville-Bordes 1970), a debate that arose from fundamentally different views about the type of behavioral information preserved in the archaeological record.

Bordes argued that variation in material remains reflected ethnic or cultural groupings. Binford argued that differences in the activities undertaken in different parts of the landscape, at different times of the year, were such pervasive features of hunter-gatherer societies that they must have been major influences on the composition of past material culture assemblages. At the heart of the debate lay the problem of disentangling the effects of functional and stylistic differences on the composition of artifact assemblages and of deciding which artifact attributes were stylistic or functional in origin.

Although the debate between Bordes and Binford dominated the literature for a time, there were archaeologists working on other time periods who were keen to explore the interpretative implications of new data being generated, not only by an expanding archaeological record but also by the incorporation of new techniques. For example, in a discussion of the implications of new dating techniques for the interpretation of the archaeological data, glyn isaac (1972a) noted that there are orders of magnitude of difference in the geographic and temporal distributions of Lower and Middle Paleolithic assemblages when compared with those recovered from the Upper Paleolithic record.

Isaac suggested that these differences could relate to the evolution of specific behavioral capacities and that different explanations for the existence of patterned variation in artifact assemblages might be sought for different portions of the record. For example, he postulated that while Upper Paleolithic artifacts may have served as cultural markers, this could not be considered an appropriate explanation for the similarities and differences exhibited, for example, by Acheulean artifact assemblages, simply on the basis of the spatial and temporal scale of the documented pattern of variation. This observation, coupled with the long-standing suggestion that the Upper Paleolithic record marked the establishment of modern human populations and a unique set of behavioral traits (e.g., Burkitt 1955, 143-161; McBurney 1950), was reinforced by studies of many different components of that record (e.g., Binford 1973; Mellars 1989).

From the 1960s to the Present

In the last four decades of the twentieth century, another shift occurred in the way Paleolithic archaeologists ascribed meaning to the succession of stone technologies first documented in the late nineteenth century. Even during the 1950s, a number of archaeologists working with the earliest Paleolithic record had expressed dissatisfaction with the multiple phyla concept (Isaac 1972b), opting instead for an explanation that involved relating assemblage differences to different activities between sites (e.g., Clark 1950, 1959; Howell and Clark 1963; Kleindienst 1961). Following this lead, archaeologists once again became interested in the comparative method as a means for learning about

human evolutionary history.

During the late nineteenth century, evolutionists like Darwin, Huxley, and Haeckel had begun to ask questions about the kind of ancestor that had given rise to humans. In trying to answer the question, they attempted to identify the closest living relatives to humans and drew up a list of human-versus-ape characteristics.

Common characteristics could then be attributed to the last common ancestor and evolutionary scenarios developed to identify the critical changes that had led to the development of modern humans. Darwin, for instance, argued that movement to the ground, bipedal locomotion, which freed the hands, and natural selection resulting from an adaptive system involving tool use, social cooperation, and warfare were all critical components leading to the development of modern humans. Paleolithic archaeologists were faced with the challenge of finding supporting evidence for such scenarios.

During the 1940s, the new evolutionary synthesis had finally done away with goal-directed change by integrating natural selection and migration with mutation and chance. Washburn (1951a, 1951b) integrated this new evolutionary theory into physical anthropology, shifting the emphasis from descriptive anatomy to the analysis of adaptation. In one of the first studies to come from the new physical anthropology, Bartholomew and Joseph B. Birdsell (1953) proposed that the loss of the estrus cycle and continuing mutual sexual attraction among humans demonstrated that the long surviving family was central to human society. These two men suggested that early hominid groups formed stable family groups providing parental care to dependent young. Following physical anthropologist raymond dart's (1949) suggestion that Australopithecines were dependent on tools for hunting and butchering animals, they proposed that sexual dimorphism was associated with competition among males for females and that aggressive hunting behavior was derived from this dimorphism (Zihlman 1997).

Studies like that of Bartholomew and Birdsell, together with work by Dart, suggested a feedback between large brains, bipedalism, and tool use. Although it is now known that Dart's interpretation of the Makapansgat faunal assemblage (literally, the animal bones that were excavated at the site) was in error (Brain 1981), his work, together with that of other scholars, set out a methodology for extracting behavioral information from the material debris left in archaeological sites. In the years since 1960, archaeologists have used evolutionary theory to generate different scenarios that can be tested against the Paleolithic record. The best-known example of this research is Isaac's food-sharing hypothesis.

Isaac noted two major differences between apes and humans: humans may feed as they forage as apes do, but apes do not regularly postpone food consumption until they have returned to their home base; also, humans actively share food as they acquire it (Isaac 1978). Based on these observations, Isaac hypothesised that the HAS and KBS sites at Koobi Fora (East Africa, Kenya) were formed by hominids carrying stones and bones to a site. These differences in turn suggested the existence of provisioning, the existence of home bases, and the sexual division of labor early in human prehistory.

Beginning in the 1940s, African archaeologists also changed the way they excavated sites. The first excavation of a “living floor” by Louis Leakey and mary leakey occurred at olorgesailie in 1943 (Fagan 1981), and it was followed by similar excavations at Isimila by F. Clark Howell (Howell, Cole, and Kleindienst 1962) and Kalambo Falls by j. desmond clark (Clark 1969, 1974).

At Isimila, Howell emphasized artifact variation within one stratigraphic horizon, thereby challenging the concept of progressive typological and morphological development through time (Gowlett 1990). Interest in defining living floors spread from Africa to Eurasia (Isaac 1972b), and a series of excavations in Europe and the Middle East were conducted at a range of sites: for example, Torralba-Ambrona (Howell 1966), Latamne (Clark 1966), Vértesszöllös (Kretzoi and Vértes 1965), 'Ubeidiya (Stekelis 1966), and Terra Amata (de Lumley 1969). In the Dordogne region in France, Hallam L. Movius (1974) selected Abri Pataud for excavation and adopted a strategy that would allow for the exposure of horizontal surfaces of contemporary occupation.

Conclusion

Among the more recent Paleolithic studies, some seek to provide a more detailed investigation of the patterns of similarity and difference which characterize each division of the record

Palynology in Archaeological Research

Archaeological palynology is the study of ancient pollen that is preserved in a few particular archaeological deposits or in natural deposits that can be related to archaeological events by dating. The on-site study of pollen from archaeological deposits can show what the vegetation around the site was like or what plant materials were deposited there. The off-site study of pollen from natural deposits such as lake sediments can show what the effects of human activity were on the surrounding landscape at various times.

Beginnings: Landscape Change, Dating, and Archaeology

The first application of pollen analysis was to explore vegetation history in the 1920s, first in sweden by the geologist Lennart von Post (Erdtman 1967). The new science spread rapidly throughout northern and central Europe (including Russia) so that by 1927 more than 150 papers had been published (Erdtman 1927). In Great Britain, following Gunnar Erdtman (1924), a. j. h. godwin and M. E. Godwin (1933; H. Godwin 1940) began a long tradition of pollen analysis with archaeological connections. As pollen analysis developed in Europe (Faegri 1981), a significant development was the division of pollen diagrams into zones representing time phases with characteristic pollen records, first in denmark (Jessen 1935) and then somewhat similar schemes in other places such as Britain (Godwin 1940). These zonations provided the basis for the initial use of pollen analysis, as they provided a means of dating suitable sediments that was used for the next twenty years until the advent of radiocarbon dating. Erdtman listed the publications on palynology in the journal *Geologiska Foreningens I Stockholm Forhandlingar* each year from 1927 to 1955, thus providing thorough coverage of the early literature.

The Effects of Human Settlements on Past Landscapes

Early research worked out vegetation history, mostly that of woodlands, from the study mainly of tree and shrub pollen. This developed into study of the influences of climate and human activity on past vegetation (Bertsch 1928). Refinements in technique led to the identification of more types of pollen, particularly those of herbs, many of which (such as weeds) are important indicators of past human activity (Firbas 1934); for example, cereal pollen indicates farming (Firbas 1937). These refinements permitted the interpretation of certain features seen in pollen diagrams from natural deposits as the faint traces of the activities of the first farmers in the Neolithic period in Denmark (Iversen 1941) and in Norway (Faegri 1944).

One such feature is the elm decline, which is a noticeable and widespread reduction in elm pollen at a particular point in many pollen diagrams that is used to divide the Atlantic pollen zone from the succeeding subboreal one. There has been much discussion over the years whether the elm decline was caused by human activity, climatic change, or other factors.

Many pollen diagrams also show changes just above (after) the decline horizon, and Iversen (1941) elegantly showed that these probably represent prehistoric episodes of woodland clearance, farming, and abandonment, which he termed *Landnam.* The pattern of landscape change as a result of human activity has since been studied and dated in detail up to the present.

Recent archaeological palynology in central Europe has concentrated on particular aspects of archaeology, such as the detailed history of vegetation change as a result of human activity near a particular settlement area, such as H.-J. Beug's (1992) study in northern Germany, covering the period from the Neolithic period to the Middle Ages, in which the cereals wheat, barley, oats, rye, and millet are distinguished. Other work has concentrated upon a particular culture, such as A. J. Kalis's (1988) work on the early Neolithic *Linearbandkeramik,* also in Germany.

Another development of archaeological palynology since the 1960s has been its extension to drier regions with fewer suitable deposits, such as the lands bordering the Mediterranean. Here the effects of human occupation are expressed rather differently when compared with human occupation effects further north. Beug (1962) worked on sites in Croatia while S. Bottema and H. Woldring (1990) have summarized results from the eastern Mediterranean region, K.-E. Behre (1990) those from the Near East, and A. C. Stevenson (1985) those from the western Mediterranean. In these areas, woodland disturbance swiftly led to its replacement by evergreen woods and then by scrub. Some typical crops

such as *Olea* (“olive”) and *Vitis* (“vine”) are also recorded.

In North America, archaeological aspects of pollen analysis from natural sites have also been a minor interest compared with quaternary vegetation change as a whole. The effects of human

Beug's (1992) study in northern Germany, covering the period from the Neolithic period to the Middle Ages, in which the cereals wheat, barley, oats, rye, and millet are distinguished. Other work has concentrated upon a particular culture, such as A. J. Kalis's (1988) work on the early Neolithic *Linearbandkeramik,* also in Germany.

Another development of archaeological palynology since the 1960s has been its extension to drier regions with fewer suitable deposits, such as the lands bordering the Mediterranean. Here the effects of human occupation are expressed rather differently when compared with human occupation effects further north. Beug (1962) worked on sites in Croatia while S. Bottema and H. Woldring (1990) have summarized results from the eastern Mediterranean region, K.-E. Behre (1990) those from the Near East, and A. C. Stevenson (1985) those from the western Mediterranean. In these areas, woodland disturbance swiftly led to its replacement by evergreen woods and then by scrub. Some typical crops

such as *Olea* (“olive”) and *Vitis* (“vine”) are also recorded.

In North America, archaeological aspects of pollen analysis from natural sites have also been a minor interest compared with quaternary vegetation change as a whole. The effects of human

activity have often been slighter than in Europe, and therefore harder to detect and to separate from other factors such as climate. E. T. Burden, J. H. McAndrews, and G. Norris (1986) succeeded in showing the vegetation changes caused first by Native Americans and then by European settlers (characterized by the presence of *Plantago lanceolata,* an alien in North America), in Ontario, canada.

Other parts of the world have been less intensively studied. In Central America, D. J. Rue (1987) has conducted archaeologically oriented palynology, and others have done so elsewhere; for example, R. L. Clark (1983) in Australia, N. Fuji (1990) in japan, and Y. V. Kuzmin (1992) in eastern russia. Although there are many other pollen results from different parts of the world, only few of them have sufficient detail with regard to data and chronology to be very useful for archaeological research.

Pollen Analyses of Wet Archaeological Deposits

K. Bertsch (1926) pioneered on-site archaeological applications of pollen analysis in Germany, and H. Harri (1929) did so in switzerland on waterlogged lake shore settlements. This kind of work has been done by a few other researchers, such as W. Beijerinck (1931), who carried out on-site studies of settlement mounds *(terpen)* in the netherlands that included pollen analyses.

Many of the later developments have been made by researchers concentrating on one particular aspect of archaeological palynology in a particular region. Where archaeological deposits were wet enough for good pollen preservation, pollen analysis could be done on the occupation deposits themselves, as in the case of occupation mounds in northern Germany (Korber-Grohne 1967).

Further work has been done on lakeshore settlements around the Alps, which provide wet sediments closely linked with the occupation of the sites. At Seeberg-Burgaschisee-Sud, one pollen diagram was obtained from a sediment profile going through the archaeological occupation layer itself, and others were obtained from profiles through natural deposits at increasing distances from the settlement, thus tracing the decreasing effects of occupation at increasing distances from the site itself (Welten 1967). This site also provided rare evidence of leafy branches having been brought to the site for fodder, evidence obtained from pollen records of plants that are in flower when the leaves are fully developed such as *Tilia* (lime), *Acer* (maple), and *Hedera* (ivy).

Wet archaeological sediments have also been studied from deposits from wells (Dauber, Fietz, and Lang 1955; Firbas 1930), ditches, etc., at otherwise dry archaeological sites. Coprolites (fecal remains), mostly from dogs, have been analyzed in Europe (Paap 1976) along with a number of other archaeological materials (Greig 1982), including human feces (Knights, Dickson, Dickson, and Breeze 1983).

Waterlogged archaeological deposits in which pollen is preserved often also contain other remains such as the seeds of plants, remains of insects, and eggs of parasitic worms. The study of a range of biological remains from a particular deposit can provide complementary results on past environments, for example the research on Lindow Man, a prehistoric bog body found in Cheshire, in England (Stead, Bourke, and Brothwell 1986).

Pollen Analyses of Dry Archaeological Deposits

Certain soil conditions can preserve pollen. Acid soils, for example, inhibit the processes of decay. Some archaeological features such as burial mounds or structures built from turf sod have buried ancient soil surfaces together with the preserved pollen content. Such soil pollen has been extensively studied in Britain by G. W. Dimbleby (1962) and in the Netherlands by H. T. Waterbolk (1950) and by A. J. Havinga (1963).

Cave sediments have been studied by M. van Campo and andré leroi-gourhan (1956) as well as a number of other workers in France. Some archaeological objects may themselves contain pollen and even contribute to its preservation by the presence of metal corrosion products, for example, the remains of honey or mead in a bronze container found in southern Germany and studied by U. Korber-Grohne (1985).

Korber-Grohne (1985).

PREV NEXT

In the United States, archaeological pollen analysis has involved much work on coprolites, often preserved in dry conditions in arid environments. Some work began in the 1960s, such as that by E. O. Callen and T. W. M. Cameron (1960), P. S. Martin and F. W. Sharrock (1964), and J. Schoenwetter (1962). Human fecal material from latrine pits has also been studied (Reinhard, Mrozowski, and Orloski 1986). The results yield much information about the diets of the people concerned, both Native American and European.

Syntheses of Results

As sufficient results have accumulated in particular regions, they have been synthesized into regional accounts of landscape change including archaeological considerations, as, for example, those covering central and northern Europe (Firbas 1949-1952), the British Isles (Godwin 1956), and the Netherlands (van Zeist 1967). Further work has resulted in highly detailed regional studies, for example, in northern Germany and southern Scandinavia (Muller-Wille, Dorfler, Meier, and Kroll 1988), southern Germany (Kuster 1988), poland (Ralska-Jasiewiczowa 1977), and a summary of Europe (Behre 1988). Useful collected works have been published on subjects such as human impact in pollen results (Behre, ed. 1986), and on archaeological palynology (Dimbleby 1985; Renault-Misovsky, Bui-Thui-Mai, and Giraud 1985).

Panama

Before World War I Panamanian archaeology was known largely through grave goods collected by dilettantes in Panama's western isthmus. Museum studies focused on the Chiriquí culture (now known as Gran Chiriquí) (Haberland 1984). Paleolithic stone tools from a Caribbean valley (along the Río Obispo) and shard scatters in Darién forests (Cana) were soon forgotten. A 1915 exhibition of pottery from Coclé included polychrome vessels that were rare in Chiriquí tombs, and in their designs German archaeologist max uhle (1924) saw Maya influences. Soon after, freelance writer Alpheus Hyatt Verrill drove disorderly trenches through the El Caño site, mistakenly believing that a volcanic eruption had destroyed a temple there. The sculpted and unsculpted monoliths of the site in fact belonged to a ceremonial center, which has been largely overlooked by professional archaeologists. In the early 1930s Harvard University sent archaeologists Henry Roberts and Samuel K. Lothrop to Sitio Conte; they excavated 59 graves in which mostly adult males were buried with large quantities of pottery and

personal ornaments, including more than 1,000 metal objects. In 1940 J. Alden Mason excavated a further 41 graves.

Lothrop derived Panama's second archaeological culture-Coclé-from Sitio Conte's mortuary arts and believed it spanned a period of 190 years before the Spanish conquest (a.d. 1330-1520). He assumed that Sitio Conte's hinterland was the Coclé culture's epicenter, from which its influences emanated to neighboring regions. He thought that most pottery and jewelry was made locally and that a few objects were imports from colombia and ecuador. Influenced by the Spanish chronicler Fernández de Oviedo, he proposed that the richest graves belonged to hereditary chiefs and nobles and the more modest ones to commoners and slaves.

In 1927 Swedish archaeologist Sigvald Linné traveled by boat with Baron Nordenskiöld to the Pearl Islands, the Darién, and the Caribbean coast east of the Calovébora River. Although his mandate was to search for contacts with “higher” cultures and for evidence of transisthmian migrations, Linné intuitively laid the foundations

Paphos

An area on the flat lands near the sea in the modern Cypriot city of Paphos has been designated a world heritage site because of the quality and quantity of archaeological material, primarily from the Hellenistic and Roman periods, to be found there. Large rock-cut tombs of the Hellenistic period (the so-called tombs of the kings) demonstrate architectural links with Alexandria. Nea Paphos was the administrative center of cyprus in the Roman period. Excavated public buildings of this period include an odeon with adjacent agora, a temple of Asklepios, and a theater. Villas of the period, excavated by a Polish team under A. W. Daszewski, are decorated with fine mosaics. One of these (the house of Theseus) may have been the villa of the Roman governor. Recent expansion of the modern city and hotel construction in the

area have placed severe stress on the archaeological resources, so the Department of Antiquities is constantly engaged in rescue excavations and related mitigation programs.

Palaepaphos, 15 kilometers east of Nea Paphos, was an important center in earlier periods and the center of the ancient cult of Aphrodite. This area has been extensively explored by a long series of archaeologists, including some working for the Cyprus Exploration Fund (1888), T. B. Mitford and J. H. Iliffe (1950- 1953), and David Rupp's long-running Canadian Palaepaphos Survey Project. Material from a late-Bronze Age sanctuary at the site was reused in the construction of the Roman Temple of Aphrodite and subsequently in the building of a medieval sugar mill. Excavations since 1966 by F.-G. Maier have covered a variety of sites, including the siege mound used by the Persians when they besieged and took the city in the fifth century b.c.

David Frankel

Papua New Guinea and Melanesia

Historical Background

One of the central theaters of anthropological research for a century, Melanesia has been systematically explored archaeologically only since the 1950s. Before that time, collections of Melanesian material culture were made, sometimes haphazardly, by explorers, sailors, missionaries, government officials, and anthropologists. Such collections sometimes included archaeological materials, which have subsequently taken on great scientific value. These materials have formed, with written descriptions of traditional Melanesian behavior by the same explorers and anthropologists, a rich ethnographic background on which some of the central themes of Melanesian archaeology have been predicated.

The University of Auckland in New Zealand was influential in opening up archaeology in the eastern Melanesian islands in the 1950s, and there is a similar connection between the 1960s development in Australian universities of formal archaeology courses and research into Australian archaeology and the development of archaeological research in western Melanesia. Fundamental to these developments was the appointment of jack golson to the Australian National University in the early 1960s. Within a couple of years of arriving in Australia, Golson, already experienced in Pacific archaeology from a previous appointment at the University of Auckland, had graduate students working in the New Guinea Highlands, the Bismarck Archipelago, and further afield in New Caledonia and Tonga.

In the Melanesian islands a compelling theme for investigation already existed, comprising some disparate and dated threads of evidence that had recently come together: decorated potsherds collected in the early 1900s by a German missionary on Watom Island, off the coast of New Britain, and deposited in the Musée de l'Homme in Paris; a 1920s expedition to Tongatapu in western polynesia where similar pottery excavated by American archaeologist W.C. McKern from midden sites went unrecognized; and the recovery of more of this pottery in the 1940s on the Île des Pins off New Caledonia by J. Avias, who recognized the similarity of the designs on his material and those on the Watom shards.

Not long afterward, E.W. Gifford, from the University of California, led archaeological expeditions to Fiji and then to New Caledonia where he excavated more decorated pottery from a site called Lapita, first reported in 1917 by Frenchman M. Piroutet. Charcoal from the site was submitted for dating by the new radiocarbon technique and produced surprisingly old dates of 2500-3000 b.p. Gifford recognized that a distinctive, highly decorated, and almost identical form of pottery, now called Lapita after Gifford's New Caledonian site, occurred in sites stretching from the Bismarck Archipelago to Tonga.

It was a small and inevitable step to link evidence from Lapita sites to long-standing questions concerning Polynesian origins first posed by English explorer Captain James Cook. Golson, himself involved in Lapita research in the second half of the 1950s from his Auckland base, proposed in 1961 that a “community of cultures,” stretching the length of Melanesia and

area have placed severe stress on the archaeological resources, so the Department of Antiquities is constantly engaged in rescue excavations and related mitigation programs.

Papua New Guinea and Melanesia

Historical Background

One of the central theaters of anthropological research for a century, Melanesia has been systematically explored archaeologically only since the 1950s. Before that time, collections of Melanesian material culture were made, sometimes haphazardly, by explorers, sailors, missionaries, government officials, and anthropologists. Such collections sometimes included archaeological materials, which have subsequently taken on great scientific value. These materials have formed, with written descriptions of traditional Melanesian behavior by the same explorers and anthropologists, a rich ethnographic background on which some of the central themes of Melanesian archaeology have been predicated.

The University of Auckland in New Zealand was influential in opening up archaeology in the eastern Melanesian islands in the 1950s, and there is a similar connection between the 1960s development in Australian universities of formal archaeology courses and research into Australian archaeology and the development of archaeological research in western Melanesia. Fundamental to these developments was the appointment of jack golson to the Australian National University in the early 1960s. Within a couple of years of arriving in Australia, Golson, already experienced in Pacific archaeology from a previous appointment at the University of Auckland, had graduate students working in the New Guinea Highlands, the Bismarck Archipelago, and further afield in New Caledonia and Tonga.

In the Melanesian islands a compelling theme for investigation already existed, comprising some disparate and dated threads of evidence that had recently come together: decorated potsherds collected in the early 1900s by a German missionary on Watom Island, off the coast of New Britain, and deposited in the Musée de l'Homme in Paris; a 1920s expedition to Tongatapu in western polynesia where similar pottery excavated by American archaeologist W.C. McKern from midden sites went unrecognized; and the recovery of more of this pottery in the 1940s on the Île des Pins off New Caledonia by J. Avias, who recognized the similarity of the designs on his material and those on the Watom shards.

Not long afterward, E.W. Gifford, from the University of California, led archaeological expeditions to Fiji and then to New Caledonia where he excavated more decorated pottery from a site called Lapita, first reported in 1917 by Frenchman M. Piroutet. Charcoal from the site was submitted for dating by the new radiocarbon technique and produced surprisingly old dates of 2500-3000 b.p. Gifford recognized that a distinctive, highly decorated, and almost identical form of pottery, now called Lapita after Gifford's New Caledonian site, occurred in sites stretching from the Bismarck Archipelago to Tonga.

It was a small and inevitable step to link evidence from Lapita sites to long-standing questions concerning Polynesian origins first posed by English explorer Captain James Cook. Golson, himself involved in Lapita research in the second half of the 1950s from his Auckland base, proposed in 1961 that a “community of cultures,” stretching the length of Melanesia and

recognized by the commonality of Lapita pottery in the sites, could be identified as the ancestors of the historic western Polynesian cultures. Accordingly, to further substantiate this view, Golson, now at the Australian National University, dispatched graduate students to Watom, the Île des Pins, and Tonga to carry out more detailed excavations.

A second thread of Melanesian archaeology was simultaneously evolving in Papua New Guinea. In 1959, the anthropologist Ralph Bulmer worked in the New Guinea Highlands with his archaeologist wife, Sue Bulmer, and it was she who conducted the first professional excavations in that country. The combination of an archaeologist and an anthropologist interested in biology and ecology as well as prehistory resulted in their seminal joint article, "The Prehistory of the Australian New Guinea Highlands," in a special issue of *American Anthropologist* in 1964. Meanwhile, the first Pleistocene date for human occupation in Australia had been announced. New Guinea, part of the same landmass during lowered Pleistocene sea levels, was one potential route of human entry onto this huge continent. Researchers set out to develop spatial and chronological frameworks for humans in the highlands, a direct counterpart to similar exploratory archaeology being initiated in northern Australia at that time.

In 1968, Ralph Bulmer became Foundation Professor of Anthropology at the newly formed University of Papua New Guinea, and he appointed Jim Allen to a lectureship in prehistory the following year. Sue Bulmer and Allen began projects delineating the prehistory of Port Moresby, which helped facilitate a further series of Australian National University graduate projects along the south Papuan coast. By the end of the 1970s, this area was, archaeologically, the best known region in Papua New Guinea.

From the beginning, systematic archaeology in Melanesia separated along colonialist lines, with Australian scholars taking the lead in Papua New Guinea, the French in New Caledonia and Vanuatu (then the New Hebrides), and the New Zealanders in the Solomon Islands and Fiji. Of course, such a generalized division of interests always has exceptions, and a smattering of American and other scholars also contributed. Today, the territorial prerogatives have fragmented as indigenous archaeologists have taken over the responsibility for their histories through a strong system of museums and cultural centers in each of the Melanesian nations. Outside archaeologists interact with them and each other on the basis of specialized research interests facilitated by regular specialized conferences within the region. Several large-scale projects, such as the Southeast Solomons Culture History Project of the early 1970s and the Lapita Homeland Project of the mid-1980s, have shown the value of multipersonnel approaches to this geographically disparate region, and a number of current projects are now using the same team-based and interdisciplinary strategy.

Such a developmental process of research has not yet produced a coherent regional prehistory for Melanesia. Lapita, an exception, is a recognizable archaeological horizon that makes archaeological sense and comprehensible narrative history, factors that explain the time and effort put into Lapita research and the emphasis put on it in syntheses of Pacific prehistory. Post-Lapita archaeology, on the other hand, too often consists only of lists of poorly described ceramic types and other artifacts from sites that frequently depend heavily on local ethnographies for coherence. If there are behavioral themes linking the later archaeologies of the separate island groups, they are yet to be convincingly articulated. At the same time, a number of researchers have sought to come to terms with the particular constraints of their oceanic world by developing theoretical perspectives, whether culture-historical, sociopolitical, economic, or ecological, that are quite advanced for the relative infancy of their subject.

Pre-Lapita

Modern humans crossed from island southeast asia into the Australasian region some time before 40,000 b.p. *Homo erectus* had reached Java a million years earlier but had failed to cross the water

barriers further east. The biogeographical boundary called the Wallace line separated the primates, carnivores, elephants, and ungulates of Asia and the terrestrial marsupial fauna of

from New Guinea or New Ireland, required that 60 to 90 kilometers be traversed totally out of the sight of any land. This is apparently the earliest known example of true seafaring anywhere in the world.

By 20,000 b.p., the change to moving resources to people is reflected in the appearance of obsidian from a New Britain source 350 kilometers away in two New Ireland sites. An introduced animal, the cuscus (*Phalanger orientalis*), also occurred in both sites at this time. This marsupial, which became an established species on New Ireland and an important food source, is the earliest of a series of animal translocations in the region and raises the possibility that useful plants and nut-bearing trees were also moved about well before the end of the Pleistocene period.

The sporadic use of caves in New Ireland in the early-Holocene period raises the contentious question of whether people were more dependent on cultivated plants and were settling down there around 8,000-10,000 years ago, as in the New Guinea Highlands. Lacking the complex evidence of later Lapita sites, some researchers continue to dismiss the various strands of supporting evidence that have emerged. These include further residues of taro and yam on various stone tools, including elaborate stemmed and hafted obsidian and chert items; the presence of domesticated *Canarium* nut shells in various island sites where wild forms were not endemic; several sites where up to twelve nut species indicate the presence of arboriculture; increasingly extensive distributions of obsidian from its several sources both east in the Bismarck Archipelago and west along the north coast of New Guinea; the appearance of stone and edge-ground axes, earth ovens in several sites, and pig remains in two lowland sites; and changing settlement patterns involving beachside, coastal, and inland open sites as well as caves and rock shelters on smaller offshore islands and atolls. It is thought that the model of gradual economic intensification reflected in these developments requires more substantial food productive systems than those provided solely by hunting and gathering.

Lapita

Beginning about 3500 b.p., an influx of Austronesian language speakers bringing exotic items of material culture from Southeast Asia transformed the history of the Melanesian peoples. The distinctions between the Lapita and what preceded it are so great that early researchers saw this migration of Polynesians-to-be as having little interaction with existing Melanesians other than bringing them agriculture, sailing technology, pottery, complex shell technologies, obsidian trading, prestige exchange, the pig, the chicken, and other benefits of their more complex society. Some researchers still hold such a view, but others now propose more interactive and integrative models that suggest the success and spread of Lapita depended on a greater economic and organizational parity between the indigenous groups and the new arrivals than previously thought. However, the new material culture, so dominant archaeologically, has acted to mask the prior levels of indigenous development. The island populations were ready for and receptive to the changes brought by Lapita. The mainland culture of New Guinea seems to have been bypassed or was more resistant since no Lapita-type sites occur there.

Lapita people almost immediately breached the previous barrier to Pacific expansion at the end of the main Solomons chain to occupy outlying islands in the southeastern Solomons, settle Vanuatu and New Caledonia, and reach Fiji, Tonga, and Samoa. The implication that a new sailing technology existed, specifically the double-hulled canoe, is strong. In any case, new spheres of influence beyond the Bismarck Archipelago added new dimensions of oceanic distance to Melanesian relationships, distances that provided the basis for the diversity that would develop in Melanesian societies.

An increased number of sites from this period may reflect higher populations, more-sedentary settlements in coastal and inland sites, a higher visibility of sites with pottery, or combinations of all three possibilities. The introduced technology of pottery-making looms large in all assessments of Lapita.

Apart from a single claim for earlier Melanesian pottery from

the Sepik area of New Guinea, Lapita pottery is the first introduction of this technology to Melanesia. However, while characteristics of Lapita pottery can be found in Southeast Asia, such similarities are at present more generic than specific, not clearly antecedent in time, or both. Any clear Lapita pottery trail into the Pacific begins in the Bismarck Archipelago. Plain and decorated pots occur, with decoration being so elaborate that its presence in sites separated by thousands of miles must reflect a historically related and almost certainly socially interactive group, especially when much of the pottery seems to have been produced on a local or island level. If the pots themselves did not move far, the trading of obsidian was more extensive (although perhaps no more intensive) than in earlier times and appears to reflect a local continuity in both production and exchange.

Dentate-stamped shard of Lapita pottery from Babase Island, New Ireland Province, late second millennium B.C.

(G. Summerhayes)

Despite claims for Pleistocene house sites in the New Guinea Highlands, Lapita sites provide us with the first clear archaeological indications of villages. No Lapita open sites have earlier preceramic deposits, and several have revealed evidence of stilt houses built over lagoons. Typically, Lapita sites contain extensive and diverse types of shell tools and ornaments, including adzes, fishhooks, vegetable peelers, armshells, and beads. Some sites have yielded diverse plant remains, and pig, dog, and fish and shellfish are typically present. Although the Lapita people were fishing agriculturists, they did not transfer rice cultivation from Southeast Asia, remaining instead dependent on root crops and fruit and nut trees.

Very little is known of Lapita social organization, and the few Lapita burials known are without grave goods. Arguments have been made for Lapita shell ornaments representing items of prestige exchange, and linguistic reconstructions suggest that some form of hierarchical structure existed. Strong and lasting social frameworks able to function at a distance seem fundamental to the transformation represented by Lapita.

Post-Lapita

Conventionally, the Lapita tradition is thought to have ended by about 2000 b.p., although various researchers have argued for both earlier and later terminal dates because the Lapita period was not static. Its stamped pottery is most elaborate in both decoration and vessel form in the earliest centuries in western Melanesia, subsequently simplifying through time and across space. The range of pot shapes diminishes, dentate

secondary burials, which suggests that deceased clansmen were re-interred with their chief.

Whether the lack of rigid hierarchical social structures over large parts of Melanesia prevented the dense populations of agriculturists, like those in the New Guinea Highlands, or complex maritime traders, like those in island Melanesia, from achieving the transformation to city-states as elsewhere in the world remains a matter of debate. In neither case did any particular group control both a stable agricultural base and access to wealth accumulation through trade, which some people believe are requisites for such transformations. Especially in the case of island Melanesia, the emergence of maritime societies followed a gradual and logical adaptation to an oceanic world that had more limited terrestrial resources than homelands to the west. This evolution was clearly aided and added to by movements of people and technologies into the region from further west, coupled with increasing local complexity and specialization if not long-term stability.

Parrot, André

(1901-1980)

André Parrot first studied theology and then, as a result of art history lessons at the École du louvre, became interested in the ancient Near East. He spent a year at the École Biblique et Archéologique in Jerusalem and then excavated at Nerab in northern Syria in 1926. In 1927, he excavated at Balbeck in Lebanon, and in 1931, he worked at the Sumerian site of Telloh, where he was director of excavations from 1931 to 1933.

Parrot began excavating Tell Senkere, the site of ancient Larsa, in 1933, but political problems with the Iraqis caused him to begin to excavate the Mesopotamian site of Mari in southeastern Syria instead; he was to direct excavations there until 1961. Mari was a city founded in the early third millenium and had a long settlement history until the late first millenium b.c. Parrot discovered major temple and palace complexes and major archives from the Old Babylonian period of the early-eighteenth century b.c.

Parrot's association with the Louvre continued throughout his career. He was appointed conservator, then chief conservator, of the Department of Near Eastern Antiquities, and during his time there, he completely reorganized the Near Eastern galleries. He was appointed director of the museum in 1965. He published on the history of art and biblical history, demonstrating links between the biblical world and other Near Eastern civilizations.

Peake, Harold John Edward

(1867-1946)

The son of a church minister, Harold John Edward Peake was trained in estate management and developed an interest in changes in the history of land tenure and land use. He spent some time on a ranch in British Columbia, canada, where he studied prehistoric pastoralism, and he then studied art and ceramics in japan and china.

Peake returned to England in 1899 and became curator of the Newbury Museum, which became well known for its prehistory exhibits of implements, pots, potsherds, and maps. Peake's catalog of 17,000 prehistoric British bronze implements was deposited in the British Library in recognition of its significance. Peake was interested in the evidence of the human past in relation to the environment of the time and its impact on people. His book *The Bronze Age and the Celtic World* (1922) attempted to link archaeology and linguistics while *The English Village,* published in the same year, was a study of social evolution. He regularly contributed to the Royal Anthropological Institute's journal.

Peake became well known for his literary collaborations with Professor herbert j. fleure, such as the ten-volume *Corridors of Time,* written between 1927 and 1936, which provided economic interpretations of the archaeological record. In these volumes, Peake contributed specifically to the debate about the beginning of cereal cultivation in northern mesopotamia during the Neolithic period and to questions on the origins of metallurgy.

Peake was a member of the council of the Royal Anthropological Institute and president of the institute between 1926 and 1928. He received the Huxley Medal in 1940.

Pei Wenzhong

(1904-1982)

Pei Wenzhong was born in Hebei Province in northern china, the son of a primary schoolteacher who was involved in local anti-illiteracy campaigns. As a young man, Pei became politically active in the areas of better education and wholesale reform of China's traditional social institutions.

In 1921, Pei was admitted to Beijing University to study geology, and in 1927 he graduated with a major in paleogeology. The following year he went to work in Hebei Province at the site of Pleistocene fossiliferous fissures at Zhoukoudian, where an international team of scientists had been endeavoring since 1921 to uncover evidence of some of China's earliest human occupants. Beginning in 1929, Pei became field supervisor of the Zhoukoudian excavations, and at the end of the year made the most important discovery of his long career-the first skull of *Homo erectus* found on Chinese soil. This specimen, later known popularly as Peking man, formed the basis for a thorough reinterpretation of human evolution in eastern Asia.

At Zhoukoudian, Pei was influenced by such scholars as the Canadian anatomist Davidson Black, the U.S. anthropologist Franz Weidenreich, the French Jesuit archaeologist henri breuil and geologist and vertebrate paleontologist Pierre Teilhard de Chardin, and the Swedish archaeologist j. gunnar andersson. The Zhoukoudian excavations from 1921 to 1937 became, in fact, a model not only of multidisciplinary science but also of multinational collegiality.

Pei's discovery of the *Homo erectus* cranium at Zhoukoudian catalyzed his lifelong interest in China's Pleistocene prehistory, and from 1929 to 1935, under his guidance, many important localities at Zhoukoudian were discovered and excavated. These included the earliest archaeological material at the site (500,000 years old), the first unequivocal stone artifacts in association with fossil humans in China, and evidence of the use of fire dating back more than 300,000 years. In 1935, Pei enrolled at the University of Paris to study for his doctorate under Breuil's direction. Pei completed his degree, returned to Beijing in 1937, and took charge of the Cenozoic research laboratory there. In 1938, he joined the Communist Party.

From 1949 until 1953, Pei was head of the museums division of the Bureau of Social and Cultural Affairs under the Ministry of Culture in the new People's Republic of China. In 1957, he transferred to the Chinese Academy of Sciences and assumed the title of reseacher in the academy's Institute of Vertebrate Paleontology

Peake, Harold John Edward

(1867-1946)

The son of a church minister, Harold John Edward Peake was trained in estate management and developed an interest in changes in the history of land tenure and land use. He spent some time on a ranch in British Columbia, canada, where he studied prehistoric pastoralism, and he then studied art and ceramics in japan and china.

Peake returned to England in 1899 and became curator of the Newbury Museum, which became well known for its prehistory exhibits of implements, pots, potsherds, and maps. Peake's catalog of 17,000 prehistoric British bronze implements was deposited in the British Library in recognition of its significance. Peake was interested in the evidence of the human past in relation to the environment of the time and its impact on people. His book *The Bronze Age and the Celtic World* (1922) attempted to link archaeology and linguistics while *The English Village,* published in the same year, was a study of social evolution. He regularly contributed to the Royal Anthropological Institute's journal.

Peake became well known for his literary collaborations with Professor herbert j. fleure, such as the ten-volume *Corridors of Time,* written between 1927 and 1936, which provided economic interpretations of the archaeological record. In these volumes, Peake contributed specifically to the debate about the beginning of cereal cultivation in northern mesopotamia during the Neolithic period and to questions on the origins of metallurgy.

Peake was a member of the council of the Royal Anthropological Institute and president of the institute between 1926 and 1928. He received the Huxley Medal in 1940.

and Paleoanthropology. In 1963, he was appointed director of the Paleoanthropological Research Laboratory, and from 1979 until his death he was chairman of the Beijing Natural History Museum. During the 1950s and 1960s, Pei excavated sites and analyzed archaeological material from all over China-including the Upper Pleistocene site of Dingcun in Shanxi Province, the Paleolithic site of Guanyin cave in southern China-and from all periods, including the Neolithic and dynastic. These expeditions not only generated much of the information on which the current understanding of early Chinese prehistory rests, they also provided opportunities for the training of most of China's cadre of professional paleoanthropologists until the 1970s.

Pengelly, William

(1812-1894)

Born in Cornwall, England, the son of a sea captain, William Pengelly was the product of a village school and self-education. He began teaching, opened his own school, and was involved with the politics of improving education and ensuring universal access to it. He helped to found the Mechanics Institute (1837) and the Natural History Society (1844), both in his home town of Torquay, and the Devonshire Association for the Advancement of Literature, Science, and Art (1862). He became a private tutor of mathematics and geology and a popular public lecturer on those subjects.

Pengelly's principal interest was in the geology of Devonshire, early human history, and the antiquity of humanity, and he published articles on these subjects in the journals of the Royal Society, the Geological Society of London, and the British Association for the Advancement of Science. In 1846, Pengelly began to reexplore the prehistoric cave site at kent's cavern, which had been excavated by amateur archaeologist Father MacEnery in 1825, where Paleolithic artifacts and the remains of extinct animals had been found beneath an undisturbed stalagmite floor. Pengelly systematically reexcavated the cave floor and found large numbers of stone and bone tools. Although the results converted Pengelly to the belief in a longer period for human antiquity, they were discounted by others.

In 1858, he explored and excavated brixham cave with the paleontologist hugh falconer under the auspices of the Royal and Geological Societies of London. They unearthed the bones of several extinct fossil animals and flint knives and thus provided convincing proof of high human antiquity. Pengelly became a fellow of the Geological Society in 1850 and received its Lyell Medal in 1886. In 1863, he was elected to the Royal Society.

Persepolis

Situated 58 kilometers from Shiraz in southwestern iran, Persepolis was developed mainly by the Persian king Darius I around 500 b.c. and destroyed by Alexander the Great in 330 b.c. Long visited by travelers and explorers, Persepolis was first systematically excavated by Ernst Herzfeld from 1931 to 1939 and later studied by E. F. Schmidt for the oriental institute of chicago. Subsequent work has been undertaken by the Iranian Archaeological Service, directed by Andre Godard initially and then by Ali

Sami. The site is an architectural masterpiece made up of a series of terraces, gateways, palaces, and staircases, the most famous of which contains exquisite carvings of people (from all parts of the Persian Empire) bearing tribute to the “Great King”-Darius I. At the head of this staircase is the Gate of All Nations built by Xerxes I, but the most magnificent structure is the Apadana (or Hall of Audience) built by Darius I and Xerxes I. Excavations and restoration work continue at the site today.

Peru

Investigation into Peru's pre-inca past began during the early colonial period in the sixteenth century. The writings of Pedro Cieza de León record his visit around 1550 to the Guamanga Valley, now called Ayacucho, where he observed and described the ruins of Huari. The Indian residents of the area ascribed the ruins to an ancient race of people who had lived in the area long before the Inca conquest. Cieza, a very observant chronicler, noted that the walls of the ruins were deteriorating and showed signs of great age. Additionally, he noted that the plans of the buildings were distinctly different from those of the Inca constructions. Later, when he visited the ruins of Tiahuanaco at the south end of Lake Titicaca, Cieza drew similar conclusions about the antiquity of that now-famous site and proposed that Huari and Tiahuanaco were part of a culture that existed in the Andes before the Incas. In linking these two sites, Cieza anticipated what is commonly accepted among Andean scholars today, but his thinking was not recognized for another 400 years.

It was not until the middle of the nineteenth century that scholars again took more than a fleeting interest in Peru's prehistory. Tschudi, visiting Peru from Switzerland between 1848 and 1852, became interested in the many ruins to be found everywhere in the valleys of the Peruvian coastal desert. He was particularly attracted to the massive adobe-walled structures of chan chan, the capital of the Chimu empire, and one of those structures now bears his name in honor of his pioneering work at the site.

In 1850, Antonio Raimondi, a famous figure in Peruvian history, arrived in Peru from Italy. During the many years that Raimondi spent in Peru, he traveled widely and explored nearly every part of Peru's very diverse geography. He wrote copiously about what he observed, and much of what he wrote was published in 1874 in his book *El Peru.* In the course of his travels he encountered many archaeological sites, the most noteworthy of which was the now-famous site of Chavín de Huantar, and one of that site's most important monuments is called the Raimondi Stone.

Moche-Chan Chan project directed by Michael Moseley and the Ayacucho botanical project under the direction of Richard MacNeish. Looting of the rich, accessible coastal sites continues, despite international efforts to stop it, and like the drug trade, it will almost certainly continue as long as there is a market in North America and Europe for Peruvian antiquities.

Petrie, Sir William Matthew Flinders

(1853-1942)

William Matthew Flinders Petrie's father, William Petrie, was a civil engineer, and his mother was the daughter of the explorer Matthew Flinders. Delicate as a child, Petrie was educated at home in England and showed early precocity in science and mathematics. As a boy he collected Greek and Roman coins, and in his teens and early twenties made triangulation surveys of earthworks and hill forts and, with his father's help, measured Stonehenge. His first visit to Egypt was in 1880. Living in a rock tomb and undertaking, almost single-handedly, a survey of the entire pyramid field, Petrie's meticulous measurement of the interior of the Great Pyramid disproved a current theory that it had been built under divine inspiration.

In 1884, Petrie was employed by the recently formed egypt exploration society (then the Egypt Exploration Fund; EEF) to dig for that group. For his excavations of Tanis (1884) and Naucratis and Daphnae (1885-1886) he adopted an entirely new approach to Egyptian archaeology. Excavators had hitherto employed forced-labor gangs, driven by overseers, and had been concerned only with recovering monumental pieces, inscribed blocks, and museum exhibits-everything else was discarded. Petrie chose and supervised his own workforce, rewarding workers for their finds-which otherwise might have gone to dealers.

Maintaining that pottery was a key to the age of a deposit, and that much could be learned from hitherto discarded objects even if broken, he began to assemble his own collection, the nucleus of what was to become a teaching museum. From 1888 to 1890 he dug in the Fayyum in Lower Egypt, penetrating the pyramids of Illahun and Hawara. Among his finds were many mummy portraits of the Roman period and a workmen's village with a wealth of domestic objects. In June 1890 he excavated Tel el Hesy for the Palestine Exploration Fund, and for the first time he dated strata of occupation by the pottery, some of which he was familiar with from Egypt. Back in Egypt, important finds at Meydum (1891) and Tell el amarna (1892) brought him his first honorary doctorate.

As a result of the will of Amelia Edwards, founder of the EEF and a novelist who had been his friend and supporter, Petrie became the occupant of the first Chair of Egyptology in Great Britain, at University

College, London, in 1892. He was expected to excavate in Egypt every winter, training students in archaeological method. With his first student, James Quibell, he found archaic statuary of a hitherto unknown type at Coptos in 1893. The next year they dug the first predynastic cemetery in Egypt (later Petrie was to devise a chronological sequence for the graves by a remarkable statistical method of his own). After three years in abydos (1900-1904), where he excavated the royal tombs of the earliest dynasties, and a winter in the copper-mining area of Sinai, he left the EEF's employment for the second time and founded the British School of Archaeology in Egypt. His wife, Hilda, whom he married in 1896, was his constant companion and right hand in the field, and she labored at home to raise funds and find new subscribers for their work; their camps, run on a shoestring, were a byword for spartan living.

PREV NEXT

During the 1914-1918 war, Petrie remained in London arranging and partly cataloging his museum. This large collection, augmented every year by objects found or bought in Egypt, had been bought by University College in 1913. As the Petrie Museum, it is today a teaching collection without rival. In 1920, Petrie returned to Egypt to dig for a few years more; in 1926, he moved his work to Palestine, where he excavated between 1926 and 1934 three large tells near the Egyptian frontier. In 1934, at the age of eighty-one, he retired from the chair at University College and two years later went to live in Jerusalem, where he died. He had dug over 50 sites and written over 100 books and over l,000 articles and reviews. He held five honorary doctorates, was made a fellow of both the Royal Society (1902) and the British Academy (1904), and was knighted in 1923.

Peyrony, Denis

(1869-1954)

Originally a school teacher, Denis Peyrony became the excavator of major French Paleolithic sites such as la Ferrasie, laugerie haute, and le moustier. Peyrony used a version of the type-fossil approach to lithic classification to establish relative chronologies in French stone tool technology, which did not always accord with the linear evolutionary sequences proposed by édouard lartet and gabriel de mortillet. Indeed, Peyrony's argument that the Aurignacian and the Perigordian lithic traditions were contemporaneous was a major step toward identifying the existence of geographical (if not “cultural”) variability in Paleolithic technologies.

Philippines

The Philippines, lying at the eastern margin of mainland Asia (see Map 1), has been a crossroad for the movements of peoples and ideas from the mainland to the Pacific islands since prehistoric times. Manila likewise has been the key entrepôt of maritime trade and commerce, notably during the almost 250 years (from 1564 to 1815) when the Manila galleons sailed the Pacific Ocean between Manila and Mexico.

Philippine archaeological resources, both on land and under water, are abundant and phenomenal. Archaeological sites range from the earliest indirect evidence for the presence of man in Cagayan Valley, northern Luzon, during the Middle Pleistocene to sixteenth-century dugout wooden coffin burials in northeastern Mindanao. Recent archaeological finds in the country also indicate the existence of complex societies in the northern, central, and southern Philippines, the latter dating as early as the ninth century a.d.

Important archaeological discoveries also include a flotilla of plank-built and edge-pegged wooden boats found in a waterlogged environment that range in date from the fourth to the thirteenth centuries a.d. Throughout Southeast Asia and, indeed, the world at this time, only in the Philippines are such prehistoric boats known to exist.

The history of archaeology in the Philippines elucidates the rich and varied archaeological wealth of the country, as well as the pivotal roles that pioneering individuals played in the evolution, history, and growth of archaeology in the country. For convenience, this updated history is presented in periods that parallel the political administrations of the archipelago from the sixteenth century to the present: the Spanish Period (1521-1898); the American Period (1898-1946); the post-World War II era and the 1950s; the l960s; the 1970s; the 1980s; and the 1990s to the present. Space limitations allow the inclusion of only the most important archaeological discoveries since the 1960s.

The Spanish Period (1521-1898)

Although Ferdinand Magellan reached the Philippines on March 16, 1521, Spanish colonization of the archipelago did not begin in earnest until 1565. The Spanish explorers and colonizers noted the variety of Philippine cultures and languages. The early Spanish chroniclers of Philippine society and culture were generally members of religious orders; they primarily wrote ethnographic reports intended for Spain's ruling monarch or their own religious superiors.

The early Spanish writings were mostly descriptive in character, depicting, in varying details, the physical appearances and lifeways of the Filipinos as observed by the writers. At a later time a great deal of linguistic studies were conducted and subsequently published together with the ethnographic reports. Several chroniclers reported on archaeological discoveries, including Antonio de Morga, the vice-governor general of the Philippines in the seventeenth century who, in his *Sucesos de las Islas Filipinas,* noted ancient artifacts found by farmers in Luzon.

The only recorded important archaeological reconnaisance undertaken in the archipelago during the Spanish period was conducted in 1881 by Alfred Marche, a French archaeologist who systematically explored the central Philippines and discovered numerous sites. He collected varied archaeological specimens, mainly porcelains and stonewares recovered primarily from burial caves. The majority of his collections are now kept at the Musée de l'Homme in Paris. Marche's exploration activities at Marinduque Island (see Map 2) became “the most successful Philippine archaeological expedition recorded from Spanish times” (Beyer 1947, 260).

An Austrian, professor Ferdinand Blumentritt, also published a series of articles about the Philippines and its people around this time. Cursory exploration of caves and open archaeological sites were undertaken in several areas in the Philippines between 1860 and 1881, including those by the German traveler Feodor Jagor in 1860 and J. Montano and Paul Rey between 1879 and 1881.

Map 2. Land archaeological sites in the Philippines

The American Period (1898-1946)

The Philippines were occupied by the United States in 1898, and the U.S. administration of the archipelago began a year later. President William McKinley created the Taft Commission in 1900 in an attempt to craft proper legislation for the Philippines. The commission, in turn, established the Bureau of Non-Christian Tribes.

This bureau, which changed names through the years, was placed under different institutions and was eventually abolished.

In 1901 the first government museum was created, designated as the Insular Museum of Ethnology, Natural History, and Commerce, and was placed under the Bureau of Non-Christian Tribes. In the course of its existence the museum went through various changes, but it was never abolished. Today, it is a government bureau within the Department of Education, Culture, and Sports and is now officially called the National Museum.

Considered the founder of Philippine archaeology, henry otley beyer (1883-1966), an American from Iowa, arrived in Manila in 1905 to join the civil service. His pioneering works resulted in much of what was known about Philippine prehistory. Three years with the Philippine Bureau of Education found him among the Ifugao of northern Luzon, serving as a schoolteacher and documenting their lifeways. In 1914 he founded the Department of Anthropology at the University of the Philippines, and his first writing on Philippine archaeology came out in 1921. As head of the anthropology department, Beyer studied the racial and cultural history of the country.

From 1922 to 1925 Carl Guthe from the University of Michigan led an archaeological expedition to the central Philippines. Guthe was the first trained archaeologist to work in the archipelago, and his exploration activities focused on the collection of ceramics in the hope that these materials would shed light on the early maritime trade between the Philippines and mainland Southeast Asia. He identified 542 archaeological sites and collected more than 30 cubic tons of archaeological specimens, which are now are kept at the University Museum of the University of Michigan.

Early 1926 saw Beyer's first involvement in field archaeology, via the accidental discovery of major prehistoric sites at Novaliches during the construction of a dam for the water supply of Manila. Beyer's ensuing investigation was to be the start of the Rizal-Bulacan Archaeological Survey. By the middle of 1930 excavation activities had also reached Bulacan Province, and in five years of work a total of 120 sites had been identified, with the collection of almost half a million specimens.

Personnel of the National Museum conducted surveys and excavations during the 1930s. In 1934 Ricardo E. Galang, the first Filipino-trained archaeologist, spent two months excavating fourteenth- to fifteenth-century sites at Calatagan, Batangas. In 1938 he investigated a jar burial at San Narciso, Quezon. He recorded a total of six jar burial and midden sites in the area and recovered associated materials of shell bracelets, beads, and ceramics.

In 1938 Generoso Maceda, another staff member of the National Museum, identified a jar burial site in Pilar, Sorsogon Province, in southern Luzon. Twenty-four jars containing artifacts were excavated in three sites (Evangelista 1962, 21). In 1940 Olov Janse, a Swedish-American archaeologist with support from Harvard University, conducted archaeological excavations in the Calatagan sites. Working in three sites, he excavated a total of sixty-six graves, the results of which were published in the annual report of the smithsonian institution (Janse 1946).

There was a complete cessation of archaeological activities during the Japanese occupation of the archipelago (1941-1945). Beyer, who was under conditional internment, was assisted by Tadao Kano, a Japanese civilian assigned to protect museums in the Philippines. The Japanese allowed Beyer to continue working at the museum of the University of the Philippines and at the Institute of Ethnology and Archaeology, which enabled him to pursue his research writing and complete the final sections of his major postwar publications (Evangelista 1962; Jocano 1975; Solheim 1981).

Post-World War II and the 1950s

An increased interest in the beginnings of Philippine society and culture developed in the years after World War II, and archaeology as a course was included in the curriculum at the University of the Philippines. Beyer's research writings during the war years resulted in two important publications, his "Outline Review of Philippine Archaeology by Islands and Provinces" and his *Philippine and East Asian Archaeology, and Its Relation*

PREV NEXT

to the Origin of the Pacific Islands Population (Beyer 1947, 1948). These major works are invaluable as references for archaeologists working in the Philippines to this date.

Archaeological exploration and excavation activities resumed in the l950s, led by two Americans, Wilhelm G. Solheim II and Robert B. Fox. Both were pivotal in arousing the interest of a number of Filipinos to pursue careers in archaeology. With an M.A. in anthropology from the University of California, Solheim published his first work on Philippine prehistory and archaeology in 1951. He conducted archaeological excavations from 1951 to 1953 in Masbate Island with two Filipino students, Alfredo E. Evangelista and E. Arsenio Manuel. Archaeological data generated from the excavations there were collated with the archaeological materials from the Guthe collection recovered in the 1920s from the central Philippines, resulting in *The Archaeology of the Central Philippines: A Study Chiefly of the Iron Age and Its Relationships* (Solheim 1964).

Fox (1918-1985) wrote avidly and extensively about Philippine ethnology, archaeology, and natural history from the late 1940s until 1973. He stayed in the Philippines after his service with the U.S. Navy during the war. With B.A. and M.A. degrees in anthropology, Fox was active in Philippine ethnography before focusing his attention on the archipelago's prehistory.

Major fieldwork in the 1950s was undertaken through the National Museum under the direction of Fox, working with Evangelista and several other members of the museum staff. In 1956 Fox and Evangelista excavated the Sorsogon Province of southern Luzon. A jar burial/stone-tool assemblage was encountered; the sites range in date from 2900 to 2000 b.p.

The most extensive archaeological project in the middle of the 1950s was the Calatagan, Batangas, Archaeological Project south of Manila led by Fox. Over 500 pre-Spanish graves were excavated in a number of burial sites, resulting in the recovery of thousands of trade ceramics-Chinese and Siamese porcelains and stonewares of the late-fourteenth to early-sixteenth centuries a.d. Extended primary burials were revealed as well as secondary burials in jars, with some graves exhibiting evidence of teeth filing and ornamentations. It is unfortunate that the 1950s excavations at Calatagan would witness the start of widespread pothunting activities, which continue to this day.

The 1960s

Fox led major archaeological activities for the National Museum from 1962 to 1966 in a number of caves along the west coast of Palawan, known collectively as the tabon caves. Work in this area resulted in the discovery of late-Pleistocene human fossil remains and associated stone implements. Going back to over 30,000 years ago, six successive periods of prehistoric occupation were found. The C-14 dates available for the Tabon Caves range from 30,500±1100 b.p. and 9250±250 b.p. At nearby Manunggul Cave an earthenware burial jar was found with incised and hematite-painted designs about the shoulder and cover (the latter having a ship-of-the-dead motif dating from 890 to 710 b.c.); it is now one of the country's National Cultural Treasures.

The preliminary results of the archaeological work at the Tabon Caves were published by Fox in 1970. This work included information on human bone fragments that, although recovered from a disturbed area of the caves, have been dated from 22,000 to 24,000 years ago-still the earliest evidence for *Homo sapiens* in the Philippines.

In 1966 significant archaeological sites were discovered right in the city of Manila. Known as the Santa Ana Sites, they exhibited both habitations and burials that “date more than 400 years before the arrival of the Spaniards in Manila” (Fox and Legaspi 1977, 1). The main burial site excavated was originally an archaeological mound on which the present Santa Ana Church was built, and the associated tradeware

ceramics recovered from the burials date from the late eleventh to the fourteenth centuries a.d.

In 1967 cursory underwater archaeological activities were undertaken by the National Museum and the Times-Mirror-Taliba, a now-defunct newspaper outfit, in Albay, 500 kilometers south of Manila (see Map 3). Believed to be a Spanish galleon, the ship was found 40 to 65 meters below the surface. In addition to two large

designs. C-14 dating of shells recovered from this site resulted in dates ranging from 8000 to 6500 b.p. Shell adzes were also noted from Duyong Cave, Palawan, in the Ryukus Islands, and on other Pacific islands.

The 1970s

The 1970s saw a profusion of archaeological research undertaken by both Filipino and foreign archaeologists. The elephant fossil sites in Cagayan Valley, northern Luzon, which had previously been reported, were explored and excavated in the 1970s by the National Museum. Led by Fox, the research uncovered hundreds of fossilized remains of mammals such as elephas, stegodon, rhinoceros, crocodile, giant tortoise, pig, and deer, as well as flaked and cobblestone tools (Fox and Peralta 1972). The first three large mammals in this group are now extinct in the Philippines.

Encumbered by geological problems in the open sites of Cagayan Valley, Richard Shutler Jr., then with the University of Iowa, was crucial in sending to the country a succession of geologists and geomorphologists from Iowa State University. Led by Carl Vondra in 1977, these researchers defined the Plio-Pleistocene terrestrial sequence in the Cagayan Valley basin, demonstrating the in situ association of artifacts and Pleistocene fauna, the age of artifacts, and the Plio-Pleistocene environments in the valley. Geological research has since solved the majority of the problems of the Pleistocene geology of the area, but the debate over the age of the artifacts still continues.

In 1972 Solheim and A. M. Legaspi led an archaeological survey of coastal southeastern Mindanao, a joint project of the National Museum and the University of Hawaii (Solheim, Legaspi, and Neri 1979). The Talikod rock-shelter sites, where flaked shell and stone tools were recovered, are the earliest sites recorded from the survey, with dates ranging from 7620 ±120 b.p. and 3950±90 b.p.

Two ethno-archaeology studies were undertaken in the 1970s. The first was conducted by Bion and Agnes Griffin among the Agta Negritos in the Sierra Madre range of northeastern Luzon from 1974 to 1976. With the goal of providing models for adjustments to hunting and gathering in wet and seasonal environments, the researchers hoped that the results of the study might be utilized for an archaeological understanding of hunters in tropical settings.

William Longacre of the University of Arizona directed an ethno-archaeological study in pottery-making villages in Kalinga Apayao, northern Luzon. Designed to provide data directly relevant to archaeological methods for inferring patterns of behavior and organization of peoples who lived in the past, the project, now in its third decade, has revealed significant insights into the manufacture, distribution, uses, breakages, and discarding of ceramics and how these and other material culture relate to human behavior.

From 1977 to 1978 archaeological surveys and limited excavations were undertaken in Iloilo Province, Panay, in the central Philippines. Australian archaeologists from the Victoria Archaeological Survey, led by Peter Coutts, focused their research on the establishment of a regional sequence, on the study of tradeware ceramics on Panay Island, on the recording of local pottery-making traditions and their trading networks, and on the collection of osteological materials for comparative studies.

While the geologists were working out the problems at the open sites at Cagayan Valley, the National Museum archaeologists concentrated their research activities in Penablanca, about 15 kilometers east of the Pleistocene open sites. Led by Wilfred Ronquillo and R. A. Santiago, exploration activities in the limestone area resulted in the recording of over 100 caves and rock shelters, eight of which have since been excavated. Basically aimed at elucidating the structure and distribution of the stone-tool industries in the area, the technological and functional analyses of the lithic flaked tools and debitage recovered

from the excavations of Rabel Cave (ranging from 4900 to 3000 b.p.) indicated the generalized functions of the flake tools, which made them ideal for use as maintenance tools; the manufacture of the stone flaked tools involved a percussion method without core preparation.

In 1977 Barbara Thiel, then a graduate student at the University of Illinois, excavated two caves at Penablanca, Cagayan Province-Arku

by the recovery of cordage of palm fibers. Their presence indicates that an older ship-building method was used. The Butuan archaeological assemblage points to a complex society in this area, indicated by craft specialization (such as wood, bone, and shell working, pottery manufacture, bead reworking, and metallurgy-specifically gold working) and the capability to participate in long-distance trade.

In 1979 an archaeological program led by Karl Hutterer of the University of Michigan started an interdisciplinary project focused on the prehistoric social and cultural development of a small geographical area in Negros Oriental. Known as the Bais Anthropological Project, the research, participated in by graduate students from Michigan, generated archaeological, ethnographic, biological, and geological data used to provide an overall understanding of prehistoric and present-day societies in Negros.

The 1980s

Archaeologists from the National Museum were busy during the 1980s. Although limited in manpower, the museum is the only institution that undertakes full-time archaeological research activities in the country. One of its priority activities is rescue archaeology, which involves the investigation of caves prior to the mining of bat droppings for use as fertilizer.

In 1981 archaeological exploration activities started at the limestone formation of Anda, in the island province of Bohol in the central Philippines. Designed to explicate the island adaptation of prehistoric man, this project, led by Santiago, resulted in the discovery of over 130 caves and rock shelters, the majority of which are archaeological sites. A number of caves exhibit wooden coffin burials as well as rich prehistoric habitation and burial sites.

Museum archaeologists were active in various areas in the country, such as Laurel, Batangas; Ma-ug, Prosperidad, Agusan del Norte; and Polillo Island, Quezon Province. Important archaeological data were generated from the continuation of the excavations at the Butuan sites in northeastern Mindanao, where primary extended burials indicate teeth filing and blackening.

Laura Junker, Hutterer's former student and now a professor of anthropology at Vanderbilt University, did research in Tanjay, Negros Oriental, in the central Philippines. Concentrating on the operation of control over the distribution of prestige goods, tradewares, and earthenware ceramics, Junker used archaeological and ethnohistoric data to test the hypothesis that early Philippine chiefdoms' participation in Southeast Asian luxury goods trade during the tenth to the sixteenth centuries a.d. was strongly linked to centralized control of a complex intraregional system of production, exchange, and resource mobilization.

In the 1980s numerous underwater archaeolgical sites were worked by the National Museum. The various shipwrecks found in Philippine territorial waters include Spanish, English, American, and Asian craft, usually with portions of the cargo still intact. The tradeware ceramics help date the ships and cargo. The associated archaeological materials have added new insights into the history of the trade from the ninth to the eighteenth centuries, as well as the nature of the trade and the societies that produced, bartered, and used the goods.

In the majority of cases the sites explored and excavated were worked as joint ventures with private entities. The shipwrecks studied include: one believed to be a merchant boat, found in 1982 on the southeast coast of Marinduque Island, about 150 kilometers south of Manila; a probable local watercraft found in 1983 at Puerto Galera, Mindoro Island; and a sixteenth-century wreck found in 1985 at the Royal Captain Shoal, a coral reef west of Palawan Island. The archaeological materials recovered from this site include porcelain plates, saucers, bowls, cups; boxes and box covers;

blue-and-white, pear-shaped, terra-cotta bottles; jarlets; jars; over 200 beads; 33 identical gongs; and bronze, iron, and copper objects. The tradewares recovered from the wreck point to the Wan Li period (1573-1620).

It was also in 1985 when the *Griffin,* an East India Company vessel, was excavated northwest of Basilan Island in the southern Philippines. Along with numerous Chinese tradeware ceramics, the few metal objects found include

iron ingots used as ballast, iron tools in the form of adzes, cannonballs, lead sheets used to line the wooden tea crates, lead musketballs, teapots, a Chinese coin of copper alloy, shoes and belt buckles of copper alloy and gilt bronze, and other objects used for daily life on board the ship.

In 1986 the exploration for the sunken galleon *San José* was started off the waters of Lubang Island, Mindoro Province. Only portions of the ship's planks, numerous shards of blue-and-white chocolate cups, and fragments of bronze, iron, and copper materials were recovered.

The 1990s to the Present

Important archaeological discoveries were made in the 1990s. In 1991 earthenware potteries with covers exhibiting anthropomorphic motifs were excavated at Ayub Cave, Pinol, Maitum, Sarangani Province. Led by E. Z. Dizon, the analysis of the potteries, designed and formed like human figures with varied and distinct facial expressions, indicates that they were used as covers for multiple secondary burial jars. Typologically the jars and the associated materials found date to the Metal Age period in the Philippines, around 500 b.c. to 500 a.d.

The year 1991 also marked the start of an archaeological survey for the Spanish warship *San Diego,* which sank off Fortune Island on December 14, 1600. A joint project of the National Museum and World Wide First, Inc., the excavation found the wreck at a depth of about 50 meters below the sea's surface. Two seasons of underwater archaeological excavation were undertaken, resulting in the recovery of over 34,000 archaeological items, including tradeware porcelains and stonewares, earthenware vessels, metal artifacts, and various organic materials.

The archaeological materials recovered from the *San Diego* site include more than 500 blue-and-white Chinese ceramics in the form of plates, dishes, bottles, kendis (spouted water containers), and boxes that may be ascribed to the Ming dynasty, specifically to the Wan Li period; more than 750 Chinese, Thai, Burmese, and Spanish or Mexican stoneware jars; over seventy Philippine-made earthenware potteries influenced by European stylistic forms and types; parts of Japanese samurai swords; 14 bronze cannons of different types and sizes; parts of European muskets; stone and lead cannonballs; metal navigational instruments and implements; silver coins; 2 iron anchors; animal bones and the teeth of pigs and chickens; and seed and shell remains of prunes, chestnuts, and coconut.

Noteworthy among the metal finds are a navigational compass and a maritime astrolabe. Also retrieved from the site is a block of hardened resin that was noted in historical accounts to have been used for caulking and for making fire in stoves. A summary of the excavations and finds is presented in C. Valdes's *Saga of the* San Diego, published in 1993.

In the northernmost islands of the Philippines, the Ijangs (megalithic structures situated in elevated hills, indicating evidence of fortification) were confirmed through archaeological explorations and limited excavations. Led by Dizon and Santiago, the cursory archaeological activities indicate that the structures closely resemble the castles reported from Okinawa and date to the twelfth century a.d. These recent finds may prove crucial in the understanding of the formation of sociopolitical complexities in the Philippines.

This concise history of archaeology in the Philippines records the fascinating story of the search for the prehistoric beginnings of the archipelago, which is inextricably linked with mainland Southeast Asia and the Pacific islands. Although it may seem that archaeological activities in the country are adequate, there are still countless archaeological sites in the country that need proper assessment, excavation, and management. Unfortunately, these important and nonrenewable components of the country's cultural resources are also subject to plunder, nearsighted exploitation, and vandalism. Properly managed and

protected, these archaeological resources have educational, recreational, and tourism potential. Without doubt, they are worth protecting for the enrichment and enjoyment of succeeding generations.

Piette, Edouard

(1827-1906)

One of the most influential French Paleolithic archaelogists of the nineteenth century, Edouard Piette gained fame as the excavator of the major cave site of le mas d'azil in the French Pyrenées, where a single sequence linking the Upper Paleolithic and the Mesolithic was identified for the first time. He named the linking assemblage Azilian (after the site). A keen student of Paleolithic art, Piette acquired a great collection of portable art (i.e., art that was moveable as opposed to Paleolithic art on cave walls), particularly the bones of animals that had been incised. He gave this collection (as well as his collection of ancient stone tools) to the French Museum of Antiquities at Saint Germain-en-Laye, where it is displayed as a unity.

Piggott, Stuart

(1910-1996)

stuart piggott is one of a small group of extremely influential archaeologists who began their careers between the First and Second World Wars and who went on to dominate British and European archaeology in the decades after 1945. The breadth of his interests are exceptional, and although his views have been the subject of considerable criticism in recent years, his work is still valued today.

Piggott's initial area of interest was the Neolithic period of Great Britain, and between 1930 and 1950 he defined the principal monument and artifact types, the chronological sequence, and the regional characteristics of the period. This work culminated in his definitive account of the period, *Neolithic Cultures of the British Isles* (1954). His approach in this work was distinctive and was characterized by detailed description, accompanied by very fine illustration, and a minimalist approach to social interpretation. It was an attempt at objectivity designed to extract accurate information for a scientific understanding of prehistoric societies. Piggott acknowledged the influence of o. g. s. crawford and Alexander Keiller in his early development, and the scientific rigor of both of those methodical Scotsmen clearly influenced Piggott's approach.

World War II was a turning point in Piggott's career. It marked an end to his employment as Keiller's research assistant at avebury and a broadening of his archaeological interests. During the war he was sent to India, and when not

working on aerial photographic interpretation he was able to do a considerable amount of research on the early prehistory of the subcontinent, which resulted in the publication of several books and papers.

On returning to Britain, he became the new Abercromby Professor in Edinburgh, a post that brought with it a commitment to fieldwork in Scotland and an incentive to research the broader field of European archaeology. The former resulted in the excavation of several important Neolithic sites. The latter led to the publication of a synthetic study of ancient Europe, which examined themes covering prehistory from the introduction of agriculture.

Ultimately, these two imperatives changed the direction of Piggott's interests. He became more interested in later prehistory and, in particular, the development of wheeled transport and the significance of Celtic art and religion. Interest in wagons, chariots, and horses was a theme that brought together many of his European interests, charting the movement of peoples and the rise and fall of political elites.

Piggott continued as the Abercromby Professor in Edinburgh until his retirement in 1978. After that time, he carried on writing, and a large number of books and papers appeared on many subjects, not just those discussed above. He also developed his interest in the history of British archaeology. In this area, he originally focused on the figure of william stukeley, an individual with an important role in the understanding of the Neolithic period at Avebury, but he later expanded his work to cover the antiquarian imagination of the sixteenth, seventeenth, and eighteenth centuries.

As his career progressed, Piggott became more and more aware of the limits of archaeological inference. He realized that much of his earlier speculation on the Neolithic period was inaccurate, which was emphasized by the radiocarbon revolution that undermined the typological chronology he had striven so hard to construct. He therefore narrowed the range of his interests in the later part of his career to emphasize the history of archaeology and the technological development of transportation.

Piltdown Forgery

The Piltdown man, one of the most famous forgeries in the history of paleoanthropology, was a composite of a skull and associated skeletal remains discovered in a gravel pit in East Sussex, England. The skull (named after Piltdown Common where it was found) was first unveiled at a meeting of the Geological Society of London in 1912 by Charles Dawson, the discoverer, and Arthur Smith Woodward of the British Museum of Natural History, the professional paleontologist who backed its legitimacy and importance. Based on excavations made at the site by Dawson, Smith, Woodward, and others, crude stone tools (or *eoliths*) were thought to have been found in association with the remains of an animal that had a large brain but an apelike jaw with “modern” teeth. Coming at a time when skeletal evidence of the physical evolution of human beings was extremely rare, especially from really remote antiquity, the Piltdown discovery gained great notoriety.

Model of the Piltdown “skull,” in fact a re-creation from parts of two animals

(Ann Ronan Picture Library)

As Frank Spencer (1990) has noted, however, from the very first the Piltdown remains were regarded as problematic by some people, but a clear understanding of just how problematic they really were was only gradually revealed. As

time passed, and other discoveries of fossil hominids were made in Asia and Africa that were dramatically different from Piltdown, the English remains came to be seen as being anomalous rather than of very great interest. It was not until 1953 that the Oxford physical anthropologist J. S. Weiner reanalyzed the remains and concluded that the braincase and jaw were from separate animals-a suspicion confirmed by fluorine testing. Further analysis demonstrated that the jaw was that of an ape and that the teeth had been deliberately altered and stained to match the color of the braincase fragments. By 1955, the entire Piltdown collection was rejected as fraudulent.

Of course, the revelation of fraud requires the identification of the forger, and this topic has become one of the most enduring detective stories in the history of physical anthropology. The list of suspects ranges from the obvious (such as Dawson) to the truly surprising (eminent physical anthropologist Sir Arthur Keith) and has included most of the people who were in any way associated with the forgery. In the absence of a signed confession by the forger, we are left with a range of probabilities. Although these may not be enough to obtain a conviction in a court of law, there is every reason to believe that there was a greater purpose to the forgery than to simply hoax the scientific community.

Pincevent

The site of Pincevent in france lies near the village of Montereau in the southeastern part of the Paris basin. It is situated on the River Seine, between its confluence with the river Yonne and its confluence with the river Loing, in a landscape of high plateaus and wide valley systems. Its immediate surroundings were quarried for gravel from 1926 onward, but its archaeological potential was recognized only thirty years later when occasional finds began drawing the attention of local collectors.

Between 1956 and 1964, volunteers made several attempts at recording and salvaging some of the abundant remains from both prehistoric and historic times. In 1963, several Magdalenian hearths were unearthed, provoking the local suspension of gravel extraction through the intervention of the Association Française pour L'étude du Quaternaire and the Société Préhistorique Française in 1964. The site was acquired by the Ministère des Affaires Culturelles, which enabled a team from the Centre de Recherches Préhistoriques of the University of Paris to initiate a comprehensive archaeological investigation, which was partly subsidized by the Centre National de la Recherche Scientifique. The excavations at Pincevent have become famous for their detailed and rigorous execution, setting a precedent for archaeological fieldwork that is still valid today. They were directed by andré leroi-gourhan until 1985 and continued by his team, including, among others, Pierre Bodu and Claudine Karlin.

Although finds suggest that the locale of Pincevent was the setting for human activities during at least parts of the late Pleistocene and the Holocene periods, research has focused on the Magdalenian remains. These assemblages owe their excellent preservation to a gentle incorporation into a two-meter-thick sequence of clays and silts deposited through the occasional flooding of the river Seine. They consist of scattered lithics, bone fragments, and clasts (archaeological debris) punctuated by hearths and are generally interpreted as representing a number of activity sites created by Magdalenian people in the context of (possibly seasonal) reindeer hunting. Two assemblages, those of habitation number one and section thirty-six, are the focus of two major publications.

The archaeological phenomenon of Pincevent is very much a product of the history of the discipline of

French archaeology and of the persons involved in the excavations and subsequent research. Leroi-Gourhan's background in ethnography and anthropology, and his belief that material culture is as meaningful a cultural manifestation as linguistic expressions, led him to adopt an ethnographic approach to the Magdalenian

PREV NEXT

remains at Pincevent. The excavations, consisting of extensive horizontal exposures, were designed to obtain information on site structure, which was treated as representing a number of settlement floors. Casts were made by Michel Brézillon of entire excavation surfaces, replicating the spatial arrangements of the archaeological remains. Ethnographic case studies were employed to illuminate butchery patterns, and the lithics were subjected to technological analysis and refitting studies to gain insight into the *chaînes opératoires* ("operational sequences"). These were taken to be forms of expression of mind and language and were therefore of vital importance for the study of cognitive evolution.

In the last decades, many researchers have been involved in analyzing and (re)interpreting aspects of the Magdalenian remains from Pincevent. Refitting and technological studies have been claimed to yield information on the age, gender, and social contexts of the Magdalenian people that visited Pincevent. Several spatial analyses have been conducted; most notably, the hut structures that were tentatively reconstructed by the excavator are now rejected by many archaeologists. Raw material analyses have provided insight into the movement of material, placing Pincevent within a wider regional framework.

Since excavation commenced at the site of Pincevent, it has increasingly acquired a model status, the influence of which reaches far beyond the boundaries of both French and paleolithic archaeology. The meticulous excavation through extensive horizontal exposures and the detailed recording practices have become models for archaeological fieldwork, and the interpretations of the structure of the site have become models for the interpretation of site structure elsewhere. Above all, however, the site of Pincevent has become the archetypal archaeological site. It has provided archaeologists with a template of what an ideal archaeological site looks like and has been used to judge the interpretative potential of other sites. Particular importance is assigned to archaeological configurations stemming from limited time spans of activity owing to rapid burial and to minimal postdepositional disturbance as a result of gentle burial in fine-grained sediments. This template betrays an enduring preoccupation with the ethnographic analysis of archaeological sites. However, discrepancies between the ethnographic approaches applied to it and the structure of the site, despite its excellent preservation and excavation, make Pincevent an important locus for a critique of current frameworks for archaeological interpretation.

Pitt Rivers, Augustus

(1827-1900)

Augustus Pitt Rivers was born Henry Lane Fox, and it was when he succeeded to the large estate of his cousin that he took the Pitt Rivers name. He began his career in the army in 1845 and thus traveled to Malta and Scutari in the Crimea during the 1850s, to Canada during the American Civil War in 1861, and to Ireland from 1862 to 1866, where he was assistant quartermaster-general in Cork.

Pitt Rivers's interest in archaeology, and in ethnography and collecting ethnographic material, was initially stimulated by the Great Exhibition of 1851 in London and his own collection became his life's passion. He was part of an upper-class, well-educated group of people who interacted socially with, or were

related to, the scientists and social scientists of the day, such as Herbert Spencer and John Stuart Mill. Pitt Rivers was an an early convert to Darwinism and through membership in the Ethnological Society of London became friends with the antiquarian and politician Sir John Lubbock (lord avebury), later his son-in-law, and the philosopher and politician Thomas Henry Huxley.

While stationed in Ireland, Pitt Rivers explored and surveyed the local historic circular forts or raths, promontory forts, ogham stones

PREV NEXT

(stones with Celtic inscriptions), and some medieval antiquities, and in 1864 he was elected fellow of the society of antiquaries of london. On his return from Ireland three years later, he began his archaeological fieldwork in earnest, and for the next thirteen years he surveyed and excavated in Yorkshire and at the hill forts and in the flint mines of Sussex Downs. He field-walked in Oxfordshire and Wiltshire, he discovered Paleolithic implements and animal bones in the drift gravels of the Thames Valley, and he excavated barrows at Guildford and Brighton in southern England. He also traveled abroad and undertook archaeological fieldwork in france and denmark.

Pitt Rivers joined the Anthropological Society of London in 1865 and in 1868 was general secretary of the International Archaeological Congress that met at Norwich and London. In 1871, he helped to form the Anthropological Institute-he was later to serve as its president-and he became a fellow of the Royal Society in 1876. By 1874, his collection of ethnographic material had grown to 14,000 pieces, which he loaned to the British Museum of Natural History to educate the public. In 1884, this collection was given to Oxford University and became the basis of the Pitt Rivers Museum. In 1880, on his inheritance of Lord Rivers's estates, he visited Egypt, where he met sir william matthew flinders petrie and discovered Paleolithic remains in the drift gravels of the Valley of the Kings.

In 1882, General Pitt Rivers retired from the army. For the remaining years of his life, his archaeological work was divided between a notable series of excavations at Cranborne Chase, mostly on his own property, and his official duties as the first inspector of ancient monuments. Lubbock's Ancient Monuments Protection Act of 1882 provided for an inspector to effect the legislation, and Pitt Rivers undertook seven journeys of inspection between 1883 and 1889, primarily in highland Britain, surveying and sketching monuments.

At Cranborne Chase, Pitt Rivers supervised the excavations of a Neolithic barrow, several round barrows, and Bronze Age enclosures; the hill fort of Winkelbury; the Romano-British settlements of Woodcutts and Rotherley; the linear ditches Bokerley Dyke and in Wiltshire, Wansdyke; and the medieval King John's house, Tollard Royal. Several exercises in experimental archaeology were also carried out, accounts of the excavations were published, and a public museum was established at Cranborne Chase detailing the excavations and finds.

Pitt Rivers's fame has rested at different times on his abilities as an excavator, a builder of typologies, and a theorist. He was one of the finest excavators of his generation, and his care in recording information in plan and section drawings rivals modern practice, but he could be inconsistent in its use. In the evidence that he chose to record, Pitt Rivers was far in advance of his contemporaries. He kept most of the potsherds and animal bones that others usually discarded, arguing for their importance for dating a site. He was not a good field archaeologist and not adept at seeing relationships between earthworks, but Pitt Rivers probably did more than anyone in his generation to promote the establishment of a sound chronology for British archaeology through his work behind the scenes in the royal archaeological institute and more particularly by the creation of typologies for field monuments as well as portable artifacts. He should perhaps also be assessed as an administrator, as one who bridged the gap between anthropology and archaeology believing that they were inseparable elements in the system of cultural evolution, and as an educator who had strong views on museum design and display and accessibility to the public. He was also present at, and instrumental in, the first faltering steps of the heritage preservation movement in England.

Poland

The interest in antiquity in Poland dates back to the thirteenth century, as evidenced in the records of mounds called "giants tombs." In the fourteenth century Jan Długosz, in his *Historia Polonica*, mentioned clay vessels rooted into the ground, which he considered to be the work of nature. The author who correctly identified those clay vessels as cinerary urns was John Jonston (1605-1675), a doctor and naturalist of Scottish origin from Szamotuły (in the Wielkopolska region). At the same time, Jacob Mellen provided the first detailed description of excavation works in the graveyard of the Lusatian culture in Śmigiel (also in the Wielkopolska region). The sixteenth and seventeenth centuries brought dis coveries of the first archaeological artifacts, such as box graves, urns, and coins. Of special note in the eighteenth century were the activities and initiatives of the last Polish king, Stanislaus Augustus Poniatowski, a great lover of antiquity. The first private collections of archaeological materials were founded in that period. At the end of eighteenth century Count Jan Potocki (1761-1815) drew public attention to archaeological artifacts as sources of knowledge about the history of the Slavs. Considered the pioneer of historical and archaeological studies on the Slavs and their culture, he was the first to formulate a hypothesis about the autochthony of Slavs and authored such important works as *Recherches sur la Sarmatie* and *Histoire primitive des peuples de la Russie.*

The year 1795 was a tragic one for Poland, for it was the year in which the country lost its political independence and was divided between russia, Prussia, and austria. For 123 years, therefore, until Poland regained its independence in 1918, the Polish interest in antiquity and then in prehistory developed independently in each of the occupied areas. The first institution to take on archaeological studies was the Warsaw Royal Society of Friends of Sciences, founded in 1800. One of its initiatives was to organize lectures, mainly on history, religion, art, or the beginnings of writing among the Slavs. The society also emphasized the importance of collecting archaeological materials, thus contributing to the formation of the nucleus of the collection of the future Museum of Prehistory. At the same time, state and private collections expanded, for example, those of the Włyńskie Lyceum in Krzemieniec, the Museum of the Czartoryskis in Lvov, the Płock Scientific Society, and the Dukes Czartoryski in Puławy.

The true turning point in the studies of prehistory was a work by Adam Czarnocki (1784- 1825) (whose

pen name was Zorian Dołega Chodakowski) entitled *On the Slavonic Lands before Christianity* (1818). Written in the romantic spirit, Czarnocki's work comprised ethnographic, archaeological, and linguistic elements; it described a program for a systematic study of prehistoric monuments and argued for comprehensive research on Slavdom. It also recognized the unique function and importance of archaeology in the study of the past, with particular emphasis on the prehistory of the Slavs. This interest in the past of Slavdom was inspired by patriotism, which for Poles was closely linked with the loss of statehood. During the whole period of romantic archaeology, that is, until the 1870s, the attention of archaeologists was almost entirely focused on the history of Slavs. In 1848 a four-faced statue of Światowid (a Slavic deity)-made of sandstone and 2.7 meters

Polynesia

Polynesia Defined

The term *Polynesia* was an invention of the European Enlightenment, a direct consequence of the great voyages of Pacific exploration associated with such famous navigators as Louis de Bougainville, James Cook, George Vancouver, and La Pérouse. The first use of the term (derived from the Greek words for "many" and "island") is generally attributed to De Brosses in his 1756 *Histoire des navigations aux terres Australes,* where it applied to all of the islands of the "Great South Sea." The modern definition of *Polynesia,* as the islands found within the vast triangle subtended by Hawai'i in the north Pacific, New Zealand in the southwest, and easter island (Rapa Nui) in the far southeast, dates to the French explorer Sebastien Dumont d'Urville (1790-1842). In his 1832 *Notice sur les Iles du grand océan,* he set Polynesia apart from Melanesia, the islands of the southwestern Pacific from New Guinea to Fiji, and from Micronesia, the islands north of the equator ranging from the Marianas and Palau in the west to the Marshall Islands in the east. This tripartite segmentation of Oceania continues to have geographic salience, even though its value for historical understanding has been greatly diminished.

Culture historians such as roger c. green (1991) have recently recognized that a more meaningful way to partition Oceania is between *Near Oceania* (comprising New Guinea, the Bismarck Archipelago, and the Solomon Islands) and *Remote Oceania* (comprising all of Micronesia, the Melanesian archipelagoes of Vanuatu, the Loyalty Islands, New Caledonia, Fiji, and all of Polynesia). This distinction recognizes the deep history of the Pleistocene human occupation of Near Oceania (beginning at least 40,000 years ago) and the relatively late expansion of Austronesian-speaking peoples into Remote Oceania (after about 2000 b.c.). Nonetheless, the term *Polynesia* retains considerable salience, for the island cultures found within this vast triangle (along with a few Polynesian "outliers" scattered to the west of the triangle proper) do cohere as a single cultural region.

The high degree of relatedness among the peoples of Polynesia was first recognized, on the basis of language similarities, by Enlightenment voyagers such as J. R. Forster, the naturalist of Captain Cook's second voyage, who published a comparative table of Polynesian words in 1778. Modern historical linguistic studies confirm that the thirty-six documented Polynesian languages form a single branch of the great Austronesian language family. They can all be traced back to a proto-Polynesian language, for which more than 4,000 words have now been reconstructed (Kirch and Green in press). As biological populations the Polynesian islanders also exhibit considerable phenotypic homogeneity and common genetic markers. Recent studies in molecular biology suggest that the Polynesian ancestors passed through a "genetic bottleneck" at some point in their early history, quite probably associated with the initial colonization the Fiji-Tonga-Samoa region.

Ethnographically Polynesia is generally subdivided into two major sectors: *Western Polynesia,* which includes Tonga, Samoa, Futuna, 'Uvea, and a few smaller islands in this region, and *Eastern Polynesia,* including both the central-eastern archipelagoes of the Cooks, Australs, Societies, and Marquesas and the more isolated islands of Hawai'i, Easter, and New Zealand. The formal distinction between Western and Eastern Polynesia was first defined on comparative ethnographic evidence by Edwin G. Burrows in 1939. Archaeological research has subsequently demonstrated that Western Polynesia was settled first, around 1000-900 b.c., and was the geographic homeland of the ancestral Polynesians (the speakers of proto-Polynesian language; see Kirch and Green in press). Subsequent dispersals out of this homeland region, to the east, north, and southwest, led to the settlement of Eastern Polynesia. Dating the settlement of Eastern Polynesia remains a controversial matter, but scholars would agree the process began sometime after 500 b.c. and was completed by a.d. 800-1000.

Nineteenth-Century Scholarship

As already noted, the late-eighteenth-century voyagers recognized the coherence of Polynesia (Captain Cook wrote of the “Polynesian Nation”), and they began to advance theories of Polynesian origins, generally suggesting that the Polynesians were related to similar peoples found in the Malay Archipelago (modern indonesia). Again, linguistic similarities provided key evidence.

Again, linguistic similarities provided key evidence.

PREV NEXT

By the early decades of the nineteenth century the islands of Polynesia were becoming the targets of increasing European interest, first by itinerant traders, followed by various missionary sects and, by mid-century, imperial efforts at colonization. The French annexed Tahiti and surrounding archipelagoes, and the British took political control of Aotearoa (New Zealand) from the indigenous Maori (but not without a protracted war of resistance). Somewhat later Samoa fell to German and then U.S. and British interests, and the legitimate Hawaiian government was overthrown by a cabal of U.S. expatriates in 1893. As was typical in other parts of the colonized world, scholarly interests in the newly subjugated populations followed missionary and imperialist expansion. The origins of modern anthropology and prehistoric archaeology, as many have argued, are closely intertwined with global European expansion.

Many missionaries and colonial officials who found themselves in Polynesia conducted pioneering ethnographic and linguistic research and used the data to construct theories of Polynesian origins and history. Although a few archaeological ruins were studied (such as the Hawaiian temple, or *heiau,* sites recorded by Thomas Thrum in Hawai'i), archaeology per se figured little in these nineteenth-century endeavors. Rather, great emphasis was placed on indigenous Polynesian oral traditions and narratives, by such scholars as Sir George Grey, Abraham Fornander, and S. Percy Smith. Their particular accounts varied, but these authors generally traced Polynesian origins back to Asia, with protracted migrations through the western Pacific into the Polynesian triangle. Fornander's *Account of the Polynesian Race* (1878) remains a classic of this genre, tracing the Polynesians back to “the Vedic family of the Arian race” that was eventually “driven out of India” and gradually spread into Indonesia and beyond.

In New Zealand, however, direct archaeological evidence in the form of prehistoric stone implements (flake tools and ground-stone adzes) came to the fore when they were found in association with the bones of several species of giant, extinct, ostrichlike birds known as moa. As early as 1872 Julius Von Haast was excavating “moa-hunter” sites in the South Island of New Zealand and using such evidence to argue for a race of Paleolithic hunter-gatherers who had preceded the classic Polynesian Maori in these southern islands.

By the fin-de-siècle, such ad hoc scholarship was giving way to more formal academic enterprises, associated with the founding of museums, universities, and other institutional bases from which ethnological and archaeological research would henceforth be sponsored. The polynesian society was established in New Zealand in 1892 to promote such research, and the *Journal of the Polynesian Society* remains a prominent publication today. The Otago Museum and Dominion Museum in New Zealand and the Bernice P. Bishop Museum in Hawai'i became leading centers for archaeological and ethnographic research. The Bishop Museum, in particular, would come to play the dominant role in Pacific archaeological research throughout the first half of the twentieth century.

The Problem of Polynesian Origins

In the first decades of the twentieth century archaeology began to come into its own in Polynesia. Katherine Scoresby Routledge, a remarkable woman and scholar, led a three-year private expedition to Easter Island to investigate its enigmatic, giant stone statues. Routledge combined archaeological survey and mapping of the ruins with ethnographic inquiries among the surviving Rapa Nui people to arrive at the conclusion that the statues and the temples upon which they stood were “the work of the ancestors” of the Polynesian-speaking Rapa Nui themselves, not the vestiges of some vanished race (Routledge 1919, 291). In Hawai'i, John F.G. Stokes carefully surveyed the remains of stone temple sites on Hawai'i and Moloka'i Islands to determine whether a sequence of temple forms could be inferred and possibly correlated with Hawaiian oral traditions of religious change. Stokes also conducted stratigraphic excavations on the island of Kaho'olawe and found a succession of fishhook types in the Kamohio rock

shelter, although the significance of his results would remain unappreciated for nearly fifty years.

The greatest impetus to Polynesian archaeology, however, occurred in 1920 when geologist Herbert E. Gregory acceded to the directorship of the Bishop Museum in Honolulu, convened the first international Pan-Pacific Science Conference, and proclaimed that the study of Polynesian archaeology and anthropology should be a major research priority (Kirch 2000, 20-24). Gregory, who continued to hold a professorship at Yale University, had important connections with the East Coast establishment in the United States and was able to secure major funding for a series of research expeditions to several Polynesian archipelagoes. The Bayard Dominick Expeditions of the Bishop Museum, from 1920 to 1922, were designed to implement the emerging Americanist vision of a holistic anthropology, combining multiple lines of evidence from ethnography, archaeology, ethnobotany, and physical anthropology (somatology). Research teams combining these disciplines were dispatched to Tonga, the Austral Islands, the Marquesas, and Hawai'i to carry out parallel investigations designed to address the overarching problem of Polynesian origins.

In retrospect, however, archaeology played a subordinate role in the Bayard Dominick Expeditions, leaving the field to be dominated by the comparative ethnologists. In the Tongan expedition, for example, archaeologist William C. McKern (later to become famous for his work on North American ceramic taxonomy) focused most of his efforts on the mapping of large stone monument sites, making only limited excavations in a few caves and kitchen middens (McKern 1929). McKern did recover an elaborately decorated form of pottery in these excavations, but lacking any method for direct dating, he interpreted this as a late-prehistoric variant of Fijian trade ceramics. Only decades later would his shards be properly recognized as part of the Lapita cultural complex, dating to the early part of the first millennium b.c. and associated with the first human settlement of Polynesia.

In the Marquesas Islands Ralph Linton (best known for his later ethnographic work in Africa) directed the archaeology but completely failed to recognize the potential for stratigraphic excavations. Without even bothering to test excavate, Linton simply concluded that “no opportunity was afforded for the gradual accumulation of stratified deposits” and that “no kitchen midden or shell heaps exist in the islands” (1925, 3). Thus he focused entirely on the mapping of late-prehistoric and early-postcontact monumental structures, interpreting these strictly within the context of a static, ethnographic reconstruction of “traditional” Marquesan culture. Even the possibility of cultural change or time depth (long periods of time) was thereby eliminated.

Consequently, despite a renewed emphasis on modern, scientific methods of archaeological survey (and sometimes excavation), the interpretation of Polynesian prehistory from the 1920s until World War II was largely dominated by comparative ethnology. The failure of archaeology to take hold partially resulted from the absence of any evident method for direct (or even relative) dating. Radiocarbon dating was still a thing of the future, and the methods of seriation being developed in North America and elsewhere for generating relative chronologies were seen as not applicable in Polynesia, given the general absence of pottery. Thus the stone structures and stone tools mapped and recorded by archaeologists in Polynesia were fitted into a largely static, ethnographic reconstruction and subsumed under the rubric of “material culture.” To be sure, a great deal of fundamental survey work was carried out during these years, such as that done by Kenneth P. Emory in the Society Islands (Emory 1933) and elsewhere or that of Wendell C. Bennett (1931) on Kaua'i Island (Bennett would later make his mark in Andean archaeology). This was archaeology, but it was not prehistory.

Migration Theories of the Early Twentieth Century

With the failure of archaeology to provide a real temporal framework for culture change and culture-history in Polynesia, the interpretive field was left to the comparative ethnologists, who adduced the new archaeological survey data only rarely. Dominant among this group of scholars was Edward S.

Craighill Handy, who had led the Marquesas party of the Bayard Dominick

Expeditions in 1920. Handy's theoretical perspective was closely allied to that of the European Kulturkreise (culture-circle) school (see, e.g., fritz graebner 1905), in which the origins of a particular people or culture were sought through a comparison of trait lists with neighboring or even far-flung cultures. Thus Handy developed an elaborate theory of Polynesian origins and migrations in which Polynesian cultural traits were correlated with "Brahmanical" and "Buddhistic" cultures ranging from India to china (Handy 1930). Rather than seeing variations among the Polynesian cultures as deriving from a lengthy process of cultural change in situ, he interpreted all variation as the outcome of successive "waves" of migration.

A more influential theory of Polynesian origins was promulgated by the Maori scholar Te Rangi Hiroa (also known as Sir Peter Buck), who had succeeded Gregory as director of the Bishop Museum in 1936. Hiroa was a seasoned ethnographer, with experience throughout much of Polynesia. He had, however, little use for archaeology, finding it a "dry subject." Hiroa relied more upon the salvage ethnographic work of Bishop Museum scientists to develop a migration theory that traced the route of Polynesian voyages into the Pacific not via the large archipelagoes of Melanesia but through the small coral atolls of Micronesia. In his widely read book, *Vikings of the Sunrise,* Hiroa argued that "the master mariners of the Pacific [the Polynesians] must be Europoid for they are not characterized by the woolly hair, black skins, and thin lower legs of the Negroids nor by the flat face, short stature, and drooping inner eyefold of the Mongoloids" (1938, 16). Hiroa's racially charged theory can be understood in retrospect in light of the severe racial prejudice he himself suffered at the hands of the dominant white academic society and in terms of the racial pigeonholing that characterized much of anthropology in the early twentieth century (Kirch 2000, 24-27). His theory was, however, a highly forced contrivance, and archaeology later in the twentieth century lent no support whatsoever to the concept of a Micronesian migration into Polynesia.

Within the genre of migrationist theories of Polynesian culture-history, mention must also be made of the highly influential writings of Thor Heyerdahl, a Norwegian zoologist and adventurer who captured the world's attention in 1947 with his daring *Kon Tiki* raft voyage from South America to the Tuamotu Islands. World War II had already focused much attention on the Pacific islands, and Heyerdahl now claimed to have a theory that explained the Polynesians as deriving from successive migrations not from Asia but from the Americas. The full theory was published in a massive volume a few years after the *Kon Tiki* voyage (Heyerdahl 1952), and Heyerdahl funded his own archaeological expedition to Easter Island and other Eastern Polynesian islands in 1955 and 1956 in an effort to prove his origins theory. His hypothesis has not survived the test of modern archaeological research, but Heyerdahl must be credited with helping to spur a reinvigoration of Polynesian archaeology in the period immediately following World War II.

Stratigraphic Archaeology and Culture-History

After several decades of being relegated to a minor supporting role in Polynesian studies, archaeology suddenly emerged in the aftermath of World War II as the primary source of data on Polynesian culture-history. This intellectual transformation can be traced to several developments. One was the heightened scientific interest in the Pacific islands generated in the wake of the war itself (a number of influential U.S. anthropologists and scientists had worked closely with military intelligence in the Pacific theater). Thus, in the later 1940s, renewed archaeological studies in the Pacific were initiated by such scholars as Edward W. Gifford of Berkeley in the Fiji archipelago and Alexander Spoehr of the Field Museum in the Marianas Islands (Gifford 1951; Spoehr 1957). Rather than continuing with surface surveys of monumental architecture, which had dominated prewar field research, these new efforts emphasized a return to stratigraphic excavations. Significantly, both Gifford and Spoehr, working outside

of Polynesia proper in island groups where pottery had been manufactured and used by the indigenous

inhabitants, were able to demonstrate sequences of material cultural change, primarily in ceramic styles. As a result materially documented time depth and culture change were finally shown to exist in Oceanic archaeology. Within Polynesia proper Kenneth Emory of the Bishop Museum also began a program of excavations in Hawaiian archaeological sites, beginning about 1950. The prehistoric Hawaiians had never used pottery, but Emory and his colleagues Yosihiko Sinoto and William Bonk realized that they could apply the methods of seriation to changing styles in bone and shell fishhooks, thus outlining a culture-historical sequence for the Hawaiian Islands (Emory, Bonk, and Sinoto 1959).

Equally important to the reapplication of stratigraphic methods were the discovery and implementation of radiocarbon dating by willard libby, beginning in the late 1940s. Emory, Gifford, Spoehr, and others were quick to take advantage of Libby's offer to date samples from various parts of the world, and by the early 1950s a number of radiocarbon dates had been published for sites ranging from Hawai'i to New Caledonia and the Marianas. The significance of this technological development cannot be underplayed, for it provided an independent means of assessing chronology, and the dates themselves left no doubt that the time depth of Polynesian prehistory could now be counted in thousands-not hundreds-of years. As Emory put it, radiocarbon dating "opened up undreamed of possibilities for reconstructing the prehistory of [Polynesia]" (Emory, Bonk, and Sinoto 1959, ix).

By the mid-1950s there was a veritable resurgence of field archaeology throughout Polynesia. In New Zealand the pioneering excavations of roger duff (1950) at Wairau Bar were followed by a series of careful excavations conducted by jack golson, a young Cambridge-trained archaeologist who had been appointed to a faculty post at the University of Auckland (Golson 1959). As mentioned earlier, Thor Heyerdahl privately financed and led his own Norwegian Archaeological Expedition to Easter Island and other Eastern Polynesian locales in 1955 and 1956, with excavations conducted by four professional archaeologists (Heyerdahl and Ferdon 1961, 1965). Their work also put the statue cult of Easter Island within a radiocarbon framework. At the same time, Robert Suggs of the American Museum of Natural History took up where Ralph Linton had left off in the Marquesas Islands, quickly demonstrating that the latter's assumptions about a dearth of stratified sites had no empirical justification. Suggs found a wealth of artifact-rich deposits, and his monograph outlined one of the first well-defined culture sequences for a Polynesian archipelago (Suggs 1961).

Coming less than two decades after Hiroa's migrationist theory had been at the fore, the new outpouring of archaeological results inspired a radical rethinking of Polynesian culture-history. Suggs (1960) wrote the classic synthesis of this period, *The Island Civilizations of Polynesia*, not only debunking the older ethnographic theories of Handy, Hiroa, and their peers but also attacking the rival Heyerdahl theory of American origins. Suggs's synthesis privileged the material evidence of "dirt archaeology," but it also drew widely upon newly emerging linguistic and human-biological research. Polynesian origins were now traced back to a Southeast Asian homeland, with a dispersal route through the Melanesian archipelagoes (not Micronesia, as Hiroa had advocated), this latter evidenced by a ceramic style that would shortly come to be named Lapita. The Western Polynesian archipelagoes of Tonga and Samoa were now argued to be the immediate Polynesian homeland, with subsequent voyages of colonization to the Marquesas and Society Islands and thence to the farthest islands of Eastern Polynesia.

Settlement Archaeology in Polynesia

The rejuvenation of stratigraphic archaeology in Polynesia and its expansion beyond Polynesia into the western Pacific was initially driven by a strong culture-historical orientation, encouraged by rapid success in defining considerable time depth and sequences of material culture change (whether in ceramic styles or in fishhooks and stone adzes). Under this culture-history paradigm, the emphasis in fieldwork was

PREV NEXT

dynamism of island ecosystems. Although the human role in the extinction of New Zealand's giant moa birds had long been documented (Anderson 1989), it became increasingly clear that there had been major episodes of human-induced avian extinctions throughout tropical island of Polynesia (Steadman 1995). Combined with evidence for deforestation, erosion and valley alluviation, and the widespread conversion of natural communities to highly anthropogenic landscapes, our view of island ecosystems and the role of indigenous peoples in shaping their landscape histories has been entirely transformed (Kirch and Hunt 1997).

A further outgrowth of the settlement-pattern reorientation in Polynesia throughout the 1960s, 1970s, and 1980s was a concern with wider theoretical issues in processual archaeology. The Polynesian societies had been taken as a virtual "type" instance for the concept of the chiefdom, which was regarded by many processual archaeologists as a key intermediary stage in the evolution of human societies from simpler band and tribal levels of sociopolitical organization to fully state-level polities. This made the study of variation and cultural change within Polynesian chiefdoms a topic of some theoretical import. T. Earle (1978, 1997), for example, drew upon his research on Kaua'i, Hawai'i, both to test Wittfogel's "hydraulic hypothesis" regarding the role of irrigation in the rise of complex societies and more generally to test notions of "how chiefs come to power." Kirch (1984) integrated ethnohistorical and archaeological approaches to construct a broad model of the evolution of Polynesia chiefdoms, arguing that the trend toward increased hierarchy and social control in certain Polynesian societies was substantially constrained by a constellation of demographic, ecological, and economic parameters. In a later study Kirch (1994) argued that a fundamental dichotomy between "wet" and "dry" agricultural landscapes strongly constrained the evolution of hierarchy and power.

New Views on Polynesian Origins and Dispersals

Perhaps because the question of how a "Neolithic" people managed to discover and colonize the most isolated islands on earth remains such an intrinsically compelling issue, the matter of Polynesian origins and dispersals did not disappear with the paradigm shift from culture-historical to processual archaeology. Rather, this question has received renewed scrutiny and been the subject of invigorated debate since the 1970s, as a result of several developments. One impetus was the expansion of modern archaeological work into Melanesia, a region that had been almost entirely neglected prior to World War II. In particular, the realization that a widespread early-ceramic horizon-the Lapita cultural complex-linked the initial stages of human settlement in both Polynesia and eastern Melanesia provoked a fundamental rethinking of Polynesia origins (Green 1979). The earliest Polynesian cultures are now seen to be a direct development out of an early eastern Lapita culture, itself the eastward extension of a process of Lapita expansion that had commenced in the Bismarck Archipelago around 1500 b.c. (Kirch 1997).

Equally important has been a rethinking of the process of dispersal and colonization of islands within the Polynesian triangle itself, where the longest voyages of discovery involved distances of as much as 3,000 kilometers against generally prevailing winds and currents. Computer simulations of the probabilities of accidental drift voyaging first led to a new realization of the high degree of intentionality in early Polynesian voyaging (Irwin 1992). But it is the dramatic experimental voyages of the replicated voyaging canoe *Hokule'a* that have particularly forced a new model of Polynesian colonization (Finney 1994). These voyages, conceived as a kind of "experimental archaeology," have taken the double-hulled, 19-meter *Hokule'a* on journeys between many Polynesian archipelagoes without the aid of instrument navigation, the most dramatic being a voyage from Mangareva to remote Easter Island in 1999.

The investigation of voyaging and interaction between Polynesian islands and archipelagoes has also been spurred by the application of new archaeometric techniques, especially X-ray fluorescence

sourcing of basalt artifacts such as adzes. M. I. Weisler and Kirch (1996) demonstrated the transport of stone adzes between

Samoa and the Cook Islands, a distance of some 1,600 kilometers, and more recently Weisler (1998) has tracked the movement of adzes from the Marquesas to the Society Islands. Equally innovative has been the work of E. Matisoo-Smith and colleagues (1998) using studies of mitochondrial DNA variation in Pacific rats (*Rattus exulans*) to show patterns of interisland contact.

Contemporary Archaeology in Polynesia

Polynesian archaeology continues to change and evolve. The very practice of archaeology has been significantly affected by changing institutional and sociopolitical contexts. Throughout the first six decades of the twentieth century, archaeology fell almost exclusively within the institutional purview of a few museums and universities. This situation began to change dramatically in the 1970s with the rise of "public archaeology" or, as it has come to be labeled in Americanist contexts, "cultural resource management" (CRM) archaeology. In Hawai'i, for example, most contemporary archaeological work is carried out not by research institutions but by private (for-profit) archaeological contractors. Thus the very definition of field projects has shifted from areas selected strictly on the basis of their research potential to specific locations subject to impact from highway construction, resort development, and the like (Graves and Erkelens 1991; Kirch 1999). Similarly, in French Polynesia much archaeological work is now undertaken to mitigate the adverse effects of "development," such as in the large-scale Papeno'o Valley project where the construction of hydroelectric dams was the main consideration. Although it has generated significant new funding sources for fieldwork, this shift to CRM archaeology also led to the production of a very large "gray literature" of archaeological reports not published in the usual academic journals and monographs-a serious problem for the long-term archiving and preservation of archaeological evidence.

The sociopolitical context of Polynesian archaeology is also rapidly evolving. Once almost exclusively the purview of white, expatriate scholars (Te Rangi Hiroa was a major exception), archaeology in the islands has begun to incorporate significant numbers of indigenous practitioners. As Polynesians themselves are trained in the theory and methods of archaeology and begin to take up professional posts in museums, universities, historical preservation agencies, and CRM firms, they bring new questions and concerns to the field. There is, for example, a renewed interest in the potential integration of indigenous oral traditions and narratives with archaeological evidence (Cachola-Abad 1993). Heightened cultural sensitivity toward the archaeological record has also changed the nature of archaeological practice. This is evidenced, for instance, in the complete reburial of several thousand human skeletal remains that had been excavated from Hawaiian archaeological sites, a direct outcome of the Native American Graves Protection and Repatriation Act in the United States.

These and other influences will continue to modify the ways in which archaeology is practiced in Polynesia and elsewhere in the Pacific islands. Certainly, however, there is no sign that interest in Polynesian archaeology is abating. The long-term history of the islands and their indigenous peoples has engaged scholars for more than two centuries, yet new questions continually emerge even as older issues receive renewed scrutiny from fresh approaches and methods.

Polynesian Society

Formed in Wellington, New Zealand, on 8 January 1892, the Polynesian Society has been publishing a quarterly journal ever since. The *Journal of the Polynesian Society* (*JPS*) is one of the oldest continuously published anthropological journals in the world and has always been the preeminent journal of its kind in the Pacific region. The journal and the society's other publications, including fifty memoirs, are the primary record of the society's activities. A bibliography of the journal was compiled by Dorothy Brown (Brown 1993), and a centennial history by M. P. K. Sorrenson (Sorrenson 1992) was published by the society. Most of the society's papers are held at the Alexander Turnbull Library in Wellington, and the remainder are in the society's office in the Maori Studies Department of the University of Auckland.

Ethnographic recording of the culture of the

Ngata was a leading Maori scholar in his own right, a longtime member of the society and later its president, and a frequent contributor to *JPS.* The board subsidized the society's publications and other activities.

Although Maori scholarship remained the main focus of the society's work and publications, the wider Pacific was not ignored. An important figure in this regard was Ngata's friend and former political colleague, Te Rangihiroa (Peter Buck), who first became a research fellow at the Bishop Museum in Hawaii in 1927. He subsequently became its director. Buck remained in frequent contact with Ngata, as can be seen by their extensive correspondence, published as *Na To Hoa Aroha* (Sorrenson, ed. 1986-1988). He was also in touch with Andersen, sometimes contributed to the *JPS,* and solicited copy from his Bishop Museum colleagues, including E. C. S. Handy and Kenneth Emory. Nevertheless, the bulk of the material for the *JPS* still came from enthusiastic amateurs.

The professional takeover of the journal and eventually the society did not occur until after World War II and the establishment of an Anthropology Department at the University of Auckland in 1950, when Bill Geddes, jack golson (the first archaeologist to be appointed to a New Zealand university), Murray Groves, and Bruce Biggs took turns as editor of *JPS.* They also infiltrated the Wellington-based council of the society. The editorship of the *JPS* has remained with the Auckland Anthropology Department, and the Auckland editors have given the journal a thoroughly professional appearance and content, drawing most of their material from academic colleagues at New Zealand universities and from abroad.

Most of the articles have been on social anthropology, linguistics, and archaeology, and the balance between New Zealand and Pacific material has gradually tilted in favor of the latter as the Pacific peoples, several of them in the process of gaining independence, became the focus of intense academic interest. A notable case was papua new guinea, the anthropologists' last frontier. But old perennials, like the quest for Polynesian origins, have continued to tease scholars and fill the pages of the society's publications. That subject got a new lease of life when the society published Andrew Sharp's controversial *Ancient Voyagers in the Pacific* in 1956, and there have been numerous subsequent contributions published in *JPS* or as separate memoirs. The subject is far from exhausted, even today.

With the later establishment of Maori studies departments in most New Zealand universities, there was a greater involvement of Maori scholars in the journal and the society. In 1979, Bruce Biggs, the first professor of Maori studies at Auckland, became president of the society, and in the following year, the society's office was shifted from Wellington to Auckland, where it remains. In 1999, Biggs surrendered the presidency to his successor in the Maori studies chair, Sir Hugh Kawharu.

The society ended its first century as it had begun: a small band of dedicated scholars, now mainly university academics, who in their “spare” time continue to put together a journal that remains preeminent in its field.

Pompeii

No archaeological site has captured the popular imagination like Pompeii, a prosperous Roman town on the Bay of Naples, some 200 kilometers south of Rome. It was effectively discovered in 1748; inscriptions and other finds made during the construction of an aqueduct between 1594 and 1600 had failed to raise interest. Destroyed by the eruption of Vesuvius in a.d. 79, ancient Pompeii covered 66 hectares within the city walls, with villas, cemeteries, and other

now regarded rather less like a time capsule than it was in the past.

In the twentieth century Vittorio Spinazzola (working from 1910 to 1923) and Amadeo Maiuri (from 1923 to 1961) cleared an enormous area of Pompeii, especially along one of the main streets of the town, the so-called Via dell'Abbondanza. Publication lagged badly behind, and Pompeii's structures suffered disastrously (especially from 1940 onward) from pollution, theft, tourism, earthquakes, bombardment during World War II, and, most particularly, neglect. Since 1980 the pace of excavation has slowed considerably, and a large-scale restoration program has been undertaken using mainly traditional materials, rather than the inappropriate modern materials used in the past. The most recent projects have concentrated on previously excavated structures, documenting what remains of the buildings and decorations in an attempt to recover the finds and their contexts; to better understand the building history of the structures and the urban development of Pompeii, digging often extends below the a.d. 79 level.

Popenoe, Dorothy Hughes

(1899-1932)

Trained as a botanist and a pioneer in the determination of cultural chronology in Honduran prehistory, Dorothy Hughes Popenoe conducted independent fieldwork in Honduras and sought the advice and sponsorship of A. M. Tozzer of the peabody museum at Harvard University. Her major works, published posthumously, dealt with the sites of Playa de los Muertos and Tenampúa in Honduras.

A brief memoir by Thomas Barbour, issued as an introduction to her posthumously published study of Antigua, guatemala, and an obituary by Alfred M. Tozzer in *Maya Research* provide sketchy details of Popenoe's early life. She was born in Great Britain, and following World War I she worked as a technical illustrator at Kew Gardens in London. She developed enough expertise to establish new species of grasses in the scientific literature. Her relocation to Washington, D.C., in 1923 as an employee of the U.S. National Herbarium led to her marriage to Wilson Popenoe. Accompanying him to Honduras in 1925, after he accepted a position with the United Fruit Company, she began a brief but highly active career that was ended prematurely by her accidental death.

Popenoe's earliest work, published with her husband in 1931, was the report of a site uncovered during construction of a botanical station at Lancetilla, near Tela on the Caribbean coast of northern Honduras in 1925. The report mixes a scientific format, a description of each category of data, with a speculative vignette about life at the site on the eve of Spanish conquest. Since both Wilson and Dorothy Popenoe were accomplished botanists, it is no surprise that they attempted to present the archaeological data

according to the standards of the time, including the use of general taxonomies of material culture, especially of lithics, that implied time depth. But the site could not be placed in any real context because of a paucity of available literature on Honduran archaeology.

Dorothy Popenoe's interest in archaeology was apparently engaged by this chance discovery. According to Barbour, she was determined not to be idle after her transfer to Honduras and had begun historical and ethnographic investigations. Following the Lancetilla excavations, she took a major step forward in archaeology by initiating excavations at Tenampúa in the Comayagua Valley in 1927, a fortified hilltop site that had been reported over fifty years earlier by American archaeologist E. G. Squier. Popenoe's Spanish-language report (1928), reissued in English after her death by the smithsonian institution (1936), is most notable for drawing on sixteenth-century ethnohistoric documents in an attempt to identify the site.

Portugal

The first Portuguese contacts with the Stone Age came through the navigators who reached the coasts of Africa, South America, and Asia in the fifteenth and sixteenth centuries. By a.d. 1500 these contacts had already resulted in the production of the first reports on such peoples as the Guanche of the Canary Islands, the San (Bushmen) of Southern Africa, and the Indians of brazil, including accurate descriptions of polished stone axes and other tools. However, these descriptions failed to produce any impact on sixteenth- and seventeenth-century humanists and scholars who studied Roman and pre-Roman antiquities.

By the end of the eighteenth century archaeology had become an established discipline. The first scientific excavations in Portugal were undertaken at the time by Friar Manuel do Cenáculo, in the Iron Age settlement of Cola (Alentejo). Several descriptions and inventories were published of dolmens, which were correctly interpreted as pre-Roman monuments but generally thought to be altars, not burial chambers. And, as elsewhere in Europe, it was not until the mid-1800s that the concept of the remote antiquity of humanity was finally accepted, mainly as a result of developments in the geological sciences.

Beginning in 1848 several organizations were created to survey the geology of the country, and prominent members of their staffs, such as Carlos Ribeiro and Joaquim Filipe Nery Delgado, became interested in the problem of human origins. Ribeiro's work on the eolith problem and the possible existence of people in Europe in the Tertiary era is well known. It led scholars of the time to agree to convene the 1880 session of the Congrès International d'Anthropologie et d'Archéologie Préhistoriques in Lisbon in order to be able to inspect his sites and finds.

Delgado's work is not as well known but is of greater general methodological relevance. He was appointed to the Geological Survey in August 1857 at the age of twenty-two, but his first independent work was the geological mapping of the Peniche area. This project eventually led him to the excavation of the Casa da Moura cave site, which he began on January 19, 1865. The results obtained after initial testing led to the almost immediate publication of an extensive bilingual (Portuguese and French) monograph whose title, *The Existence of Man on Our Soil in Very Remote Times Proved by the Study of Caves,* leaves no doubt as to the research design that drove him in this early stage of his scientific career.

At that time the evidence from caves was regarded as untrustworthy. It was the fluvial deposits of the Somme Valley that played a key role in the establishment of the remote antiquity of humans. They, in turn, were used to validate some of the associations between artifacts and extinct fauna found in various caves of Germany, England, france, and belgium. Several objections had been raised against such evidence. Some argued that deposits of very different ages could easily be intermixed during the flooding to which caves are often submitted; others contended that the use of caves by people to bury their dead may have caused the occurrence of human bone in apparent association with extinct faunas; and still others suggested that although the deposits might have been originally undisturbed, mixing could arise from careless investigation.

Since his work was wholly based on the exploration of caves, Delgado had to deal with these objections, which probably explains the most remarkable characteristic of his monograph: the fact that it represents an integrated geo-archaeological approach to site-formation processes. Moreover, the great detail with which he recorded stratigraphic observations (the correctness and precision of which have since been demonstrated by reexcavation of the residual deposits at Casa da Moura) was intended to avoid any objections that his conclusions were based on careless excavation.

His most important find was a carefully described and measured human skull and mandible, which were enveloped in a matrix of concreted red sands just like the ones that composed the in situ lower deposit of the site. This cranial material was clearly of Pleistocene age and should therefore be counted, alongside better-known fossils such as the Engis adult skull and the Red Lady of Paviland, as one of those early findings of Upper Paleolithic human fossil remains that took place before the 1868 discovery of the Cro-Magnon burials. However, unlike the material at Paviland and Engis, the Casa da Moura material's age was correctly recognized and established by the discoverer.

Later revision of the Paleolithic artifacts from the cave identified Gravettian and Solutrean components. At that time, however, investigations

Potocka Zijalka

Potocka Zijalka is an alpine Paleolithic cave site in slovenia, approximately 1700 meters above sea level, on the southern edge of the Karavanke mountain ridge on the Slovenian-Austrian border. The site was discovered by srecko brodar in 1928 and was systematically excavated until 1935.

The archaeological record comprises numerous cultural layers all belonging to the Wurm I-II phase of the Aurignacian period, around 34,000 years ago. Brodar's excavation revealed numerous finds, the most outstanding among them being 133 bone points of the Mladec, or elongated oval-shaped, type (also Lautscher type), the largest known collection of points of this type found in one site. Some of them have traces of the earliest known ornamentation of parallel incisions while others seem to be the prototype of a needle and a simple flute with three holes made from the cave bear's mandible. The total artifact assemblage consists of more than 100 tool types.

The vast majority (99 percent) of the faunal remains belong to the cave bear (*Ursus speleaus*) with the more poorly represented other species being musk ox (*Ovibus moscatus*), wolf (*Canis lupus*), and smaller mammals (*Micromammalia*). Several hearths containing charcoal of tree species *picea* and *pinus* were detected some 20 meters from the entrance to the cave. Owing to the extreme altitude and the artifact richness of the site, Brodar proposed that Olschevien (called after Olseva, the location of the Potocka Zijalka) was a distinctive cultural phase of the alpine Aurignacian hunters and gatherers. However, his proposal has not been accepted.

Poverty Point

Brought to public attention in 1873 by Samuel Lockett, Poverty Point is one of the most significant sites in North America, located near the Mississippi River in northern Louisiana. It is most closely linked to the work of James A. Ford, who began research there in 1953. Constructed between 1730 b.c. and 1350 b.c. by a preagricultural people, the site features complex earthworks undertaken on a massive scale. The central construction is composed of six rows of concentric ridges, which are thought to have been 1.3 meters high originally. The five aisles and six sections of ridges created by this construction take the form of a wheel; the diameter of the outermost ridges measures three-quarters of a mile. Scholars believe that these ridges served as foundations for dwellings, although little evidence of structures has been found. However, features and midden deposits uncovered during excavations offer some support for this theory. Large earth mounds were also constructed on the site; among them are Poverty Point Mound, which measures about 210 by 195 meters at its base and is 21 meters high, and Mound "B," which is conical in shape.

We know quite a bit about the people who lived at Poverty Point. For example, they imported stone for projectile points from as far away as the Ouachita and Ozark Mountains. Indeed, the evidence indicates that Poverty Point was part of a major trading network that spanned the eastern United States.

Powell, John Wesley

(1834-1902)

John Wesley Powell grew up in the midwestern portion of the United States, fought in the American Civil War, and later became an explorer of the Colorado River canyons. He began fieldwork among the Soshone, Ute, and Paiute Native American Indian peoples of the Great Basin and Grand Canyon regions. He founded the smithsonian institution's Bureau of American Ethnology (BAE), which he directed from 1879 until 1902.

As an early anthropologist, geologist, and member of the Anthropological Society of Washington, D.C., Powell was an evolutionist. Greatly influenced by Charles Darwin, Herbert Spencer, and lewis henry morgan, he envisaged a rigid framework for human development. As director of the BAE, he supported the Cyrus Thomas Survey of North American Indian mounds and sponsored the fieldwork of archaeologists frank cushing and william henry holmes, among others. He also supported the preparation of the 1891 linguistic map of North American native peoples and the collection of Native American Indian vocabularies.

Powell argued for applied government anthropology to improve reservation conditions; for federal government support of linguistic, archaeological, and ethnographic fieldwork; and for the preservation of antiquities such as Great Serpent Mound in Ohio and casa grande in Arizona. The publication of his own

fieldwork was not realized until a century after his death; however Powell contributed many essays to the BAE's annual reports as its director.

Prestwich, Sir Joseph

(1812-1896)

Born in London and educated at University College, London, Joseph Prestwich abandoned a career in chemistry to work in his father's wine merchant business. He took up geology and became particularly interested in stratigraphical analysis. His papers on the Tertiary geology of southeastern England and on Quaternary geology published in the mid-1840s and 1850s established his reputation and his place among the elite of British science. In 1874, Prestwich finally retired from business and took up the chair of geology at Oxford University.

In 1858, Prestwich was a member of the committee of the Geological Society of London that presided over the excavation of brixham cave by william pengelly, but Prestwich agreed with Richard Owen and geologist sir charles lyell that the evidence was not enough to establish greater human antiquity. In 1859, hugh falconer insisted that Prestwich visit French archaeologist jacques boucher de perthes in France and examine the evidence of human antiquity that he had found in the Somme River gravels. Prestwich was persuaded of the validity of this evidence, and from then on he supported the notion of a high human antiquity and the value of the discoveries at Brixham Cave.

Prestwich was elected fellow of the Royal Geological Society in 1833 and fellow of the Royal Society in 1853. He was knighted in 1896.

Prinsep, James

(1799-1840)

If any person in addition to alexander cunningham can be called a founding father of Indian archaeology, the honor should go to James Prinsep. He was the assay master of the East India Company mints and was posted first to Varanasi and then to Calcutta. Prinsep initiated the tradition of field investigations by members of the company and other European officials in various parts of the country where they traveled in their private capacities. Prinsep became the secretary of the Asiatic Society of Bengal in the 1830s and began the new and regular publication of the society, which continues even today: the *Journal of the Asiatic Society of Bengal* first appeared under his editorship in 1832. His stimulation and encouragement of the antiquarian interests of his European contemporaries in India has been well expressed by Abu Imam (1966, 21-22): “A new breed of officers arose who interested themselves in the mysterious remains of the country's past, although preoccupied with their official duties.… On their

various rounds in the four corners of India, these officers began to shower on Prinsep coins, inscriptions and rubbings in profuse numbers.… Soon both the collectors and the interpreters were acting in a spirit of friendly competition."

Prinsep's own special fields of study lay in coins and inscriptions. He studied and cataloged a large series of north Indian coins, beginning with Roman coins in "upper India" (Prinsep 1832). His study of Greek coins in the possession of the Asiatic Society (Prinsep 1833) was the first study of the Indo-Greek phase of history in the northwestern part of the subcontinent. He was also astute enough to realize the significance of the nameless early historic coins of northern India, and in the Indian area he was certainly the first to appreciate the dating value of coins in archaeological contexts (Prinsep 1834).

It is, however, principally for his decipherment of the ancient Brahmi script of the Asokan inscriptions of the third century b.c. and of the similarly dated Kharoshti script (confined principally to the northwest) that Prinsep is most famous. The study of the late form of Brahmi script began in the late eighteenth century on the basis of its resemblance with the script form

works portrayed the aztec and inca as civilized peoples and remain the standard authorities on the Spanish conquistadores in the New World. Both works brought Prescott widespread recognition in Europe.

Prinsep's own special fields of study lay in coins and inscriptions. He studied and cataloged a large series of north Indian coins, beginning with Roman coins in "upper India" (Prinsep 1832). His study of Greek coins in the possession of the Asiatic Society (Prinsep 1833) was the first study of the Indo-Greek phase of history in the northwestern part of the subcontinent. He was also astute enough to realize the significance of the nameless early historic coins of northern India, and in the Indian area he was certainly the first to appreciate the dating value of coins in archaeological contexts (Prinsep 1834).

It is, however, principally for his decipherment of the ancient Brahmi script of the Asokan inscriptions of the third century b.c. and of the similarly dated Kharoshti script (confined principally to the northwest) that Prinsep is most famous. The study of the late form of Brahmi script began in the late eighteenth century on the basis of its resemblance with the script form

of late medieval Bengali and related manuscripts in eastern India. The task of decipherment then proceeded from the known to the unknown and culminated in Prinsep's reading of the Asokan inscriptions around 1837 (Prinsep 1837). He achieved this task between 1834 and 1838. The main source of study of the Kharoshti script for Prinsep was a series of Indo-Greek coins bearing royal names both in Greek and Kharoshti, which made the task of decipherment comparatively easier.

Pinsep's spirit comes through when, writing about the framework of archaeological researches in India, he advocates “the need of an independent pursuer of the object for its own sake; or for his own amusement and instruction” (Prinsep 1835, 623).

Proskouriakoff, Tatiana

(1910-1985)

Tatiana Proskouriakoff was one of the greatest scholars of the maya civilization. She made major contributions in the areas of Maya art and architecture as well as in the decipherment of Maya hieroglyphics.

Proskouriakoff was born in Russia in 1910 and emigrated to the United States with her family while still a child. She graduated from university with a degree in architecture just as the Great Depression set in. She was a wonderful artist, and her talents were spotted by Linton Satterthwaite, who at the time was excavating the classic Maya site of Piedras Negras, guatemala, as part of a University of Pennsylvania project. He hired her as staff artist for the project, and her superb reconstruction drawings of ancient Maya sites and temples caught the attention of scholars working for the Carnegie Institution of Washington, D.C., at the time the largest and best-funded institution working in the Maya area. Proskouriakoff was hired by the Carnegie Institution in 1940 and spent the rest of her career as one of its staff archaeologists, working at sites such as Copan, Uaxactun, and Mayapan in Central America.

In 1946, Proskouriakoff published *An Album of Maya Architecture,* which is a compendium of her reconstruction drawings of classic Maya buildings. In 1950, she published *A Study of Maya Art,* a brilliant analysis of the motifs and details contained in Maya sculptural art that contained as a major

component a technique for “style dating” monuments that had no legible dates. These two books immediately became “classics” in Maya studies.

But Proskouriakoff did not stop there and focused her attention on Maya hieroglyphs. In 1960 she published an article that is perhaps the most important in all of Maya studies. Cogently, and in great detail, she deciphered the dynastic sequence of Piedras Negras, identifying a 200-year succession of kings and their birth and accession dates at the site. Such work might not seem particularly earthshaking, but the article must be seen in the context of the then-current views on ancient Maya society. Increasingly over the previous thirty years or so, Mayanist scholars had come to the conclusion that classic Maya society was not ruled by secular kings but was made up of a peaceful rural peasantry overseen by a priestly class that lived almost as ascetics in otherwise unoccupied “ceremonial centers.” Proskouriakoff's article changed this view overnight, and since the 1960s there has been a tremendous advance in the understanding of classic Maya society and politics. Scholars can now decipher Maya hieroglyphic inscriptions almost completely, and the intricacies of Maya politics within and between kingdoms are increasingly understood.

Proskouriakoff continued leading that aspect of Maya research until the Carnegie Institution withdrew from the field of Maya studies in the 1960s. By this time she was living in Cambridge, Massachusetts, and was affiliated with the peabody museum at Harvard University. Even in retirement, Proskouriakoff continued to make major contributions to the field: for instance, in 1974 she published a major study of the thousands of jade objects thrown into the sacred well at chichén itzá, Yucatán, once one of the principal centers of the Maya.

Pueblo Bonito

Pueblo Bonito is the largest Anasazi site of chaco canyon in northwestern New Mexico. It is located on the north side of Chaco Canyon, between Chaco Wash and the canyon wall. Built in the Pueblo III style during the early tenth century, Pueblo Bonito has 800 rooms in a D-shaped complex over three acres, with evidence of earlier settlements underneath the remaining structure. Approximately 1,000 residents were accommodated by this site. Pueblo Bonito is characteristic of the southwestern Anasazi sites of the Pueblo III period, with Black-on-red pottery; rectangular pit houses; multistory, multiroom pueblos; and well-developed kivas.

Among the many sites of Chaco Canyon, Pueblo Bonito is remarkable for offering scientists a chance to accurately date the structures. Besides being the largest and most outstanding site of the time, Pueblo Bonito contains many wooden support beams. The wood was well preserved in the southwestern climate of dry heat and affords a uniquely precise insight into the timeline of the building. Dendrochronology, a dating technique developed using tree rings to measure time, was used very successfully to pinpoint the age of the building. Pueblo Bonito has been accurately dated to between a.d. 919 and a.d. 1130 through tree-ring dating of the large number of wooden beams.

The structure itself is the most impressive site in the entire Southwest at this time for several reasons. It is the largest masonry structure; and judging by its sameness throughout was most likely planned as a unit. It contains many kivas (large meeting or ceremonial rooms), and is similar to pueblos nearby, but the scale of Pueblo Bonito is very large in many aspects. The walls are very thick and the rooms much larger than other pueblos. The walls are rubble-filled, with a shaped sandstone exterior that encloses an inner court. Pueblo Bonito is three to four stories high at the back, with one great kiva and several smaller kivas.

The site has advanced architecture and similarly complex cultural traits. This conclusion is reached, according to Lister and Lister, because of the social organization needed to create such a large and planned village. The site shows evidence of population increase, localization of the population, and craft specialization. All these factors represent a complex, stable social organization. Most likely the Pueblo Bonito site was influenced by the casas grande sites in Mexico.

In an 1877 visit to Chaco Canyon William H. Jackson drew a map of the Pueblo Bonito site and a reconstruction. Pueblo Bonito was first photographed by Victor Mindeleff in 1888. From 1897 to 1899,

George H. Pepper and Richard Wetherill cleared 189 rooms and several kivas, published in their field notes. Neil M. Judd completed excavation of the rest of Pueblo Bonito between 1921 and 1927. The more significant reports were published by *National Geographic Magazine.* Gordon Vivian of the National Park Service worked on stabilizing and opening more rooms in the 1930s. Judd and andrew e. douglass collected tree-ring specimens for dating, as did Deric O'Bryan at Gila Pueblo. Tree-ring dates range from a.d. 828 to 1130. Construction and minor reconstruction continued between two main building periods, first in the early tenth century, after a.d. 919, and the second in the second half of the eleventh century.

Many of the Pueblo Bonito rooms contained burials and funerary items, but do not contain remains of the entire population. Many rooms excavated were previously undisturbed, and had intact floors and ceilings which preserved artifacts

that would normally deteriorate, such as wood, basketry, cordage, and shell. Pueblo Bonito is the most studied of sixteen great towns built in the Pueblo III era.

Pumpelly, Raphael

(1837-1923)

Raphael Pumpelly was born in canada, lived in the United States, and studied to be a mining engineer in Freiberg, Germany. In 1859 he returned to the United States to mine silver in Arizona, and in 1861 he went to San Francisco where he was appointed geologist for the Japanese government. When this job finished in japan in 1863, Pumpelly traveled to china and then, in 1865, made his way overland to Europe via central Asia and Siberia.

Pumpelly returned to the United States in 1869 and began to explore the copper and iron deposits of Michigan; in 1871, he became that state's state geologist. Ill-health caused him to resign, and he returned to the eastern states. In 1884, he began working for the New England Division of the U.S. Geological Survey under john wesley powell. In 1903, the Carnegie Institution of Washington, D.C., hired him to organize and conduct expeditions to central Asia to look for prehistoric sites and evidence of climatic changes. His excavation of the site of Anau in Russian Turkistan led Pumpelly to propose an “oasis theory” for the origins of food production during the Neolithic period. This theory was based on the fact that as the Near East became drier after the last Ice Age, its hunter-gatherers were forced to group around water sources and domesticate wild animals and crops in order to survive. sir grafton elliot smith, harold john edward peake, and herbert j. fleure popularized this theory during the two decades after Pumpelly's death, and vere gordon childe was especially influenced by it.

Putnam, Frederic Ward

(1839-1915)

After early training under Henry Wheatland at the Essex Institute in Salem, Massachusetts, Frederic Ward Putnam studied with Louis Agassiz and Asa Gray at Harvard University. After the revolt of Agassiz's students in 1863, Putnam returned to Salem, where he had been born, and founded and published *The American Naturalist,* directed the new (1868) Peabody Academy of Science, and pursued a career in ichthyology and herpetology.

Upon the death of Jeffries Wyman in 1874, Putnam returned to Cambridge, Massachusetts, as director and curator of the peabody museum of American Archaeology and Ethnology at Harvard. He became Peabody Professor of Anthropology as well in 1887, and he held all three positions until retirement in 1909. He served as permanent secretary of the American Association for the Advancement of Science (AAAS) from 1873 to 1898 and president of AAAS from 1898 to 1899. He was a founding member of the archaeological institute of america in 1879 and was largely responsible for its early work in the Western Hemisphere. From 1891 to 1894, he served as chief of the Department of Ethnology of the World's Columbian Exposition in Chicago, directing the work of anthropologists Franz Boas, Alice C. Fletcher, Zelia Nuttall, Marshall Saville, George Byron Gordon, George A. Dorsey, Warren K. Moorehead, and many others. From 1894 to 1903, he served as curator of anthropology at the American Museum of Natural History in New York. He and Boas supervised the Jesup North Pacific Expedition and the Hyde expeditions to the American Southwest in the late nineteenth century. In

Quatrefages, Jean Louis Armand de

(1810-1892)

Jean Louis Armand de Quatrefages studied medicine at the University of Strasbourg and practiced as a doctor in the southwestern French city of Toulouse until 1840 when he moved to Paris to become a scientific writer and illustrator. De Quatrefages was a talented draftsman and began to work for the National Museum of Natural History in Paris while publishing extensively on invertebrate biology and classification.

In 1850, he was appointed to a university chair of natural history, but in 1855 he returned to the museum to take up the chair of anthropology (formerly anatomy and human natural history) and his research and publications became focused on anthropological issues. He was strongly opposed to Darwinian evolutionary theory and to the theories of English scientist Thomas Henry Huxley, and he remained firmly convinced that mankind had not evolved from apes but was a separate entity in the rest of the animal world. He was also against polygenism and an opponent of the French anthropologist Paul Broca.

Although a conservative, de Quatrefages was an early believer in the idea of human antiquity, which, allied with his anti-evolutionist views, explains why he was such an ardent supporter of the authenticity of the moulin-quignon Jaw. De Quatrefages's major publication, *Crania ethnica* (1882), produced jointly with colleague Theodore Hamy, followed the rejection of his arguments concerning the validity of the Moulin-Quignon fossil. The book stands as his most significant contribution to the debate about the nature of human physical evolution in Europe.

R

"Race" and Ethnicity, Archaeological Approaches to

Concepts of race and ethnicity have played an important role in the production of archaeological knowledge throughout the history of the discipline. One of the first questions that antiquarians and archaeologists have asked of the physical remains that they deal with is, Who was responsible for these creations? The answers have almost always been sought in terms of named groups of people, and embedded in these attributions are theories about the nature of the groups concerned. Here, the concepts of race and ethnicity have taken center stage, alongside the related concepts of culture, nation, and tribe. Yet despite their apparently straightforward role in the initial naming and classification of archaeological remains, race and ethnicity have a checkered history within the discipline. Their complex and overlapping meanings and uses have changed dramatically over time, as have the different theories surrounding them. They have also been implicated in some of the major epistemological shifts within the discipline. Finally, archaeological interpretations of race and ethnicity have been intricately bound up with the construction of modern ethnic, national, and racial identities, adding greater weight and urgency to the development of critical approaches to these concepts within the discipline.

Race, Culture, and Language

During the nineteenth century the study of archaeological remains became intertwined with the task of defining the "races" of humanity. A complex range of theories and definitions developed over this time, but a number of general trends can be observed. Race was thought to be *the* primary basis of human differentiation. Other concepts that later became associated with very different forms of group identity-concepts such as nation, ethnic group, and tribe-were often used interchangeably, but they were all heavily racialized. Races were regarded as discrete, objective entities, each possessing its own unique character. Scholars attempted to identify and describe the different races of humanity on the basis of empirical criteria. Physical and anatomical features were given a primary role in the definition of races, but language, psychology, and cultural and intellectual ability were also seen as important. Indeed, racial theories posited a direct relationship between biological and cultural capabilities, and it was argued that physical features such as cranial shape and size determined cultural and intellectual ability. Research was also devoted to explaining the origins of different races, which entailed the study of the historical and evolutionary relationships between them. Many different disciplines were involved in the study of race, including anthropology, archaeology, philology (historical linguistics), biology, psychology, and anatomy, and the individual scholars often moved between two or more disciplines. Recent historiographical studies of nineteenth-century theories of race include George Stocking's *Culture and Evolution* (1968), Michael Banton's *The Idea of Race* (1977), and I. Hannaford's *Race: The History of an Idea in the West* (1996).

Archaeological research played an important role in the development of racial typologies and in historical and evolutionary theories of race.

Archaeological research played an important role in the development of racial typologies and in historical and evolutionary theories of race.

closely interrelated and coeval with one another. On the basis of this methodology he claimed that it was possible to identify major prehistoric racial groups, such as the Aryans and the Slavs, and trace their relationships through time. The work of others, such as the early archaeology of vere gordon childe, although of a very different political persuasion, was embedded in similar concepts and methodology, as exemplified in Childe's book *The Aryans* (1926). The conflation of race, language, and culture in the study of archaeological remains can be confirmed by a glance though the volumes of any early archaeological journals. For more recent historiographical overviews see Colin Renfrew's *Archaeology and Language* (1987), K. Sklenár's *Archaeology in Central Europe* (1983), and Siân Jones's *Archaeology of Ethnicity* (1997).

The Politics of Race

Racial typologies and classifications remained all-pervasive throughout the nineteenth century and the first few decades of the twentieth century, penetrating many aspects of social life and informing ideological and political debates. The idea that the physiological characteristics of particular races determined cultural and intellectual ability, allied with evolutionary theories, provided a convenient way to justify relationships of power in the context of slavery and colonialism. For instance, applied to colonial America or Africa, such approaches placed the indigenous inhabitants lower down on the evolutionary ladder and members of European "civilization" at the top. Archaeologists maintained this idealized evolutionary racial hierarchy by going to great lengths to attribute "sophisticated" sites and assemblages to migrating races of European or Near Eastern origin (despite evidence to the contrary) rather than to the supposedly backward non-European races. For classic examples see Peter Garlake's *Great Zimbabwe* (1973) and R. Silverberg's *Mound Builders of Ancient America* (1968). Recent historiographical studies highlighting the politics of racial theory and the role of archaeology more generally include Bruce Trigger's *A History of Archaeological Thought* (1989) and "Archaeology and the Image of the American Indian" (*American Antiquity* 45, 1980), Martin Bernal's *Black Athena* (1980), and K. Sklenár's *Archaeology in Central Europe* (1983); further case studies are provided by contributions to a number of books in the One World Archaeology Series (Routledge), in particular *Archaeological Approaches to Cultural Identity* (S.J. Shennan, ed. [1989]) and *Social Construction of the Past: Representation as Power* (G. C. Bond and A. Gilliam, eds. [1994]).

The concept of race played an equally important role in European politics of the nineteenth and early twentieth centuries. Nations were conceived of in racial terms, and states justified their actions toward one another and their own populations on the basis of racial theory. Once again archaeology's role in legitimizing and informing contemporary political thought concerned historical relations between races, in particular the evolution of European civilization. Archaeological evidence was employed in the competition between nation states as to whose racial pedigree was superior and which nations had played a decisive role in the development of European civilization. The most notorious case in this regard is the way in which the Nazi regime used the work of archaeologists, including Kossinna, to support its misplaced claims about the superiority of the Germanic race, contributing to the ideological apparatus that supported the destruction of millions of Jews in the Holocaust. Other European nations also employed archaeological evidence in support of racial theories that would be used to legitimate their relationships with others. The English, for instance, used archaeological evidence to emphasize their Roman and Anglo-Saxon heritage and to justify their superiority over the Welsh, the Scottish, and particularly the Irish, all of whom were considered to be racially inferior. For an overview of the German case see Bettina Arnold's "The Past as Propaganda: Totalitarian Archaeology in Nazi Germany" (*Antiquity* 64, 1990); for an analysis of the English case see Richard Hingley's *Roman Officers and English Gentlemen* (2000).

Culture-History and Typology

The political importance of race in contemporary society goes some way toward explaining

closely interrelated and coeval with one another. On the basis of this methodology he claimed that it was possible to identify major prehistoric racial groups, such as the Aryans and the Slavs, and trace their relationships through time. The work of others, such as the early archaeology of vere gordon childe, although of a very different political persuasion, was embedded in similar concepts and methodology, as exemplified in Childe's book *The Aryans* (1926). Recent historiographical studies highlighting the politics of racial theory and the role of archaeology more generally include Bruce Trigger's *A History of Archaeological Thought* (1989) and "Archaeology and the Image of the American Indian" (*American Antiquity* 45, 1980), Martin Bernal's *Black Athena* (1980), and K. Sklenár's *Archaeology in Central Europe* (1983); further case studies are provided by contributions to a number of books in the One World Archaeology Series (Routledge), in particular *Archaeological Approaches to Cultural Identity* (S.J. Shennan, ed. [1989]) and *Social Construction of the Past: Representation as Power* (G. C. Bond and A. Gilliam, eds. [1994]).

The concept of race played an equally important role in European politics of the nineteenth and early twentieth centuries. Nations were conceived of in racial terms, and states justified their actions toward one another and their own populations on the basis of racial theory. Once again archaeology's role in legitimizing and informing contemporary political thought concerned historical relations between races, in particular the evolution of European civilization. Archaeological evidence was employed in the competition between nation states as to whose racial pedigree was superior and which nations had played a decisive role in the development of European civilization. The most notorious case in this regard is the way in which the Nazi regime used the work of archaeologists, including Kossinna, to support its misplaced claims about the superiority of the Germanic race, contributing to the ideological apparatus that supported the destruction of millions of Jews in the Holocaust. Other European nations also employed archaeological evidence in support of racial theories that would be used to legitimate their relationships with others. The English, for instance, used archaeological evidence to emphasize their Roman and Anglo-Saxon heritage and to justify their superiority over the Welsh, the Scottish, and particularly the Irish, all of whom were considered to be racially inferior. For an overview of the German case see Bettina Arnold's "The Past as Propaganda: Totalitarian Archaeology in Nazi Germany" (*Antiquity* 64, 1990); for an analysis of the English case see Richard Hingley's *Roman Officers and English Gentlemen* (2000).

Culture-History and Typology

The political importance of race in contemporary society goes some way toward explaining

why the concept was so all-pervasive and persistent until the 1920s and 1930s. However, race politics also contributed to the demise of race within the social sciences because those in contemporary institutions abhorred the notion of race and the practices associated with it. By the 1930s a critique of the concept of race was emerging in archaeology, just as it was in social and cultural anthropology, as expressed in J.S. Huxley and A.C. Haddon's *We Europeans: A Survey of Racial Problems* (1935). This critique consisted less of an attack on the concept of race per se than of a dismantling of the correlation of cultural and physical groupings and a questioning of the appropriateness of the concept of race for archaeological analysis. For instance, in "Races, Peoples and Cultures in Prehistoric Europe" (*History* 18, 1933), Childe argued that any confusion between cultural-linguistic and physiological similarity should be studiously avoided, as culture is a "social heritage" that has no direct link to the physical traits acquired through heredity. Writing in the early 1930s, Childe was concerned with the political implications of archaeological research, most notably the political use of Kossinna's claims about the superiority and the purity of the Nordic Aryan race. This concern to distinguish race from cultural forms of differentiation was heightened following World War II and the ensuing outrage over the political appropriation of the past under the Third Reich. Racial-ethnic labels, such as the "Germani," the "Aryans," and the "Indo-Europeans," were avoided by many due to their political associations. Following the rejection of the grand evolutionary schemes of the late nineteenth century, the empiricist trend that emerged was consolidated, at least in Europe. However, the emphasis now was on the description of empirical evidence in terms of artifact "types" and "archaeological cultures," rather than on past peoples.

By the mid-twentieth century the definition of culture areas had become the principal means by which prehistory was delineated in space and time, producing a mosaic of discrete peoples and cultures. But despite the uncoupling of race and culture, the culture concept carried over many associated ideas about the nature of human groups, in particular their holistic, bounded, and homogeneous character. The normative theories of culture that were employed were based on the idea that within a given group, cultural practices and beliefs tended to conform to prescriptive ideational norms or rules of behavior. Further, these norms were said to be maintained by regular interaction within the group and the transmission of shared cultural norms to subsequent generations through the process of socialization. A culture was therefore regarded as the product of a particular society or ethnic group, and at the same time it was assumed to provide the distinguishing characteristics of that group. Within an archaeological framework such ideas led to the assumption of a fixed and one-to-one relationship between material types and particular past peoples, even if they were no longer referred to as races. Thus, as Ulrich Veit argued in "Ethnic Concepts in German Prehistory" (in *Archaeological Approaches to Cultural Identity,* S.J. Shennan, ed. [1989]), the term *archaeological culture* became merely a quasi-ideology-free substitute for the terms *race* and *ethnic group.* Peoples of the past still lurked behind the apparently neutral archaeological cultures. Useful summaries of the place of culture-history in the archaeological traditions of various European countries can be found in contributions to *Archaeological Theory in Europe* (I. Hodder, ed. [1991]). For a discussion of developments in other regions of the world see the contributions to *Theory in Archaeology: A World Perspective* (P. J. Ucko, ed. [1995]).

Recent Approaches and Debates

During the 1960s and 1970s a concerted shift occurred in archaeological theory and method with the emergence of the "New Archaeology" (later more widely referred to as "processual archaeology"). The normative concept of culture that had dominated traditional archaeology was overturned within New Archaeology. It was argued that culture constitutes an integrated system, made up of differently functioning subsystems such as subsistence, exchange, politics, ideology, and religion. Consequently, it

was argued, archaeological remains must be regarded as the product of a variety of past processes,

the communication of similarity and difference, which ethnicity inevitably entails. Thus, from an archaeological perspective, it cannot be assumed that there is any fixed relationship between particular material types and particular identities. And furthermore, rather than consisting of neat, coherent cultural entities, the resulting pattern is more likely to be a complex web of overlapping styles of material culture relating to the repeated realization and transformation of ethnicity in different social contexts. Examples of such an approach to ethnicity are provided by Stephen Shennan in his introduction to *Archaeological Approaches to Cultural Identity* (S. J. Shennan, ed. [1989]) and by Siân Jones in *Archaeology of Ethnicity* (1997). Peter Wells's analysis entitled "Identity and Material Culture in the Later Prehistory of Europe" (*Journal of Archaeological Research* 6, 3, 1998) provides a convincing application of such an approach. Other general studies of cultural identity that reach similar conclusions include Julian Thomas's *Time, Culture and Identity* (1996) and Andrew Jones's "Where Eagle's Dare" (*Journal of Material Culture* 3, 3, 1998). Studies focusing on the discourses involved in the construction of identity, particularly the role of myth and tradition, are also becoming common; for instance, see Jonathan Hall's *Ethnic Identity in Greek Antiquity* (1997).

Conclusions: The Present Past

Recent research focusing on ethnicity in archaeology has overturned many traditional assumptions about the discrete, bounded, and homogeneous nature of cultures and the straightforward link between culture and identity that is central to culture-historical archaeology. But studies focusing on ethnicity still tend to be sporadic. The relationship between cultures and ethnic groups remains a problematic area of archaeological analysis. There is, therefore, a pressing need for further research, at the very least because of the role of archaeological knowledge in the construction of modern ethnic and national identities. Of all the recent developments concerning identity in archaeology, perhaps the most significant in terms of its impact on the discipline as a whole is the concern with the role of archaeology in the construction and legitimation of national identities. The 1980s and 1990s witnessed an increasing body of conferences, symposia, and publications devoted to this topic. (Examples include the contributions to *Nationalism and Archaeology in Europe,* M. Diaz-Andreu and T.C. Champion, eds. [1996]; *Nationalism, Politics and the Practice of Archaeology,* P.L. Kohl and C. Fawcett, eds. [1995]; *Nationalism and Archaeology,* J. Atkinson et al., eds. [1996]; and Philip Kohl's overview entitled "Nationalism and Archaeology" in *Annual Review of Anthropology* 27, 1998.) Clearly, traditional approaches to race and ethnicity have enabled history, place, and people to be tied together in an exclusive and monolithic fashion, reinforcing essentialist representations of ethnic and national identity in the present. The challenge for archaeologists is twofold. First, they must recognize the relationship between present constructions of group identity and our interpretations of the past. And second, rather than abandon the study of ethnicity and identity altogether, they must pursue more sophisticated analytical and interpretive approaches in order to ensure that essentialist perspectives are not merely imposed on the past.

Ratzel, Friedrich

(1844-1904)

Born in germany and educated at Munich University, Friedrich Ratzel originally studied zoology. After graduating in 1869 he spent six years traveling before returning to Munich to study for a doctorate in geography. He is one of the most important figures in the development of nineteenth-century geography, and he contributed to the development of ethnology as a separate discipline in the German-speaking world.

Friedrich Ratzel

(Science Photo)

Ratzel's work focused on the influence of the environment on human life and on political geography. He also supported German colonialism, inventing the word *lebensraum* ("living space"), used later by the Nazis as a means of justifying territorial expansion in the 1920s, 1930s, and 1940s. Ratzel also coined the term "anthropogeography," which was used during the nineteenth century to distinguish the discipline now known as human geography.

With colleagues fritz graebner, Leo Frobenius, and Wilhelm Schmidt, Ratzel founded the cultural-historical school of anthropology. His concept of a culture area (*Kulturkreis*) was widely used within both German and American anthropology and in describing cultural regions such as Melanesia and Mesoamerica, becoming one of the common concepts within the discipline. Ratzel taught for most of his life at the University of Leipzig and wrote about diffusion and diffusion routes, another fundamental interest of the cultural-historical school.

Although this approach to archaeology had dire consequences and many limitations, it also resulted in some interesting interpretations and directions within the discipline. Because Russian archaeologists had to concentrate on how ordinary people lived, they undertook large-scale excavations of settlements, camps, and work sites and therefore collected important data in the areas of Paleolithic and Neolithic houses and settlements in particular.

Rawlinson, Sir Henry Creswicke

(1810-1895)

Henry Creswicke Rawlinson was born in England the son of wealthy middle-class parents. He took up a military cadetship in the East India Company in 1827 and while serving in that capacity met the governor of India, Sir John Malcolm, a diplomat and oriental scholar who inspired and encouraged the young Rawlinson's prodigious interest in languages. In 1839, he was sent to Persia (now iran) to help reorganize the Persian army by raising regiments from frontier tribes in order to prevent the spread of Russian influence toward India. Also in 1839, he helped with the crisis in Afghanistan, becoming a British political agent in Kandahar where he raised Persian cavalry that fought in subsequent battles with the Afghanis.

Henry Creswicke Rawlinson

(Hulton Getty)

Rawlinson continued to study throughout his military career, and his language and leadership abilities were so exceptional that he was appointed to explore unknown areas of the subcontinent, central Asia, and the Middle East. These included Susiana (now southwestern Iran) in 1836, and in 1838 he explored Persian Kurdistan for the Royal Geographic Society, for which he was awarded the society's gold medal. It was during this trip that he first became interested in cuneiform inscriptions. In 1843, Rawlinson became a political agent for the East India Company in Turkish Arabia, as well as becoming a British consul in Baghdad, and combined his new interests in epigraphy and archaeology with his diplomatic career.

He began to locate and copy, decipher, and translate Persian cuneiform inscriptions and to publish them in the *Journal of the Royal Asiatic Society.* At the same time that he was working in Iraq and Iran, several other scholars of philology in England and Ireland were endeavoring to decipher cuneiform from the direction of its vowel systems. All of the independent translators, including Rawlinson, were given an undeciphered inscription to test their ability. The results so closely resembled each other that cuneiform was officially recognized as deciphered-an epigraphic triumph similar to that by the great French philologist jean-françois champollion in the field of Egyptian hieroglyphics. But it was Rawlinson's translations of inscriptions “in the field” that were the most important contribution-and earned him the title of the first successful decipherer of cuneiform.

Rawlinson returned to England in 1849 and was commissioned by the british museum to excavate in

Babylonia for the benefit of that institution's collections. In 1851, Rawlinson was asked by the British Museum to revise the second

PREV NEXT

half of the early cuneiform texts brought back by sir austen henry layard from nimrud. From this work he published *Inscriptions of Assyria and Babylonia* (1850) and *Outline of the History of Assyria as Collected from the Inscriptions by A.H. Layard* (1852). He remained involved with Layard's collection and oversaw the publication of six volumes of inscriptions between 1861 and 1880.

In 1856, Rawlinson resigned his diplomatic position and returned to England for good to become a member of Parliament. He became a trustee of the British Museum in 1876 and remained one until his death. He continued to be involved in the Royal Asiatic Society and was its president from 1878 to 1881, and he was president of the Royal Geographic Society 1871- 1872 and 1874-1875. Rawlinson helped with the state visits of the shah of Persia in 1873 and 1889 and was a royal commissioner for the Paris Exposition of 1878 and the India and Colonial Exhibition of 1886. He was made a baronet in 1891.

Reinecke, Paul

(1872-1959)

A German pre- and proto-historian and chief curator at the museum in Munich, Paul Reinecke contributed to European archaeology for over fifty years while remaining independent of the influential archaeologist gustaf kossinna and the German cultural-historical school under friedrich ratzel and fritz graebner.

Reinecke's interests ranged from the Neolithic to Roman provincial archaeology, but he is best known for his studies of and interest in categories of objects, such as metal helmets and fibulae from the late Bronze and early Iron Ages. It was Reinecke who named the later Bronze/early Iron Age period "Halstatt" after the cemetery and mining site excavated in austria on Lake Halstatt. The later Iron Age was named "la tène" after a site in switzerland. Detailed typological analyses of these objects and of funeral rites and rituals of this period enabled him to differentiate between northwestern German and Scandinavian developments and to propose his own southern German Iron Age regional variations.

Reisner, George Andrew

(1867-1942)

George Andrew Reisner was an eminent Egyptologist, a pioneer in the archaeology of nubia and the

Sudan, and the organizer of the world's first archaeological salvage project. He was born in 1867 into a German-American family in Indianapolis, Indiana. A youthful interest in the ancient Near East led him to study Assyriology and Semitic languages at Harvard, where he graduated in 1889 and took a Ph.D. in 1893. He then went abroad for further study in germany, at that time the world center for Near Eastern research. While in Berlin, however, he fell under the spell of the great Egyptologists Adolf Erman and Ludwig Borchardt, who diverted the young American's interests from the Near East to Egypt. In 1897, he accompanied Borchardt to Egypt and assisted him for two years in the enormous task of cataloging the collections in the Egyptian Museum of Antiquities.

Reisner began fieldwork in 1899 when he led a University of California expedition excavating at Naqa el-Derr in Middle Egypt. In 1903, the expedition transferred its activities to the enormous necropolis of Giza, in the shadow of the Great Pyramids, the area that was the major focus of Reisner's activities for the rest of his life. When funding from the University of California was discontinued in 1905, Reisner organized the Harvard-Boston Expedition, a joint enterprise of Harvard University and the Boston Museum of Fine Arts, and remained its director for nearly forty years.

The Harvard-Boston Expedition was originally designed to work only in Egypt, but a development in 1907 resulted in a major enlargement of its focus. The first Aswan Dam (now often called the Low Dam) was then under construction

half of the early cuneiform texts brought back by sir austen henry layard from nimrud. he investigated, Reisner also developed formal typologies of pottery and other artifacts. Finally, his introduction of the use of standard grave-recording forms has already been mentioned. He was fond of saying that a well-conducted excavation should be recorded in such a way that future scholars could reconstruct every detail of the conditions found by the original diggers. His British colleague, Herbert Winlock, asserted that Reisner was the greatest excavator of Egyptian antiquities then alive, while walter b. emery went so far as to assert that he was the greatest archaeologist America had ever produced.

Although from 1910 onward Reisner held appointments both as professor of Egyptology at Harvard and as curator of Egyptian Art at the Boston Museum, he was quintessentially a field man. He spent nearly the whole of every year in the Nile Valley, digging in Egypt in the summer and in the Sudan in the winter, and returned only intermittently to give courses at Harvard and to attend to his curatorial duties at the museum. His later years were plagued by poor health and failing eyesight, which eventually forced him to give up his university appointment, but he remained active as director of the Harvard-Boston excavations until the end of his life. He died in his field camp on the Giza Plateau on 6 June 1942.

Because of his almost single-minded dedication to fieldwork, Reisner published final reports on only a few of his excavations. After his death, final reports on most of his Sudan excavations were published by his longtime assistant and colleague, Dows Dunham, and William Kelly Simpson published individual reports on many of the Giza tombs.

Remote Sensing

Remote sensing has been defined as the science and art of obtaining information about an object, area, or phenomenon through the analysis of data procured by indirect means. In other words, information is obtained by the use of a device that is not in direct contact with the subject under investigation. In the broadest sense, different techniques can be considered as remote sensing. These range from subsurface sensing methods, such as ground-penetrating radar, seismometer, and soil resistivity, to the analysis and interpretation of the electromagnetic energy radiated from the surface of the earth, recorded on air- and spaceborne platforms in the form of aerial photography, and satellite and radar imagery. This article deals only with the latter forms.

Basic Principles of Electromagnetic Energy

In simple terms, electromagnetic energy is the energy that is emitted or reflected from all objects. The emission of this energy is picked up by special airborne or spaceborne sensors and is processed in photographic or digital form. In reality, only the sun emits strong enough electromagnetic energy to be picked up by the sensors; the remaining objects on the earth's surface will reflect the energy they receive from the sun. Visible light is the most common form of electromagnetic energy, but other familiar forms of electromagnetic energy are heat, ultraviolet rays, radio waves, microwaves, and X-rays.

Electromagnetic energy radiates in waves that travel in harmonic sinusoidal movements. The length of the waves varies, and in the process gives place to a range of wavelength variation known as the electromagnetic spectrum. The part of this spectrum that we are more familiar with is the optical wavelength, which is divided into several bands for remote sensing purposes. The visible light that can be perceived by the human eye forms a fraction of the optical wavelengths. It comprises the blue, green, and red bands with a wavelength range that goes from about 0.4 to 0.5 m, 0.5 to 0.6 m, and 0.6 to 0.7 m, respectively. Outside the visible range adjoining the blue band is the ultraviolet band (UV), which has a wavelength

he investigated, Reisner also developed formal typologies of pottery and other artifacts. Finally, his introduction of the use of standard grave-recording forms has already been mentioned. Remote sensing has been defined as the science and art of obtaining information about an object, area, or phenomenon through the analysis of data procured by indirect means. In other words, information is obtained by the use of a device that is not in direct contact with the subject under investigation. In the broadest sense, different techniques can be considered as remote sensing. These range from subsurface sensing methods, such as ground-penetrating radar, seismometer, and soil resistivity, to the analysis and interpretation of the electromagnetic energy radiated from the surface of the earth, recorded on air- and spaceborne platforms in the form of aerial photography, and satellite and radar imagery. This article deals only with the latter forms.

Basic Principles of Electromagnetic Energy

In simple terms, electromagnetic energy is the energy that is emitted or reflected from all objects. The emission of this energy is picked up by special airborne or spaceborne sensors and is processed in photographic or digital form. In reality, only the sun emits strong enough electromagnetic energy to be picked up by the sensors; the remaining objects on the earth's surface will reflect the energy they receive from the sun. Visible light is the most common form of electromagnetic energy, but other familiar forms of electromagnetic energy are heat, ultraviolet rays, radio waves, microwaves, and X-rays.

Electromagnetic energy radiates in waves that travel in harmonic sinusoidal movements. The length of the waves varies, and in the process gives place to a range of wavelength variation known as the electromagnetic spectrum. The part of this spectrum that we are more familiar with is the optical wavelength, which is divided into several bands for remote sensing purposes. The visible light that can be perceived by the human eye forms a fraction of the optical wavelengths. It comprises the blue, green, and red bands with a wavelength range that goes from about 0.4 to 0.5 m, 0.5 to 0.6 m, and 0.6 to 0.7 m, respectively. Outside the visible range adjoining the blue band is the ultraviolet band (UV), which has a wavelength

ranging from 0.3 to 0.4 m. On the other end, following the red band, are three different categories of infrared (IR) waves: near-IR (.07-1.3 m), mid-IR (1.3-3 m), and thermal-IR (less than 3 m).

The still-enigmatic Nazca geoglyphs in Peru were not discovered until the 1920s, when planes began to fly over the desert; the glyphs, often over 100 meters in diameter, are visible only from the air.

(Marilyn Bridges/Corbis)

Length of wave is of prime importance in remote sensing because it will determine the type of interaction that electromagnetic energy will have with the objects sensed from the earth's surface. For example, the blue band is able to penetrate water bodies; thus it is particularly useful in coastal mapping. The red band is useful for sensing chlorophyll absorption and, hence, in differentiating vegetation cover from nonvegetation, including cultural features, while the near-IR has proved useful for determining vegetation types.

On the other side of the spectrum, we have the microwave radiation of electromagnetic energy, which consists of radio waves that range from 1 millimeter to 1 meter in length, and it cannot be recorded by standard optical means but it can be recorded by special radar. Radar is the acronym for *radio detection and ranging,* and as its name suggests, it uses radio waves to detect the presence of objects and determine their position. Radar imagery, then, is rather different from aerial photography or satellite imagery. The latter are passive sensors that depend on the sun as the source of electromagnetic energy and can therefore use only the visible and infrared wavelengths of the spectrum to create images. Radar is an active sensor that emits its own electromagnetic energy in the form of radio waves to create images.

Aerial Photography

Remote sensing in the form of aerial photographs has been used in archaeology since at least the early 1900s. J. Capper is credited with having taken the first photographs of an archaeological site, Stonehenge, from a hot air balloon in 1906. These photographs, however, were more a novelty than a conscious archaeological venture. The first conscious use of aerial photography for archaeological purposes was in 1913 when Sir Henry Wellcome took photographs of his excavations in the Sudan using a

box kite. And between 1919 and 1921, there occurred the first systematic application of aerial photography by European and American archaeologists, working in mesopotamia and the Cahokia Mounds, Illinois, respectively.

Since many archaeological sites leave no traces detectable at ground level but can produce distinctive soil patterns that are easily discernible from the air, archaeologists saw the clear advantages that aerial photography offered and readily embraced this new tool. The decade of the 1920s witnessed a boom in the use of aerial photography in archaeology. In 1925, Poidebard traced ancient caravan routes that led to Roman fortifications in Syria, and alfred kidder and Charles Lindbergh photographed a series of archaeological sites while flying over the Yucatán Peninsula and the American Southwest.

The onset of World War II in Europe not only did not stop the use of aerial photography, it virtually furthered its development. For obvious reasons, aerial photography was perfected during this period, both by technological innovations in aircraft and cameras and by further developments in its interpretative principles. In this process archaeologists played a leading role; some, such as glyn daniel, were even recruited by the military as photo interpreters.

The success of these early ventures and the developments in the technique that followed World War II secured a place for aerial photography in archaeology. However, the differences between the European and North American academic traditions, along with differences in the nature of the archaeological sites per se, resulted in very distinct approaches in the use of this new method of archaeological survey. European archaeologists were more concerned with a classical-historical approach and centered their efforts on site detection. North American archaeologists, on the other hand, who by this time had been greatly influenced by julian steward's cultural-environmental approach, put the emphasis on more regional approaches.

These theoretical orientations had an important effect on the preferred method of aerial photography that was adopted. In Europe, where the main interest was the architectural characteristics of spectacular sites, oblique photography was favored because of the better perspective that it produced. This method assisted European archaeologists in the discovery of thousands of sites throughout the countryside. In the Americas, where archaeologists put greater emphasis on anthropological issues such as subsistence activities, vertical photography was the preferred method because it facilitated regional mapping in which the location of archaeological sites was considered in relation to resource areas. Examples of this type of project are Ralph Solecki's 1952 Missouri River survey and gordon willey's 1953 seminal settlement pattern study of the virú valley in peru.

But interpreting aerial photography to locate sites and/or resource areas is just the initial stage in archaeological research. Regardless of the method applied-oblique or vertical photography-the archaeologists' final intent is to map the features that are of relevance to their research. The application of reliable methods to measure the observed features with the intent of producing a map is a subject covered by photogrammetry. Through the application of the principles of photogrammetry, the photo interpreter can quantify-in terms of location and extent-the interpreted features on the surface of the earth. Thus, the quantification process complements the information obtained by the initial interpretation and is geared toward identifying what features are present in the photograph, where they are on the ground, and over what areal extent.

With the advent of more sophisticated methods of remote sensing, such as satellite and radar imagery, the new developments in aerial photography technology have centered more on photogrammetry computer applications, image enhancing, and digital photography. Nevertheless, because of its lower cost, greater scale, and extensive coverage, the traditional black-and-white aerial photography still

remains a favored methodological tool in archaeological research.

Satellite and Radar Imagery

Remote sensing from space has its origins with the development of the first meteorological satellites, which in 1960 transmitted back to earth the first coarse images of the earth's surface

PREV NEXT

dust, smoke, and even tree canopy and soil and thus provide images for targets that cannot be seen with the other platforms.

These characteristics have proved to be of great value not only for the detection of archaeological features situated underneath a tree canopy or other covering but also for the detection of subsurface archaeological features. One SIR-A radar image made over the Sahara revealed a prehistoric river system located between one and four meters beneath the sand. Subsequent excavation yielded human artifacts dating back to the Paleolithic period and other archaeological data that indicated a moister environment.

The complex nature of the archaeological data, comprising cultural and environmental elements, requires archaeologists to take advantage of all the available methodological tools. With the changing emphasis in archaeological research, which has shifted from site-oriented problems to more-regional approaches, the adoption of remote sensing along with other new technologies such as geographic information systems makes perfect sense. Although still in its early stages, remote sensing provides an excellent means of gathering data that describe the biophysical context where human groups developed. The growing access to affordable computer power along with the increasing availability of satellite and radar images will soon consolidate the position of remote sensing as an essential component of the archaeologist's tool kit.

Rock Art

The study of rock art in all its various forms has no specific point of origin. Indeed, rock art was never really “discovered” at all with the obvious exceptions of caves blocked since the Ice Age, sites buried by deposits (which had to be excavated), and areas no longer frequented by humans (deep jungle, remote desert). Local people always knew the rock art was there, often believing it to be the work of devils, evil spirits, sorcerers, or fairies, and would sometimes point it out to visiting explorers or scholars. Most early “scholarly discoveries” of rock art came about accidentally as traveling missionaries or explorers reported on anything of interest that they encountered.

It was not until the late ninteenth or early twentieth century that systematic searches for rock art began. Naturally, early reports had no concept of the art's age (even today, most rock art remains undated) since archaeology had not yet become an established discipline and there was as yet no idea of the antiquity of humankind or of the very concept of prehistory.

It seems that it was the Chinese who were the pioneers, since the earliest known written reports of rock art are to be found in *Han Fei Zi,* a book written 2,300 years ago by the philosopher Han Fei (280-233 b.c.). In the fifth century a.d., Li Daoyuan, a geographer of the northern Wei dynasty (a.d. 386-534), wrote a famous geography book called *Shui jing zhu* (Notes on the Systems of Rivers), which consists mostly of his personal experiences and describes places he had seen. He mentions a score of places with rock art in about half of china's provinces and states that he had also heard of rock art in India and Pakistan. The book also describes techniques (painting and engraving) and subjects (tigers, horses, goats, and chickens as well as divinities and masks, footprints, and hoofprints).

The earliest known reference to rock art in Europe occurred 1,000 years after Li Daoyuan's book when, in 1458, Calixtus III, one of the Borgia popes from Valencia, forbade the Spanish to carry out cult ceremonies in a cave with horse pictures-presumably a decorated cave of Ice Age date-showing the persistence of beliefs

attached to prehistoric images. Only two years later, one traveler, Pierre de Montfort, wrote a letter to his wife that mentioned the Vallée des Merveilles in the Alps as "an infernal place with figures of devils and a thousand demons carved everywhere on rocks." In the sixteenth century, Onorato Lorenzo, a priest from the same region wrote a large unpublished manuscript called "Accademio dei Giordani di Belvedere" that contained information obtained from shepherds, and this manuscript mentions the "Meraviglie" and provides a long list of rock-art motifs and subjects.

The earliest known documentation of rock carvings in Europe occurred in sweden when some seventeenth-century drawings of petroglyphs at Backa Brastad near tanum, Bohuslän (at that time part of Norway, itself linked to denmark) were made by Peder Alfssön, a schoolmaster from Kristiania (Oslo), and sent to one ole worm, the king of Denmark's doctor. Worm, a renowned polymath and founder of museums, had sent out questionnaires to educated people in the provinces, mainly priests, asking them to notice the location, setting, and dimensions of ancient monuments and, if possible, to make drawings, investigate how the monuments were constructed, and ascertain what the local people said or believed about them. Alfssön produced freehand wash drawings and accompanying text, which, amazingly, still survive in Copenhagen, having escaped several wars and great fires (they remained forgotten until published as small copperplate engravings by P.F. Suhm in 1784). It is not known exactly when the drawings were made, but they were made a part of the Copenhagen archives in 1627, which makes them the oldest known drawings of rock art in the world.

Alas, Worm made no mention of rock art in his 1643 book on ancient Denmark, and Alfssön, of course, had no inkling of the art's antiquity. The latter believed that the carvings-including a large human figure subsequently nicknamed *Skomakeren* ("the shoemaker")-were medieval graffiti by apprentice stonemasons working on the construction of a church in the vicinity. It was only in the eighteenth century that scholars came to realize that such carvings were very old, though at first it was believed they depicted historical events such as battles between Viking ships.

In the Alps, a French historian, Abbé Pietro Gioffredo, wrote *Storia delle Alpi Marittime* (ca. 1650) and based his somewhat fanciful account of the Vallée des Merveilles on Onorato Lorenzo: "Various stones of all colours, flat and smooth, decorated with engravings of a thousand imaginary subjects, representing quadrupeds, birds, fish, agricultural or military mechanical instruments dating from several centuries, and… the authors of such merry jokes were shepherds trying to avoid boredom."

In russia, petroglyphs (*pissanye kamni,* or "written stones") were mentioned in the notes made by travelers, ambassadors, and merchants during the seventeenth and eighteenth centuries. For example, a Moldavian prince, Nikolai Milesku Spafarii, an ambassador for Czar Alexei Romanov, traveled through Siberia to China in 1675 and mentioned petroglyphs in the Yenisey Valley in his travel notes. Tomskaya Pisanitsa in Siberia was described in a Russian chronicle of the seventeenth century as a big stone with the images of animals, birds and people, and in 1692, the Dutch traveler and scientist Nicolaas Witsen, a friend of Peter the Great, published a book *Nord und Ost Tartaray* (North and East Tartary) in Amsterdam (2d ed., 1705). In effect, that work was the first Siberian encyclopedia, and it contained descriptions of "ancient paintings," including rock pictures on the River Irbit in the Ural Mountains.

Developments in the New World

The major development of the sixteenth century occurred in the New World where "inscriptions" of various kinds were spotted, and sometimes described and illustrated, by conquering Europeans exploring the interior of Brazil. During the first centuries of the conquest, members of various religious orders also penetrated the interior of Amazonia. The earliest known information on rock art in this area is attributed to Ambrósio Fernandes Brandão, who, in 1598, recorded the existence of rock engravings

in the present state of Paraíba on the Araçai River. In 1618, Brandão published drawings of motifs in

soon followed: on the east bank of the Taunton River in Massachusetts, the first drawing of Native American petroglyphs on Dighton Rock (a large rock covered with deeply incised abstract designs and highly stylized human figures) were made by colonists in 1680-although the markings have been attributed by some people on the fringe of archaeology to Norsemen, Phoenicians, Scythians, and Portuguese explorers. The pictograph site of La Roche-à-l'Oiseau on the Outaouais River in quebec was mentioned in 1686 in connection with Indians throwing down offerings of tobacco when they passed close to the rock.

The Age of Enlightenment

In the eighteenth century, a time when so many fields of inquiry began to be transformed into serious topics of study, a more profound and sustained interest began, and rock art was reported on two more continents. As yet, however, serious study developed very sporadically and slowly.

For instance, in Ireland, Newgrange and the other decorated tombs were frequently described and illustrated in the eighteenth and nineteenth centuries, and “rude carvings” at Killin, County Louth, were reported by Wright in 1758. Regarding Scandinavian rock art, a letter from a superintendent of the Swedish-Norwegian border written in 1751 mentions carvings in Bohuslän: “In the parish of Tanum, not far from the sea, I have also visited a sloping rock, where a man with spear in his hand is cut, and about whom is said that a Scottish commander had been killed in his flight during a military campaign and that the position of his dead body was reproduced in the rock.” The letter's plea for an inventory to be started in the parish fell on deaf ears.

Also in the mid-eighteenth century, the great cairn of Kivik in Skane, southern Sweden, was discovered, and the carved figures on the stone slabs of its central cist were drawn in very professional fashion by Carl Gustaf Hilfeling, an antiquarian who specialized in depiction and description. The much-traveled Hilfeling also visited Bohuslän, and his travel books published after 1792 include several drawings of monuments and rock carvings in that region. He produced measured drawings done to scale, not freehand sketches, and his pictures are full of comments on size, distance, and location. Unfortunately, he had a tendency to see nonexistent runic inscriptions on some rocks.

In 1719, Czar Peter the Great sent a young doctor and naturalist, Daniel-Gotlieb Messerschmidt, to lead a scientific expedition to study the nature and population of Siberia. In Tobolsk, Messerschmidt met Philip Johann Tabbert von Strahlenberg, a Swedish officer who was a prisoner in Siberian exile, and together they carried out the first scientific excavations in the region. In 1722, Messerschmidt made a drawing of a rock with symbols, images of animals, and a man. He also discovered runic inscriptions on rocks that were determined to be old Turkic in 1893; earlier, they conjured up romantic ideas about Vikings and Germans and led Messerschmidt to investigate ancient rock images more closely and make copies of them.

In his diary entry for 23 February 1722, he reported that by the Yenisey River, not far from the village of Birjusa, near Krasnoyarsk, there were all kinds of “characters” and figures, written in red, to which the locals ascribed all kinds of meanings because the motifs were quite high above the river on smooth, steep rocks so the locals could not understand how people could have made them there. He also noted that the locals called them *pisannyj kamen.* On 18 August of the same year, Messerschmidt saw numerous Scythian graves bearing stones covered with figures, some of which he published as drawings. His diary entry for 26 September mentions that at the Gordovaja stena he once again saw characters and figures about eight and a half meters above the river level that were made with a crimson and indelible color.

In 1730, liberated and back home in Sweden, von Strahlenberg published a book (*Das Nord- und Östliche Theil von Europa und Asia*), the first scientific publication about the archaeological monuments of the Yenisey region (Siberia), including petroglyphs. Other expeditions to Siberia followed, and these also examined the archaeology and rock art of the region. For example, the historian Gerhard-Friedrich Mueller

PREV NEXT

produced a book in 1750 in Russian (*Opisanie Sibirskogo carstva*) in which he refuted the supposition that these ancient rock drawings could be taken as a special form of writing. In this work, which was later also published in German, he published sketches of some figures.

Further Work in the New World

Discoveries of rock art continued to be made in the Americas. In 1711, Father Eusebio Kino described and mapped "the painted rocks"-actually engravings-near Gila Bend, Arizona. In Quebec, the Nisula site on Lac de la Cassette was mentioned on Father Pierre-Michel Laure's maps, drawn between 1731 and 1733 during the French regime in Canada and showing the so-called Domaine du Roy in Nouvelle france, where it says "Pepéchapissinagan [the stone thing on which there are paintings] naturally painted figures can be seen on the rock." Heads, or faces, carved at the foot of the great falls on the Connecticut River in the village of Bellows, Vermont, have been commented on by travelers and researchers since 1789, the petroglyphs being described variously as Indian chiefs, families, symbols of male authority, memorials of noteworthy events, idle artwork, and the work of shamans recording vision experiences.

In the eighteenth century, a Jesuit missionary called Schabel visited Pedrazza, Venezuela, and thought the petroglyphs there to be engraved by "angelic hands." Alexander von Humboldt himself saw many petroglyphs during his travels through South America at the end of the century, and he put forward some interpretations of petroglyphs in the Orinoco region. Father Pedor Lozano, in about 1730 to 1760, interpreted the abundant engravings and paintings of colombia, brazil, Paraguay, and peru as tracing the itinerary of St. Thomas, with all footprints being attributed to the saint as usual (conversely, red handprints were often attributed to the devil in Latin America). But Filippo Salvadore Gilii, another Jesuit missionary in Venezuela, reported in 1781 that, according to the Tamanaco Indians, rock inscriptions there had been made by the creator-god Amalivaca.

There was a great deal of activity in Mexico in the eighteenth century. For example, a 1792 compilation commissioned by the Spanish viceroy of New Spain, Conde Revilla Gigedo, contained a natural history of Baja California that was attributed tentatively to the Jesuit Juan Bautista Mugazábal, who died in 1761. If correct, the compilation would be the oldest known reference to rock art on the peninsula, and it describes a clear attempt to obtain relevant ethnographic information:

In all of civilized California, from south to north, and particularly in the caves and smooth cliffs, rustic paintings can be seen. Notwithstanding their disproportion and lack of art, there can be easily distinguished the likenesses of men, fish, bows and arrows, and diversely assembled lines in the fashion of written characters. The colours of these paintings are four: yellow, red, green and black. The majority of the images are painted in very high places, and from this, some infer that there is truth in the constant tradition of giants among the ancient Californians.… It has been impossible to ascertain what these figures, lines and characters mean, despite extensive questioning of the California Indians. The only thing which has been determined from what they say, is that they are from their ancestors, and that they have absolutely no knowledge of their significance.

An eighteenth-century Jesuit missionary, the Spaniard Miguel del Barco, wrote hundreds of pages about California that were not published until 1972 by Miguel Leon-Portilla in *Historia natural y crónica de la Antigua California*. This account contains an extended reference to the great murals of Baja California, and it quotes Joseph Mariano Rothea, a missionary at San Ignacio from 1759 until 1768:

I happened to investigate several painted caves.… one would be about 30 to 35 feet long, about 16 feet wide.… From top to bottom it was all painted with various figures of men, women, and animals.… The colours were the same that are found in the volcanoes of the Tres Virgenes: green, black, yellow and

flesh-coloured. The durability of these colours seemed notable to me; being there on the exposed rock in the inclemencies of sun and water where they are no doubt struck by rain, strong

wind or water that filters through these same rocks from the hill above, with all this, after much time, they remain highly visible.… Without scaffolds or other implements suitable for the purpose, only giant men would have been able to paint at so much height.

Hence, the Cochimí, the local people, had legends disassociating them and their ancestors from the painters, and the missionaries thought the paintings impressively old. Del Barco also wrote:

The people of this land say that the giants were so large that, when they painted the ceiling of a cave, they lay on their backs on the ground and that even thus they were able to paint the highest part. An enormous fable that, for its verification, would necessitate those men to have a height of at least thirty feet, unless we imagine extremely long paint brushes in their hands!… It is simpler to persuade oneself that, for this work, they found and conveyed to the cave, or caves, some wood with which to form a scaffold.

Africa and Australia

The eighteenth century also saw the first discoveries of rock art in africa. The earliest reference is from 1721, when an ecclesiastic in the Portuguese colony of Mozambique mentioned paintings of animals on rocks in a report to the Royal Academy of History in Lisbon. In 1752, explorer Domingo van de Walle de Cervellón reported engravings in the cave of Belmaco on Las Palmas in the Canary Islands. These meandering pecked motifs were considered to be mere doodles, produced by chance or the imagination of the ancient barbarians. That same year, explorers led by Ensign August Frederick Beutler, who were more than 200 miles from their Capetown base, noticed rock paintings in the valley of the Great Fish River in the Eastern Cape, which they recognized to be the work of “the little Chinese” (bushmen).

The first known copies of rock art in the region were made in 1777-1778 by an expedition to the Sneeuwbergen (“snowy mountains”) of the Eastern Cape led by Governor Joachim van Plettenberg. The copies were made by Colonel Robert Jacob Gordon and his draftsman servant Johannes Schumacher-the latter had already copied probable petroglyphs or rock paintings (he called them *teekeningen*) in 1776 on an expedition to the western area area of the Cape that had been led by H. Swellenberg. In 1790-1791, on an expedition led by Grosvenor, Jacob van Reenen noted in his diary that “on a rocky cliff the Bushmen had made a great many paintings or representations of wildebeeste, very natural, and also of a soldier with a grenadier's cap.”

The French traveler Le Vaillant published a book on South Africa at this time in which he dismissed the bushman paintings as “caricatures” and said of pictures in a cave in the Eastern Cape, “the Dutchmen believe them to be a century or two old and allege that the Bushmen worship them, but though it is quite possible, there is no evidence to show it.”

One of the first people who made an attempt to understand the rock art of southern Africa was Sir John Barrow, who was excited to see rock paintings on his journeys through Cape Colony and beyond in 1797 and 1798. He was filled with wonder that they could have been produced by people described by one writer in 1731 as “troops of abandon'd Wretches” lacking laws, fixed abodes, and religion: “In the course of travelling, I had frequently heard the peasantry mention the drawings in the mountains behind the Sneuwberg made by the Boujesmans; but I took it for granted they were caricatures only, similar to those on the doors and walls of uninhabited buildings, the works of idle boys; and it was no disagreeable disappointment to find them very much the reverse.”

The art's beauty made him think that the San (bushmen) had been rendered “more savage” by the conduct of the European settlers. He was especially interested in the aesthetic aspects of the art, which he assumed was indeed “art” in the European sense. On inquiring about their age, he was told that some

paintings were known to be new while others had been present since the first settlement of this part of the colony.

The other new continent whose rock art was “discovered” in this period was australia. There had been a report in 1678 by J. Keyts, a Dutch trader, of rock paintings on a cliff face in Speelmans Bay, western New Guinea (Irian Jaya), but

it was ignored at the time. European discoveries in Australia began during the first months of colonization in 1788 and continued sporadically over the next century as explorers and pioneers pushed further into the country. At first, very few sites were discovered or documented, and the colonizers made little effort to inquire about the meaning of motifs and designs. The art was considered to be childish attempts by primitive people to produce paintings and radically inferior to the European art of the period.

A San (bushman) in South Africa standing by an example of ancient rock art

(South African Tourist Board)

The first known European discovery of Australian rock art was made in Bantry Bay, near Sydney, by Governor Arthur Phillip, the commander of the First Fleet and of the first settlement at Port Jackson, in 1788, when he led short expeditions into the surrounding area. The expedition surgeon's journal describes how, on 16 April 1788, “We saw… some proofs of their ingenuity in various figures cut on the smooth surfaces of some large stones. They consisted chiefly of representations of themselves in different attitudes, of their canoes, of several sorts of fish and animals; and considering the rudeness of the instruments with which the figures must have been executed, they seemed to exhibit tolerably strong likenesses.”

In his first dispatch of 15 May 1788 to Lord Sydney, Phillip wrote: “In Botany Bay, Port Jackson and Broken Bay we frequently saw the figures of men, shields, and fish roughly cut on the rocks; and on the top of a mountain I saw the figure of a man in the attitude they put themselves in when they are going to dance, which was much better done than I had seen before, and the figure of a large lizard was sufficiently well executed to satisfy every one what animal was meant.”

The Nineteenth Century

By the end of the eighteenth century, therefore, prehistoric rock art was being noticed and even copied with increasing frequency, though no great accuracy. In the next century, a turning point was to be reached, not only in numbers of discoveries but also in the realization that some of the art was of great antiquity. Just as archaeology became established by the mid-nineteenth century, when the great antiquity of humankind

careful and true observations create better conditions for interpretation.

The earth on the carvings was taken away, the mosses were scratched off by an iron scraper, the water was led another way and the bedrock was cleaned and washed somewhere. If the figures were small and unclear, I had to-in order to be sure-visit the place at that hour of the day when the sun was shining so that a separation of the figures was possible by light and shadow. It is possible to have the same effect after the sun set by the help of a lantern. If the observation was difficult I had to revisit the place. On these occasions chalk was brought to make contours. It was also rewarding to use the finger tips to know if a line was natural or artificial.

To produce his drawings, Brunius laid a grid system over the rock surface and copied the figures onto a corresponding grid paper, all within a controlled scale. Figures that were hard to identify were visited several times in different conditions-as mentioned in the above quotation, in oblique sunlight, by night lantern, or after a rain. The figures were marked on the rock with chalk and drawn onto paper with pencil in such a way that a darker line denoted a deeper carving. Finally, he also discussed the location, age, and significance of the figures; noted differences in their condition, from intact to almost totally disappeared; and looked at the sites' environs, their setting in the landscape, and the presence of monuments nearby.

Since Brunius was such a pioneer, he had very little comparative material to help him with interpretation. He also had a moral problem in his documentation-should the impressive sexual organs of the male figures be depicted or not? He therefore referred to other tribes such as the Lapps or the Huns as the creators of the rude customs shown on the rocks and claimed that the original Nordic people were above this cultural level.

The bombshell of Paleolithic (Ice Age) art came after decades of sporadic and misunderstood finds. Its existence was first established and accepted through the discovery, in the early 1860s, of engraved and carved bones and stones in a number of caves and rock shelters in southwestern France, particularly by édouard lartet and his English associate henry christy. These objects were found with Paleolithic stone and bone tools and the bones of Ice Age animals, which proved their great age-in particular, the famous engraving from la madeleine of a mammoth on a piece of mammoth tusk. There followed a kind of “gold rush,” with people plundering likely sites for ancient art treasures.

Some French scholars had noticed art on cave walls in the 1860s and 1870s but had not realized its age or significance. The pioneer who did make the crucial mental leap was a Spanish landowner, Marcelino Sanz de Sautuola, who noticed in 1879 that the bison figures painted on the ceiling of the cave of altamira , near the north coast of Cantabria, were closely similar in style to the figures in Paleolithic portable art. Unfortunately, most of the archaeological establishment refused to take his published views seriously, dismissing him as naive or a fraud. One prehistorian who did accept Altamira, however, was edouard piette, who, in the late 1880s, was to find the famous painted pebbles in the cave of le mas d'azil in the French Pyrenees, a discovery the establishment found equally hard to swallow. One of the doubts raised about Altamira was that the cave was too humid and the rock too friable to have preserved painting for so long, but the stratigraphic position of the Azilian pebbles finally proved that ocher could adhere to rock for millennia.

It was in southwestern France once again that the final breakthrough occurred when engravings were found, in 1895, in a gallery of the cave of La Mouthe in the Dordogne region. Since the gallery was blocked by Paleolithic deposits, it was obvious that the engravings must be of the same age. Other discoveries soon followed in other caves in southern France, culminating in those of Les Combarelles and Font de Gaume in 1901, which served to at last establish the authenticity of Paleolithic cave art.

The Twentieth Century: A Splintering of Approaches

In the twentieth century, the discoveries made involved not just individual sites but whole classes of art and brought more countries onto

vociferously to having their ancestors or sacred objects excavated and stored in museums without their knowledge or permission, so rock-art researchers in several parts of the world (especially Australia) have had to modify their procedures and outlook after aboriginal groups campaigned for control of their own culture and provided input into (and demanded feedback from) research into their art. It is safe to say that, today, nobody in Australia would dream of beginning a study of rock art without consulting the aboriginal custodians of the region in question.

On the technical side, photography was adopted quite early-the first photograph of an African rock painting was taken in 1885-but the procedure became commonplace within a decade. Much later, color photography began to be used, at first by pioneers such as Alex Willcox in South Africa beginning in 1951, and technology such as digital cameras, video, and computer enhancement is now coming into its own. In the last few years of the twentieth century, new techniques of direct dating began to revolutionize (in some cases) or at least fine-tune (in others) the traditional chronologies built up over decades, and newly dated rock art at last joined the already well-dated portable art in being embraced by mainstream archaeologists as data worthy of attention. It remains to be seen in what new directions the latest technology and the impending discoveries of the twenty-first century will take rock-art studies, especially as the field is one of ever-increasing popularity in many parts of the world.

Romania

Romania is rich in archaeological discoveries because of its geographical location in southeastern Europe, through which important roads used since ancient times have passed, and because of its temperate climate (*Istoria României* 1 1960; *Istoria României* 2 1962). Its diverse landscape includes thick forests and mountainous areas that afforded natural protection from invaders, and broad plains where native populations could live during peaceful times, allowing them to survive for millennia on Romania's plentiful natural resources.

In the early nineteenth century, amateur archaeologists began to collect artifacts from ancient settlements, which led to the founding of the first museums: in Sibiu in 1817, the National Museum in Bucharest in 1834, the Historico-Natural Museum in Iaşi also in 1834, and another in Cluj in 1859. In the late nineteenth century, these amateurs began to unearth and study some Neolithic and Geto-Dacian settlements. In 1880 Grigore Tocilescu published a paper entitled “Dacia before the Romans,” and in 1912 Ion Andrieşescu published the “Contribution to Dacia before Romans.” These publications encouraged Vasile Pârvan, with the aid of Ion Andrieşescu, to train some young scholars to specialize in archaeology, and Romanian archaeological research blossomed. Young researchers started their fieldwork with university scholars such as Ion Nestor in Bucharest, Constantin Daicoviciu in Cluj, and Mircea Petrescu-Dâmboviţa in Iaşi; all over the country, archaeologists began prospecting and excavating and publishing the results in the journal *Dacia,* which was translated into several languages. Other museums based on small collections were founded in counties, towns, and villages (mostly small

collections). Between 1926 and 1948, sites representing all historical periods were systematically excavated (Nestor 1933). Since 1950, the Institute of Archaeology in Bucharest has published *Studies and Research of Ancient History and Archaeology* (in Romanian) in addition to the internationally translated *Dacia* and numerous monographs. In the last few decades of the twentieth century, dozens of specialized periodicals were being published (almost

Rouse, Irving Benjamin

(1913-)

Born in Rochester, New York, Irving Benjamin Rouse went to Yale University in 1930 with the intention of studying botany, but some cataloging work at the Peabody Museum began his interest in archaeology. He went on to study for his doctorate in archaeology and received it in 1939.

Rouse spent the whole of his career at Yale University: at the Peabody Museum as an assistant curator of anthropology from 1938 to 1947, associate curator of anthropology from 1947 to 1954, research associate and affiliate from 1954 to 1962 and 1975 to 1977, curator of anthropology from 1977 to 1984, and curator emeritus. His fieldwork during this long period added substantially to the Peabody's research collections in the Caribbean area, giving it one of the premier Caribbean archaeological collections in the world. At the same time, Rouse worked in the Department of Anthropology from 1939 to 1943 as instructor, from 1943 to 1948 as associate professor, and from 1954 to 1970 as professor. He was appointed Charles J. McCurdy Professor of Anthropology in 1970, a post he held until his retirement in 1984. He played a significant role in the education of a number of students who have gone on to prominence of their own in archaeology, including Robert C. Dunnell, Patrick V. Kirch, and Bruce G. Trigger.

Rouse's primary area of interest has been the Caribbean. He has excavated in Puerto Rico, Cuba, Florida, Venezuela, Trinidad, Antigua, Guadeloupe, the Bahamas, the Dominican Republic, the Virgin Islands, and Jamaica. This tremendous breadth of first-hand experience, coupled with the fact that Rouse constructed the chronologies of many key areas in the region and his proclivity for synthetic writing, guaranteed Rouse a central position in Caribbean archaeology, a position he still holds. Many of Rouse's publications synthesize Caribbean culture-history, or aspects of it, and he has often been called upon to summarize Venezuela and/ or the Caribbean area in large syntheses, such as the *Handbook of South American Indians* (1948), and in several synopses of current work in the *Handbook of Latin American Studies.* He has contributed chapters to many of the significant books about settlement

patterns, chronologies, and biogeography in archaeology, and some of his more influential pieces were journal articles: masterful areal syntheses such as “Prehistory of the West Indies,” published in *Science* in 1964, and “Pattern and Process in West Indian Archaeology,” in *World Archaeology* in 1977.

His interest in early human culture developed initially as a result of his Caribbean research but then expanded well beyond it, and his most recent research has focused on contact-era and postcontact inhabitants of the region. He has continued his culture-historical research as well, which culminated in the publication of *Migrations in Prehistory* in 1986.

Rouse's level of activity and methodological contributions have garnered an impressive array of awards and honorific positions. He served as editor of *american antiquity* from 1946 to 1950, and he served on the executive board of the American Anthropological Association from 1950 to 1953 and was that assocation's president

in 1967-1968. His honors and awards include the Viking Fund Medal in Anthropology (1960), election to the National Academy of Science (1962), and the Distinguished Service Award from the American Anthropological Association.

Royal Archaeological Institute

The Royal Archaeological Institute (RAI) is one of the older archaeological societies in Great Britain and has a tradition based on the broadest study of the past, a study that encompasses aspects of the art and architectural history of Britain and adjacent areas as well as the full temporal range from the Paleolithic to the early modern periods.

In December 1843, a group of people with a passionate interest in the past came together to form a new national organization to promote their antiquarian interests, which were becoming increasingly popular at the time. They acted out of disillusionment with the only existing national body, the society of antiquaries of london, which was by then effectively moribund. The new group was drawn from a wider social spectrum than the members of the Society of Antiquaries, but it remained largely drawn from the London establishment.

The organization was founded as the British Archaeological Association and organized the first national archaeological congress, which was held in Canterbury, England, in 1844. The meeting was a major success, but there was a serious dispute over the rights to the publication of the congress, which led to a split in the membership. The result was the birth of two separate organizations: one kept the name British Archaeological Association; the other styled itself the Archaeological Institute of Great Britain and Ireland but retained ownership of the journal that had been established-the *Archaeological Journal* has been published annually ever since). The latter organization became the Royal Archaeological Institute of Great Britain and Ireland in 1866, and in 1962, it received a royal charter and dropped the reference to Great Britain and Ireland from its title.

Through the nineteenth century, the RAI became firmly established as the center of archaeology and antiquarian studies in Britain. Its members were eclectically drawn from the British establishment and, at times, included influential politicians and thinkers. The pattern of meetings established in the early years continues today. Through the winter, there are monthly meetings in London, at which lectures and reports on research in archaeology and architectural history are presented. In the summer, there is a residential meeting, lasting a week, for which participants travel to a locale, visit key buildings and monuments, and listen to talks about them. In more recent years, these activities have been supplemented by day-long excursions at other times of the year. The institute also has a long tradition of sponsoring fieldwork and research. Most notably, it engaged in a broad-based project to study the origins of the medieval castle during the 1960s. Some of the most distinguished of British archaeologists (e.g., Sir Alfred Clapham, Dame Joan Evans, christopher hawkes, Sir John Lubbock [lord avebury], and sir mortimer wheeler) have served as officers of the organization over the years.

One of the enduring legacies of the institute is its publications. The *Archaeological Journal* has appeared annually since the 1840s, and a series of other volumes have appeared as well. The proceedings of the summer meetings, sometimes printed in the *Journal*, otherwise as separate volumes, represent a key source for understanding the topography, archaeology, and buildings of the British Isles. Equally, the articles in the earlier volumes of the *Journal* represent a prime source for understanding the emergence of the discipline, its concepts, and its methods of study. During the twentieth century, the *Journal* published a variety of key articles for understanding the archaeology of Britain. For many years until 1978 the *Journal* attempted to provide an annual review of research progress

PREV NEXT

across the full range of British archaeology. In more recent years, as archaeology has become more compartmentalized, the journal has developed a reputation as one of the few places where multiperiod sites can sensibly be published.

As the twenty-first century begins, the RAI remains one of the few archaeological societies in the United Kingdom that has a mixed membership of both interested members of the public and professional archaeologists. It also retains a broadly based organization catering to people who have a truly catholic interest in Britain's past.

Russia

Historiographic Literature

General surveys of the history of Russian archaeology were written only during Soviet times, and only one of them encapsulates the whole history-the chapters written by A.V. Arcikhovsky and published in a collective work of the history of historic disciplines in the USSR (Arcikhovsky 1973). His chapters are primarily factual and are carefully filtered to correspond to the Marxist and nationalist demands of the state ideology of the time.

The rest of the literature may be divided into two parts. One part comprises books describing prerevolutionary times, and the other part books dealing with Soviet times. The first accounts (Ravdonikas 1932; Khudyakov 1933), issuing from Marxist dogmatists, are too nihilistic in their evaluations of the prerevolutionary past, and few are objective (Formozov 1961). The most complete historiographic work (Lebedev 1992) is subjective and disordered.

Books describing Soviet times are often very critical (Miller 1956). Although written in freedom and abroad, Miller's book was not particularly competent because he was a provincial archaeologist, and the essence of great scholarly debates eluded him. In contrast, the apologetic book by A.L. Mongait (1956) was written inside the country, and it is not so much a history of the discipline as a survey of its state during Soviet times. Two later books are also apologetic: V.F. Gening's book (Gening 1961) was written in the framework of militant dogmatism, but A.D. Pryakhin's work (Pryakhin 1986) is more moderate and factual. Pryakhin tried to present a more objective and frank exposition, as much as that was possible, first abroad in some articles in English (in 1977 and 1982) and then in a book published in

Russian and Spanish in 1993 and later in German and English.

In the works of V.I. Ravdonikas and M.V. Khudyakov, the history of archaeology is viewed as a series of changing class approaches to archaeological activity: feudal, bourgeois, and proletarian (Marxist) archaeology. In A.A. Formozov's work (1961), the history of Russian archaeology is divided into periods according to the changing place of archaeology among disciplines and to the shifts in its interests: geographic, art criticism, and historic (but not ethnographic). G.S. Lebedev has maintained that Russian archaeology experienced a change of paradigms “à la Kuhn” (in the sense used by the philosopher of science Thomas Kuhn) and that these determined the methodological character of the study of antiquities. These paradigms were antiquarian, encyclopedic, applied-arts, and everyday-life-describing. The last, according to Lebedev, was developed in Russia instead of an evolution paradigm.

Russian Society and the Knowledge of Antiquities

The attitude toward antiquities in the days before Czar Peter the Great, before the beginning of the eighteenth century, was one of traditionalism and negligence. The Tatar yoke hampered

across the full range of British archaeology. In more recent years, as archaeology has become more compartmentalized, the journal has developed a reputation as one of the few places where multiperiod sites can sensibly be published.

As the twenty-first century begins, the RAI remains one of the few archaeological societies in the United Kingdom that has a mixed membership of both interested members of the public and professional archaeologists. It also retains a broadly based organization catering to people who have a truly catholic interest in Britain's past.

These paradigms were antiquarian, encyclopedic, applied-arts, and everyday-life-describing. The last, according to Lebedev, was developed in Russia instead of an evolution paradigm.

Russian Society and the Knowledge of Antiquities

The attitude toward antiquities in the days before Czar Peter the Great, before the beginning of the eighteenth century, was one of traditionalism and negligence. The Tatar yoke hampered

the development of Russia and kept it separate from the rest of Europe. In Russia, there was no Renaissance, no Reformation, and certainly no Crusades or Inquisition. Hence, until Russia was "Europeanized" by Peter the Great, there was no antiquarian tradition as in the rest of Europe.

Some kinds of antiquities were revered not because of curiosity about or sympathy for ancient culture but because of sacred and religious reasons. There was a special reverence for Greek Christian culture rather than for Greek pagan culture, which was revered in Western Europe. For Russia, Greek Byzantine civilization was the source of the Russian Orthodox religion, and some antiquities were esteemed as insignia of power or attributes of rulers and heroes. So "Monomach's cap," the Russian crown, was revered as a Byzantine article even though, in reality, it had been made during the time of the Golden Horde. In Pskov, "the sword of Litvanian Count Dovmont," the defender of the city, was saved and respected. It was to save such treasures that the czars created a state armory in the Kremlin in Moscow. First mentioned in documents in 1504, the armory still exists as a museum today.

The attitude toward other antiquities was utilitarian and not always good for the monuments. People extracted saltpeter from ancient earthworks, and barrows were simply robbed. In Siberia, special bands of barrow robbers, called *bugrovshchiki* (from *bugor* or "hillock," the local term for "barrow"), made their living pillaging ancient monuments, and hundreds of the monuments disappeared. Observing the robbery of ancient graves and the melting down of treasures from them, the Dutchman Vitsen, who visited Russia during the time of Peter the Great, wrote that the Russians did not like antiquities. The collecting of classical antiquities had begun in Italy the late fifteenth century, in England in the sixteenth century, and in France in the seventeenth century, but it did not occur in Russia before the early eighteenth century.

Czarist Antiquarianism: The First Forms of Scholarly Attitude to Antiquities, 1696-1762

The development of antiquarianism in Russia was a result of the enlightened absolutism of Peter the Great. In the last years of the seventeenth century he traveled incognito throughout Europe, and on his return in 1698, he began to reform the whole of Russia based on European standards. These reforms involved changed attitudes to antiquities as well. Peter demanded that ancient numisma (coin collections) and other finds, as well as all kinds of curiosities and rarities, be sent to him from all over Russia. Between 1715 and 1716, a Uralian factory owner, Demidov, and Count Gagarin sent him collections of golden antiquities that had been taken away from the *bugrovshchiki*. In 1718, Peter created the Kunstkammer Museum in the newly founded capital of Saint Petersburg and issued a special edict ordering that everything that was very old and unusual was to be sent there. In 1721, he ordered that the curious things that were being found in Siberia were to be sent to him, and so the well-known Siberian collection of Scythian and Sarmatian gold, which is now in the Hermitage Museum, was established.

Under Peter the Great, scientific expeditions to Siberia began. In the 1720s, the German naturalist Messerschmidt was sent there for seven years to study Siberian natural resources and folk art and to buy and collect antiquities. The Russian Academy of Sciences, created by Peter and consisting in part of foreigners, took over the organization of the primary expeditions to Siberia only after Peter's death. The great Siberian expedition of 1733-1743, led by Justus Bering, opened the strait between Asia and North America, and the archaeological survey of this expedition was conducted by the Germans Gerhard Miller and I. Gmelin.

Sentimental Opening of Classical Heritage, 1762-1812

After 1762, the German-born queen Catherine II ruled Russia. She was educated in the spirit of the French Enlightenment and corresponded with the French encyclopedists and the French writer

François-Marie Voltaire. The cult of the civil ideals that grew out of the Enlightenment was connected with an interest in classical antiquity and with fashionable sentimentality, and the purchase of classical antiquities from elsewhere became common. In 1768, just a year after

the development of Russia and kept it separate from the rest of Europe. In Russia, there was no Renaissance, no Reformation, and certainly no Crusades or Inquisition. Hence, until Russia was "Europeanized" by Peter the Great, there was no antiquarian tradition as in the rest of Europe.

François-Marie Voltaire. The cult of the civil ideals that grew out of the Enlightenment was connected with an interest in classical antiquity and with fashionable sentimentality, and the purchase of classical antiquities from elsewhere became common. In 1768, just a year after

the death of the great art historian johann joachim winckelmann, the new Hermitage Museum opened in Saint Petersburg. Built near the Winter Palace of Russian czars, it was established especially for the royal collections of classical art and Renaissance European paintings.

Shards of pottery from a Siberian barrow

(Image Select)

The treaty that concluded the war between Russia and Turkey from 1768 to 1774 gave Russia the northern shores of the Black Sea and part of the Crimea, which included sites of ancient Greek colonies. Russia finally had its own piece of classical antiquity, and the main focus of scientific and collecting expeditions shifted from the extreme north to the extreme south of the country. In the early nineteenth century, two books of travelers' tales about expeditions to Taurida (the ancient name of the Crimea) were published, and both authors-Pavel Sumarokov and Ivan Muraviev-Apostol-had been charmed by the monuments of classical antiquity. Antiquities other than those of classical times were neglected and damaged. “For all the Russian antiquities I wouldn't give even a Grosh [the smallest piece of money]” wrote the well-known Russian poet Batyushkov in a private letter. “Quite another thing Greece, quite another Italy!”

Romantic and Patriotic Insights into Russia's Past

As in many other European countries, Napoleon's invasion, national humiliation by the French, and the ensuing patriotic war of 1812 produced a burst of nationalist sentiment in Russia and awakened interest in the ancient past of the Russian people. This impulse was part of a broader romanticism based on political and social discontent, and the regard for antiquities manifested itself in two different ways.

First, the passion for classical antiquities did not cease and became even more popular, but its character changed. Sentimentality and enlightenment for their own sake disappeared, and antiquities now endowed their owners with prestige and profits. Museums needed collections to help educate society and to help artists depict the ancient world, and the latter was the aim of a prominent archaeologist of the time, Olenin, the president of the Academy of Arts. The archaeological study of Scythian monuments

Crystallization of Archaeology during the Epoch of the Great Reforms, 1855-1881

In 1855, Czar Nicholas I, unable to bear Russia's defeat in the Crimean War, died. The defeat was partly the consequence of a delay in the reformation of the country's archaic social order, a point the new czar, Alexander II, understood. He began the necessary all-embracing reforms, such as the abolition of the serfdom and changes to laws, and one of his first reforms concerned archaeology. In February 1859, the Archaeological Commission (AC) was created by the Ministry of the Court as the central state office to control archaeological excavations, the collection of data on antiquities, the stimulation of their studies, and expert knowledge of them. All archaeological finds from state and municipal land, i.e., not in private ownership, came under the authority of the AC. The Hermitage was also under the Ministry of Court, so the AC was closely connected to it and the most valuable finds went to the Hermitage. The AC published annual reports of its studies and activities, which listed all archaeological finds and their fates.

In 1864, in addition to the archaeological institutions in Saint Petersburg, two were created in Moscow-the Moscow Archaeological Society (MAO) and the Society of Amateurs of Natural Science, Anthropology, and Ethnography (OLEAE). The founder of MAO was Count Alexey Uvarov, now thirty-seven years old and an archaeologist. Beginning in 1869, MAO organized the all-Russian archaeological congresses, held every three (later four) years, each in a different town. Ivan Zabelin, a venerable Moscow archaeologist, was for many years invited to work in Saint Petersburg in the AC. Zabelin had no university education, in fact no education at all, and he obtained his great knowledge from practice. He was the real head of the Historical Museum founded by Uvarov in Moscow.

Uvarov's and Zabelin's methodological articles reveal their interest in Slavic archaeology, mainly with the ethnic identification of monuments and the widely understood *byt* (everyday life and equipment) of ancient peoples, i.e., their cultures. The two men did not separate archaeological sources of information into a special branch, instead considering it side by side with ethnographic evidence from the field, museum observations, and written sources. They included all of these sources of information into the study of archaeology. They separated the discipline of archaeology not by specific sources but according to two criteria: practically, as a period not enlightened, or poorly enlightened, by chronicles, and theoretically, not by events but *byt* (culture). Archaeology for them, from the beginning, was something like paleoethnography.

In 1874, when the participants in the Third (Kievan) Archaeological Congress went to see the Sophian Cathedral, its dean, according to the historian Kostomarov, asked them, “Haven't you come in order to search for arguments in favor of the origin of man from the ape?” Count Uvarov, leading the archaeologists, reassured the archpriest, “We do not march into such a distance.”

However, some Paleolithic discoveries were made in Russia, especially in the late 1870s and early 1880s. These included the excavations of kostenki near Voronezh on the Don River by Polyakov, the exploration of Crimean caves by Merezhkovsky, and even the discovery of a Paleolithic site in Karacharovo, on Uvarov's own land. The main explorers of these sites were naturalists, not humanists. In Uvarov's book *Archaeology: The Stone Age* (1881), there is no long chronology, and Darwin is not mentioned. Uvarov really did not march “into such a distance.”

Separation of Archaeology into a Special Discipline, 1881-1917

Liberalization ended when Czar Alexander II was assassinated by a terrorist in 1881. The majority of the archaeologists were on the side of the counterrevolution, and there were many aristocrats and priests in archaeology. Countess Praskovia Uvarova, who replaced her husband as the head of MAO after his

death, once said that archaeology is knowledge for the rich.

In 1889, as part of a general centralization, the AC received the monopoly on issuing permits for excavations. Count Bobrinsky, a well-known Saint Petersburg archaeologist and the head of the AC, began to issue permits with great fervor. Uvarova and her colleagues at MAO protested, initiating a long quarrel between Saint Petersburg and Moscow archaeologists.

The split mirrored the competencies of the two main schools and centers for archaeology in Russia, each with its own tradition. The Saint Petersburg school, with the Hermitage and state support, stood for a more professional approach, preferring the detailed study of material and strong methodology. The Moscow school was more open to amateurs, and its members had broader interests and more often made generalizations and historical inferences.

At the end of the nineteenth century, two very great and influential archaeologists were growing up-aleksander spitsyn in Saint Petersburg and vasiliy gorodcov in Moscow. Their eventual profession was not their only similarity. Both came from the provinces, both were of middle-class origin (Spitsyn was a teacher's son; Gorodcov, the son of a deacon). Neither attended a school of archaeology, and both contributed greatly to the development and systematization of Russia's archaeology.

Classical archaeology continued along traditional lines with a preference for the analysis of the art of antiquity. The most prominent representative of this school was nikodim kondakov, a Muscovite originally, who created his own school of archaeology in Odessa and then moved with it to St. Petersburg, together with his pupils Farmakovsky and Rostovcev.

Catastrophe and Change of Structures, 1917-1924

At first, the 1917 Revolution had no impact on the content of archaeological studies, but it did cause a sharp decrease in excavations and the complete breakup of all the old institutions of archaeology. The AC and the Hermitage were subsumed into the Ministry of the Court, but both the ministry and the court suddenly disappeared. The majority of the members of the MAO, mainly from the nobility and clergy, were suppressed and lost their influence and possessions. Archaeology had developed in Russia as "knowledge for the rich," and there were now no rich in the country. Private collections were partially robbed and annihilated, and what was left was nationalized and put into the large museums.

At the same time, the new government tried to give a civilized form to its power. In November 1917, the new Peoples Commissariat (ministry) of Enlightenment asked the people to save their cultural monuments. On 19 September 1918, a decree concerning the state registration of monuments was issued, and on 10 October 1918, the exporting and selling abroad of any artifacts of Russian art and history was forbidden.

A new central institution, the Academy for History of Material Culture in St. Petersburg, was created to replace the AC. The academy was a more powerful, centralized, and all-embracing institution that studied history, linguistics, ethnography, and the arts and later concentrated on archaeology. There was only a section of this academy in Moscow. The head of the academy was Nikolay Marr, half-Georgian, half-Scot and a linguist by profession. He was a talented man but emotionally unbalanced and not self-critical. Although his education was very narrow, his pretensions were enormous. He applied his revolutionary ideas to linguistics, declaring, for instance, that Caucasian languages (Japhetic in his terminology) were previous stages of Indo-European languages not only in structure but also in substance. For him, the main process was not the splitting of languages but their fusion. Linguists closed their ears to his wild ideas, hoping that he would adopt cultural studies and archaeology, while archaeologists excused his evident ignorance of archaeology and regarded him as a great linguist. In 1923, Marr finished formulating his "new learning on language" (or Japhetic theory), which, as yet, had no influence on archaeology.

There was another important institutional novelty, the teaching of archaeology at universities where faculties of social sciences were opened. However, these new structures were unstable, the revolutionary impulse was not exhausted, and they were constantly reconstructed and reorganized.

Before the Revolution there were as many as 150 museums in Russia, and this number increased five times after 1917, mainly owing to the founding of small local museums. The development of archaeology was considerably damaged by the emigration of many of its great scholars, such as Kondakov, Rostovcev, Shtern, Bobrinsky, and Uvarova.

Revolution in Archaeology:Muscovian Control, 1924-1929

Even before Lenin died, in 1924, Joseph Stalin took over the reigns of political power, and after Lenin's death, Stalin soon got rid of any opposition and “the Lenin guard” to become the sole ruler of Russia. This change meant a very different style of government, the end of any private-sector economic freedoms, and an increasing ideological monopoly, with Moscow-based organizations dominant.

In 1926, the Russian Academy based in Moscow (RAIMK) modified its title to encompass all of the USSR and was renamed the State Academy (GAIMK). From 1924 on, to centralize control, all the scholarly institutions of archaeology were united into the Russian Association of Research Institutes of Social Sciences (RANIION). This framework facilitated the reeducation of scholarly cadres in the ways of the new communist spirit.

In Moscow the well-known Bolshevik sociologist and art critic Friche surrounded himself with a group of Gorodcov's students, who, under his influence, became very keen on Marxism and on building a Marxist archaeology. These students were Arcikhovsky, Bryusov, Kiselev, and Smirnov, and all of them later became well-known Soviet archaeologists. They fought against another group of young Moscow archaeologists from Zhukov's paleoethnological school. Zhukov was Anuchin's pupil, and he was interested in the impact of the natural environment on cultures and ethnic development. His pupils were Bader, Tolstov, and Voevodsky-they, too, became well-known Soviet archaeologists. Eventually, Zhukov was arrested and the paleoethnological school dispersed. However, Archikhovsky's “Marxist archaeology” did reign supreme in Russia before it was demolished by colleagues from Leningrad (formerly St. Petersburg).

However, Archikhovsky's “Marxist archaeology” did reign supreme in Russia before it was demolished by colleagues from Leningrad (formerly St. Petersburg).

Revolution in Archaeology: Leningrad Campaign, 1930-1934

In 1930, Stalin had finished with any opposition to his power and was ostensibly the dictator of Russia. Lenin's new economic policy (NEP) was rejected, and the revolutionary ideas of freedom, internationalism, and annihilation of state apparatus were anathema to the tyrant. His slogan, "dictatorship of the proletariat," aimed at building socialism in the country by increasing the power of the state and exacerbating the class struggle. Resistance was ruthlessly suppressed. The collectivization of agriculture was accompanied by the mass deportation of well-to-do peasants to Siberia, and the church, the peasants' main spiritual support, was suppressed as well. Local archaeological and folklore studies were forbidden, and organizations were disbanded if they were sympathetic to and protective of old customs and church buildings.

The old archaeological cadres were badgered and accused of "creeping empiricism," of "naked artifactology," and of controlling archaeology with formal typological studies. If their work reflected idealism, nationalism, or other -isms, they were even worse off and forced to make public renunciations and repentances.

Bolsheviks from the Communist Academy (not to be confused with Academy of Sciences) came to help Marr at GAIMK, and their careers provide a study in the politics of the times. Sergey Bykovsky was a mathematician prior to the Revolution, a commissar during the civil war, a member of the Red Army's secret political security service, and then a historian in the Communist Academy. Fedor Kiparisov was a philologist and had earlier worked as a trade-union organizer. sergey semenov was a young secret political security investigator when he began his postgraduate study of stone tools using modern criminological techniques at GAIMK. Marr became a member of the Communist Party, and his courses became obligatory.

In 1930, in Leningrad, Spitsyn's pupil vladislav ravdonikas developed a work program according to orders from the Bolshevik rulers of GAIMK even though he himself was not a member of the Communist Party. Called "the Marxist history of material culture," not of archaeology, it contained sharp criticism of many contemporary archaeologists for their unwillingness to work in the new way. The use of the new term *material culture* instead of archaeology was significant. Bykovsky and other Marxists favored a model that divided material culture in general, not by its sources or its methods of manufacture, but by epochs and their socioeconomic

formation. This division was later rejected.

RANIION, because of its own reconstruction, had not caught up with all the new ideas and was dismissed. Some Moscow archaeologists joined GAIMK and built a little Muscovite department. Inspired by Marr, Leningrad archaeologists Ravdonikas and Krichevsky transferred ideas from the "new learning on language" to archaeology and built the theory of stadial (i.e., stages of history) development. This theory ignored the national specifics of cultures and their migrations and emphasized their fusions and sharp changes from epoch to epoch. It supported the current Soviet policy with regard to the maintenance of power in the multinational state inherited from the Russian Empire.

In the GAIMK periodicals of the time, theoretical articles and reviews (usually crushing) composed 47 percent of the contents, particular research themes 35 percent, and field reports 17.5 percent. However the enthusiasm for theory did not last long.

Soviet Archaeology: In the Service of Stalin's State, 1934-1956

On 1 December 1934, Sergei Kirov, the ruler of Leningrad, the second-ranking person in the Communist Party and state hierarchy, and Stalin's competitor, was killed. His murder was probably organized by Stalin, and in any case, Stalin used it as a pretext for a campaign of mass terror across the country. Stalin introduced Draconian laws, and all members of "Lenin's guard" were annihilated along with hundreds of the participants in the Sixteenth Party Congress and nearly all of the army's general officers. Terror was used initially against the top members of the Party, but it spread to involve ordinary people simply to bring the whole population under control. The cult of Stalin was introduced.

The repressions affected many archaeologists. Some, like Zhukov, had been eliminated even earlier; some, like Miller and Borovka, perished in detention; others, like Rykov and Teploukhov, committed suicide; and still others, including Rudenko, Latynin, Gryaznov, Bonch-Osmolovsky, and Sychev, languished in prisons and prison camps or were deported. It became very dangerous to have any scholarly position, and theoretical studies ceased immediately. Sociology was abolished, and sociological interests, described as "sociologization," were regarded as harmful. Marr's successors, Bykovsky and Kiparisov, were both shot.

There was a section of archaeology at the Institute of Ethnography at the Academy of Sciences in Moscow, which included the archaeologists Ravdonikas, aleksei p. okladnikov, Zamyatnin, and Bibikov. The section was allowed to issue the serial *Sovetskaya Arkheologiya* (later a journal) and then fused with GAIMK to form the Institute for the History of Material Culture (IHMK) within the framework of the Academy of Sciences. The mighty GAIMK became a demoted institution.

Archaeologists were advised to stick to the empirical facts, to stay close to the "real" history written by Soviet historians, and to use the same methods as the historians, which were based on historical materialism. With this in mind, Muscovite archaeologists, former builders of the "Marxist archaeology," reoriented their archaeology from sociology toward history, aiming their studies at historical reconstructions on the basis of known archaeological facts and written sources. Arcikhovsky described archaeology as "history armed with the spade." There were about 300 archaeological expeditions under way at this time. Knowledge about the former provinces of the Russian Empire greatly increased, and the monuments of Urartu, the barrows of Pazyryk and Trialeti, and the ancient center of Parthia Nissa were discovered in Russian Central Asia.

World War II (1941-1945) delivered yet another blow to the development of archaeology in Russia. Expedition activity ceased, and many archaeologists perished in the fighting. The German invasion annihilated many museum collections while others were taken to Germany and destroyed there. As a

result of the siege of Leningrad, IHMK archaeologists Zhebelev, Podgaecky, Zograf, Rydzevskaya, Degen-Kovalevsky, and Golmsten starved to death, and others were evacuated in an emaciated state. After the war, the institute established a department in Leningrad, but its headquarters were transferred to Moscow. By this time, Stalin's

long-term suspicion that the people of Leningrad secretly longed for their city to be the capital again meant that he did the opposite and centralized most government institutions in Moscow. He also dismissed and then executed some of what was left of the Leningrad elite.

The inglorious Soviet-Finnish War (1939- 1940) and the defeats in the first year of the Patriotic War (1941-1945) revealed the weakness of Stalin's brand of socialism, which was in reality equal to the old feudal order with elements of slave ownership. Stalin was forced to resort to the patriotic feeling of the people of the USSR, and more particularly to the patriotic feeling of the Russian people, because Russian soldiers were the basis and the majority of the Soviet army. Soviet archaeologists glorified the national character of the Russian people and some other peoples of the Soviet Union, tracing their noble ancestors and their ethnic peculiarities back in antiquity and searching for their ethnic territories and broadening their boundaries during the remote past in order to justify any new “historic claims” on territory.

Marr's position was no longer fashionable, and his theories were dismissed personally by Stalin in a public discussion in 1950 in the party newspaper *Pravda*. Stalin declared that Marr was not a Marxist, and Indo-European linguistic studies were restored. The theory of staged development was rejected as well, and another detachment of scholars was forced to publicly repent. Although the repression this time was not as dramatic as earlier, it still existed, and “cosmopolites” (mainly Jews) became “antipatriotic critics” and “slanderers” and were expelled from scholarly organizations.

Soviet Archaeology: From Thaw to Moderate Frosts to Stagnation, 1956-1991

Nikita Khrushchev's speech during the Twentieth Party Congress exposed Stalin as a despot and took power from his nearest associates. It was a kind of liberalization, and the writer Ilya Erenburg coined the word “thaw” for it. The dictatorship of the proletariat was repudiated, and normalization of relations with the West began.

All of this change led to some shifts in archaeology. Gradually, the concern for “historic rights” on maps disappeared, the details of local origins were no longer so important, and archaeologists were able to argue for migration in their explanations of cultural change. Slavic archaeology began to be as well regarded as other branches of the discipline, and ethnogenesis lost its priority. However, the new ruler of Russia neither understood humanist intellectuals nor had any special sympathy for them.

In 1956, Boris Rybakov, a specialist in Slavic-Russian archaeology, was appointed as head of the IHMK, which was shortly renamed the Institute of Archaeology. Rybakov earlier had made his name by encouraging patriotic ideals in archaeology, specifically by the glorification of ancient Russian handicrafts.

In the middle of the 1960s, Khrushchev, whose political experiments were considered dangerous for the regime, was demoted by a palace revolution. To justify this change in policy, it became necessary to introduce objective and reliable methods in all disciplines. Archaeologists seized this opportunity to develop theoretical studies, their relationships with western non-Marxist scholars became more positive and respectful, and debates took place. However, the new scholarly freedom that led to the invasion of Prague by Russian troops in the spring of 1968 badly frightened the Brezhnev oligarchy, and debate and discussion, even critiques of Stalin, ceased.

Archaeological activity continued to grow enormously. In 1985 there were some 700 expeditions; more recently, it has been estimated that every two years 8,000 archaeological books and articles are published in the USSR, i.e., as much as was published between 1918 and 1940. Using state donations, planned economy, and centralized organization, Rybakov managed to initiate the twenty-volume edition *The Archaeology of the USSR*, and although only a small number of the volumes have been published,

hundreds of other volumes entitled *Corpus of Archaeological Sources* have appeared.

Russian Archaeology in the Struggle for Survival since 1991

In 1985, Mikhail Gorbachev's rise to power initially caused considerable liberalization and the

long-term suspicion that the people of Leningrad secretly longed for their city to be the capital again meant that he did the opposite and centralized most government institutions in Moscow. He also dismissed and then executed some of what was left of the Leningrad elite.

The inglorious Soviet-Finnish War (1939- 1940) and the defeats in the first year of the Patriotic War (1941-1945) revealed the weakness of Stalin's brand of socialism, which was in reality equal to the old feudal order with elements of slave ownership. Archaeological activity continued to grow enormously. In 1985 there were some 700 expeditions; more recently, it has been estimated that every two years 8,000 archaeological books and articles are published in the USSR, i.e., as much as was published between 1918 and 1940. Using state donations, planned economy, and centralized organization, Rybakov managed to initiate the twenty-volume edition *The Archaeology of the USSR*, and although only a small number of the volumes have been published,

hundreds of other volumes entitled *Corpus of Archaeological Sources* have appeared.

Russian Archaeology in the Struggle for Survival since 1991

In 1985, Mikhail Gorbachev's rise to power initially caused considerable liberalization and the

introduction of moderate freedoms. But in archaeology nothing changed during the period of "*perestroika*" (reconstruction), except for the destruction of the socialist camp and then the fall of all the socialist regimes in Europe. Glasnost (quite considerable freedom of the press) and intensive contacts with the West increased the amount of information available to the Soviet people, and their preference for capitalism became evident.

Real transformations began in 1991 when Boris Yeltsin was elected president and the Soviet Union fell to pieces as a result of an attempt to overthrow the government in August. Communist power broke down completely, and the new government began radical economic reforms. The disintegration of the old economic system without a new system to take its place, and the disruption of old economic connections among national republics, were the very painful consequences of democratization and growing capitalism. They were also very destructive with respect to archaeology.

Independent national archaeological programs emerged in the Ukraine, Belorussia, Moldavia, all the Transcaucasia, central Asia, and the Baltic areas. The monuments that had been studied for a long time by many Russian scholars were now located in countries other than Russia. Archaeology was decentralized, and the role of local centers increased. The Institute of Archaeology was split into two independent institutes in Moscow and St. Petersburg (formerly Leningrad, now St. Petersburg once again), and in the latter, the name Institute for the History of Material Culture (IHMK) was restored.

Another consequence for archaeology has been a sharp decrease in state allocations of funding for academic disciplines, including money for archaeology. The lack of state ideology has also deprived archaeologists of any material support. They have been forced to search for new sources of funding from western foundations, local sponsors, or their own earnings. The amount of foreign literature in specialist libraries decreased as the availability of foreign currency decreased.

On the positive side, communications with foreign colleagues have intensified, and the choice of methodology and direction in archaeology appears to be completely free now. The main journal has changed its name to *Archaeology of Russia,* but attempts to rebuild professional archaeological societies have not met with much success. The milieu that gave the societies their members and made them strong and influential has disappeared, and new sources of support for archaeology have not been formed as yet. Russian archaeology is at another turning point in its history.

The Development of Archaeological Thought

Antiquarianism

Peter the Great's enthusiasm for antiquities as rarities was undoubtedly antiquarian in character. Although an interest in antiquarianism came to Russia two a half centuries later than it had come to Italy, two centuries later than to England, and a century later than to France, it took the same forms. Antiquities were sampled and connected at random with ancient peoples known from written chronicles. Scholarly activity proceeded in newly annexed or explored territories on the periphery-Siberia, the Urals, northwestern Russia-and the study of antiquities was seen as a part of geography and as part of broad encyclopedic interests, as they were in other countries. However Russian antiquarianism was different in two respects.

First, Russian antiquarian interest was originally directed toward local antiquities-at colonial antiquities-rather than toward classical Greek or Roman antiquities. This difference was connected with ethnographic interests. Classical antiquities attracted attention later, when Russia received part of the lands around the Black Sea where there were ancient Greek colonies, and Russian-Slavic antiquities received attention later still.

The second distinction existed because the motivating force in Russian antiquarianism was the czar and the state. In other European countries, collecting antiquities was initially a bourgeois intellectual hobby that was later taken up by the aristocracy. Antiquarianism in Russia spread, from the very beginning, from above as one of the important aspects adopted by the Russian state from the western European way of life.

Under the influence of the German art historian Winckelmann, classical antiquities were considered everywhere, including in Russia, as the greatest monuments of art and as an ideal. This sentimental attitude was an important part of antiquarianism, and it was alive and well in Russia until the beginning of the Soviet era, for example, in Zhebelev's *Introduction to Archaeology,* published in 1923. The final demise of these values was recognized in Marr's statement: "Down with Venus of Milos, long live the hoe!"

Romantic Ethnography

The romantic movement gave birth to a widespread interest in local medieval monuments all over Europe, and Russian romanticism was especially patriotic because it developed as a result of the war against Napoleon's invasion in 1812. In the early nineteenth century, this interest was best expressed by Chodakovsky's program of scholarly travels. He was as carried away by hill forts, as was william stukeley by megaliths in England-and like Stukeley, Chodakovsky suspected that his hill forts were sacred places. Passek had the same passion for barrows, but both men were interested in the ethnography of these monuments.

Passek's investigations of barrows occurred during the middle of the nineteenth century and were inspired by the grand excavations of barrows by Uvarov and Savelyev. Uvarov published the results of these excavations in 1871 and described the barrows as belonging to the Merya (a Finnish people), although later it became clear that they were, in fact, ancient Slavic monuments. This episode shows that leading Russian archaeologists still did not have means to properly identify ancient peoples with the peoples of today and thus identified them ethnically. It also shows that at least some Russian scholars had no nationalist subplot they were trying to justify via archaeology and that they did not try to widen the ancient territories of the Russian people to this end. Their national self-esteem was not dependent on the past.

Archaeology was considered to be the simple expansion of ethnography into the distant past. The same scholars undertook both the archaeological and the ethnographic exploration of a region. The principle that every people had distinct peculiarities of culture and distinct material or types of things seemed quite natural and was the view that the German archaeologist rudolf virchow and other German scholars of his circle took.

The best example of this point of view can be found in an 1899 article by Spitsyn, "The Distribution of Ancient Russian Tribes According to Archaeological Data," in which he established that the territory of Russian "tribes" (as they were called in the chronicles Polyane, Drevlyane, and Vyatichi) reflected the area of their temple ring types, i.e., each "tribe" had its own type of ring. Spitsyn's work resembles that of the twentieth-century German archaeologist gustav kossinna in his article "On the Decorated Iron Lanceheads as Attribute of Ancient Germans" (1905). However free Spitsyn was of Kossinna's nationalist and racist overtones, he could still get carried away by the possibilities of migrations. The notion of archaeological culture also originated in Russia at this time and has been used widely since 1901.

Migrations were only one part of Kossinna's overall concerns and not really central to them. For central Europe, where the Germans lived, Kossinna preferred to argue for local and continuous development so that, in fact, the central part of his argument was autochthonism. This concept was more widely held in Russia than migrationism. Within the framework of the "*byt*-descriptive" (everyday-life-descriptive) approach developed by Zabelin and Samokvasov, there was also an argument for a very long and continuous development of the Russian state and culture from the same territories as Kievan Rus, which must have originated from the Scythians ("the noble ancestors"). Despite the cold reception this

hypothesis received and numerous critiques, it remained tenacious and was revitalized again and again. In the middle of the twentieth century (from the 1930s to the 1970s), Boris Grekov and Boris Rybakov built a scheme for Russian state development that was still longer than that of Zabelin and Samokvasov, as they included not only Scythians but also Tripolye agriculturists, from the Eneolithic period. There are many weak points in this concept,

and its political and nationalist motivations help to explain its popularity during the Soviet period. Paradoxically, it now receives new support-from Ukrainian ideologists.

Progressivism

The three-age system made its way into Russia, as in the rest of Europe, from Scandinavia. For its establishment, it was necessary to elaborate on the Enlightenment idea of progress that declared that the contemporary was a higher cultural state than the ancient classic ideal. This idea was in harmony with the reforms of Czar Peter the Great, whose ideals were contemporary Europe and European civilization. Thus, as distinct from Germany, in Russia there was fertile soil for the idea of progress. In the middle of the nineteenth century, a series of translations (including the writing of Danish archaeologist jens jacob worsaae) acquainted Russian archaeologists with the achievements of Scandinavian progressivists. In 1881, the leader of Russian archaeologists, Count Uvarov, based his book *Archaeology: The Stone Age* on the three-age system. Thus, the basis for archaeological periodization was introduced.

The corresponding ethnographic periodization in three steps (savagery, barbarism, civilization) was merely elaborated by American anthropologist lewis henry morgan in the evolutionary spirit. However, it had been advanced earlier by Vedel-Simonsen, and in his version it was properly a progressivist scheme and was adapted by Fredrich Engels into the basics of Marxist revolutionary ideology.

Evolutionism

Created in England, France, and Sweden, archaeological evolutionism became known in Russia comparably early-through reviews, surveys, expositions, and, later, translations of Lubbock and gabriel de mortillet's work. It had an impact on Russian ethnography but little impact on Russian archaeology. Russian archaeologists were more conservative than Russian ethnographers (some of whom were deported as revolutionaries), and archaeologists were confused by the connection of archaeological evolutionism with the ideas of Charles Darwin.

The revolutionist periodization of de Mortillet was transferred to Russia by Fedor Volkov, who studied in France, and by his pupil Petr Efimenko, whose fundamental work on the Paleolithic was published in 1934. In that work's exposition of data, the periodization of the Stone Age was elaborated in the spirit of de Mortillet's evolutionism at a time when, in France, much of de Mortillet's approach was being revised by henri breuil and others. Russian archaeologists first learned about the methodological elaborations of Swedish archaeologist oscar montelius in the first volume of Ravdonikas's *History of Primordial Society* (1939).

In the first half of 1930s, the theory of stadial development rejected the primacy of the *Ursprache* (“ancestor language”) as well as the importance of ethnic boundaries and insisted on the mixing, crossing, and fusion of peoples. Nevertheless, it retained the autochthonistic principle of a gradual, slow sojourn of peoples in places. To substantiate the theory, Kruglov and Podgaecky, in their book *The Clan Society of East-European Steppes* (1935), introduced a correction into the concept of a revolutionary replacement of stages (the break of continuity) by using the concept of “stadial transitions,” i.e., connecting chains or intermediate types, in what was an evident retreat from revolutionary phraseology to evolutionism. Gradual evolutionism began to mark the Irkutsk school of Soviet archaeologists, especially Teploukhov and his pupil Gryaznov. For them, development occurred independently at each place, and an archaeological culture was considered identical to its period.

Anthropogeographism (Paleoethnological Trend)

Anthropogeographism, named after friedrich ratzel's school of Anthropogeography, rejected the evolutionary aspects of ancient cultures and moved the center of consideration to territorial

aspects-development in the space and distribution of culture complexes, which were considered as very steady and unchanging. A large role was given to the interaction of the sciences of man with geography and, in general, with the sciences of the natural environment.

In Russia, this trend developed independently of western anthropogeography and had a

In Russia, this trend developed independently of western anthropogeography and had a

Leningrad paleoethnologists was Alexandr Miller, who studied in the École Anthropologique in Paris after the death of de Mortillet and was friendly with Breuil and hugo obermaier grad. Miller published very little but trained very strong pupils-Artamonov, Piotrovskiy, Iessen, Passek, Latynin, Kruglov, Podgaecky, and Krichevsky. Miller was also arrested in the 1930s, and his pupils were encouraged to maintain an interest in ethnic problems rather than any paleoethnological directions.

This trend in Russia was strangely unlucky, but there was a logic to its bad luck. During the time of the czars, in the 1880s, the Department of Anthropology at Moscow University was closed and what survived was transferred as the Department of Ethnography from the historical-philological faculty to the natural sciences faculty in order to hinder the intrusion of naturalist scientific ideas into humanist studies. During Soviet times, it was dangerous for social scientists to look for explanations in natural factors instead of socioeconomic ones or (in the early period) to have an interest in ethnic problems. The attitude of paleoethnologists, whether consciously or not, was opposed to the historicizing and politizing of archaeology and to its Marxist directions. Thus, the heads of both schools of paleoethnology-Moscow and Leningrad-were arrested and annihilated, and some members of the schools also "visited" prisons and camps. Paleoethnology remained disorganized and broken.

After interests in ethnogenesis were allowed, and even encouraged, again in the USSR, the pupils of paleoethnologists who had survived started to research ethnogenetic questions. The leading figures in this respect were Artamonov, the pupil of Miller; Tretyakov, the pupil of Efimenko; and Tolstov, the pupil of Zhukov.

Diffusionism

An interest in cultural influences first appeared in Russia in the late nineteenth century in a paper by Anuchin entitled "On Cultural Influences on the Prehistoric Soil of Russia" (1880). Yet the proper bearer of the diffusionist concept in Russia became, partly as a result of the influence of Anuchin, Vasiliy Gorodcov. His generalizing works were built on the idea of *ex Oriente lux* (out of the East comes light). He sought the origins of any novelty in a given culture-as an invasion or borrowing. He attentively observed the activity of the prominent European diffusionist sophus müller, especially his remarkable excavations of Jutland barrows, and in 1901-1903 exactly copied those excavations in the Izyum and Bakhmut districts of the Ukraine, discovering the pit-grave, catacomb-grave, and framework-grave cultures. Gorodcov's "typological method" was opposed to that of Montelius, mainly because Müller was an opponent of Montelius.

The controversy between Gorodcov and the head of the Moscow paleoethnological school, Zhukov, is characteristic of these different points of view. Zhukov built the periodization isophenomenologically, that is, he divided material into periods exclusively according to typological similarities and distinctions regardless of time. Gorodcov did so isochronologically, that is, he divided the periods into chronological sections regardless of material types. If some leading regions entered the Bronze Age, all others were considered as being in the Bronze Age; contacts were held to be more important than the level of development.

Some particular manifestations of Gorodcov's approach existed after World War II (Foss in 1949 stuck to such a periodization, as did Bryusov in part), but all in all, diffusionism did not continue in Russia, even though Gorodcov had many well-known pupils, Arcikhovsky, Bryusov, Smirnov, and Kraynov among them. They continued his interests in classification but not his diffusionism.

Combinationism

The designation of the term *combinationism* is not well known and belongs only to the historiographer,

the author of this article, who formed a special school for it (Klejn 1977). All the main schools of archaeology tried to answer the question of why there were breaks of continuity in the development of culture, because there had to be continuity in terms of process between past and present for the present to be understandable. The question of why or how cultures change requires us to limit the two notions of

Combinationism

The designation of the term *combinationism* is not well known and belongs only to the historiographer,

the author of this article, who formed a special school for it (Klejn 1977). All the main schools of archaeology tried to answer the question of why there were breaks of continuity in the development of culture, because there had to be continuity in terms of process between past and present for the present to be understandable. The question of why or how cultures change requires us to limit the two notions of

heredity and continuity with innovations. Some western scholars in the late nineteenth and early twentieth centuries stated ideas about the importance of joining various traditions together. The French historian Tarde defined invention as “logical copulation.” The German ethnologist Leo Frobenius described cultural creation as the “coupling of cultures.” In the second and third decades of the twentieth century, the English anthropologist augustus pitt rivers clearly believed that new cultural elements emerged as a result of the fusion and crossing of the old elements of culture.

In Russian archaeology at the turn of the century, Kondakov, who moved from the University of New Russia in Odessa to St. Petersburg and studied ancient art on the basis of archaeological records, advanced the idea that anything new in art emerged out of the crossing of old forms. For instance, he stated that ancient Russian art was the result of a fusion of Byzantine, nomad, and local elements. In the first decades of the twentieth century, his methodological ideas were further developed by his pupils-Rostovcev on the example of the Bosporus and Scythia and Farmakovsky on the materials of the archaic culture of the Caucasus. In the first case, the Iranian ethnic element crossed with the Greek one; in the second, the Ionian crossed with the Oriental. After the Russian Revolution, Kondakov and Rostovcev emigrated. Another pupil of Kondakov, Zhebelev, remained in Soviet Russia and managed to publish Rovtovcev's *Scythia and Bosporus,* in Leningrad in 1932. Rostovcev became a widely known specialist in the economic history of Hellenistic culture.

The ideas of the Russian combinationists influenced the development of stadialism. The idea of cultures crossing was adapted by Soviet archaeologists from the linguistics school of Marr (see below). The impact of this approach in archaeology was first made by Kondakov and Rostovcev. It was based on combinationism and a broad trend of Euro-Asianism that became very popular among Russian emigrants abroad. They believed that the Russian people were the result of a crossing of European and Asian cultures. However this trend was even more popular in history than in archaeology.

Stadialism

In the first decades of the Soviet period, the director of RAIMK/GAIMK, the main archaeological institution of the country, was Academician Nikolay Marr, a linguist and orientalist. In the middle of the 1920s he formulated his “new learning on language” (Japhetic theory), which completely rejected the concept of an Indo-European *Ursprache* (“ancestor language”), a concept that had been well elaborated by many generations of linguists, and explained the close similarity of languages, not by affiliation (common origin), but by their mixing and crossing. This theory depicted the history of speech as a series of language revolutions within the melting pot of one language family that are instantly transformed into languages with quite another structure and substance without any alien intrusion. There was no serious substantiation of these assumptions, but the revolutionary phraseology and defaming of Indo-European studies as “bourgeois” gained Marr the support of Communist Party ideologists.

This linguistic theory was picked up by some young archaeologists, especially those of the Leningrad school (such as Ravdonikas, Krichevsky, and Okladnikov), and transformed into an archaeological theory-that of stadial development. Ethnic cultures were placed under languages, and the whole of their history was depicted as a series of leaps from one stage to another-leaps in which the ethnic nature of the culture was instantly transformed. The theory resolved some of the most difficult problems of ethnogenesis as it became possible to derive any culture from any other. Such a large role was assigned to the interaction of cultures that the question of roots, of ancestors, simply no longer arose. All peoples appeared mixed, the ancestors of all of them being similar and, to some extent, common. All had behind them the various and finely crumbled mixture out of which modern peoples were formed by gradual junctions or crossings and mainly by sudden stadial transformations.

The first observable realization of this theory was Ravdonikas's work “The Cave Towns of Crimea and the Goths Problem in Connection with Stadial Development of the Northern

Black Sea Region" (1932). In it, Ravdonikas suggested that the reader believe that Cimmerians who had populated the region earlier were Japhetides, i.e., they were related in language to the Caucasians of today, that they turned as the result of revolutionary transformations into Iranian-speaking Scythians, that they in their turn became German-speaking Goths, and that the Goths became Slavs. Nobody came from the outside into Crimea; everything evolved within it. Language and culture changed sharply and abruptly. Why? Because the sharp transformations are the dialectical law of being and because language and culture are connected with social structures, which, of course, went through revolutions.

In 1934 and 1935, Efimenko attempted to represent the development of the Paleolithic through stages and in 1935 Kruglov and Podgaecky postulated a series of stages in the Bronze Age of the steppes. In their work, however, the ethnic aspect was completely absent. They timed the stages according to technical shifts, to steps in the development of production, and while showing the revolutionary character of these shifts they tried to allot all of the phenomena of culture, including "superstructional" (projective) ones, to these steps. This work looked more realistic than the fantastic transformations of languages and peoples, but the more realistic it looked, the less it retained of the theory of stadial development. Because the essence of that theory was miraculous transformations, it resisted explanations that were logical and that proposed any continuity of development. However, stadial development depends on logic and on intermediate chains-"stadial transitions" as they were called by Kruglov and Podgaecky.

During the Patriotic War (World War II in Russia), considerable mass opposition against Stalin began, which forced the state to reconsider the patriotic feelings and nationalist temper of the peoples of the Soviet Union, especially the Russian people. Ethnic groups within the USSR were encouraged to take pride in their independent origins and to search carefully for their roots. Marr's Japhetic theory contradicted this activity. In 1951, there was a multiweek linguistic discussion in the central Communist Party newspaper *Pravda* in which Stalin personally took part. He argued against Marr's works, and both the Japhetic theory and the theory of stadial development were rejected.

It was now possible to criticize Marr. He was described as a bad linguist and really not an archaeologist at all-not even knowing that there was no metal in the Paleolithic period. Despite the lack of arguments, the theory of stadial development did bring some fresh ideas into the explanation of the most difficult problems of archaeology. It insisted that archaeologists begin to consider the sources of transformations in each society, i.e., to the importance of socioeconomic shifts for the transformation of culture, to leaps that are really inherent in every development. Later, such ideas began to be discussed seriously in many archaeological schools of the West, especially those interested in "the new archaeology."

Marxist Sociohistoricism

After the victory of the Bolsheviks in Russia, Marxist doctrine and its values were imposed on the entire scholarly world, and young archaeologists began to search for methodological ideas that could distinguish their activity from "bourgeois" archaeology. One of the first to be proposed, "the complex method" (Nikolskiy 1927) was a dim conglomerate of ideas, and it was understood variously as a demand to consider things as being associated in assemblages, which was not a new idea in Europe at all. It also argued for the involvement of many source-studying disciplines in complete historic reconstruction and for the organization of "complex," that is, multidisciplinary, expeditions.

In the middle of the 1920s, a group of young archaeologists in Moscow, disciples of Gorodcov, proceeded to engage in reeducation under the guidance of the Marxist sociologist Friche. They tried to superimpose Marxist concepts and principles onto archaeological material-to study the development of implements and to show how this development conditioned the whole appearance of economy and culture-and they tried to search for a connection between dwelling forms and the economy and

socioeconomic structure of society. For a Marxist

reconstruction of the past on the basis of material remains they invented “the method of ascending.” Supposing that Marxism gives absolutely reliable schemes for a one-to-one correlation of implement types with the socioeconomic structures of society, these archaeologists believed it possible to “ascend” in reconstruction from implements of labor as a fundamental aspect of social building to economic structures (in Marxism, the basis of society) and even further to social as well as ideational relations (in Marxism, superstructures). As this process of “ascending” came to be regarded as completely plausible, there appeared to be no need to address oneself to neighboring disciplines-such as ethnography and linguistics-or even to written sources. Archaeology itself appeared as history, a history that was more trustworthy than the written one, for material records were considered as more objective evidences of the past, free from subjective distortions and admixtures.

True, history supposes an interest in personalities and particular events that is mostly inaccessible to archaeologists. Yet in the Marxist view, another notion about history dominated in which “collectives” (societies, masses) and processes acted instead of personalities and personalities figured only as “products” and “markers” of social relations. This type of history could be “built” by archaeologists.

Later on, the theoretical basis of “the method of ascending” was not further developed by its creators (Arcikhovsky, Kiselev, Smirnov, and Bryusov), who became prominent and authoritative Soviet archaeologists. However, those same students and their pupils used the method in their work and considered the whole of archaeology as another history-a “history armed with the spade” (Arcikhovsky). That idea became the initial premise of this approach. Arcikhovsky became the head of the Department of Archaeology at Moscow University and the editor of the main archaeological journal, and his younger associate and disciple Rybakov acted for three decades in the post-Stalin era as the head of the leading archaeological institution of the country and all of Russian archaeology. Given the problematics of ethnogenesis, these students preferred local development (in Russia, this preference is called “autochthonism”), and in that respect they did not diverge from Marr's ideas. After those ideas had been discredited, they restored the argument of the old Russian autochthonists Zabelin and Samokvasov and combined it with Marxist discourses on the inner sources of the state origins in each society.

This trend corresponded more than the others to Soviet ideology and was skillfully adjusted to it. It appeared to be very tenacious. In the last decades of the Soviet regime, Vadim Masson in Leningrad advanced methodological elaborations in the spirit of sociological historicism (1976, 1990), and Vladimir F. Gening in Kiev put forward a detailed methodological substantiation of “sociological archaeology” as he understood it-quite in the spirit of the 1930s. Masson's recommendations do not go beyond searching for stereotyped correlations to social structures in archaeological materials, and the expansive works of Gening are distinguished by dogmatism and scholastics. Thus, one can say the trend has been exhausted. However, analogous interests have started to appear in the West (the “sociological archaeology” of Colin Renfrew among others), so it appears that Russian archaeologists initiated a worldwide movement.

Sequention of Cultures

The views and interests of Efimenko and Artamonov were formed in the Leningrad paleoethnological school. Efimenko first studied Slavic-Russian barrows and then the Paleolithic period before moving from Leningrad to Kiev to become the head of the Institute of Archaeology there. Artamonov dealt with many branches of prehistoric archaeology-from the Bronze Age to Scythian and Slavic-Russian antiquities-as well as heading the Leningrad University Department of Archaeology and serving as the director of the Hermitage. After World War II, when the dogmatic settings of the stadialist theory were first weakened and then dismissed entirely, Efimenko and Artamonov, their pupils, and the pupils of their pupils began to reconstruct migrations in any direction, including invasions into the territory of the country

of the researcher. This was not migrationism, for they

did not seek explanations for any novelties in the migrations. Simply, the fact was recognized that peoples moved in the past and the ethnic frontiers changed. Elsewhere, these searches have been called "submigrationist" (Klejn 1994).

The interests of these students were mainly in the problems of ethnogenesis. They opposed the autochthonism of the stadialists and the ultrapatriotic autochthonism of the state glorifiers; nor did they believe in the necessity of "archaeological right"-of the deep antiquity of habitation that was necessary to substantiate the right of a people to live where they did. Their reconstructed migrations, therefore, were a kind of challenge to the then-dominate doctrine-and to official politics.

However, their position did have some scholarly basis. In order to study culture-historical processes correctly, one needs first to establish the channel by which the development proceeded, and such a channel does not necessarily occur only in the cultures of one country. Cultural traditions are transferred, not through the earth, but through human contacts. From time to time, the human masses begin to move themselves, sometimes by jerks and sometimes for great distances.

Scientism

The scientific and technical revolution in archaeology did not occur in Russia until the post-Stalin period, later than in the West. Chemical, metallographic, and petrographic analyses, and the techniques of scientific dating, began to be used more intensively in archaeological research, and many archaeologists started to look to these methods for clues to the solutions to the main problems of archaeology. It was believed that it was possible to separate archaeological cultures and epochs by material attributes that could be more easily discovered with scientific methods and technological analyses and to search for evolution and hereditary continuity in this way.

However, the founder of the functionalist-traceological method (the investigation of implement traces with a binocular microscope) in the 1930s to 1950s, Semenov, proposed his method of typology (i.e., the determination of the function of an implement by its form) as the proper scientific method. Later on, the baton of this method passed to the archaeologists who utilized mathematical methods in the service of archaeology-especially statistics and combinatorial mathematics-Yakov Sher, Boris Marshak, Vera Kovalevskaya, the German Fedorov-Davydov, and Igor Kameneckiy. In the main, they developed methods that had already been developed in the West, but the first attempts of this kind emerged in Russian archaeology in the work of Efimenko and Gryaznov in the 1930s, even earlier than in the West.

Computers began to be used by Russian archaeologists much later than they began to be used in the West, but some decades earlier Russian archaeologists, observing computerization in the West and trying to keep up with it with the help of perforated cards, had grasped that computerization demands a theoretical restructuring of all of archaeology. More measuring, more exactness in descriptions, a strictness of determinations, and an elaboration of algorithms is needed. *Descriptive archaeology* became the phrase used by Kameneckiy, Marshak, and Sher and the Gening school in Kiev.

Relativist Subjectivism

After Marxism was discredited, and with it objectivist optimism in general, the dizzying successes of science and the superb perfectness of computer programs led archaeologists to believe that research implements were all important and that research results were completely dependent on those who possessed those implements. The crisis of positivist and postpositivist methodology pushed researchers to the opposite extreme-to the absolute freedom of the researcher's intelligence in the interpretation of sources and to an exaggeration of the role of the subjective factor in the reconstruction of the past. In addition, the recent cases of Soviet and Nazi scholarship have shown how dependent the inferences of

archaeologists and historians are on social conditions and the position of the scholar is on his subjective bias. By contrast, the Marxist type of sociological analysis, which became very influential in archaeology in the West ("the critical theory"), provided the basis of the

S

Salamis

Salamis, an Iron Age and classical site on the east coast of cyprus, has a long history of archaeological work. The Cesnola family worked on the site in the mid-nineteenth century, but fortunately they found too little to encourage further depredations on their part. Toward the end of the nineteenth century, M. Ohnefalsch-Richter and others excavated on behalf of various British institutions.

In the 1920s and 1930s, small-scale work was carried out by the Department of Antiquities, Cyprus. After World War II, work was resumed under the direction of vassos karageorghis, who excavated at Salamis between 1953 and 1974. During that time, the Department of Antiquities cleared and restored large areas of the classical city, including the gymnasium and the theater. French archaeologists, including J. Pouilloux and M. Yon, worked at several sites together with the Department of Antiquities between 1964 and 1974. Further work has been precluded by the Turkish occupation of northern Cyprus. In a nearby Iron Age necropolis, tumuli cover the built tombs of the eighth century, some of which have horse-and-chariot burials and luxury grave goods (such as a bronze cauldron and ivory furniture fittings).

Sankalia, Hasmukh D.

(1908-1989)

For many years Hasmukh D. Sankalia was a professor of archaeology at the Deccan College, Pune (Poona) in India, and he was also director of the college for some time before his retirement. Initially, he undertook surveys in Gujarat, his home state, and published, among other things, an analysis of the ancient historical geography of the region. Subsequently, he excavated Langhnaj, a Mesolithic to early-historical site in northern Gujarat.

At Deccan College, he initiated a well-coordinated field-based program of Ph.D. studies covering areas that included the modern states of Rajasthan, Gujarat, Nadhya Pradesh, Naharashtra, Andhra, Earnataka, Orissa, and Uttar Pradesh (the Son Valley and the Kumaun Hills). The emphasis was on area surveys and on prehistory and proto-history. He and his colleagues excavated major proto-historic sites from Rajasthan to Karnataka-Ahar, Navdatoli, Kayatha, Somnath, Nasik, Jorwe, Nevasa, Sanganakallu, Tekkalakota, Inamgaon, and others. In each case, the emphasis was on horizontal exposures, and the plethora of details on the proto-historic village life of the region is entirely owing to a range of excellently conducted and published excavation reports. In each case, there was also emphasis on the scientific analysis of materials, especially in the identification of animal, plant, and human remains.

Sankalia did not extensively excavate many historical sites except Brahmapuri in the southern part of Naharashtra. He was ever receptive to the changing ideas of archaeology and more keen than anybody else of his generation about the establishment of archaeology as an independent

Saqqara

Saqqara is one section of the great necropolis of Memphis, the capital of the Old Kingdom in Egypt. Most of the kings of the First and Second Dynasties were buried there. Though it is best known for the Step Pyramid built by Imhotep for King Djoser of the Third Dynasty, the site is also famous for mastaba tombs (low, rectangular, flat-roofed tombs with a shaft to the burial chamber), the Serapeum, and the numerous private tombs that date between the Old Kingdom and Greco-Roman times. Saqqara has been under virtually continuous excavation since the nineteenth century and is particularly associated with French archaeology in Egypt, especially the work of auguste mariette, who founded the Egyptian Antiquities Service and excavated the Serapeum. The Serapeum was a funeral complex where the mummified sacred Apis bulls were entombed. It was a place of pilgrimage.

the Austrian Archaeological Institute, honorary member of the Society of Antiquaries, and correspondent member of the Slovenian Academy of Arts and Sciences.

At first, Šašel's research focused on the archaeology of major Roman towns in slovenia (Ljubljana, Ptuj, and Celje), but later he was more interested in Roman epigraphy. His numerous works include studies in epigraphy (writing/inscriptions), prosopography, ancient history, Roman military history, the ancient economy, and the historical topography of northeastern italy and the Roman provinces in the Balkans (Pannonia, Noricum, Dalmatia, Moesia). Together with his wife, Ana Šašel, he published the supplement to the *Corpus inscriptionum Latinarum* in three volumes (1963, 1978, and 1986). In his onomastic studies, he analyzed the structure and distribution of some Roman family names, and together with colleague P. Petru, he initiated research on the late Roman limes on the northeastern border of Italy.

Šašel also contributed to the *Tabula Imperii Romani* (1976), *Pauli-Wissowa Real Encyklopadie der klassischen Altertums-Wissenschaft, Princeton Encyclopedia of Classical Sites* (1976), *Der drosse Plotz* (1980), and the archaeological map of Slovenia *(Arheoloska najdisca Slovenije),* in which he published a synthesis on Roman roads. He was also the editor of numerous Slovenian and Yugoslav archaeological journals and publications.

Schele, Linda

(1942-1998)

One of the greatest Mayanist scholars of the late twentieth century, Linda Schele began her academic career as a studio art teacher. A tourist trip to Yucatán with her husband, David, changed her life. She was fascinated by the amazing ruins that she saw and the beauty of Maya art, and she resolved to learn more about them.

In the early 1970s Schele began to study Mayan hieroglyphic writing. By this time the basic structure and some of the content of Maya inscriptions were understood, but more precise details were still unclear. Over the following quarter century that situation was to change, and Schele was at the forefront of efforts aimed at “breaking the Maya code,” as one scholar has put it.

In 1973 Schele attended the first round table conference at palenque in mexico. At this, her initial professional conference, she and colleague Peter Mathews presented a proposed king-list (chronology of rulers deciphered from Maya inscriptions) of Palenque. Over the following fifteen years she worked not only on the inscriptions of Palenque but also on those of other classic Maya sites. In the studies she conducted during these years, she was indefatigable in her attempts to evaluate the archaeological sequence in conjunction with the epigraphic history of individual sites-an approach that has paid huge dividends. At Copán, Honduras, she worked with a number of other epigraphers and archaeologists conducting excavations in and around that site, and the result was a detailed synthesis of the archaeology, architectural sequence, and history of Copán, which is now one of the best understood of

all classic Maya centers.

By the early 1980s Schele was a recognized leader in the field of Maya studies. She and a colleague from Yale University, Mary Miller, were asked to prepare a major exhibition of Maya art and to write the descriptive catalog to accompany it. The exhibition, called “The Blood of Kings,” was a tour de force. For the first time masterpieces of Maya art from collections in both Europe and North America were exhibited together. The accompanying catalog was much more than a series of descriptive paragraphs about individual objects, preceded by a brief introduction: in addition to describing the exhibition pieces in detail, the book also contained essays by Schele and Miller on several great themes in Maya art, ranging from kingship to warfare to bloodletting. These essays were major statements on various aspects of elite life among the classic Maya, and *The Blood of Kings*

the Austrian Archaeological Institute, honorary member of the Society of Antiquaries, and correspondent member of the Slovenian Academy of Arts and Sciences.

At first, Šašel's research focused on the archaeology of major Roman towns in slovenia (Ljubljana, Ptuj, and Celje), but later he was more interested in Roman epigraphy. His numerous works include studies in epigraphy (writing/inscriptions), prosopography, ancient history, Roman military history, the ancient economy, and the historical topography of northeastern italy and the Roman provinces in the Balkans (Pannonia, Noricum, Dalmatia, Moesia). Together with his wife, Ana Šašel, he published the supplement to the *Corpus inscriptionum Latinarum* in three volumes (1963, 1978, and 1986). In his onomastic studies, he analyzed the structure and distribution of some Roman family names, and together with colleague P. Petru, he initiated research on the late Roman limes on the northeastern border of Italy.

Šašel also contributed to the *Tabula Imperii Romani* (1976), *Pauli-Wissowa Real Encyklopadie der klassischen Altertums-Wissenschaft, Princeton Encyclopedia of Classical Sites* (1976), *Der drosse Plotz* (1980), and the archaeological map of Slovenia *(Arheoloska najdisca Slovenije),* in which he published a synthesis on Roman roads. He was also the editor of numerous Slovenian and Yugoslav archaeological journals and publications.

Schele, Linda

(1942-1998)

One of the greatest Mayanist scholars of the late twentieth century, Linda Schele began her academic career as a studio art teacher. A tourist trip to Yucatán with her husband, David, changed her life. She was fascinated by the amazing ruins that she saw and the beauty of Maya art, and she resolved to learn more about them.

In the early 1970s Schele began to study Mayan hieroglyphic writing. By this time the basic structure and some of the content of Maya inscriptions were understood, but more precise details were still unclear. Over the following quarter century that situation was to change, and Schele was at the forefront of efforts aimed at “breaking the Maya code,” as one scholar has put it.

In 1973 Schele attended the first round table conference at palenque in mexico. At this, her initial professional conference, she and colleague Peter Mathews presented a proposed king-list (chronology of rulers deciphered from Maya inscriptions) of Palenque. Over the following fifteen years she worked not only on the inscriptions of Palenque but also on those of other classic Maya sites. In the studies she conducted during these years, she was indefatigable in her attempts to evaluate the archaeological sequence in conjunction with the epigraphic history of individual sites-an approach that has paid huge dividends. At Copán, Honduras, she worked with a number of other epigraphers and archaeologists conducting excavations in and around that site, and the result was a detailed synthesis of the archaeology, architectural sequence, and history of Copán, which is now one of the best understood of

all classic Maya centers.

By the early 1980s Schele was a recognized leader in the field of Maya studies. She and a colleague from Yale University, Mary Miller, were asked to prepare a major exhibition of Maya art and to write the descriptive catalog to accompany it. The exhibition, called “The Blood of Kings,” was a tour de force. For the first time masterpieces of Maya art from collections in both Europe and North America were exhibited together. The accompanying catalog was much more than a series of descriptive paragraphs about individual objects, preceded by a brief introduction: in addition to describing the exhibition pieces in detail, the book also contained essays by Schele and Miller on several great themes in Maya art, ranging from kingship to warfare to bloodletting. These essays were major statements on various aspects of elite life among the classic Maya, and *The Blood of Kings*

represented an important step in Maya studies, in which art, hieroglyphs, and archaeology were brought together to arrive at an exciting new interpretation of classic Maya society.

Schele's next book, written with David Freidel, continued in this same vein. Entitled *A Forest of Kings*, it was an ambitious look at Maya history, combining the archaeological sequence with history gleaned from the glyphs. It did so in such a detailed way that the classic Maya elites almost leaped off the page: for the first time the "mysterious" Maya were becoming more accessible to twentieth-century readers.

Schele was a great popularizer of the ancient Maya. One of her lasting contributions to the field of Maya studies was the development of public workshops on how to read Maya hieroglyphs. Over the years she presented many such workshops, most notably the "Texas Workshops" held in Austin, where she was based. The audience regularly included many of the major scholars in the field of Maya studies, as well as several hundred members of the general public, all of whom were as captivated by Schele's infectious enthusiasm as they were by new discoveries about the ancient Maya. With another colleague, Nikolai Grube, Schele also conducted workshops for the Maya themselves in guatemala and mexico. This was her proudest achievement: as she put it, she was giving back to the Maya people their own history, which had been taken from them in the years and centuries following the Spanish conquest.

In all her work Schele displayed rare analytic and synthetic skills in making groundbreaking discoveries herself and leading her field to still others. She was not afraid to try new approaches, and with her brilliant insights her efforts were more often than not rewarded. By fostering the same attitudes among her many students, she ensured that her intellectual heritage would survive her untimely death from cancer in 1998.

Schliemann, Heinrich

(1822-1890)

Heinrich Schliemann was born in northern Germany and became a sailor, shopkeeper, and merchant; he taught himself fluent French, Dutch, Greek, Russian, and English. A short visit to California in the gold rush days and a longer period trading in russia consolidated his personal fortune, and he began to travel extensively and to write about his experiences. He also became interested in history and archaeology, learned Latin and Greek, and was inspired by the successful careers and the great fame of famous archaeologists sir austen h. layard, sir henry rawlinson, and auguste mariette.

Heinrich Schliemann

(Ann Ronan Picture Library)

In 1866, Schliemann began to study at the Sorbonne in Paris and became interested in the debates about the veracity of Homer's legends. In 1868, he visited the places in greece and turkey mentioned by Homer, taking the same route as Odysseus to Turkey, and published a popular account of his travels. In 1869, he divorced his Russian wife and married a young Greek woman who was as passionate about Homer as he was and well connected within Athenian society.

In 1870 Schliemann began to excavate at Hissarlik,

enormous. First and foremost, he discovered the Trojan and Mycenaean civilizations at Ilios, Mycenae, Orchomenos, and Tiryns. Scholars had doubted their existence, and the unearthing of that world was one of the great moments of archaeology, and because of it, Homer's epic poetry and mythology became sources of historical information. Schliemann enriched Greek history by bringing 2,000 years into the historic record, and his findings linked classical, oriental, and prehistoric archaeology in a new way. Finally, Schliemann brought public attention to archaeology and raised the profile of the discipline through his discoveries, his publications, and his extraordinary success.

Schmerling, Philippe Charles

(1790-1836)

Born in Delft in the netherlands, Philippe Charles Schmerling served as a medical officer in the Dutch army from 1813 to 1816. In 1825, he completed a degree in medicine at the University of Liège, but during his four years of study Schmerling became interested in paleontology and geology after being given presents of fossils collected by workers in a nearby quarry. Beginning in 1829, he systematically explored over forty caves in and around the Liège region of belgium and became professor of geology at the University of Liège in 1835.

Schmerling's published finds (especially in his *Recherches sur les ossemens fossiles* [1833- 1834]) included more than sixty extinct fossil animal species, but it is for his discoveries of human remains that he has gained lasting fame. Schmerling excavated at the caves of Engis and Engihoul, Chokier and Fond-de-Foret, and under a layer of brecchia he found human remains in association with the bones of extinct fossil animals and with what he described as stone and bone tools. He also found an infant skull that, in 1935, was proved to be that of a Neanderthal child. Although Schmerling's work attracted the cautious interest of the English geologist sir charles lyell, the latter was unable to accept the possibility of high human antiquity until hugh falconer and others had conclusively demonstrated the case at brixham cave and had argued for the validity of French archaeologist jacques boucher de perthes's discoveries in the gravels of the Somme Valley in 1859.

Shanidar

Shanidar is a major cave site in the foothills of the Zagros Mountains, in northeastern Iraq, excavated by Ralph Solecki from 1957 to 1961. The site is considered to be particularly significant due to the excavation of the remains of

nine Neanderthal adults and children, but there is a strong sequence exemplifying technological evolution from the Mousterian (between 60,000 and 40,000 years ago) through to Upper Paleolithic industries dating to about 25,000 years ago. Most attention has been focused on the Neanderthal skeletons, one of which shows evidence of a disabling disease from which the individual must have suffered for a considerable time before death. The prolonged care this individual received has been taken as evidence of the social bonds existing among Neanderthals. Some researchers have also claimed that flowers were placed in one of the burials-an indication, according to some interpretations, of sentiment among these people. Although the claim has been disputed, novelists have nonetheless readily incorporated this notion in their imaginative reconstructions of everyday life among the Neanderthals.

Sharma, Govardhan Rai

(1919-1986)

Govardhan Rai Sharma was one of the most effective university teachers of archaeology in postindependence India. He built up a strong tradition of field research in the Department of Ancient History and Archaeology at Allahabad University, where he served throughout his working life. His early years were spent excavating the historic city site of Kausambi, in northern India, on which he published two major excavation reports (Sharma 1960, 1969).

However, his work in the fields of prehistory and proto-history in the neighboring Vindhyan Hills brought him more prominence in Indian archaeology. The easternmost section of the Vindhyas touches the Gangetic Plain near Allahabad, and although the prehistoric potential of the region had been known since the nineteenth century, it was Sharma who rigorously built up a section profile from the Acheulean to the Mesolithic Periods and excavated a number of what he called “advanced Mesolithic” sites both there and in the Pratapgarh area of the adjacent plain. At the site of Koldihawa in the same area, he found evidence of cultivated rice in the context of sixth-fifth millennia b.c. (Sharma et al. 1980). Between Varanasi and Allahabad, especially in the Mirzapur section of that stretch, he found a large number of Megalithic burials and painted rock shelters in association with microliths. Finally, in collaboration with j. desmond clark of Berkeley, Sharma extended his prehistoric sequence up to the Son Valley in Madhya Pradesh (Sharma and Clark 1983).

Sharma had a strong personality, which did not make him popular with his colleagues (some of whom disputed his claims after his death), but the field team he built up in Allahabad is unquestionably among the best in India.

Shaw, Charles Thurstan

(1914-)

One of the pioneers of West African archaeology, Charles Thurstan Shaw, or Thurstan Shaw as he has always preferred to be known, was born on 27 June 1914 in Plymouth, England. Shaw was educated at Blundell's School in Tiverton, England, and Sydney Sussex College, Cambridge, where his main archaeological teachers were Miles Burkitt and grahame clark. In 1937, Shaw joined the staff of Achimota College in the Gold Coast (now Ghana), then one of the nearest things to a university in sub-Saharan Africa. There, in addition to his teaching duties, he was in charge of the Anthropology Museum at the college and found time to conduct archaeological

research in the south of the country, the most notable being his excavations at Bosumpra rock shelter and at a midden mound at Dawu. Shaw left the Gold Coast in 1945, but his work subsequently led, during the 1950s, to both the creation of the Ghana National Museum and the establishment of a Department of Archaeology in the University of Ghana, which grew out of Achimota College.

From 1945 to 1963, Shaw held educational posts at Cambridge University and continued to publish on African archaeology. In 1959-1960, he was invited by the Nigerian Federal Department of Antiquities to excavate at Igbo-Ukwu in eastern Nigeria, and there he uncovered important evidence for the emergence of social complexity, the development of sophisticated metallurgical skills, and the growth of long-distance trade by the late first millennium a.d. This work, together with his previous publications, led to his being appointed in 1963 to a research professorship in archaeology at the University of Ibadan in Nigeria, which he held until his retirement in 1974.

During his time at Ibadan he did further work at Igbo-Ukwu as well as excavating a rock shelter at Iwo Eleru in the Nigerian rain forest. From the latter site he recovered evidence of late-Stone Age occupation from about 10,000 b.c. to about 1500 b.c., including a human skeleton from the earliest deposits that was proto-negroid in character and the earliest such evidence in West Africa. At Ibadan, he built up a successful research team that supported not only his own work but also that of fellow archaeologists Graham Connah, Steve Daniels, and Adebisi Sowunmi. Shaw not only researched and published widely but founded and edited the *West African Archaeological Newsletter* and the *West African Journal of Archaeology,* which subsequently replaced it. His most important contribution to the future of African archaeology, however, was his creation in 1970 of a teaching Department of Archaeology in the University of Ibadan that could train some of the future generation of African archaeologists.

Following retirement, Shaw did further excavation in the Kaduna Valley of northern Nigeria and also continued to publish extensively. He lives quietly near Cambridge, England, having donated his library and papers to the Institute of Archaeology in the University of London.

There can be no doubt that Shaw's contribution to West African archaeology, and indeed to African archaeology as a whole, was an important one. His career straddled the change from colonial to independent rule in black Africa, and his vision and hard work, in his search for West Africa's past, contributed significantly to Africa's rediscovery of itself.

Shell Midden Analysis

After stone artifact scatters, archaeological deposits dominated by shell are the most commonly encountered evidence of the past, yet the infrequency of published accounts of midden analyses in the current archaeological literature suggests that archaeological deposits of shell contribute little to our understanding of human history. In this brief history of midden analyses, I locate the source of this contradiction in shifting explanatory paradigms in archaeology in general.

A shell midden is any archaeological site with a visible quantity of mollusks, which indicates the human consumption of shellfish. Shell is durable, and the preservation of shell middens is high when compared

to other faunal material. That fact, combined with the generally large number of shells in a midden site, makes them highly visible in the landscape and easily recognized. Shell deposits also provide a matrix in which other kinds of cultural material, both artifacts and bone, are preserved. In this article, the focus is on shell middens that come under the rubric of “hunter-gatherer sites,” that is, sites that reflect behavior associated with nonagricultural peoples for whom marine resources probably constituted a seasonal or year-round food source.

The modern analysis of midden sites owes much to the earliest systematic midden excavation

Silcott, Washington

Located on the lower Snake River, eight miles downstream from Lewiston, Idaho, Silcott was a bustling little farming and ranching hamlet in the early twentieth century. White settlement began in 1861, and in 1888, Alpowa City was platted, but it eventually became known as Silcott. By 1930, the town was extinct, largely because of automobiles and better roads, which allowed people to travel and shop in nearby towns.

In 1972, three field seasons were conducted in Alpowa under the direction of Frank C. Leonhardy of Washington State University. David R. Brauner directed the excavation of Alpowa's prehistoric and historic Nez Percé sites, and Timothy B. Riordan investigated the migrant-worker sites. William H. Adams directed the excavations of Silcott, including Bill Wilson's General Store, Cliff Wilson's General Store, Trapper Wilson's House, the Ireland Place, the Ferry Tender's House, and the Weiss Ranch Dumps. These sites dated from 1890 to 1930, and their excavation marks the first time that archaeologists intentionally excavated twentieth-century sites.

The project used a multifaceted ethnoarchaeological approach involving in-depth informant interviews, documentary research, and excavations combined synergistically into an historical ethnography of the community. Using oral history to cross-verify documentary and archaeological data was innovative and provided a model for future work. The study pioneered the use of a broader context-the community-instead of focusing on individual sites. The study also represented a shift in historical archaeology away from sites associated with famous people and events and toward a broader understanding of American culture.

Sipán

Sipán is a moche site in northern peru, near the coastal city of Chiclayo (Lambayeque).It consists of a lavish tomb complex that was discovered in 1987 by looters. Four tombs have been explored, and in 1988 Peruvian archaeologist Walter Alva excavated the tomb of the “Lord of Sipán,” which was so extraordinarily rich that it is now popularly known as the tomb of “the King tutankhamun of the Americas.” Without doubt, the scale of the offerings, which include masks, necklaces, earrings, and

other elaborate jewelry, make this the most spectacular tomb discovered in Peru and excavated by archaeologists. The tomb was built by the Moche, who ruled the northern coast of Peru between the first and sixth centuries a.d. These people are justly famous for their pottery, and the tomb of the lord of Sipán clearly demonstrates the quality of Moche metalwork in gold, copper, and silver.

Silcott, Washington

Located on the lower Snake River, eight miles downstream from Lewiston, Idaho, Silcott was a bustling little farming and ranching hamlet in the early twentieth century. White settlement began in 1861, and in 1888, Alpowa City was platted, but it eventually became known as Silcott. By 1930, the town was extinct, largely because of automobiles and better roads, which allowed people to travel and shop in nearby towns.

In 1972, three field seasons were conducted in Alpowa under the direction of Frank C. Leonhardy of Washington State University. David R. Brauner directed the excavation of Alpowa's prehistoric and historic Nez Percé sites, and Timothy B. Riordan investigated the migrant-worker sites. William H. Adams directed the excavations of Silcott, including Bill Wilson's General Store, Cliff Wilson's General Store, Trapper Wilson's House, the Ireland Place, the Ferry Tender's House, and the Weiss Ranch Dumps. These sites dated from 1890 to 1930, and their excavation marks the first time that archaeologists intentionally excavated twentieth-century sites.

The project used a multifaceted ethnoarchaeological approach involving in-depth informant interviews, documentary research, and excavations combined synergistically into an historical ethnography of the community. Using oral history to cross-verify documentary and archaeological data was innovative and provided a model for future work. The study pioneered the use of a broader context-the community-instead of focusing on individual sites. The study also represented a shift in historical archaeology away from sites associated with famous people and events and toward a broader understanding of American culture.

Situla Art in Slovenia

Situla art is an artistic style peculiar to the Veneti and Illyrians between the seventh and fourth centuries b.c. It is named after the figural ornamented vessels (Latin *situlae*), the most common and popular objects of this art.

The main centers of situla art production were in the region of the middle and lower Po

Valley (Este and Bologna), in the alpine foothills and Alto Adige, and in central slovenia. In addition to *situlae,* objects such as helmets, belt plates, vessel lids, and shields were also decorated in the same style. Situla art represents the most refined and elaborate art pieces of the eastern early Iron Age Hallstatt cultures. All known objects of situla art have been found in rich male graves (often princely graves), and are considered among the most precious grave goods, which demonstrates the high status of the dead. All objects are normally made of hammered sheet bronze and decorated in the repoussé technique. The design was initially drawn on the interior and then hammered with punches. Some details were later also engraved. *Situlae* and other more-complex objects were bent and riveted together.

The first component (geometrization) in situla art is primarily rooted in the art and craftsmanship of the native Urnfield tradition. The second component (the orientalizing Etruscan, Greek, and Levantine elements) can be found in iconography and many other decorative elements foreign to the Hallstatt cultures (sphinxes, palmettos, lions, etc.).

The development of situla art in Slovenia can be divided into three main phases. In the earliest phase (seventh-sixth century b.c.) only a few objects (helmets, vessel lids) and almost none of the *situlae* were decorated, and the motifs were usually simple (isolated figures, animals, and floral ornaments). The classical phase of situla art belongs to the fifth century b.c., and the most frequent objects are the *situlae* with very developed and complex composition and iconography. Classic examples have normally tripartite zonal division of the scenes, and the motifs are not isolated figures any more but represent the feasts of the Hallstatt aristocracy-horse riding, symposia, boxing for a trophy, drinking precious potions, dancing, etc. The decline of situla art occurred in the fourth century b.c. Feasting and collective scenes and figural representations of men gradually disappeared, and the most frequent motifs were once again animals and floral ornaments.

The sites with the richest examples of situla art in Slovenia are the barrow cemeteries of the princely hill forts: stična, Vace, magdalenska gora, novo mesto, etc. The most classical and famous object from Slovenia is a bronze bucket from Vace, which is 23.8 centimeters high and dates to the sixth century b.c.

Skara Brae

Skara Brae is one of the most notable Neolithic village sites in the British Isles. Located in a sand dune on one of the Orkney Islands off the north coast of Scotland, the site was inhabited between 3200 b.c. and 2200 b.c. and comprises eight houses with stone “furniture” of beds and storage areas. The houses are connected by covered passageways. Archaeological evidence testifies to the inhabitants keeping sheep and cattle, fishing and growing cereal crops. The site was exposed during a violent storm in 1850 and was excavated by vere gordon childe between 1928 and 1930.

Škocjan

Škocjan is a series of prehistoric sites in a complex of caves near the village of Škocjan in southwestern slovenia. The majority of the sites were excavated by Carlo Marchesetti (1850-1926) of the Trieste Museum at the end of nineteenth century and the beginning of the twentieth. In the same period, J. Szombathy of the Naturhistorisches Museum in Vienna excavated the cave sites Musja Jama (other names Fliegehohle, Grotta delle Mosche) and Skeletna Jama (Knochenhohle, Grotta degli Scheletri), and some caves and the Škocjan hill fort itself

were excavated by R. Battaglia, also of the Trieste Museum, after World War I. Test excavations were carried out in the caves of Roska Spilja and Tominceva Jama by srecko brodar and F. Leben after World War II.

Archaeological evidence from the late Upper Paleolithic to the Bronze Age was documented in the cave sites of Roska Spilja, Tominceva Jama, and Pecina v Sapendolu. The most important late prehistoric settlement is the hill fort of Škocjan, occupied from the late Bronze Age to the Roman period. There are four recorded cemeteries from this period, the largest (containing some 325 graves) being the flat cremation cemetery at Brezec dated to the late Bronze Age (twelfth-eighth centuries b.c.) Some very rich burials from the tenth-eighth centuries b.c., comprising sword graves, the earliest presence of iron from the tenth century, have been discovered in this cemetery.

The large ritual hoard found at the bottom of the vertical cave Musja Jama belongs to the late Bronze Age. Among other things, the hoard contained 244 bronze and 10 iron spearheads, 1iron and 19 bronze swords, and many fragments of bronze helmets and vessels. The objects and ritual offerings were mostly fragmented and destroyed by fire. According to typological analysis, this ritual center functioned between the twelfth and eighth centuries b.c. Analogies for the metal finds can be found in the Pannonian Plain in central italy and on the Balkan peninsula.

The hoard and the Brezec cemetery are evidence of a well-stratified society intensively incorporated in long-distance exchange systems at the time of transition from the late Bronze Age to the early Iron Age. Iron Age graves found in three smaller cemeteries demonstrate a certain decline in comparison with the previous period, but two major exceptions should be mentioned: another ritual hoard (Tesoretto di San Canciano), found in the Škocjan hill fort, and a rich burial with a situla with an inscription in the Venetic language found in Skeletna Jama. Both examples are dated in the fifth century b.c.

Slovenia

The term *Slovenian archaeology* in the sense of a national institutional framework can only be fully applied for the period after 1918. In that year parts of the former Austrian provinces of Carniola, Styria, and Carinthia and the region of Prekmurje were united and joined the newly established Kingdom of Serbs, Croats, and Slovenes (renamed the Kingdom of Yugoslavia in 1929). Prior to that period, archaeology in Slovenian lands (i.e., Austrian provinces) was part of the Austrian institutional framework organized on the provincial level and governed by central institutions and scholarly societies in Vienna.

Antiquarian Background

The beginnings of studies on ancient history and antiquities in Slovenian lands can be traced to the

fifteenth and sixteenth centuries a.d. The first such attempts developed in the coastal towns of northern Istria (Koper/Capodistria, Izola/Isola, and Piran/Pirano-Slovenian/Italian names respectively), which were under Venetian rule and predominantly settled by a population that spoke a Romance language. The first known text on local ancient history is *De situ urbis Iustinopolitanae* [About Ancient Aegida/Koper] by Pier Paolo Vergerio the Elder (1370-1444). Another important early work is a topographic essay entitled *Del sito de Listria* (*The Ships of Listria*), published in Venice 1540 and written by the famous cartographer and geographer Pietro Coppo (1469/ 1470-1555/1556).

The establishment of the bishop's court in Ljubljana in the late fifteenth century gave a strong boost to the development of the Austrian province of Carniola (the central Slovene province) and to Ljubljana, the provincial capital. The central figure in this regard was August Prygl (also known as Tyffernus) (1470-1535), a

were excavated by R. Battaglia, also of the Trieste Museum, after World War I. Test excavations were carried out in the caves of Roska Spilja and Tominceva Jama by srecko brodar and F. Leben after World War II.

The establishment of the bishop's court in Ljubljana in the late fifteenth century gave a strong boost to the development of the Austrian province of Carniola (the central Slovene province) and to Ljubljana, the provincial capital. The central figure in this regard was August Prygl (also known as Tyffernus) (1470-1535), a

sciences and arts in Carniola. The idea for the excavations came from Ettiene Marie Siauve (?-1813), a French archaeologist who was a member of the Académie Celtique as well as the French military commissioner in the Illyrian Provinces. Vodnik recorded these activities in his *Itineraria* (1809). Siauve himself published a book on the ancient history and antiquities of the Slovene lands, entitled *De Antiquis Norici viis, urbibus et finibus epistola* (Verona 1811).

Beginnings of the Scientific Discipline of Archaeology

A decisive step forward was the establishment of the museums and heritage protection service in the Austrian Empire in the first half of the nineteenth century. Provincial museums, which covered the territory of Slovenia, were located in Graz in 1811 around Styria, in Ljubljana in 1821 around Carniola, and in Klagenfurt in 1844 around Carinthia. Local museums were established later in Celje (1893), Ptuj (1893), Maribor (1909), and Koper (1911). The Littoral Province was left without a provincial museum, but the role was filled by the Trieste municipal museum (1875).

The Provincial Museum at Ljubljana played a decisive role in the development of the archaeological discipline in Slovenia. Although the museum was established in 1821, its archaeological activities did not start until the mid-1870s with the excavations of the prehistoric pile-dwellings in the ljubljansko barje (Iron Age sites in Carniola). Challenged by the discoveries of pile-dwellings on Swiss lakes and encouraged by the Anthropological Society from Vienna, dragotin dezman (1821-1889), the curator of the museum, directed the first large excavation in the history of Slovene archaeology, from 1875 to 1877.

Dezman's close collaboration with the Anthropological and Prehistoric Societies in Vienna proved to be decisive for further developments of this discipline in Slovenia, and in less than fifteen years (from 1875 to 1889) he succeeded in providing a firm basis for its disciplinary framework. Dezman, being a zoologist, botanist, and geologist, developed an anthropological and evolutionary concept of prehistoric archaeology; contrary to the long tradition of antiquarian and historical research in Slovenia. In this short period he excavated a series of sites (Ljubljansko Barje) and published the first synthesis on the prehistory of Carniola ("Prähistorische Ansiedlungen und Begrabnisstätten," in Krain I. Bericht, *Denkschriften der k.k. Akademie der Wissenschaften, Matematisch-naturwissenschaftliche Classe* 42, 1-54 [Vienna 1880]; "Zur Vorgeschichte Krains," in *Die österreichisch-ungarisch Monarchie in Wort und Bild, Kärnten und Krain,* 305-324 [Vienna 1891]). He tried to apply the most recent developments and standards in prehistoric science in his work. For example, he defined the la tène period in Slovenia only a few years after O. Tischler had proposed the division of the Iron Age. His research results were highly esteemed by his colleagues in austria. The Austrian Anthropological Society was very interested in his work and held its annual meeting in Ljubljana in 1879. At the end of his career Dezman succeeded in lobbying for a new museum palace (opened in 1888), whose archaeological collections and museum guide (*Führer durch das Krainische Landes-Museum Rudolfinum in Laibach* [Ljubljana 1888]) became the pride of the scientific community in Carniola.

Alfons Müllner (1840-1918) succeeded Dezman in the museum in 1889. Müllner had already published some important archaeological and historical works in the period prior to his transfer to the museum. These included *Archaologische Excurse durch Steiermark und Krain* (1878, 1880), the first topographic work in Slovenian archaeology, and a monograph on the Roman site of emona (1879). Despite the fact that he was also a naturalist, Müllner applied a different concept of archaeology in the museum-that of typological and chronological principles of artifact analysis-and he rearranged prehistoric collections accordingly. He published *Typische formen aus der Sammmlungen des krainischen Landesmuseums "Rudolphinum" in Laibach* (1900), a catalog of key forms of artifacts for prehistoric Carniola. However, in rearranging the collections, Müllner did not keep records on contexts, and a great deal of contextual data was irreparably lost.

Walter Schmid (1875-1951), who studied in

in 1830, and the museum was established there in 1893. Large excavations of the Roman cemeteries in the area took place in the first decade of the twentieth century.

In Search of a National Framework of Archaeology (1918-1945)

In 1918, after the collapse of the Austrian Empire, the regions of Upper and Inner Carniola, Lower Styria, southern Carinthia, and Prekmurje were united in Slovenia in the Kingdom of Serbs, Croats, and Slovenes. The Littoral, Istria, and the western parts of Carniola were annexed by italy, and central and northern Carinthia remained in Austria. Such a radical change left archaeology in Slovenia almost without any institutional framework; of the provincial museums, only the one in Ljubljana lay in the territory of Slovenia. A new framework had to be constituted almost from scratch, but in the newly formed state, with different traditions and priorities, this was not an easy task.

Nevertheless, the new state provided a political context for some decisive steps toward the national emancipation of the Slovenes. For the first time national institutions were established, and among those important for archaeology were the University of Ljubljana (1919), the national museum of slovenia (1921, formerly the Provincial Museum of Carniola), and the Slovene Academy of Arts and Sciences (1938).

Generally, the period from 1918 to 1945 was marked by a decline in archaeological research as compared to the "Austrian" period, and the National Museum was left without a professional archaeologist for the first ten years. The only notable exception in this regard during these years was Mihovil Abramić (1884-1962), the former director of the Archaeological Museum of Aquilea (from 1913 to 1919) who researched Poetovio in the 1920s and published the results in *Poetovio: Führer durch die Denkmäler der römischen Stadt* (Vienna 1925).

Archaeology was introduced into the university curriculum in 1924, and Vojeslav Mole (1886-1973) was appointed the professor of classical archaeology in Ljubljana. However, his role in archaeology was minor, and two years after his appointment he moved to Krakow University in poland.

The contributions of Balduin Saria (1893- 1974), a historian and epigrapher, the curator of the National Museum of Belgrade, and a professor at Belgrade University (1922-1926), were much more important. From 1926 to 1942 Saria was a professor of ancient history at Ljubljana University, and he published major works on Roman epigraphy and Roman military history: *Antike Inschriften aus Jugoslawien, Noricum und Pannonia Superior* (Zagreb 1938), and "Doneski k vojaški zgodovini naših krajev v rimski dobi" [Contributions to the Military History of Slovenia in the Roman period], *Glasnik Muzejskega društva za Slovenijo* 20, 115-151 (Ljubljana 1939). He was also very active in the organization of the Archaeological Map of Yugoslavia project, for which he designed criteria and standards. In 1936 he published a model map for the region of Ptuj (*Archäologische Karte von Jugoslawien: Blatt Ptuj* [Belgrade-Zagreb 1936]) and, together with josip klemenc, the map for the region of Rogatec (*Blatt Rogatec* [Belgrade-Zagreb 1938]).

In 1929 rajko lozar (1904-1985)) became the first archaeologist employed in the National Museum, twenty years after Schmid. Since he was the only professional archaeologist in Slovenia, he had to cover a vast array of activities, and it was only from the late 1930s that he succeeded in publishing some important works. Lozar, who was also an art historian, was the first to try to provide a conceptual framework for the history of archaeology as a national science in Slovenia, including the earlier (provincial) traditions within it, with an essay on history and conceptual issues in Slovene archaeology ("Razvoj in problemi slovenske arheološke vede," *Zbornik za Umetnostno Zgodovino* 17: 107-148 [1941]). His study on Slavic and medieval pottery production (*Staroslovansko in srednjeveško lo*

nčarstvo v Sloveniji, Glasnik Muzejskega društva za Slovenijo 20: 180-225 [1938]), also attempted to push forward this branch of archaeological research, which he considered the primary task of archaeology in Slovenia.

Although somewhat apart from major developments in central institutions in Ljubljana,

srecko brodar (1893-1987), a naturalist and schoolteacher in Celje, was able to lay foundations for Paleolithic archaeology. In 1928 he excavated the potočka zijalka Cave, and the results proved to be crucial for the interpretation of the glaciation in the Alps (see J. Bayer and S. Brodar, "Die Potočka Höhle, eine Hochstation der Aurignacschwankung in die Ostalpen," in *Prähistorica*, vol. 1 [Vienna 1928]). In the 1930s he extended his research to other sites in Slovenia and Yugoslavia (see S. Brodar, "Das Paläo lithikum in Jugoslawien (The Palaeolithic in Yugoslavia)," *Quartar* 1: 140-172[1938]).

Reconstruction of Archaeology and Definite Establishment of the National Disciplinary Framework (1945-)

Political and Social Conditions and New Beginnings

After 1945, when the king's rule in Yugoslavia was abolished, the Yugoslav Communist Party took over the government and started the process of "rebuilding the society" on a new, Marxist-Leninist basis. Another important political change was the annexation of the Littoral and Istria back from Italy to the Yugoslav Republics of Slovenia and Croatia.

These political and ideological changes had important consequences for archaeology. Lozar was a political opponent of the Communist-controlled Liberation Front during World War II, and he left the country in 1945. Mole, who had returned from Poland in 1942 and accepted a professorship at the Italian-controlled University of Ljubljana, also left in 1945. And Saria, an ethnic German who has been openly sympathetic to the German greater national cause, went to Graz, in Austria, immediately after the Italian occupation of Ljubljana in 1941. There were also experiences entailing Italian and German abuses of archaeology in Slovenia in the prewar and war years. The Italian annexation of the Littoral and Istria (from 1918 to 1943) and subsequent occupation of western Slovenia (from 1941 to 1943) were "justified" with claims about the allegedly historical borders of Roman Italy, and many individuals in Italian institutional archaeology in these regions were involved in providing "scientific" evidence for such claims. And during World War II Germans conducted several excavations in northern Slovenia in order to prove the existence of early medieval Germans south of the Alps and to provide a supposedly scientific basis for Adolf Hitler's project of ethnic cleansing and the annexation of Styria to the Third Reich.

The almost complete absence of professional archaeologists and the lack of an infrastructural framework demanded an urgent and complete reform of archaeological science in Slovenia. The leading scholars from the Faculty of Arts at the University of Ljubljana and from the Slovene Academy of Arts and Sciences played a prominent role in renewing the institutional framework. Two new institutions were established-the Department of Archaeology in the Faculty of Arts at the University of Ljubljana, begun in 1946, and the Archaeological Commission of the Slovene Academy of Arts and Sciences, which was founded in 1947 and later known as the Institute of Archaeology. The first two professors of archaeology were appointed in 1946 and 1947: Klemenc for classical and Roman archaeology and Korošec for prehistoric and Slavic archaeology. paleolithic archaeology also entered the curriculum with the 1946 appointment of Brodar as professor for Quaternary studies in the Faculty of Mathematics and Natural History, all at the University of Ljubljana. Klemenc and josip korošec were also among the founders of the Archaeological Commission, together with Milko Kos, a historian and chancellor of the University of Ljubljana, and France Stele, an art historian and conservator. A new generation of scholars also took leading positions in the National Museum. jože kastelic, a classical philologist, became the director of the museum in 1945, and stane gabrovec, an archaeologist and classical philologist, started to work in the Archaeological Department there in 1948.

The problem of repairing and maintaining monuments was even more urgent, particularly because of the war damage. In August 1945 an Office for the Protection and Scientific Research of Cultural and

Natural Monuments was established (later renamed the Office for the Protection of Natural and Cultural Heritage),

srecko brodar (1893-1987), a naturalist and schoolteacher in Celje, was able to lay foundations for Paleolithic archaeology. A new generation of scholars also took leading positions in the National Museum. jože kastelic, a classical philologist, became the director of the museum in 1945, and stane gabrovec, an archaeologist and classical philologist, started to work in the Archaeological Department there in 1948.

The problem of repairing and maintaining monuments was even more urgent, particularly because of the war damage. In August 1945 an Office for the Protection and Scientific Research of Cultural and

Natural Monuments was established (later renamed the Office for the Protection of Natural and Cultural Heritage),

and a series of government bills secured the protection and management of monuments from 1946 to 1948. This was the first integrated solution in the field since the abolition of Austrian legislation in 1918. Another important move was the establishment of the *Arheološki Vestnik* in 1949, designed to be the central archaeological journal; it was published by the Slovene Academy of Arts and Sciences.

It is interesting that the Communist authorities did not intervene to any great extent in the conceptual issues of archaeological research in the postwar period. Of course, all the scholars who were appointed to the leading positions had studied in the prewar period and were politically acceptable to the new regime, since they either supported the Liberation Front or were not compromised by collaboration with Germans or Italians. The official program of the Yugoslav (and Slovene) Communist Party encouraged the further emancipation of the Yugoslav nations (on a Marxist-Leninist basis, of course), and the development of a national cultural, scientific, and educational framework was part of this program. Had the new leaders in the field of archaeology been too rigidly selected on an ideological basis, the country would have lacked the cadre of intellectuals needed for the reconstruction.

The new ideology *was* expressed in various resolutions, manifests, and similar protocol documents presented at conferences, in new publications, and so on, but this had no operable effect on conceptual issues. Marxism could not anchor in archaeology as it could in historiography, philosophy, economics, and similar disciplines because the Yugoslav and Slovene Marxist ideologists were not capable of providing an applicable apparatus. Consequently, the positivist and culture-history paradigm in archaeology not only persisted but also further developed.

The late 1940s and 1950s were formative years that were decisive for the establishment of a stable archaeological institutional and conceptual framework. The formative process concluded in the mid-1970s when two networks were established: a network of regional Offices for Protection of Natural and Cultural Heritage and a network of regional museums. After that point the institutional framework remained largely unchanged. Today, there are three national archaeological institutions (the National Museum; the Institute of Archaeology of the Slovene Academy of Arts and Sciences, Department of Archaeology, University of Ljubljana; and the Agency for Protection of Cultural Heritage, with seven regional offices) and ten regional museums. The stability of the institutional and conceptual framework can be seen in the developments after 1991. Although Slovenia underwent another radical political change and became an independent, democratic state, the functioning of archaeological institutional and the conceptual frameworks were not affected. In fact, the only notable change was the development of contract archaeology on a much larger scale.

Conceptual Issues

The 1950s and 1960s witnessed the first clear division of specialization in archaeological periods among Slovene archaeologists. Their field was organized in five subdivisions: Paleolithic and Mesolithic archaeology (traditionally the domain of the naturalist scholars); Neolithic and Eneolithic archaeology; Bronze and Iron Age archaeology; Roman archaeology (classical and provincial); and early Medieval and Slavonic archaeology. This structure is largely intact today.

The field's major effort in this period was the Archaeological Map of Slovenia project,coordinated by the Institute of Archaeology. In 1966, after almost fifteen years of intensive work, the data were collected, but it took another ten years to revise the data and publish *Arheološka najdišča Slovenije* (Ljubljana 1975). This gazetteer of sites and monuments contained more than 3,000 entries from the Paleolithic to the early Medieval period (nearly ten times more than any previous archaeological map). Particularly important was the series of syntheses on settlement history for each archaeological period, the first studies of this kind based on highly detailed information.

The archaeologies of the individual periods in Slovenia also needed new conceptual tools. Indeed, the only branch that was developed in the prewar period to a level comparable with

at U.S. and British universities, and joint projects in Slovenia and elsewhere. These developments have also provided something of a counterpart and a challenge to the mainstream culture-history approach.

At the same time, the scholars who came from Gabrovec's school of prehistoric archaeology-Biba Teržan, Mitja Guštin (from the University of Ljubljana), and Janez Dular (from the Institute of Archaeology)-decisively contributed to the further development of a distinctive school of prehistoric research that is well respected on an international level.

In the 1980s and 1990s other fields of archaeological research also gained recognition on the international level. In numismatics, for example, A. Globočnik and P. Kos, after less than four decades of systematic work, were able to present rich collections on an exemplary level. Šašel's work became a reference for the epigraphy and ancient history of Roman Pannonia, Noricum, Dalmatia, and Venetia et Histria, and the very high standards he set are continued in the work of M. Šašel Kos.

Slavonic archaeology was established in a proper sense only after 1945, and in its first years it was beset by political problems arising from World War II, as well as conceptual disputes with historians about its interpretative potentials. Yet, despite all these constraints, it has matured admirably in recent decades and become a respected discipline with a developed critical apparatus.

Smith, Sir Grafton Elliot

(1871-1937)

Born in Grafton, New South Wales, Australia, Smith graduated with a degree in medicine from the University of Sydney in 1895. He won a scholarship and traveled to Cambridge to further his anatomical research. In 1900 he became professor of anatomy in Cairo, Egypt, and returned to England in 1909 as anatomy professor at Manchester University. In 1919 he became professor of anatomy at University College London. He received a Fellowship of the Royal Society in 1907, a Royal Medal in 1912, and a knighthood in 1934.

During his time in Cairo, Smith was a major participant in the planning and completion of the

Archaeological Survey of nubia. The creation of the Aswan Dam in 1902 had caused widespread flooding, which had destroyed many monuments and sites. When the Egyptian government decided the water level of the dam had to be raised another 7 meters, it was decided that this time they would record all threatened antiquities and examine and photograph all burials that would be destroyed by the new water levels-hence the survey. More than 10,000 burials were recovered and studied, the largest sample of burials ever excavated from an archaeological site. This was also the largest skeletal population ever studied and it revealed the prevalence of many interesting diseases and provided a detailed picture of everyday life and death in Egypt. The methods Elliot Smith and his colleagues developed during these studies changed the nature and significance of paleopathology forever.

Smith also contributed to the ongoing debate about primate evolution, believing that it was characterized by an increase in neurological sensory development in the areas of sight and hearing. He examined the Piltdown skull and declared it “the most primitive and most simian of human brains so far recorded,” lending some credibility to this scientific hoax at the time of its perpetration.

Elliot Smith's interests in and thoughts about ethnology and paleopathology, the results of his participation in the Archaeological Survey of Nubia, later led him to theorize that all cultural development-especially agriculture, pottery, clothing, monumental architecture, and kingship-had originated uniquely in Egypt, "the cradle of civilization," and then Egyptian merchants had carried Egyptian innovations and culture and spread them to the rest of the world. His books *The Migrations of Early Culture* (1915) and *The Ancient Egyptians and the Origin of Civilizations* (1923) elaborate these "hyper-diffusionist" ideas and were popular at the time of their publication.

Smithsonian Institution

Although the Smithsonian Institution (SI) became operational in 1846, its foundation actually stemmed from an 1835 bequest by James Smithson, an Englishman who had never visited the United States. Smithson's gift of over half a million dollars created one of the most significant institutions in the history of U.S. archaeology as part of one of the world's leading museum organizations.

Under its first secretary, John Henry, the Smithsonian made a vital contribution to the archaeology of North America when it published Ephraim G. Squier and edwin h. davis's *Ancient Monuments of the Mississippi Valley in 1848.* Its influence continued with the publication of Samuel Haven's *The Archaeology of the United States, or Sketches Historical and Biographical, of the Progress of Information and Opinion Respecting Vestiges of Antiquity in the United States* (1856). Both works had a significant impact on the history of prehistoric archaeology in North America.

The Smithsonian soon became an important element in the U.S. government's network of information sources, and its prominence in this arena remains undiminished. Not only would it become a storehouse of national knowledge, it would also use that knowledge in the service of government. In this sense the Smithsonian responded to a thirst for knowledge about the United States and through its work increased the desire for knowledge. This was especially true in the case of ethnology and archaeology. In 1861 the SI published "Instructions for Research Relative to the Ethnology and Philology of America" by George Gibbs, which mirrored the scope and purpose of the famous "Notes and Queries" produced by the British Association for the Advancement of Science. Gibbs's questionnaire, included in the instructions, was used by many of those undertaking primary ethnological and archaeological research, as well as others, such as missionaries and government agents, who sought a more direct understanding of indigenous Americans. In 1864, the SI sought to gather information about collections of artifacts derived from earthworked archaeological sites known as "mounds" and also about the "moundbuilders" who

built them in order to

divide), the Smithsonian has been responsive to the interests and concerns surrounding the Native American Graves Protection and Repatriation Act (NAGPRA) legislation.

Society for American Archaeology

The Society for American Archaeology, founded in 1934, is an organization of professional and avocational archaeologists devoted to the study and preservation of the archaeology of North and South America. The 1930s were a period of tremendous growth in American archaeology-many state archaeological societies were founded, and new regional conferences provided forums for local archaeological communication. The Great Depression actually led to a vast increase in archaeological fieldwork as a way to relieve unemployment, and the increased work led to new organizations, new journals, and a perceived need for greater communication among archaeologists on the national level.

Concurrent with the increased scientific archaeological activity was increased looting and vandalism of sites. A number of archaeologists felt the need for better communication and cooperation between amateurs and professionals as well as for more effective communication within the archaeological community. Since 1920, the Committee on State Archaeological Surveys (COSAS) of the National Research Council had served as a clearinghouse for U.S. archaeology-promoting the formation of state archaeological surveys, publishing guides to archaeological fieldwork and site recording, and organizing regional conferences. The American Anthropological Association (AAA) also served as a focus of

archaeological communication through meetings and publications. *American Anthropologist* was the journal of choice for professional archaeological articles of national interest, and until 1932, it published an annual compilation of archaeological fieldwork in the United States. COSAS was quite successful in its endeavors, but its last chairman (1927-1937), Carl E. Guthe, realized that the committee's private funding would not be continued indefinitely. This fact, along with the unwillingness of the editor of *American Anthropologist* to continue publishing the annual archaeological fieldwork summary, created the need for a national organization.

In 1933, COSAS members approved the idea of a national archaeological organization, and in 1934, Guthe sent a prospectus to 192 interested individuals for comment. Response was positive enough that COSAS formed a subcommittee to write a constitution and bylaws, and an organizational meeting held in Pittsburgh, attended by 31 people, created the Society for American Archaeology on 28 December 1934 (Griffin 1985; Guthe 1967).

The society's activities originally were governed by an elected executive council consisting of a president, vice-president, secretary-treasurer, editor, and eight other members. As the years passed, the composition of the council (later called the executive committee and finally the executive board) changed with the needs of the society. A nominating committee has always

guidelines for archaeological reports, communication, archaeology and Native Americans, and certification (McGimsey and Davis 1977).

The problem of site looting and vandalism was one of the factors that influenced the original founding of the society, and official activities of the society on this issue have usually been in the form of editorials in *American Antiquity*. Activities on the international level have included authorizing the use of society funds to assist in prosecuting an illegal antiquities case (1972) and a long-term effort leading to implementation of the UNESCO Convention on Cultural Property in 1983. On the national level, the society began a major antilooting project, Save the Past for the Future, in 1988.

During its more than sixty years, the SAA has evolved from a national learned society concerned principally with communication among scholars through meetings and publication to an international professional society concerned with influencing governmental activities and defining professional standards as well as including the interests of non-U.S. Americanist scholars. The archives of the society are located in the National Anthropological Archives of the National Museum of Natural History, Smithsonian Institution.

Society for Historical Archaeology

In early January 1967, an ad hoc Committee of Fifteen, made up of most of the leading historical archaeologists in the Americas, met in conjunction with an International Conference on historical archaeology in Dallas, Texas, and over a three-day period organized the Society for Historical Archaeology (SHA). The new society's origins can be traced back over three decades before the meeting in Dallas. Special symposia at both the society for american archaeology (SAA) and the American Anthropological Association and the 1960 creation of the more-regional Conference on Historic Site Archaeology by Stanley South served as precedents. By the middle of the 1960s, the growing community of historical archaeologists realized that the SAA, which was dominated by New World prehistorians, could not represent their developing interests and that their numbers were now adequate to support an autonomous association.

Independence and formal organization led to visible success and rapid growth, with the SHA

becoming the central social, and to some degree intellectual, base for the emerging discipline. By the 1990s, its annual meetings, held in January, had more than 1,000 attendees, and its quarterly journal, *Historical Archaeology,* and substantial *Newsletter* had gained international standing and distribution. Although fundamentally a scholarly association, the SHA has also served as an effective lobbying base, as is seen by its primary role in the passage of the 1987 Abandoned Shipwreck Act by the U.S. Congress.

Phenomenal growth has resulted in a 2,000 individual membership, which makes the SHA the second-largest association of anthropological archaeologists in the world. Nevertheless, these numbers have not created an economy of scale. Across its three-decade history, a small number of dedicated volunteers have preserved and nurtured the society. The terms of office of the journal editor, Ronald L. Michael (1978- 2001), the recent book review editor, Roderick Sprague (1977-1997), secretary-treasurer, Stephanie H. Rodeffer (1978-2001), and newsletter editor, Norman Barka (1982-2001) highlight this unusual situation for a mature and national-international organization.

Even though the core of its membership is in North America, the SHA has always been international in its orientation. In 1967, scholars from canada and mexico joined their colleagues from the United States at the Dallas meeting, and during the 1960s and 1970s, the society built early linkages to both the Society for Post-Medieval Archaeology in Europe and the Australasian Society for Historical Archaeology in Oceania. The SHA is the only truly global organization in the field; it is also one of the few of these collateral associations to self-reflexively recognize its own disciplinary history. In 1981, it created the j. c. harrington medal in historical archaeology and followed that in 1989 with the Carol V. Ruppé Distinguished Service Award and in 1998 with the John L. Cotter Award. It also established the flexible and successful category of SHA awards of merit.

The Society for Historical Archaeology, and parallel organizations in North America (including the Advisory Council on Underwater Archaeology, long associated with the SHA; the Society for Industrial Archaeology; the Council for Northeastern Historical Archaeology; and the former [1960-1982] Conference on Historic Site Archaeology) and similar scholarly associations overseas, have been pivotal in the history and growth of the discipline.

Society of Antiquaries of London

The Society of Antiquaries of London, founded in 1707, is the oldest learned society in Great Britain and Ireland concerned with archaeology and history. The Elizabethan College of Antiquaries, with such scholars as william camden, Sir Robert Cotton, and John Stow, disbanded in the reign of James I (van Norden 1946). The Royal Society, founded in 1660, had an early interest in historical monuments such as avebury (Ucko et al. 1991) and published much material on archaeological finds in its *Philosophical Transactions,* but by the end of the eighteenth century, its attention was focused purely on science.

The Society of Antiquaries of London was founded by three friends-Humfrey Wanley, John Talman, and John Bagford-who met informally in various London taverns. At the time, people who were interested in the physical and documentary evidence of the past were called antiquaries. The society has a continuous history from 1717, when there were twenty-three members, and the first Articles of Association defined

the purpose of the new society as making knowledge of British antiquities more universal (Evans 1956). The Society of Antiquaries of London's early *Minutes* recorded the discoveries and exhibits of members, often with drawings, and are still of great interest. The drawings by the director, Charles Frederick, of the Arreton Downs hoard on the Isle of Wight, found in 1734, has made it possible for a group of Bronze Age metalwork items, now widely dispersed, to be reconstituted by later scholars and given their true provenance (Needham 1986).

The first secretary after 1717, william stukeley, made important discoveries at Stonehenge,

PREV NEXT

made by both the society and its fellows to archaeology over nearly 300 years have been considerable.

society of antiquaries of scotland

The second-oldest antiquarian society in Great Britain, the society of antiquaries of scotland was founded in 1780. David Steuart Erskine, eleventh earl of Buchan, called a meeting of eminent historians and antiquaries at his home in St. Andrews Square in Edinburgh on 14 November, and the new society was formally constituted on 18 December. Its first meeting followed on 16 January 1781, and it set the pattern for years to come: an academic lecture and a display of items donated to the society's museum. In the terms of the charter granted in 1783, the aim of the society was "to investigate both antiquities and natural and civil history in general," and King George III and his successors were to be the society's patrons. The current laws of the society define its purpose as "the study of the antiquities and history of Scotland, more especially by means of archaeological research." The society was granted a coat of arms in 1827.

The publication of academic papers began in 1792 with the first volume of the *Transactions;* the name of the journal was changed with volume four in 1831 to *Archaeologia Scotica,* and its publication ceased with volume five in 1890. It was replaced by the *Proceedings of the society of antiquaries of scotland,* the first volume of which was published in 1854, and it remains the primary journal of archaeological record in Scotland (Graham 1969-1970). The society's minute books and correspondence, together with original drawings and manuscripts of antiquarian interest, are in the National Museums of Scotland Library, and other manuscripts formerly belonging to the society are in the National Monuments Record for Scotland.

Initially, the society occupied a number of different properties in Edinburgh, and at one time it shared a building with the Royal Society of Edinburgh. As the collection grew in size and importance, however, concern about its long-term future led to the transference of responsibility for its housing and financing to

the government in 1859, in return for which the society agreed to give the collection to the nation. In 1890, the museum was moved to a purpose-built museum and portrait gallery in Queen Street; an ornate building was designed by Rowand Anderson in the Italianate Gothic style.

The museum had become the National Museum of Antiquities of Scotland, and the society had rooms, including a splendid library, in the new building. An act of Parliament in 1954 relieved the society of the management of the museum, but the library remained mutual and the society continued to be housed by the museum. The name of the museum was changed to the Royal Museum of Scotland when it was amalgamated by an act of Parliament in 1985 with the Royal Scottish Museum under the overall title National Museums of Scotland. Before the end of the twentieth century, the Scottish collections were to be redisplayed in a new building in Chambers Street, and the society was to move into new rooms there.

Members of the society are known as fellows and are admitted by election. There were 50 fellows in 1780 and almost 3,000 in the 1990s. Membership is worldwide and includes both professional and amateur archaeologists and historians. There are also up to 25 honorary fellows, elected in recognition of their services to

Scottish or international archaeology and history. Office-bearers consist of a president, three vice-presidents, a treasurer, and an editor, and there is currently a professional staff of three, headed by the director of the society. The society celebrated its bicentenary in 1980 with special meetings and exhibitions, and a commemorative medal was struck in bronze for fellows and in silver as a presidential badge of office. A volume of essays about the society, the museum, and leading antiquarians was published to mark the bicentennial year (Bell 1981).

From the 1850s onward, reports of excavations featured strongly in the *Proceedings,* and the society sponsored its own excavations from the 1890s to the 1930s, including work on the Roman forts at Birrens, Ardoch, Inchtuthil, and Newstead; the native forts at Dunadd and Traprain; the broch at Gurness; and the Viking settlement at Jarlshof in the Shetland Islands. Although the society no longer conducts excavations today, it supports excavation and research through grants awarded from its research fund and through conferences.

A leading fellow of the mid-nineteenth century, A.H. Rhind, funded an annual lectureship that began in 1876-1878 with a series of lectures on Scottish ethnography by Sir Arthur Mitchell; these lectures were published as *The Past in the Present* (1880). The next series was given by Joseph Anderson, the keeper of the society's museum from 1869 to 1913. His lectures represented a milestone in Scottish archaeology because of their scientific analysis of sites and artifacts, and they were published in two volumes as *Scotland in Early Christian Times* (1881) and in another two volumes as *Scotland in Pagan Times* (1883-1886). The prestigious Rhind Lectures still continue to provide a platform for scholars to present the most up-to-date research in a wide variety of archaeological, historical, architectural, and ethnographical fields.

Apart from the *Proceedings,* there have been occasional publications such as the great tome *The Early Christian Monuments of Scotland* (1903) by J. Romilly Allen and Joseph Anderson, and since 1982, the society has published its own series of monographs, mostly recording excavations in Scotland. From its inception, the society has been consulted on important developments relating to Scottish history and archaeology, and it continues to have a powerful voice on matters concerning Scotland's heritage and the management of archaeology in Britain.

Society of Dilettanti

Founded in 1734 in London by a group of gentlemen who had taken the grand tour of Europe, the primary purpose of the Society of Dilettanti was to promote the study of classical antiquities. The society gained great fame during its history by funding research, the most important being a survey of Athenian monuments by James Stuart (artist) and Nicholas Revett (architect), which took place between 1751 and 1754, and a highly detailed survey of the ruins of Ionia by Richard Chandler beginning in 1765. The society sealed its place in the history of archaeology by publishing both surveys. Stuart and Revett produced the four-volume *Antiquities of Athens* (1762-1816), and Chandler brought out *The Antiquities of Ionia* (1769-1797).

Solutré

Solutré, an open site in the Ardèche region of southeastern france, was selected in 1869 as the type site for the Solutrean industry. The site is located at the base of a cliff and dates from about 30,000 b.p. to 17,000 b.p. Solutré contains an excellent sequence of French Paleolithic industries from the Mousterian to the Magdalenian, but it is most famous for the presence of the distinctive laurel leaf points and shouldered points that are characteristic of

Scottish or international archaeology and history. Office-bearers consist of a president, three vice-presidents, a treasurer, and an editor, and there is currently a professional staff of three, headed by the director of the society. South Asia

Introduction

Considering the enormous geographical area involved, the number of its modern nation states, and the rich spectrum of its archaeology, one would expect the literature on the history of archaeology in South Asia to be fairly analytical and detailed. This is not the case. Straightforward narrative accounts, sometimes viewed in relation with contemporary government policies and other historical factors, are available for the period up to 1947 when the British rule of the subcontinent ended (*see* Roy 1953, 1961; Ghosh 1953; Allchin 1961; Imam 1966; Chakrabarti 1988a, 1988b; Possehl 1990; Mirsky 1977). These histories deal fully (*see* Roy 1961; Chakrabarti 1988a) or partly with the history of archaeology in British India, which was dominated almost exclusively by the official Archaeological Survey of India that came into existence, although tentatively, in 1861. But at least two other dimensions of this period remain unresearched. First, some major "native" states of the subcontinent that enjoyed varying degrees of autonomy during British rule, such as Hyderabad, Mysore, Travancore, Gwalior, Kashmir, Baroda, and Nepal, ran, on the British Indian model, their own archaeology departments. The history of these departments lies untouched. Second, the different nuances between archaeology and nationalism provide great scope for research, especially in view of the long struggle for Indian independence, but this is another field of study that remains neglected. The development of the concept of an Indian past among the different sections of Indian people is closely related to this issue. The main source of study in this case is the great amount of vernacular literature from the second half of the eighteenth century onwards in different parts of the country in different major languages. This concept has to be seen separately from the Western concept of the past of India. In any case, the interaction between these two major concepts of the Indian past should provide a separate field of study in itself.

After 1947 the history of subcontinental archaeology becomes the history of archaeology in its different nation-state components. For obvious historical reasons, one of which is the difference in majority religion between these countries (Hinduism in India and Nepal, Islam in Pakistan and Bangladesh, Buddhism in Bhutan), the concept of the past in these individual nation states need not exactly be the same. Still, the model of archaeological organization in them has a lot in common because of close ancestral links with the pre-1947 Archaeological Survey of India, and, more significantly, this possible difference in attitudes to the past has not changed the pattern of archaeological research in these countries. Also, the interaction between the Western concept of the past of South Asia and the concept of the past developed by South Asians themselves merits close study even in the post-1947 period, mainly to analyze the extent to which the hegemonic ideas of Western Indology still retain their grip over the intellectual tradition in a Third World region like South Asia.

The Beginning

The middle of the eighteenth century is as convenient a starting point for South Asian archaeological studies as any. At about this time Anquetil du Perron, a Frenchman with knowledge of Oriental languages, and Karsten Niebuhr, a Danish engineer and voyager, wrote about the need to open up India as a field of scientific inquiry. They also prepared measured drawings of the West Indian monuments of Elephanta and Kanheri, both easily accessible to Europeans because of their proximity to Bombay. In fact, these and other conveniently located monuments had been drawing the attention of European travelers and sailors since the sixteenth century, and although most of these descriptions were fanciful and deprecatory, some writers like the Italian Pietro della Valle of the seventeenth century insisted on some accuracy, aided in the case of della Valle by a few temple plans. There are two other reasons for selecting the mid-eighteenth century as our starting point. First, in 1753 J.B. D'Anville, a French geographer, published a book on Indian geography with detailed discussions of the locations of some ancient sites mentioned in classical writings on India. Second, in the writings of the French philosophers of Enlightenment, which attempted to move away from Judaeo-Christian thought, there was a strong emphasis on India as the original center of culture and religion (seeMitter 1977; Chakrabarti 1988a, 1-15).

Second, in the writings of the French philosophers of Enlightenment, which attempted to move away from Judaeo-Christian thought, there was a strong emphasis on India as the original center of culture and religion (seeMitter 1977; Chakrabarti 1988a, 1-15).

The Asiatic Society of Bengal

An institutional focus of inquiry into the history and antiquities, the arts, sciences and literature of Asia was provided by the Asiatic Society of Bengal, established on 15 January 1784 in the contemporary British Indian capital of Calcutta with the Governor General Warren Hastings as its patron and William Jones, a senior judge, as the president. The ascending British supremacy in India, the trend of forming "societies" for scientific and other investigations in contemporary Britain, and a concern with "how far the products of India could be turned to account" explain the establishment of this institution. A major focus of interest was to understand Indian civilization in light of the contemporary notions of Universal History, which, because of its implicit acceptance of the biblical theory of creation, found no difficulty in believing that all human families were related and that one of the major tasks of historical investigation in India was to seek out proof of such relations. Having argued that the race he called Indian was descended from Ham, one of the three sons of Noah, Jones traced the ramifications of this concept in various fields of Indian endeavor, including Sanskrit, the speakers of which were supposed to have "had an immemorial affinity with the old Persians, Ethiopians and Egyptians, the Phoenicians, Greeks and Tuscans; the Scythians or Goths, and celts; the Chinese, Japanese and Peruvians…" (Jones 1788). Interests in India both as the original center of civilization and for the identification of its ancient sites continued during this period. Among other things, Indian priests were supposed to have moved out of a climatically more equable central Asia, spreading civilization wherever they went (Chakrabarti 1976). In the field of historical geography there were some significant publications, notably those by James Rennell, whose *Memoir of a Map of Hindoostan,* which combined both modern and ancient data, "one illustrating and explaining the other," underwent three editions between 1783 and 1793 (Chakrabarti 1988a, 14, 16-18).

The Leadership of james prinsep

Field archaeology gained no momentum until the 1830s, although some major archaeological sites were noticed by then in a few regional surveys (Roy 1953). The man who inspired field-archaeological studies was James Prinsep, Assay Master of the British mint in Calcutta, Secretary of the Asiatic Society of Bengal, and the principal decipherer, in collaboration with Indian traditional language scholars, of the ancient Indian scripts of Brahmi and Kharoshti. His attitude toward field research is clear from his statement, "What the learned world demands of us in India is to be quite certain of our data, to place the monumental record before them exactly as now exists, and to interpret it faithfully and literally" (Prinsep 1838).

One of the major developments of the period was the enumeration and excavation of Buddhist funerary remains, called stupas, in the northwestern part of the subcontinent. Leadership in this matter was given by some European army officers in the employ of the contemporary Sikh ruler of the region, Ranjit Singh, but nobody expressed it better than Alexander Burnes of the Bombay Army, who in his quest for the stupas and "Grecian remains" found himself referred from place to place "like one in search of the philosopher's stone" (Burnes 1833). None, however, was more extensive in his observations and collections in this region than Charles Masson (Possehl 1990), an alias for James Loews, who deserted from Bengal Horse

The Asiatic Society of Bengal

An institutional focus of inquiry into the history and antiquities, the arts, sciences and literature of Asia was provided by the Asiatic Society of Bengal, established on 15 January 1784 in the contemporary British Indian capital of Calcutta with the Governor General Warren Hastings as its patron and William Jones, a senior judge, as the president. The ascending British supremacy in India, the trend of forming "societies" for scientific and other investigations in contemporary Britain, and a concern with "how far the products of India could be turned to account" explain the establishment of this institution. The Leadership of james prinsep

Field archaeology gained no momentum until the 1830s, although some major archaeological sites were noticed by then in a few regional surveys (Roy 1953). The man who inspired field-archaeological studies was James Prinsep, Assay Master of the British mint in Calcutta, Secretary of the Asiatic Society of Bengal, and the principal decipherer, in collaboration with Indian traditional language scholars, of the ancient Indian scripts of Brahmi and Kharoshti. His attitude toward field research is clear from his statement, "What the learned world demands of us in India is to be quite certain of our data, to place the monumental record before them exactly as now exists, and to interpret it faithfully and literally" (Prinsep 1838).

One of the major developments of the period was the enumeration and excavation of Buddhist funerary remains, called stupas, in the northwestern part of the subcontinent. Leadership in this matter was given by some European army officers in the employ of the contemporary Sikh ruler of the region, Ranjit Singh, but nobody expressed it better than Alexander Burnes of the Bombay Army, who in his quest for the stupas and "Grecian remains" found himself referred from place to place "like one in search of the philosopher's stone" (Burnes 1833). None, however, was more extensive in his observations and collections in this region than Charles Masson (Possehl 1990), an alias for James Loews, who deserted from Bengal Horse

Artillery in 1827. In the southern part of the country there was a period of “barrow-hunting,” when megalithic burials of various kinds were dug in their hundreds by British officials in the cool of the Nilgiri hills or literally in their backyards. At Jiwarji in the Deccan, Captain Meadows Taylor (1851) in his digging employed more care and precision than others. On the north Indian plains some major historical sites were identified or recorded during this period, the foremost coming from alexander cunningham, a military engineer and a close associate of Prinsep. In the newly translated itineraries of the two famous Chinese pilgrims to India-Fa-Hian (early fifth century a.d.) and Hiuen-Tsang (the first half of the seventh century a.d.)-he found an important geographical base for conducting ground investigations. One could follow the pilgrims in their travels and mark out the places they reported. In 1843 he discovered the location of the early historic city-site of Sankisa in Uttar Pradesh by following this method (Cunningham 1843), but systematic surveys had to wait until 1861 when the government established an organization for the purpose, with Cunningham (then retired with the rank of Major General) at its head. In 1865 the Archaeological Survey of India was disbanded, to be reorganized in 1871 with Cunningham again in charge, this time with the services of two assistants, J.D. Beglar and A.C.L. Carlyle. Beglar left this job in 1880 and was succeeded by H.B.W. Garrick.

The Surveys of Alexander Cunningham (1861-1865, 1866-1885)

Cunningham conducted his surveys across the entire area between the northwestern hills and the Bengal delta, including the Vindhyan orbit in central India, eastern Rajasthan, the Chhotanagpur hills, and Orissa in eastern India. Some of the work was done by his assistants but the principal work was done by Cunningham personally. The results of these surveys were incorporated in twenty-three volumes published between 1871 and 1887 (Imam 1966).

The standard features of a Cunningham report are the following: a ground survey studying the height, character and extent of the mounds, including their structural features and the plans and measurements of the more important of them; the record of their local traditions; the mention, if any, of the place in the ancient Indian literary texts; the description in Hiuen-Tsang's and/or Fa-Hian's records; an attempt to identify the various sacred spots, monasteries, stupas, etc. in Hiuen-Tsang's and Fa-Hian's account of the place with the various surviving features on the ground; and the mention of the still available coins, images and inscriptions at the place with notes on them. To do all these even in the context of a single site would require a strong measure of versatile scholarship and practiced eyes. What lends Cunningham's survey work great distinction is that he could set down these points for hundreds of sites of different types throughout north India.

(Chakrabarti 1988a, 59)

The basic achievement of these surveys was the mapping out of sites on a large scale and this was something like the achievement of the Great Trigonometrical Survey of India, which mapped out the Indian landmass in considerable detail.

Archaeology as Architecture (1885-1901)

There was a sharp contrast in archaeological attitude between Alexander Cunningham and his successor James Burgess (1886-1889), who had considerable prior experience as an architectural surveyor in Gujarat and the Deccan and to whom archaeology was nothing but architectural study (Burgess 1905). The last quarter of the nineteenth century witnessed the publication of many studies of ancient and medieval monuments, principally by “provincial” surveyors, such as James Fergusson and R.L. Mitraand, under Burgess, and some by Burgess himself. At the same time the study of ancient Indian epigraphy was undertaken by a specially appointed government epigraphist and a curator of ancient

monuments, to which Captain H.H. Cole (1880-1883) was appointed. This marked a departure from the earlier government attitude, reflected by its resolution to auction the Taj Mahal for the value of the marble of its construction-a resolution mercifully abandoned later. One of the significant field-archaeological

Artillery in 1827. In the southern part of the country there was a period of “barrow-hunting,” when megalithic burials of various kinds were dug in their hundreds by British officials in the cool of the Nilgiri hills or literally in their backyards. At Jiwarji in the Deccan, Captain Meadows Taylor (1851) in his digging employed more care and precision than others. On the north Indian plains some major historical sites were identified or recorded during this period, the foremost coming from alexander cunningham, a military engineer and a close associate of Prinsep. In the newly translated itineraries of the two famous Chinese pilgrims to India-Fa-Hian (early fifth century a.d.) and Hiuen-Tsang (the first half of the seventh century a.d.)-he found an important geographical base for conducting ground investigations. One could follow the pilgrims in their travels and mark out the places they reported. In 1843 he discovered the location of the early historic city-site of Sankisa in Uttar Pradesh by following this method (Cunningham 1843), but systematic surveys had to wait until 1861 when the government established an organization for the purpose, with Cunningham (then retired with the rank of Major General) at its head. In 1865 the Archaeological Survey of India was disbanded, to be reorganized in 1871 with Cunningham again in charge, this time with the services of two assistants, J.D. Beglar and A.C.L. Carlyle. Beglar left this job in 1880 and was succeeded by H.B.W. Garrick.

The Surveys of Alexander Cunningham (1861-1865, 1866-1885)

Cunningham conducted his surveys across the entire area between the northwestern hills and the Bengal delta, including the Vindhyan orbit in central India, eastern Rajasthan, the Chhotanagpur hills, and Orissa in eastern India. Some of the work was done by his assistants but the principal work was done by Cunningham personally. The results of these surveys were incorporated in twenty-three volumes published between 1871 and 1887 (Imam 1966).

The standard features of a Cunningham report are the following: a ground survey studying the height, character and extent of the mounds, including their structural features and the plans and measurements of the more important of them; the record of their local traditions; the mention, if any, of the place in the ancient Indian literary texts; the description in Hiuen-Tsang's and/or Fa-Hian's records; an attempt to identify the various sacred spots, monasteries, stupas, etc. in Hiuen-Tsang's and Fa-Hian's account of the place with the various surviving features on the ground; and the mention of the still available coins, images and inscriptions at the place with notes on them. To do all these even in the context of a single site would require a strong measure of versatile scholarship and practiced eyes. What lends Cunningham's survey work great distinction is that he could set down these points for hundreds of sites of different types throughout north India.

(Chakrabarti 1988a, 59)

The basic achievement of these surveys was the mapping out of sites on a large scale and this was something like the achievement of the Great Trigonometrical Survey of India, which mapped out the Indian landmass in considerable detail.

Archaeology as Architecture (1885-1901)

There was a sharp contrast in archaeological attitude between Alexander Cunningham and his successor James Burgess (1886-1889), who had considerable prior experience as an architectural surveyor in Gujarat and the Deccan and to whom archaeology was nothing but architectural study (Burgess 1905). The last quarter of the nineteenth century witnessed the publication of many studies of ancient and medieval monuments, principally by “provincial” surveyors, such as James Fergusson and R.L. Mitraand, under Burgess, and some by Burgess himself. At the same time the study of ancient Indian epigraphy was undertaken by a specially appointed government epigraphist and a curator of ancient

monuments, to which Captain H.H. Cole (1880-1883) was appointed. This marked a departure from the earlier government attitude, reflected by its resolution to auction the Taj Mahal for the value of the marble of its construction-a resolution mercifully abandoned later. One of the significant field-archaeological

investigations of this period was the exploration of the ancient city of Pataliputra, modern Patna, by L.A. Waddel of the Indian Medical Service. In the course of a hurried visit to Patna in 1892 he was surprised to find that not only was the ancient city practically intact but that "most of the leading landmarks of Asoka's palaces, monasteries and other monuments remained so very obvious" as to enable him "in the short space of one day to identify many of them beyond all doubt" (Waddel 1903). Excavations began at this site under the Public Works Department in 1894 and the general identifications, proposed by Waddel on the basis of his keen eye for the details on the ground and a close familiarity with the literary data on the topography of the place, were confirmed.

The John Marshall Era (1902-1944)

The fortunes of archaeological research in India changed considerably during the Viceroyalty of Lord Curzon, who took personal interest in such a non-revenue-earning matter as archaeology. Curzon imported the 26-year-old john marshall, an alumnus of King's College, Cambridge, with some archaeological experience in greece and turkey, and appointed him the director general of archaeology. As subsequent developments proved, he could not have chosen better. To begin with, various aspects of archaeology in India-explorations, excavations, conservation of ancient monuments, and epigraphy-were consolidated within the aegis of the Archaeological Survey of India. Archaeological research and the task of conservation came to be considered as permanent government responsibilities, which in itself was a very big step forward. The director general could now lay down clearly defined policies for his officers in various regions. Moreover, a system of publishing annual reports containing detailed accounts of the manifold activities of the survey was introduced right from the first year of Marshall's office (1902-1903). These volumes, the publication of which continued up to 1937, were substantial scholarly and administrative endeavors. Finally, there was a system of awarding annual research scholarships, one for Sanskrit and another for Persian and Arabic, to two students at Indian universities, enabling the induction of Indians at a superior level in the survey, which fostered over many years a strong core of primary scholarship. Epigraphical studies received much-needed impetus with the regular publication of *Epigraphia Indica.* On the whole archaeology was put on an even keel right from the early days of Marshall's director generalship.

In field archaeology the first great achievement of the Marshall era (notwithstanding his personal retirement in 1928-1929) lay in the excavations of major historical sites in virtually all areas of the subcontinent, which continued until 1944. It is true that many of them were mapped out by Cunningham but the details still needed working out with the help of physical excavation. From the Indian perspective, throughout the nineteenth century there was a constant discussion in vernacular literature on the theme of India's past, especially India's ancient past. This was primarily based on literature and partly on the study of standing monuments, but there was a need for the knowledge of archaeological details. Marshall's own early works were at Charsada in the northwest and Bhita and Rajagriha in the Gangetic valley, but after these he was mostly busy with excavations at Taxila, where the landscape reminded him of Greece and where there were numerous finds to illustrate the subcontinent's link with the West Asian and Mediterranean world. Marshall's personal report on Taxila (Marshall 1951) came out in three volumes in 1951, its earlier publication being reputedly prevented by the destruction of his notes during the London blitz. The people he recruited were busy at other sites, many of which enjoyed great reputation in the annals of early historic India-Pataliputra, Vaisali, Purushapura or Peshawar, Amaravati, Nalanda, Sravasti, Kusinara, and others. In each case, as in the case of Marshall's own work at Bhita, which arrived at stratigraphy based on floor levels, the work was largely horizontal and successful in offering a visual image of the famous cities and monuments of ancient India.

The second great field achievement of the period was the discovery of the Indus Civilization, the first

formal announcement on which was made in the *Illustrated London News* on 20

September 1924. This was based on D.R. Sahni's work at harappa between 1920 and 1921 and rakal d. banerji's work at Mohenjo Daro between 1921 and 1922. It was Mohenjo Daro that received major attention, because a large section of the ruins at Harappa were destroyed by the brick-robbing activities of the contractors of the Lahore-Multan railway. The results of work at Harappa were published in 1940. However it was the three-volume *Mohenjodaro and the Indus Civilization,* edited by Marshall and including a long introduction and discussion by him on religion and art, chronology, and the like, that brought out the first integrated image of this civilization. Its town planning, its concern with water supply and sanitation, its excellently crafted glyptic art and well-ordered rows of short inscriptions on seals, the evidence of its internal and external trade, a distinct level of technological excellence, and an art and a religious system whose principal elements were carried into the later historic periods-all of these suggested to Marshall a strong factor of continuity between this Bronze Age civilization and modern India. The discovery of this unique civilization, as unique in its own way as the civilizations of Egypt, was a great achievement of the Archaeological Survey of India under Marshall. With independence in 1947, India, in the eyes of western scholarship, became part of the Third World. But Marshall never had the compulsion to denigrate India's unique antiquity, believing that the origins of historic India, including its major religion, Hinduism, could be traced back to the Bronze Age Indus civilization.

During the world Depression in the 1930s and World War II in the 1940s, archaeology survived somehow in India, although its budget was severely cut. N.G. Majumdar's surveys in Sind elucidating the antecedents and transformations of Indus civilization and the excavations by K.N. Dikshit at the major Buddhist monastery of Paharpur in eastern India belong to this period. In 1939 the government of India decided, for unexplained reasons, to seek the opinion of the famous British archaeologist leonard woolley of ur on the state of Indian archaeology. The resultant “Woolley Report,” no worse and no better than many such pontificatory reports on India by Western experts, suggested, among other things, prolonged excavations at a major historic site for “in-service” training of the survey officers and the appointment of another famous British archaeologist, sir eric mortimer wheeler, as the director general for four years.

Mortimer Wheeler (1944-1948)

Wheeler knew the value of vertical sequences established on the basis of layers, he appreciated archaeology as an academic discipline in its own right, and he fully understood the potential of the application of natural-scientific techniques in archaeology. His work at Taxila, where he operated a training school for survey recruits and university students, and at Harappa, Arikamedu, and Brahmagiri were exercises both in stratigraphic layer-based digging and in pursuing specific issues. In retrospect Wheeler's contribution to Indian archaeology lay in his determination to develop archaeology as an academic discipline in Indian universities, and this overall concern is obvious in his own writings during his stay in India in an annual publication he himself created, *Ancient India.* From the Indian academic point of view “he was no Elizabethan hero or a 'mad sahib' set among the natives to stampede them into a frenetic albeit well-ordered archaeological activity.... His role in India was basically that of a university teacher with firm, single-minded commitment to his subject” (Chakrabarti 1988a).

Prehistory until 1947

Until Wheeler organized a prehistory section in the survey, there was no official interest in prehistory, which had a checkered history of investigations in India since the early years of the twentieth century. During the second half of the nineteenth century, especially after the discovery of a hand-axe near Madras by Geological Survey of India officer robert b. foote, there were many prehistoric discoveries that were initiated almost exclusively by geologists. In 1923 an Indian teacher of anthropology at Calcutta University (Mitra 1923) published a book called *Prehistoric India.* In the 1930s, in the wake of stone tool discoveries in the outer Himalayan

region, H. de Terra, a geologist from Yale, and T.T. Paterson, an archaeologist from Cambridge (England) formulated a scheme of river terrace successions associated with lithic industries in the Soan River Valley of Panjab (now in Pakistan). The Soan terraces were related to the evidence of four glacial phases in Kashmir, which in turn were related to the four-fold glacial cycle in the Alps, thus bringing a sense of geochronology to Indian prehistoric studies. This work enjoyed influence for a long time and generated further interest in prehistoric studies in different parts of the country. In the 1940s stuart piggott , then in the Royal Air Force in India, studied protohistoric material from Baluchistan, arranging it into regional cultures with ties to central and west Asia. But on the whole prehistoric and protohistoric studies had to wait for an upsurge in interest until the postcolonial era.

The Post-1947 Situation

After 1947, the year of Partition and Independence from British rule, the history of South Asian archaeology becomes the history of archaeological research in five nation-states: India, Pakistan, Bangladesh, Nepal and Bhutan.

Bhutan and Nepal

There are no positive reports of early sites in Bhutan, and to the best of our knowledge there has been no detailed survey work either. The Himalayan kingdom of Nepal, on the other hand, has an established government archaeology department, complemented by archaeology and ancient history teaching at Tribhuvan University, Kathmandu. Considering the nature of sites in the Kathmandu valley and the tarai region of the country, the orientation of Nepalese archaeology has always been toward sites associated with the life of the Buddha and generally Buddhism (for a comprehensive survey, *see* Slusser 1982; for a representative excavation report, *see* Mitra 1971). At one point there was a great reluctance to come to terms with the fact that the site of Kapilavastu, the capital of the kingdom where the Buddha's father was king, was, as the discovery of Kapilavastu monastic seals by an Indian team showed, at Piphrawa on the Indian side of the Nepal-India border (Rijal 1979). The birthplace of the Buddha has always been, of course, on the Nepalese side of the border. The standard archaeological publication of Nepal is *Ancient Nepal,* officially published by the government department of archaeology.

Bangladesh

Bangladesh became an independent nation state in 1971 and archaeological research there between 1947 and 1971 was conducted by the Pakistan Department of Archaeology. The principal sites are the Buddhist monastery of Mainamati, which had its heyday in the seventh and eighth centuries a.d., and Mahasthangarh, one of the most imposing early historic city-sites of the subcontinent, dating back certainly to the third century b.c. when it was a provincial administrative center of the Mauryan empire, which stretched from south Afghanistan to Bengal. Buddhist monastery sites remain the focal point of contemporary Bangladesh archaeological research. Among its official publications *Bangladesh Archaeology,* of which regrettably only one issue has been published, must be considered the most important. Archaeology is taught at only one Bangladesh university, Jahangirnagar University near the nation's capital of Dhaka. The only evidence of Stone Age industry in Bangladesh is a late Acheulean/Upper Paleolithic industry made from the locally abundant fossilwood in the Lalmai hills (Chakrabarti 1993).

Pakistan

Archaeology in Pakistan has concentrated on protohistory and on the elucidation of the process of cultural development leading up to the development of Indus civilization. Initially Baluchistan received close archaeological scrutiny, notably with the beginning of a new phase of protohistoric research in this

area by W.A. Fairservis, who was soon followed by a host of other researchers, notably B. de Cardi, G.F. Dales, and, more recently, J. Jarrige, who established the beginning of wheat-barley and cattle-sheep-goat domestication at around 7000 b.c. in the Bolan Valley site of Mehrgarh. From the point of view of subcontinental archaeology, the discovery of this level at Mehrgarh was a

region, H. de Terra, a geologist from Yale, and T.T. Paterson, an archaeologist from Cambridge (England) formulated a scheme of river terrace successions associated with lithic industries in the Soan River Valley of Panjab (now in Pakistan). The Soan terraces were related to the evidence of four glacial phases in Kashmir, which in turn were related to the four-fold glacial cycle in the Alps, thus bringing a sense of geochronology to Indian prehistoric studies. From the point of view of subcontinental archaeology, the discovery of this level at Mehrgarh was a

momentous event. French research in this part of Baluchistan has continued, and this and other activities in this region may best be seen as the continuation of a long preoccupation in archaeological literature to understand Baluchistan as an intermediate zone between the Gulf, Central Asia, Iran, Afghanistan, and the Indus valley. In the Indus valley itself the antecedents of the Indus civilization have been highlighted by excavations at a number of sites, notably Kot Diji and Amri. The steady sequence of development toward the Indus civilization has been traced through the excavation of the dried-up drainage system of the Ghaggar-Hakra to the east of the Indus valley in Bahawalpur. R. Mughal's work in this area has revealed not only the largest agglomeration of mature Harappan sites in a single area but also the successively earlier Kot Diji/early Harappan and Hakra Ware phases, the last one possibly going back to the fifth millennium b.c. The ramifications of different protohistoric levels all over Pakistan constitute the general theme of archaeological investigations in Pakistan, and excavations at sites such as Rehman Dheri in the Gomal valley, Jalilpur near Multan in the Indus valley, Saraikhola near Rawalpindi, Lewan, and Tarakai Qila and Sheri Khan Tarakai in Bannu, have contributed to our understanding of the protohistoric cultural picture of the subcontinent. Among the classic sites Mohenjo Daro, excavated further between 1964 and 1965 with some interesting results, formed the subject of intensive ground surveys and structural documentation in recent years. Harappa has an ongoing phase of excavations with specific targets in the eastern part of the ancient city. In the area between Swat and Chitral a sequence from the third millennium b.c. has been established and is best known for the distinctive grave assemblage known as Gandhara Grave Culture. Prehistoric studies gained some prominence in recent years with the claim of 2-million-year-old artifacts at Riwat to the south of Rawalpindi, and there are other finds in the Sukkur-Rorhi hills. Among the universities, Peshawar has a full-fledged teaching program in archaeology, with one or two other universities following suit. In addition to the central government department of archaeology, there are government archaeology departments in each province of Pakistan.

India

Continuity of the pre-1947 Archaeological Survey of India is most obvious in India, partly because of the rich diversity of archaeological remains and partly because of a much greater number of archaeology-teaching universities than in the other nation-states. Indian archaeologists began where Mortimer Wheeler left off. The building up of vertical sequences and the widening of the dimension of what was already known were pursued with great vigor, which was commensurate with other spheres of national activity, such as laying the base of industrialization. Within about twenty-five years of independence Indian archaeology had undergone a sea-change in terms of activities. Before the nature of some of these activities is outlined, it is necessary to emphasize the somewhat-changed character of the relevant institutional focus. Whereas the old survey went on opening more “branches” and “circles,” now archaeology and museum directorates came up on state or provincial levels, each entrusted with the care of monuments and other archaeological activities within their own regional jurisdiction. In addition, from 1960 onwards a number of universities (twenty to twenty-five) began to offer postgraduate courses in archaeology leading up to master's and Ph.D. degrees in the subject. At about the same time, the Archaeological Survey of India began to run its own School of Archaeology for the training of university students and its own in-service officers. The universities that offered archaeology courses had usually their own excavation and exploration programs in the same way that the state departments ran their own field programs. A radiocarbon laboratory started functioning in the early 1960s. In the field of prehistory the initial cue was from the Terra-Paterson work mentioned earlier, and gradually the issues of prehistoric stratigraphy and geochronology came into focus. There was a great spurt in prehistoric discoveries, and in this field the survey was soon overtaken by the universities, where a new crop of Ph.D. students preferred to study regional prehistory and protohistory (*see* Sankalia 1974).

PREV NEXT

Stratigraphy and typology have formed the basic archaeological parameters of Indian prehistoric studies because that was what was needed first and because geoarchaeological techniques and the necessary adjunct of radiometric dating remain undeveloped. In view of this there is an increasing emphasis on the "settlement-subsistence" approach, based on modern analogies (Paddayya 1978; Murty 1985; Nagar and Misra 1989; Misra 1989) or on the amalgamation of prehistoric data in the long-term settlement history of a geographical region (Chakrabarti 1993). Fossil evidence does not extend beyond the Mesolithic except in one case where a skull cap, presumably associated with late Acheulean artifacts and found in the cliff section of the Narmada river in central India, has been interpreted either as an Asian variety of *Homo erectus* or as an archaic *Homo sapiens.* Some cultural details are available from the Upper Paleolithic but earlier primary occupation sites associated with organic remains are still to be discovered, and their climatic background also remains to be worked out on a pan-Indian level, some regional efforts notwithstanding (*see* Agrawal 1992).

In the field of protohistory the discovery of Indus civilization sites on a large scale within Indian territory was among the primary archaeological targets after Independence, and the rapidity with which the vast space of Gujarat, Rajasthan, Haryana, eastern Panjab, and western Uttar Pradesh came to be dotted with "Harappan" sites of early, mature, and late denomination is enviable by any standard of archaeological research (for maps, *see* Joshi, Bala, and Ram 1984). Major excavations of Harappan sites in modern India include those at Rupar, Lothal, Kalibangan, Surkotada, Banawali, and Dholavira, all undertaken by the archaeological survey. Another major breakthrough in this context has been the discovery of a late Harappan phase in Maharashtra and Malwa. The regional protohistoric data are ever increasing in quantity. All major agricultural regions of India have their protohistoric antecedents, and again the discovery of this horizon is among the bright spots of archaeological research since 1947 (*see* Sankalia 1974).

Discoveries of the historical period have been no less abundant, and there is now a much clearer appreciation of early historic and later India as parts of the cultural development with protohistory and prehistory at its roots. Both civic and religious sites have been identified and excavated all over the country.

Dimensions of Archaeological Research in the Third World: Examples from Modern India

In any global survey of the history of archaeological research it would be invidious not to draw a distinction between the contexts of this research in the First and Third Worlds. Archaeological literature unconsciously hides this distinction because, generally speaking, data from the Third World are discussed primarily on the basis of the work done in those areas by experts from the First World and published in First World languages. However well meaning such archaeologists and their publications are, they have taken upon themselves the task of interpreting the past heritage of a very large number of people who belong to various nation states and who may themselves like to interpret their own past. No understanding of the context of archaeological research in India can be meaningful unless it is put firmly in the context of the broader framework of archaeological research in the Third World done by Third World archaeologists themselves. If Third World archaeology is to go anywhere, it must first learn how not to imitate the fashions and jargons of First World archaeology, with which, for various historical reasons, it cannot cope satisfactorily anyway. It has to pose problems that are meaningful and necessary in its own contexts and that can be pursued and solved by its own resources. To begin with, it has to be vigorously empirical and at least try to reach a position in which the basic questions regarding the past of the nation concerned can be answered in a way that will be understood by most of the population.

One of the unifying features of Third World archaeology is that there is far less money to spend on conservation and archaeological research. This paucity of money is glaringly manifest in the general

absence of scientific analytical

Spain

The development of archaeology in the territory of the Spanish state has been marked by the long history (beginning in the fifteenth century) of that state's unity and by the discipline's strong dependence on state institutions. The latter factor enables us to link the general situation in Spain to the trajectory of archaeological practice in its various historical subdivisions (prehistoric, proto-historic, classical, medieval, American, Oriental). Thus, the history of Spanish archaeology can contribute to the debate on scientific neutrality by demonstrating the interdependence between science and society in a particular case.

The intellectual currents that marked Spanish archaeology's development are analogous to those in other European countries (Suarez Otero 1993, 331): (1) the antiquarianism and learning that largely inspired classical archaeology from the Renaissance to the nineteenth century; (2) the enlightened concern, linked with the natural sciences, with the antiquity of humanity and its early cultures that led to the origin of prehistoric archaeology in the last third of the nineteenth century, and (3) the ideologically motivated search for, and celebration of, national identity (Gilman 1988, 47-50) that influenced all archaeological practice-more specifically, medieval (Salvatierra 1990, 71-72) and proto-historic (Ruiz Zapatero 1993a, 40)-as well as Spanish archaeological research abroad. In all these instances, the goals of research shift from the universal to the particular.

Preliminaries: Antiquarianism from the Fifteenth to the Eighteenth Centuries

During the classical period and throughout the Middle Ages, there were treasures (war booty, votive offerings) but no collections (Barril 1993, 39-42), but in the fifteenth century, collections acquired a scientific and educational value linked to humanism. The Greek and Roman world, natural wonders, and objects brought from the New World were at the center of attention. In Spain, a prominent collector was Cardinal Mendoza, counselor to the Catholic kings.

In the sixteenth century, Charles I and Philip II encouraged collecting, so the duke of Villahermosa wrote a treatise on Roman religion based on Roman antiquities, and other courtiers opened their collections to scholars such as Lucio Marinero Siculo, Ambrosio de Morales, and Antonio Agustín (sometimes dubbed the "first Spanish archaeologists"). In the seventeenth century, connections with foreign scientific

circles to exchange, borrow, and acquire pieces became very important.

Those are the roots of eighteenth-century collecting. The monarchy and the enlightened aristocracy used archaeology to legitimize and give prestige to their power, to justify reforms (Mora 1991, 31), and to display and reinforce Spain's foreign image, which had been brought into question by other European powers.

This archaeology consisted of branches of classical erudition (epigraphy, numismatics, iconography, topography, mythology) that were secondary to literary sources. The monarchy created *gabinetes de antigüedades y de historia natural* ("cabinets of antiquities and natural history," which included archaeological remains), libraries, and academies. It financed archaeological excavations, scientific expeditions (Malaespina in 1789), and "literary journeys" inside the country itself. In addition, it gave legal protection

Spain

The development of archaeology in the territory of the Spanish state has been marked by the long history (beginning in the fifteenth century) of that state's unity and by the discipline's strong dependence on state institutions. The latter factor enables us to link the general situation in Spain to the trajectory of archaeological practice in its various historical subdivisions (prehistoric, proto-historic, classical, medieval, American, Oriental). Thus, the history of Spanish archaeology can contribute to the debate on scientific neutrality by demonstrating the interdependence between science and society in a particular case.

The intellectual currents that marked Spanish archaeology's development are analogous to those in other European countries (Suarez Otero 1993, 331): (1) the antiquarianism and learning that largely inspired classical archaeology from the Renaissance to the nineteenth century; (2) the enlightened concern, linked with the natural sciences, with the antiquity of humanity and its early cultures that led to the origin of prehistoric archaeology in the last third of the nineteenth century, and (3) the ideologically motivated search for, and celebration of, national identity (Gilman 1988, 47-50) that influenced all archaeological practice-more specifically, medieval (Salvatierra 1990, 71-72) and proto-historic (Ruiz Zapatero 1993a, 40)-as well as Spanish archaeological research abroad. In all these instances, the goals of research shift from the universal to the particular.

Preliminaries: Antiquarianism from the Fifteenth to the Eighteenth Centuries

During the classical period and throughout the Middle Ages, there were treasures (war booty, votive offerings) but no collections (Barril 1993, 39-42), but in the fifteenth century, collections acquired a scientific and educational value linked to humanism. The Greek and Roman world, natural wonders, and objects brought from the New World were at the center of attention. In Spain, a prominent collector was Cardinal Mendoza, counselor to the Catholic kings.

In the sixteenth century, Charles I and Philip II encouraged collecting, so the duke of Villahermosa wrote a treatise on Roman religion based on Roman antiquities, and other courtiers opened their collections to scholars such as Lucio Marinero Siculo, Ambrosio de Morales, and Antonio Agustín (sometimes dubbed the "first Spanish archaeologists"). In the seventeenth century, connections with foreign scientific

circles to exchange, borrow, and acquire pieces became very important.

Those are the roots of eighteenth-century collecting. The monarchy and the enlightened aristocracy used archaeology to legitimize and give prestige to their power, to justify reforms (Mora 1991, 31), and to display and reinforce Spain's foreign image, which had been brought into question by other European powers.

This archaeology consisted of branches of classical erudition (epigraphy, numismatics, iconography, topography, mythology) that were secondary to literary sources. The monarchy created *gabinetes de antigüedades y de historia natural* ("cabinets of antiquities and natural history," which included archaeological remains), libraries, and academies. It financed archaeological excavations, scientific expeditions (Malaespina in 1789), and "literary journeys" inside the country itself. In addition, it gave legal protection

to the country's antiquities. Some of these initiatives were in response to European educational thinking (Barril 1993, 44); others, to specific subjects, such as the study of the situation in the colonies or the defense of royal rights against the papacy (Mora 1991, 31).

The most prominent institutions were the private Sociedades de Amigos del País (Societies of Friends of the Country) and, among the public ones, the Real Academia de la Historia (Royal Academy of History, founded in 1738) the Real Academia de Bellas Artes de San Fernando (Royal Academy of Fine Arts of San Fernando, 1752), the Librería Publica (Public Library, 1716, the forerunner of la Biblioteca Nacional [National Library], which was founded in the nineteenth century), and the Gabinete de Historia Natural (Cabinet of Natural History, 1773), whose collections constitute the original nucleus of the present Museo Arqueológico Nacional, Museo Etnológico y Museo de America (National Museums of Archaeology, Ethnology, and the Americas).

The documentation and material preservation of archaeological monuments and finds were one of this period's great advances (Barril 1993, 45). Archaeological excavations were carried out to enlarge collections and to identify those ancient cities (Munda, Numantia, Segobriga, Saguntum) that had once contributed to the glory of the nation. In a sense, the appreciation of these ruins more for their aesthetic and picturesque than for their historical value prevented studies as broad as those that Charles III, as king of Naples, had sponsored at pompeii, herculaneum, and Stabia (Fernandez 1988, 384; Mora 1991, 32).

Beginnings of Scientific Archaeology

In the nineteenth century, archaeological research was carried out against a social background of civil and colonial wars and sharp conflict over the organization of the state. And it was carried out not by public sponsors, but by private initiatives. These initiatives, in the political and intellectual context of the times, were increasingly centered on local and national concerns. At the same time, isolation was broken by reading, contact with foreign researchers (Gran-Aymerich and Gran-Aymerich 1991), participation in international congresses (Ayarzaguena l99l, 69), and universal expositions (Barril 1993, 50). Basic to this broadening of outlook was the establishment of the Institución Libre de Enseñanza by Francisco Giner de los Rios in 1876 (Moure 1993, 206-207), which had the patriotic goal of understanding and renewing Spain. Against Catholic conservatism, it represented a secular and innovative attitude and sought to renew Spanish secondary and university education by encouraging studies abroad and receptivity to French, British, and German pedagogical approaches (Jutglar 1971, 148-153).

Scholarly and scientific societies (numismatic, archaeological, and so on) began to be established early in the nineteenth century, and their publications, generally local, played a fundamental role in the popular and scientific spread of culture and education. Some demanded the protection and recovery of ancient monuments (Salvatierra l990, 22); others participated in debates on evolution and prehistoric archaeology, topics censored until the Revolutionary Sexennium, a revolutionary period between 1868 and 1874 (Ayarzaguena 1991, 69). These initiatives, and those of booksellers, maintained the interest in knowledge of the past. The state sought to centralize that interest through institutions that would define a historic heritage common to the whole national territory: royal academies, museums, and (after 1900) universities, whose activities had hitherto been unimportant in the development of archaeology in Spain (Cortadella I Morral 1991, 161; Pasamar and Peiró 1991, 73).

The cabinets and royal academies were converted into public museums with ever more specialized collections. As a result of their participation in the *juntas cientifico-artisticas* (“scientific- artistic councils”) and the *comisiones de monumentos provinciales y central* (“provincial and central monuments commissions”) established to recover ecclesiastical properties after the disentailments

decreed between 1835 and 1843 (Barril 1993, 47), the royal academies widened their work of protecting and collecting the cultural heritage. The Academy of History likewise devoted its efforts to the promotion of archaeological

University of Barcelona was an exception (Pasamar and Peiró 1991, 75).

Research became institutionalized at the national, regional, and local levels and, for a brief time, abroad. The Junta para la Ampliación de Estudios e Investigaciones Científicas (Board for the Expansion of Study and Scientific Research, 1907) had among its missions the establishment of scientific exchanges abroad. It created the Escuela Española de Historia y Arqueología en Roma (Spanish School in Rome for History and Archaeology, 1910), which did not outlast World War I, and sections on Spanish archaeology both within the Centro de Estudios Históricos (Center for Historical Studies, 1910) and the Comisión de Investigaciones Paleontológicas y Prehistoricas (Commission for Paleontological and Prehistoric Research, 1912). The commission had prestigious members (the marquis of Cerralbo, the count of la Vega del Sella, Juan Cabre, Eduardo Hernandez Pacheco, Hugo Obermaier Grad, Paul Wernert) and collaborators (Pere Bosch Gimpera, Hubert Schmidt, henri breuil) and carried out a vast program of systematic research and publication. Its foundation was encouraged by research in the region of Cantabria financed by Prince Albert I of Monaco.

The Servei d'Investigacions Arqueologiques (Archaeological Investigation Service, 1915) of the Institut d'Estudis Catalans (Institute for Catalan Studies, 1907) was established as part of the program of cultural modernization advocated by the Catalan bourgeoisie first through the Mancomunitat and later through the Generalitat (Cebria, Muro, and Riu 1991, 83; Dupre and Rafels 1991, 175). As in the case of analogous services established by provinces (Valencia and Sevilla) and cities (such as Madrid), the service represented the culmination of a process started the century before by local scholars and naturalists.

French research in Spain also became institutionalized. On Pierre Paris's initiative, the Escuela Francesa de Arte y Arqueología (French School of Art and Archaeology), or Casa de Velazquez, was established in Madrid in 1928 (Gran-Aymerich and Gran-Aymerich 1991, 117). In turn, German archaeology's great influence in Spain arose as the result of training that important Spanish archaeologists received in Germany and of work in Spain by scholars such as Georg and Vera Leisner on megaliths; Adolph Schulten on proto-history; Hans Zeiss on funerary archaeology of the Visigothic period; and Helmut Schlunk, who later became the first director of the Madrid branch of the deutsches archäologisches institut (German Archaeological Institute), on late Roman and early medieval art and archaeology (Grunhagen 1979; Marcos 1993, 80).

As this period closed, only prehistory had succeeded in freeing itself from a philological and art-history perspective (Arce 1991, 209; Pasamar and Peiró 1991, 75; Rosello-Bordoy 1986, 8-9), which it had managed to do because of its empirical orientation and the national and international importance of discoveries in the Cantabrian region-altamira by Marcelino Sanz de Sautuola in 1879-and the southeastern part of the peninsula-Los Millares, El Argar, and Villaricos by Louis Siret (Moure 1993, 207-210). In general, field archaeology did not involve stratigraphic controls or a detailed register of data, but enough evidence was available to permit Bosch Gimpera to create the first great federalist synthesis of pre- and proto-history, *Etnología de la Península Iberica*, in 1932 (Ruiz Rodriguez 1993, 308; Ruiz Zapatero 1993b, 47-48).

Meanwhile, classical and medieval archaeologists were concerned not so much with research as with the restoration of cities, ecclesiastical buildings, and large Islamic architectural complexes (Salvatierra 1990, 40-49). All of this initial structuring of Spanish archaeology was truncated by the Civil War of 1936-1939.

Institutionalization of the 1950s and 1960s

The Franco regime suppressed centers of debate and institutions of regional self-government but maintained other organizations (the network of provincial museums, universities) once their memberships had been purged. Academic institutions were particularly affected; for example, Pere Bosch Gimpera and Jose Miguel de Barandiaran were exiled, and Leopoldo Torres Balbas was compelled to retire. In other instances, such as Martin Almagro Basch's

PREV NEXT

Prehistória (Institute of Spanish Prehistory, 1958) and the Instituto Rodrigo Caro (Rodrigo Caro Institute, 1951) of classical archaeology, directed by Martin Almagro Basch and Antonio Garclia Bellido, respectively. These are still the only institutions of the central government specifically dedicated to archaeological research, and their journals, *Trabajos de Prehistória* and *Archivo Español de Arqueología,* have become among the most important in their respective specialties. As this period ended, Spain had a centralized administrative infrastructure responsible for the growing number of sites of all periods throughout its territory, and meetings of specialists and numerous publications made known the state of research. Antonio Beltran organized the Archaeological Congresses of Southeast Spain, which began in 1946, became national congresses in 1949, and have met biennially since then. In turn, the less regularly scheduled Symposia for Peninsular Archaeology established by Juan Maluquer de Motes in 1959 have served as important points of reference.

Academic Expansion and the "Science of Archaeology" in the 1960s and 1970s

Spain's general development in the 1960s and 1970s had very positive consequences for archaeology, such as the expansion of university education as the first members of the baby boom of the 1950s and 1960s came of age and an increase in funding both for university personnel and for archaeological field and laboratory research. In contrast, theoretical and methodological debate was tardy and scanty, and the centralization of archaeological policy, tied to the interests of an elitist academic community, limited the discipline's social impact.

During this period, Spanish archaeological missions were sent to Central and South America (Anonymous 1987) and to the Sudan, Egypt, jordan, and Syria (Perez Die 1983). The importance of universities to Spanish archaeology was reinforced by the general increase in the number of students and professors and, toward the end of the period, by the creation of specialized degree programs in prehistory or prehistory and archaeology in the larger universities (Ruiz Zapatero 1993b, 51). Museums were revitalized formally and functionally as exhibits were remodeled and outreach programs were expanded. Martin Almagro Basch's directorship (1968-1981) of the National Museum of Archaeology exemplifies this pattern (Marcos 1993, 95). A very important monographic series, Excavaciones Arqueológicas en España, began to be published by the central government in 1962, and various university and museum journals appeared.

A strongly positivist research orientation characterized the first decade of this period, but at the end of the second, this orientation began to be questioned by a minority group of newly appointed university professors in Barcelona, Jaen, and Madrid. Fieldwork improved, with a better appreciation of stratigraphy and more detailed recording becoming prevalent. Prehistoric research increasingly (but other branches of archaeology only rarely) involved collaboration with the natural sciences. Meetings on scientific archaeology held in the late 1970s promoted the formation of the incipient Spanish infrastructure in this area (Chapa 1988, 137). In general, the role of biologists and archaeologists from Germany (M. Hopf, J. Boessneck, A. von der Driesch, E. Sangmeister, H. Schubart, W. Schule, W. Grunhagen, K. Raddatz, W. Hubener, T. Hauschild, H. Schlunk, T. Ulbert, Ch. Ewert) and France (Arlette and andré leroi-gourhan, françois bordes, C. Domergue) was decisive in these developments, as was North American research on the Paleolithic period (C. Howell, K. Butzer, and L.G. Freeman at Torralba, Ambrona, and Cueva Morin) (Moure 1993, 217).

Throughout this period, Spanish archaeology was centered on the prehistoric and classical periods, and medieval archaeology was included in the National Archaeological Congresses only from 1971 on (Rossello-Bordoy 1986, 8). Americanist archaeological research developed completely independently from Old World archaeology, as the Museum of the Americas, with its own premises (subject to long closures) as of 1965 (Cabello 1989, 51-52), did not encourage a convergence.

At the end of the 1970s, several factors led to a reconsideration of the disciplinary tradition and laid the groundwork for future debate. The editorial work of the members of the Departamento

de Antropología y Etnología Americanas (Department of American Anthropology and Ethnology) of the Complutense University of Madrid resulted in the publication of contributions on archaeological epistemology and European pre- and proto-history by lewis binford, C. Renfrew, and david clarke, and a new generation of archaeologists became aware of the enormous disproportion between the technical means of the discipline and the historical knowledge it had attained. At the same time, the increasing amount of radiocarbon dating demonstrated the inconsistencies of traditional archaeological chronologies and weakened the authority of the theoretical approaches they embodied (Vicent 1994, 219). Finally, the greater intellectual freedom resulting from the new political situation-the end of the Franco regime and the transition to democratic government, the great increase in the number of university students and professors, and the generational turnover among the latter-favored the development of attitudes critical toward academic authority, which was generally elitist and conservative (Riu 1992, 10; Vicent 1994, 220).

Decentralization and Popularizing of Archaeology in the 1980s and 1990s

The restoration of democracy and the approval of the new constitution of 1978 led to the decentralization of the state. From 1979 on, responsibility for archaeological policy began to be transferred to the seventeen autonomous communities into which Spain was divided. The important Ley de Patrimonio Histórico Español (Law on Spanish Historical Heritage, 1985) responded to this new political reality and established the framework for the archaeological legislation of the autonomous governments (Garcia Fernandez 1989). This process coincided with the high points of the country's liberalization: joining the Common Market in 1985 and joining the North Atlantic Treaty Organization in 1986.

The new organization of the state had a pervasive effect on archaeological activity. It produced large differences in regional policies with respect to the legal and administrative frameworks for archaeology, the available infrastructure, and the degree of governmental intervention. Generally, the management, protection, and conservation of archaeological heritage, such as surveys, mapping, cataloging and restoration projects, and emergency excavations (Jimeno, Recio, and Moreno 1993; *Jornadas* 1991), particularly in urban areas (*Arqueología* 1985; *Primeras jornadas de arqueología* 1983), have taken precedence over research as such (long-term excavations, analyses, dating, publications). Public financing has increased but has focused on the management of archaeology, with the new “contract” archaeologist being responsible for its execution (Querol et al. 1994).

At the same time, the academic world has lost its previous position of almost exclusive dominance, precisely at the time when the increasing specialization of archaeology by historical periods, research projects, and theoretical and methodological outlooks has diversified and increased archaeological activities and their financial cost. A solution to this paradox has been sought through increased participation by research centers and, above all, universities; in projects funded by regional governments; and by an increased appeal to private or other public patronage (bodies responsible for landscape planning and public works).

The teaching of prehistory and classical archaeology still receives most funding, and the two fields had 145 and 62 permanent professors, respectively, by the mid 1990s. The greater influence of prehistory is owing to its role in the discipline's methodological renewal. American and Oriental archaeology have not seen their limited presence in universities compensated for by the possible impact of archaeological expeditions abroad. Those expeditions are either sporadic and strongly dependent on Spanish foreign policy or are organized by the National Museum of Archaeology (Perez Die 1993), which (given the current trend toward decentralization) does not have the administrative structure and the resources required to achieve an impact.

Medieval archaeology has become increasingly important in terms of practice, but its academic presence continues to be small. The increased importance of urban archaeology has led to its scientific consolidation, an association

PREV NEXT

and other scientific disciplines more favored by governmental priorities. Foreign collaboration in part mitigates this problem. The whole of Spain has one thermoluminescence and three radiocarbon-dating laboratories, eleven teams working on paleobotany (mainly palynology), seven working on paleontology, and two devoted to archaeometallurgy. The majority of these specialists and specialist laboratories were established in order to serve regional research favored by the ongoing administrative decentralization.

The Future of Spanish Archaeology: The Challenge of Decentralization

Archaeology was an element in all of the nationalist claims to legitimacy made in Spain from 1800 to 1936. As in other European countries, the *españolista* ("Hispanicizing," a term used to refer to an identification between what is Spanish and what is Castilian, in the broad sense of claiming a single historical tradition for all the peoples of Spain) oligarchy and the various regional elites (especially in the Basque country and Catalonia) traced their national roots at least to the peoples that resisted the Roman conquest (Ruiz Zapatero 1993a). This archaeologically justified nationalism was reflected in the literature (Olmos 1992a) and in the plastic arts. Modern events presented in ancient guise were combined with direct allusions to events in antiquity so as to glorify either Hispanic or regional individuality.

Archaeological cultures were used quite differently in the construction of each national identity. Thus, the Vascones would have avoided a Roman occupation of the Basque country, creating a clear break between that region and the rest of the peninsula, as it had been completely Romanized (Dupla and Emborujo 1991). This notion could be combined with a claim for the homogeneity and continuity of the Basque people from the Paleolithic period on (Diaz Andreu 1993, 79; Rua 1990, 207-209). For its part, Spanish Hispanicist nationalism appealed to antiquity to reinforce ideas such as independence, liberty, and heroism and to the Middle Ages and the Renaissance to promote key concepts such as unity, religion, and monarchy (Quesada 1994, 39), in line with traditionalist historical thinking. This defense of the essential continuity of the Spanish as defined by Catholicism established a trajectory from the late empire to the Catholic kings and the Habsburg empire by way of the Christian "reconquest" of the peninsula from the Arabs by the fifteenth century (Salvatierra 1990, 72-73). Meanwhile, Catalans emphasized their Greek roots, using Ampurias as an emblem (Guitart and Riu 1989, 28).

The governments of the Second Republic (1931-1936) were attuned to decentralizing, federalist political goals and assisted in the institutionalization of nationalist (regionalist) archaeologies, the most successful program being the Catalan Generalitat's (Dupre and Rafels 1991, 175). The Franco uprising put a violent end to this process, and the regime that emerged from the Civil War was characterized by a centralism and Hispanicism (Diaz Andreu 1993) that disappeared only after the restoration of democracy in 1975. During the 1940s and 1950s, all the nineteenth-century historical clichés were revived, illustrated, and incorporated in the textbooks (Prieto 1979; Valls 1993), and all other nationalist (regionalist) manipulations of the archaeological record were prohibited. In the years of nationalist Hispanicist self-assertion, the Iberian Iron Age was repeatedly interpreted as a precedent for leadership by a caudillo and as the origin of essential Spanish traits that were still part of the folklore and supposed national character (Olmos 1992b, 10-12). This ideological policy was most important in the years immediately after World War II when the Franco regime was internationally isolated and striving for self-sufficiency. In the later Franco years, Spanish archaeology gave greater emphasis to technical issues.

The present regionalization of archaeology has not led to a direct return to the process of inventing regionalist traditions interrupted by the Civil War. Other factors are more important, although the lack of specific studies on the most recent period could occasionally leave any interpretation open to question. On the one hand, interest in the social history of Spanish archaeology is still in its infancy and mostly oriented toward the early periods of the discipline's

Spitsyn, Aleksander Andrevich

(1858-1931)

Aleksander Andrevich Spitsyn was one of the first archaeologists in russia to adopt the cartographic method of research, that is, comparing information from both historic and archaeological sources. He compiled and published systematized archaeological reviews of many Russian provinces, and his chronologies are still used today. He was primarily concerned with the Bronze Age, the Volga-Kama region, and Slavic peoples.

In 1892, he became an associate of the Archaeographic Commission, and in 1919, he joined the Russian Association for the History of Material Culture. At the Upper Paleolithic site of kostenki on the Don River in western Russia, the lowest level of Kostenki XVII, dating to about 40,00-32,000 b.p., was named "the Spitsyn culture" in his honor. It was characterized by burins, retouched blades and scrapers, and some bone tools and ornaments.

Tim Murray

St. Acheul

St. Acheul, the type site for the Acheulean, an early Paleolithic industry (dating roughly from 1.5 million years ago to about 100,000 years ago), was first identified in the Somme River gravels of northern france

near Amiens. The Acheulean stone tool industry has been found in sites in western and central Europe, over much of Africa, and in Asia as far east as India.

The area of St. Acheul has long been known as a source of flint tools. As early as 1854, stone tool finds were recorded in this area, and, consequently, in 1859, Albert Gaudry of the Académie des Sciences commented very favorably on Amiens as a locality for studying early human history. In recognition of this fact, in 1872 gabriel de mortillet named the distinctive industry based around biface hand-axes the Acheulean industry.

Stein, Sir (Mark) Aurel

(1862-1943)

Aurel Stein was born in Budapest. Educated there and in Dresden, Germany, and at the universities of Vienna and Leipzig, he received his Ph.D. in 1883 from the University of Tübingen, where he studied Persian and Indian archaeology. Between 1884 and 1887, he studied classical and oriental archaeology and languages at Oxford University and the British Museum, where he met, and was greatly influenced by, sir henry rawlinson.

Sir Aurel Stein

(Image Select)

In 1888, Stein traveled to India to become the principal of the Oriental College at Lahore and registrar for the Punjab University. For the next ten years he spent his vacations on antiquarian and geographical research in Kashmir in northern India and on the North-West Frontier (now northern Pakistan and eastern Afghanistan) and his spare time learning and translating Sanskrit. He became well connected with the civil and vice-regal establishment of British colonial India.

In 1900, with the support from Lord Curzon (the viceroy of India) and the Survey of India, Stein led his first expedition into central Asia, where he was to lead three more in 1906-1908, 1913-1916, and 1930. He took different routes each time to and from Turkistan, surveying, exploring, mapping, and excavating as he went. He traveled huge distances and brought back to India and England thousands of artifacts and, it is rumored, intelligence information for the British government. He became a naturalized British subject in 1904, and between 1910 and 1929 was directly employed by the Archaeological Survey of India. He was knighted in 1912. Stein's achievements were substantial-here was a whole area of the world that was unknown archaeologically, and its history was little known as well. Stein filled in this huge gap.

On his first expedition he explored the southern oases of the Taklamakan Desert, and at settlements in the Khotan region he discovered numerous documents in ancient Tibetan, Chinese, and Kharoshti. On the second expedition, he explored the dried-up Lop Sea bed and traced the long-used caravan route between china and the West by following the trail of Neolithic implements, metal objects, beads, and

ancient Han coins. He visited the watchtowers of the ancient Chinese frontier, and at the site of Miran in what is now Chinese Central Asia, which had been abandoned in the third century b.c., he found wall paintings of classical design. Stein's greatest find was not only the fabulous “Cave of the Thousand Buddhas” but the large

PREV NEXT

number of documents and temple paintings at the same site, which had been undisturbed since the eleventh century a.d.

Stein's third expedition completed his circuit of the Taklamakan Desert via Russian territory, and he traced the Silk Route to Samarkand, returning south through eastern Persia to Baluchistan. The difficult political situation in central Asia between the two world wars prevented the completion of his fourth trip-but he did manage to travel 2,000 miles around the Taklamakan once more. The scientific record of Stein's trips was published in *Ancient Khotan* (1907, 2 vols), *Serindia* (1921, 5 vols), *Innermost Asia* (1928, 4 vols), and *Memoir on Maps of Chinese Turkistan and Kansu* (1923), and his narrative accounts of the same appeared in *Sand-Buried Ruins of Khotan* (1903), *Ruins of Desert Cathay* (1912, 2 vols), and *The Thousand Buddhas* (1921).

Difficulties traveling in central Asia led Stein to travel in Baluchistan and Persia between 1927 and 1936 to explore the connections between the Indus Civilization, unearthed by sir john marshall in what is now Pakistan, and the civilizations of the Euphrates in the Near East. He discovered extensive Chalcolithic and Neolithic remains and published *Archaeological Reconnaissances in North-Western India and South-Eastern Iran* (1937) and *Old Routes of Western Iran* (1940). In 1929, with the help of the Royal Air Force, Stein had carried out an aerial survey of the Roman frontier in Iraq and the Jezira, and he investigated these finds on the ground and in detail between 1938 and 1939.

As a consequence of his travels throughout the Near East and central Asia, Stein became interested in searching for traces of Alexander the Great's eastern campaigns between 331 and 323 b.c. He had already found some evidence of Alexander in southwestern Persia near persepolis and in the Greco-Buddhist remains in the Swat Valley of northern Pakistan. In 1931, Stein traveled from Taxila east of the Indus River to the Jhelum River, where he located the site of the defeat of Poros and explained Alexander's tactics. In 1943, at the age of eighty, Stein's last expedition traced the retreat of Alexander's army through Baluchistan. He then went on to visit Kabul, in Afghanistan, where he died suddenly.

In many ways, Stein was the last of the great nineteenth-century explorers: physically tough, fearless, possessed of a brilliant intellect, a superb linguist, independent, and able to travel with only loyal and local colleagues and guides as companions. In other ways, he was unique in the breadth of his achievements. Stein was a nomad with no home base to speak of, and on his occasional visits to England he stayed at Corpus Christi College, Oxford. He never married, but he had many close friends and he supported relatives in Hungary after World War I. He left his estate to create the Stein-Arnold Fund to be used for the geographic and antiquarian exploration of central and southwestern Asia. He received the founder's gold medal from the Royal Geographical Society in 1904, the gold medal of the Royal Asiatic Society in 1932, that of the society of antiquaries of london in 1935, the Flinders Petrie Medal in 1928, the Huxley medallion, and honorary degrees from the universities of Oxford, Cambridge, and St. Andrews.

Steno, Nicolas

(1638-1686)

Born in Copenhagen, Nicolas Steno went to Amsterdam to study anatomy and became the physician of the grand duke of Florence, Ferdinand II, in 1665. Steno became interested in geology, and in 1669 he published a landmark geology book on basic crystallography in which he claimed that fossils were the remains of ancient living organisms and that many rocks were the result of sedimentation. He also proposed that the chronological history of the earth could be understood by studying the earth's strata (stratigraphy) and that landscape was the result of changes in the earth's crust. Although he believed that all of this change had occurred over a long time, he was restricted by religious dogma to only being able to estimate 6,000 years for the entire history of the earth.

Steno abandoned science and converted to Catholicism in 1667. He became a priest in

PREV NEXT

1667 and a bishop in 1677 and died in Schwerin in Germany. His discovery of the parotid salivary duct was named “Stensen's duct” for him, as is his work on the faces and angles of crystals, which is known as “Steno's law.”

Drawing by Nicholas Steno in 1671, illustrating his theory of how rock strata can fold and produce different formations

Stephens, John Lloyd

(1805-1852)

John Lloyd Stephens was born in New Jersey and studied classics at Columbia College, after which, in 1822, he studied law. He was a successful lawyer in New York City for eight years until ill health caused him to embark on a two-year voyage to the Mediterranean and eastern Europe. He began to publish accounts of his travels, which were so successful that he became known as “the American traveler.” He met and befriended the English architect and draftsman frederick catherwood and collaborated with him on *Incidents of Travel in Egypt, Arabia, Petraea, and the Holy Land* (1837) and *Incidents of Travel in Greece, Turkey, Russia, and Poland* (1838). Both books proved to be popular and made Stephens enough money to finance his first expedition to Central America.

In 1839, with personal recommendations from U.S. President Martin Van Buren and in the company of Catherwood, Stephens traveled to belize and then through the dense rainforest of the Yucatán to the site of Copán in western Honduras, which had to be cut out of the forest. He left Catherwood to draw the site and traveled on to guatemala and el salvador, then to costa rica and nicaragua, and then back to Guatemala where he again met up with Catherwood. Together they traveled to mexico under difficult and dangerous circumstances via palenque, a classic Maya site in Chiapas, and visited the ancient city of Uxmal. By this point, the health of both was dire and they were carried on stretchers to the boat back to New York. The resulting book, *Incidents of Travel in Central America, Chiapas, and Yucatan* (1841, 2 vols.), with text by Stephens and illustrations by Catherwood, became a best-seller.

Although Stephens was no archaeologist, he had seen enough archaeological monuments in Egypt, the Near East, and eastern Europe to understand that the New World sites were astounding and rivaled Old World sites in their artistic achievements. He was more than able to convey their power and significance and his own excitement, and his books attracted great interest in the United States.

In late 1841, Stephens and Catherwood returned to Uxmal to finish their work by taking new daguerreotypes, and they then visited the site of chichén itzá. Once again, they had to clear a site in order to survey it. After Chichén Itzá it was on to Cozumel and Tulum before returning to New York where the two men published another book, *Incidents of Travel in Yucatán* (1843).

Stephens became the promoter and director of a steamship company and then became involved in building railways. Between 1849 and 1851 he helped to survey and prepare for the construction of the Panama railway, where the malaria he had caught during his earlier explorations flared up again and forced him to return in 1852 to New York City, where he died.

Tim Murray

Steward, Julian

(1902-1972)

Born in Washington, D.C., Julian Steward studied zoology and geology at Cornell University. He completed a Ph.D. in anthropology in 1929 at the University of California, Berkeley, and then worked for the Bureau of American Ethnology at the smithsonian institution.

Steward began his ethnographic career among the western Shoshone Indians, one of the most simple of societies, and moved on to study complex cultures such as those in Puerto Rico. By the end of his career he was managing a cross-cultural, worldwide inquiry into the modernization of peasant societies. In 1943, he became director of the Smithsonian's Institute of Social Anthropology; from 1946 to 1952, he was professor of anthropology at Columbia University; and from 1952 until he retired in 1970, he was professor of anthropology at the University of Illinois.

Steward is best known for his theories about “cultural ecology,” which held that a society's environmental resources and available technology determine the kinds of labor used by them and, consequently, inform their entire social system-an ecological, neo-evolutionist, and materialist view of human behavior. He formulated a theory of “multilinear evolution,” which described the ways in which societies progress toward greater complexity.

He was one of the few ethnologists of his time who was interested in archaeological data and its potential for contributing to the study of human behavior over long periods of time, and he had a great impact on the development of archaeology in the United States after World War II. He taught and supported a number of archaeologists, such as robert braidwood and Richard MacNeish, who undertook pioneering multidisciplinary research programs into the origins of food production in the Near East and mesoamerica . And he inspired many others, such as gordon willey, who initiated the use of settlement archaeology in the virú valley in peru.

Stična

Stična (or Vir pri Sticni or Stiski cvinger, as it is also called) is an early-Iron Age site in lower Carniola, in slovenia, a center for the Dolenjska (lower Carniola) group of the Hallstatt culture. The hill-fort type of settlement covers an area of more than 21 hectares.

The settlement was intensively excavated between 1967 and 1974 by stane gabrovec and several other collaborators. The excavations were limited to the hill-fort ramparts and revealed three main early-Iron Age occupation phases (contemporary with the nearby barrow cemetery) and a late-la tène phase. The cemetery was partly excavated during the twentieth century by the duchess of Mecklenburg (1905-1914), rajko lozar (1936), jožef kastelic (1946, 1952- 1953), and Gabrovec (1960-1964).

The burial rites are almost exclusively inhumations in earthen barrows. Approximately 125 barrows were documented in an area approximately 15 to 50 meters in diameter. The number of inhumations in a barrow varies from a few graves (e.g., in Mecklenburg's Glogovica barrow, 3 graves) to more than 150 graves (e.g., barrow 48 has 183 graves). On average there are 20-30 graves per barrow.

In late 1841, Stephens and Catherwood returned to Uxmal to finish their work by taking new daguerreotypes, and they then visited the site of chichén itzá. Once again, they had to clear a site in order to survey it. Stična

Stična (or Vir pri Sticni or Stiski cvinger, as it is also called) is an early-Iron Age site in lower Carniola, in slovenia, a center for the Dolenjska (lower Carniola) group of the Hallstatt culture. The hill-fort type of settlement covers an area of more than 21 hectares.

The settlement was intensively excavated between 1967 and 1974 by stane gabrovec and several other collaborators. The excavations were limited to the hill-fort ramparts and revealed three main early-Iron Age occupation phases (contemporary with the nearby barrow cemetery) and a late-la tène phase. The cemetery was partly excavated during the twentieth century by the duchess of Mecklenburg (1905-1914), rajko lozar (1936), jožef kastelic (1946, 1952- 1953), and Gabrovec (1960-1964).

The burial rites are almost exclusively inhumations in earthen barrows. Approximately 125 barrows were documented in an area approximately 15 to 50 meters in diameter. The number of inhumations in a barrow varies from a few graves (e.g., in Mecklenburg's Glogovica barrow, 3 graves) to more than 150 graves (e.g., barrow 48 has 183 graves). On average there are 20-30 graves per barrow.

The cemetery covers the period between the eighth and fourth centuries b.c. The graves vary considerably in the amount of grave goods they contain, from very poor graves to warrior graves containing weaponry (mostly axes and spears) to so-called princely graves containing body armor, helmets, weapons, horse-riding equipment, decorated bronze vessels *(situlae),* buckets, and great quantities of personal ornaments and ceramic vessels. Grave goods, especially those imported from or influenced by the Etruscan culture, indicate a distinguished and well-stratified community with very rich individuals at the top that flourished between the seventh and fifth centuries b.c.

Stone, Doris Zemurray

(1909-)

Doris Stone was one of the pioneers of Central American archaeology. She was educated at Radcliffe College and conducted fieldwork in Honduras and costa rica while she was research associate for the Middle American Research Institute of Tulane University and for the peabody museum, Harvard University.

Born the daughter of Samuel Zemurray, an early developer of the banana trade in Central America, Stone spent parts of her formative years in Honduras and Costa Rica. As an undergraduate at Radcliffe College, she was able to attend classes offered by Alfred M. Tozzer, Harvard's specialist in Mayan archaeology. She was not encouraged to continue studying archaeology after receiving her undergraduate degree in 1930 and returned to New Orleans, her home town.

Stephen Williams (1986) identifies an unpublished study of Ulua Valley figurines that was filed at Tulane University in 1930 as Stone's earliest known written work. In that same year, she donated a pottery figurine found near La Lima, Honduras, to Harvard's Peabody Museum. Williams speculates that the figurine paper was completed for Tozzer's senior research course. The date of the manuscript makes this theory plausible, but there is no sign of it in Tozzer's papers, now in the archives of the Peabody Museum, or in the manuscript holdings of the Tozzer Library at Harvard University. It was not until much later that Stone was actively encouraged by Tozzer. Her early research was sponsored by the Middle American Research Institute (MARI) at Tulane University, of which her father was a supporter, and she was appointed an associate there in 1930. By 1934, she was publishing field reports based on her own work in Honduras in the MARI-affiliated journal, *Maya Research.* MARI also published her landmark comparative study of the Ulua marble vases (Stone 1938) that was based on collections in multiple institutions, including both MARI and the Peabody Museum.

When Honduran archaeology received renewed attention during the 1930s, Stone, already in the country, was instrumental in encouraging the interests of first MARI and later the Peabody Museum. Stone's own approach centered on identifying linguistic groups described in the sixteenth century with archaeological remains, which encountered some resistance on the part of the director of the Peabody's

Honduran expedition, william duncan strong. Despite the reservations of Harvard archaeologists about Stone, which is well documented in Tozzer's correspondence at the Peabody, by the end of the 1930s she had established herself as an authority on Honduran archaeology. Although Tozzer, in his "Foreword" to her first monograph on Honduran archaeology, went so far as to state that "her indefatigable energy, her enthusiasms and her intuitive impressions have, at times, been handicaps" (Stone 1941, v), he acknowledged that the handicaps he ascribed to her "have all contributed to the ultimate success of her work." He cited as the foundation of her strength as an authority on Honduran archaeology Stone's laboring "for long periods and in all possible seasons" in the country. The same claim to authority was featured by Stephen Williams in his introduction to her general study of Central American archaeology: "her numerous journeys on mule

Stone downplays the difficulties she faced as a woman in archaeology, she has been a significant benefactor of women in academia, endowing a tenured position at Harvard and supporting Radcliffe's research centers, and thus ensuring others opportunities she did not have herself.

Strong, William Duncan

(1899-1962)

Born in Portland, Oregon, William Duncan Strong became a major figure in U.S. anthropology, distinguished in archaeological research as a theorist and as a teacher. After serving in the U.S. Navy in World War I, he went to the University of California, Berkeley, and received his B.A. in 1923. From an early interest in natural history he turned to anthropology as a result of the influence of Alfred A. Kroeber, with whom he worked on material excavated in peru many years earlier by max uhle. Strong's 1926 Ph.D. dissertation, "An Analysis of Southwestern Society," combined archaeological and ethnological data on the house-lineage-fetish complex.

He joined the staff of the Field Museum of Natural History in 1926 and took part in a fifteen-month

expedition to Labrador where he spent a winter living with and studying the Naskapi Indians. In 1929, he moved to the University of Nebraska and began two years of archaeological research that completely revised the prehistory of the Great Plains. Instead of the mounted bison hunters of historic times being preceded only by nomads hunting and foraging on foot, he showed that there had been a long period of settled farming villages. Strong also excelled as a teacher, especially in informal, work-related settings, and several of his students at Nebraska went on to have distinguished careers in anthropology.

From 1931 to 1937, Strong was a member of the Bureau of American Ethnology of the smithsonian institution and began archaeological research in Honduras. Like the Great Plains, this was a relatively neglected area, and he quickly identified key problems and laid the foundations for answers, particularly by establishing a firmer chronology of past occupations.

After Strong was appointed to the anthropology faculty of Columbia University in 1937, he turned again to Peruvian archaeology. In 1941, he headed one of ten field parties, under the sponsorship of the Institute for Andean Research, in a program of survey and stratigraphic excavation in lesser-known areas of Latin America. He worked at Pachacamac on the coast of Peru with gordon willey and John Corbett as student assistants. When he published the results

of all ten field parties in 1943, he included a tabular presentation of cultural sequences for twenty regions from the United States to chile, aligned to permit continentwide comparisons of cultural development. This and later comparative studies by Strong reflect the change taking place in U.S. archaeology, with emphasis being placed on functional interpretations rather than local chronological sequences.

During World War II, Strong directed a new federal Ethnogeographic Board, which provided the military with information from anthropological sources on little-known parts of the world. In 1945, he returned to his teaching at Columbia, and he was in the field in Peru again the next year with the viru valley program, a combined geographical, ethnographic, and archaeological study of a single Peruvian valley. It was a landmark in coordinated research and in introducing new concepts and improved chronology. His last work in Peru was in 1952.

Strong's career was cut short by his sudden death. His research combined the details of ceramic sequences with hemispheric comparative studies, and he was influential in moving archaeology toward greater concern with cultural growth and change.

Stukeley, William

(1687-1765)

William Stukeley can be regarded as the last of the great English antiquarians and the first of that country's reliable archaeologists. He was born in Lincolnshire, England, the son of a country lawyer and attended Cambridge University from 1704 to 1709. He then moved to London to train as a doctor and later practiced medicine in Boston, Lincolnshire. From 1710 until 1725, he undertook an annual antiquarian tour on horseback to different parts of England viewing churches, abbeys, remarkable buildings and gardens, and sites of historic interest. A competent draftsman, he made many drawings on these tours, and these were published in 1724 in a well-illustrated volume, *Itinerarium Curiosum* [List of Curiosities].

William Stukeley

(Science Photo)

Stukeley returned to London in 1717 and became the secretary of the newly revived society of antiquaries of london. He became interested in stone circles and their association with the Druids after reading a copy of john aubrey's *Monumenta Britannica.* For the next few years, he applied himself to elucidating the many problems raised by megalithic monuments, effectively advancing the work that Aubrey had begun. He gathered notes on circles and allied monuments from all over the British Isles and undertook intensive fieldwork on the two major sites of Stonehenge and avebury in Wiltshire. His work at Avebury was especially valuable because the local landowner had begun its wanton destruction, breaking up the great stones for building materials and lime. Without Stukeley's meticulous record of the location of every stone, and his perceptive tracing of depressions and contours, current knowledge of

the monument would be greatly reduced.

Similarly, Stukeley carried out intensive fieldwork at Stonehenge over the same period.

He was able to identify that the stone circle was part of a much larger site comprising avenues and ditches and an earthwork enclosure. He was also the first to notice the significance of the orientation of Stonehenge and its potential astrological significance. Stukeley and his patron and friend, the earl of Pembroke, engaged in some limited excavations within the stone circle and learned that the monoliths had been levered into holes in the solid chalk floor of the plain and then packed in with flints for stability.

Accurate measurement, precise draftsmanship, intelligent understanding of the relationship of monuments to landscape, and an ability to make rewarding comparisons with similar sites and structures-all of these qualities made Stukeley a pioneer in field archaeology. He became a minister of the church in 1726 and gave up field archaeology to work on his books *Stonehenge* (1740) and *Avebury* (1743). His record of the sites as they stood in the early-eighteenth century were invaluable to archaeologists of the twentieth century.

Su Bingqi

(1909-1997)

Su Bingqi was the major archaeological theoretician in the People's Republic of china. Born in Gaoyang (Hebei Province), he graduated from Beiping Normal University in 1934 and then worked at the Society (after 1936, the Institute) for Historical Studies of the National Beiping Academy. As an assistant to the historian Xu Xusheng (Xu Bingchang, 1888-1976), who sought to substantiate archaeologically the then-novel theory that China's early dynasties each had different ethnic origins, Su had his first taste of fieldwork when he participated in excavations at Doujitai, Baoji (Shaanxi Province) in 1934-1937. After the academy had relocated to Kunming in Yunnan Province in southern China during World War II, Su wrote an archaeological report on the Doujitai tombs (published in 1948), applying the method of Swedish archaeologist oscar montelius in his meticulous typological analysis of ceramic vessels.

After the Communist takeover in 1949, the Beiping Academy was dissolved. In 1950, both Su and his teacher Xu Xusheng were appointed research fellows at the newly founded Institute of Archaeology of the Chinese Academy of Sciences (since 1977, the Chinese Academy of Social Sciences) in Beijing. Su participated for a time in the institute's fieldwork, and his chronology of late Zhou tombs at Luoyang (Henan Province), excavated in 1955, was long followed as the standard yardstick for cross-dating finds from all over China.

In 1952, Su was appointed professor in the History Department of Beijing University, where he founded mainland China's first academic archaeology program. He served as the program's chair until 1983, simultaneously maintaining his position at the Institute of Archaeology. In 1958, students targeted Su in their criticism of archaeology, which they found insufficiently concerned with real people and society. This spurred Su to conceptualize a new system for the study of prehistoric cultures, enriched with elements of Marxist social theory and an analysis of historical texts. The resulting “Chinese school of archaeology,” tailor-made to accommodate the characteristics of Chinese history as well as contemporary political strictures, became widely influential.

Leading his students in excavations at Neolithic sites in Shaanxi Province in 1958-1959, Su first applied

Montelian principles in working out the filiation of chronological and regional phases of the Yangshao culture. He subsequently worked out a general theory of simultaneously developing and interacting regional networks and sequences of cultures from which the Chinese civilization gradually emerged. In the 1980s and 1990s, Su traveled widely across China to inspect Neolithic and early-Bronze Age finds, refining and expanding this grand framework.

During the Cultural Revolution (1966- 1976), Su was subjected to criticism and sent to perform manual labor in the countryside (1970-1972). Marginalized at the Institute of Archaeology because of differences with its

PREV NEXT

director, xia nai, Su developed an independent power base with his former Beijing University students, many of whom came to occupy important positions in the provinces. As provincial-level archaeology became increasingly important in the course of China's economic reforms, their adoption of Su's ideas have shaped a new, regionalist discourse in Chinese archaeology.

Sumerians

The Sumerians were the first recorded occupants of the southern half of mesopotamia; the northern half of this region was referred to as Akkad, with the line of demarcation at Nippur. Famous as the earliest literate society, the Sumerians were unknown until the decipherment of the cuneiform tablets in the nineteenth century revealed the existence of a language (Sumerian) that predated the languages of the Babylonians and Assyrians (which were related to Akkadian, the language of the people of Akkad). The Sumerians are thought to have migrated from the mountains of Elam, almost certainly before the fourth millennium b.c., to the swamps at the head of the Persian Gulf. They drained the swamps, developed means of using floodwaters for irrigation, and established agriculture in the region. Agricultural surpluses became a basis of Sumerian wealth and underpinned intensive participation in long-distance trade as far east as the Indus Valley. Although the Sumerians influenced areas far outside their borders in southern Mesopotamia (certainly through the use of writing), the core of the culture lay in the great city-states such ur, Eridu, Lagash, Larsa, Nippur, and Uruk, which were often at war with each other. Notwithstanding shared language and strong cultural and religious ties, political volatility and instability were common threads through Sumerian history at least until the sacking of Ur in 2004 b.c.

Swahili Coast of Africa

Introduction

The Swahili towns on the East African coast have attracted the attention of scholars for many years. Colonial accounts of the origins of this widespread complex of sites, with visible architectural features comprising tombs, mosques, and palaces and substantial subsurface deposits, underplayed the indigenous contribution to the growth and development of the Swahili civilization. Recent archaeological and historical scholarship has gone some way toward reestablishing the urban identity of the peoples of the coast, and the Swahili are now recognized as centrally important in the western Indian Ocean system linking the Middle East, India, and the far interior of Africa.

The great majority of Swahili settlements and towns along the East African coast are found in a narrow coastal strip of sandy soils that support the Zanzibar-Inhambane vegetational mosaic (White 1983). In the northern zone, the Somali-Maasai mosaic provides a dry hinterland that is most suited to herding and hunting while to the south, the vast Zambezian forested areas provide resources for mixed agriculture and hunting and, of course, gold on the Zimbabwean plateau. The offshore island archipelago of the Comoros, which is partly volcanic, and northwestern madagascar, with its sheltered bays and richly forested interior, provide substantial opportunities for subsistence, trade, and urban development.

Hafun, near the Horn, which dates from the early centuries b.c. to about a.d. 200, is the earliest trading site yet located on the East African coast (Smith and Wright 1988)-quite possibly, it was one of the entrepôts mentioned in the Periplus of the Erythraean Sea (a document written ca. a.d. 50 in Greek and Egyptian, author unknown, describing contact with East Africa). Southward, the coastal zone is punctuated by a series of important rivers that provide access to the interior and often have trading sites at their mouths. The earliest town site in eastern Africa, that of Rhapta (known from the Periplus), has still not been located, but it was perhaps situated in the Rufiji delta where finds of early trade goods dated approximately 200 b.c.-a.d. 200 have been recently located by Felix Chami.

The existence of a town at that time might presuppose a settlement hierarchy of early farming community sites. Sites of the Kwale Matola tradition dating from the b.c.-a.d. transition to ca. a.d.400 are known to have existed in a great distributional swath along the coastal hinterland from Kenya down to southern Mozambique and into South Africa (Sinclair 1987; Soper 1971). The possibility that these early sites of

iron-using farmers constituted a prestate settlement system

were not displayed until after World War II.

Swahili Coast of Africa

Introduction

The Swahili towns on the East African coast have attracted the attention of scholars for many years. Colonial accounts of the origins of this widespread complex of sites, with visible architectural features comprising tombs, mosques, and palaces and substantial subsurface deposits, underplayed the indigenous contribution to the growth and development of the Swahili civilization. Recent archaeological and historical scholarship has gone some way toward reestablishing the urban identity of the peoples of the coast, and the Swahili are now recognized as centrally important in the western Indian Ocean system linking the Middle East, India, and the far interior of Africa.

The great majority of Swahili settlements and towns along the East African coast are found in a narrow coastal strip of sandy soils that support the Zanzibar-Inhambane vegetational mosaic (White 1983). In the northern zone, the Somali-Maasai mosaic provides a dry hinterland that is most suited to herding and hunting while to the south, the vast Zambezian forested areas provide resources for mixed agriculture and hunting and, of course, gold on the Zimbabwean plateau. The offshore island archipelago of the Comoros, which is partly volcanic, and northwestern madagascar, with its sheltered bays and richly forested interior, provide substantial opportunities for subsistence, trade, and urban development.

Hafun, near the Horn, which dates from the early centuries b.c. to about a.d. 200, is the earliest trading site yet located on the East African coast (Smith and Wright 1988)-quite possibly, it was one of the entrepôts mentioned in the Periplus of the Erythraean Sea (a document written ca. a.d. 50 in Greek and Egyptian, author unknown, describing contact with East Africa). Southward, the coastal zone is punctuated by a series of important rivers that provide access to the interior and often have trading sites at their mouths. The earliest town site in eastern Africa, that of Rhapta (known from the Periplus), has still not been located, but it was perhaps situated in the Rufiji delta where finds of early trade goods dated approximately 200 b.c.-a.d. 200 have been recently located by Felix Chami.

The existence of a town at that time might presuppose a settlement hierarchy of early farming community sites. Sites of the Kwale Matola tradition dating from the b.c.-a.d. transition to ca. a.d.400 are known to have existed in a great distributional swath along the coastal hinterland from Kenya down to southern Mozambique and into South Africa (Sinclair 1987; Soper 1971). The possibility that these early sites of

iron-using farmers constituted a prestate settlement system

is widely accepted and increasingly they are also believed to have had the potential to have undergone an urban transformation.

Archaeology on the East African coast from the 1950s through the 1970s was concerned mainly with visible architectural remains. The tombs, temples, and palaces of the Swahili coast were located stratigraphically through archaeological excavation, chronologically by using imported ceramics, and architecturally in relation to better known building styles from the Middle East and India. These often very impressive scholarly efforts were strongly influenced by colonial ideology, which tended toward invasionist interpretations based on ethnic definitions expressed in terms of "Africans," "Arabs," or "Austronesians" and often underestimated the creativity of the indigenous peoples of the coast. The limited excavations on the Kenyan coast of stone buildings of "the Arab city of Gedi" and Ungwana (Kirkman 1954, 1966) were superseded by investigations of the Portuguese Fort Jesus in Mombasa (Kirkman 1974) and extensive excavations of the mosque and palace complexes at the major urban site of Kilwa on the southern Tanzanian coast (Chittick 1974).

In the 1980s, extensive archaeological excavations by Chittick (1984) at Manda in the Lamu archipelago off the east coast of Kenya were followed by excavations at Takwa, a site off the coast in an archipelago (Wilson 1980; Wilson and Omar 1996, 1997). Detailed stratigraphic excavations by M. Horton (1996) at Shanga in the same archipelago provided fine resolution chronological sequences and spatial layout of mosque construction and house forms. G. Abungu (1989), working at Ungwana, extended previous work by J.S. Kirkman (1966) and followed the settlement pattern inland up the river Tana. Work at Pate (located again in the same archipelago) by T. Wilson and A.L. Omar (1996, 1997) produced new insights into urban structure.

On the southern Kenyan coast, work by Wilding and later by C. Kusimba (1996) at Mtwapa was carried out in conjunction with investigations at Mombasa. First steps to investigate the role of symbolic values in shaping architectural features, especially Swahili houses, were implemented by L.W. Donelly (1982) on the Kenyan coast. This cognitive approach was extended to the settlement level by S. Kus (1982) in highland Madagascar.

The central coast of Tanzania has been the focus of numerous recent excavations, notably those by Felix Chami of the University of Dar es Salaam, which have transformed our view of the first millennium a.d. chronology and external trading contacts of the early farming communities of this area (Chami 1994, 1998). On Zanzibar and Pemba, a series of surveys focused on stone-built sites have been carried out and followed by excavations (e.g., Clark and Horton 1985; Juma 1996; La Violette and Fleisher 1995). Recent excavations at Unguja Ukuu on Zanzibar have demonstrated trading contact with Roman Egypt as early as the mid-fifth century a.d. (Horton 1996; Juma 1996).

By the eleventh century, the Swahili settlements extended more than 3,000 kilometers along the coastal strip from Somalia to Mozambique, and more than 400 sites were occupied before the sixteenth century (Horton 1987). The settlement system also encompassed the Comoros and the northwestern coast of Madagascar (Vérin 1986, Wright 1984), which were important foci of East African urban development from at least the ninth century a.d. on. The subsistence economy was based on hunting, fishing, cultivation, and livestock and included pottery and ironworking. Trade commodities included slaves, ivory, salt, rock crystal, animal skins, and cloth as well as iron and also gold from the south.

The earliest architectural evidence for the adoption of Islam from the latter first millennium a.d. comes from Shanga in the Lamu archipelago (Horton 1996) and early mosque construction at Sima in the Comorian archipelago. The 1100s and 1200s a.d. saw the widespread adoption of Islam, and this period is marked by a marked increase in settlement area (Wright 1993).

On the Comoro Islands, small fishing and farming communities were established in the late first millennium a.d. (Allibert, Argant, and Argant

1990; Wright 1984), and they maintained trading contact with the East African coast. Early settlements with stone mosques, for example, at Sima on Anjouan, developed into a network of stone-built trading towns. In northwestern Madagascar, traces of human activity occur from ca. a.d. 770.

A number of settlements were established, and these were at first called trading *échelles* by Pierre Vérin (1986) and later discussed in terms of being towns and city-states or part of larger states (Vérin 1992). At Mahilaka in Ampisindava Bay, one such settlement, established ca. a.d. 900, grew to be a large walled town greater than twenty hectares in extent in the thirteenth and fourteenth centuries. Mahilaka maintained extensive trading contacts and had an estimated population of 3,500 before it declined in the fifteenth century (Radimilahy 1998).

The Southern Swahili Coast

Far to the south, in Mozambique, a series of publications concerning work on Portuguese remains on the Sofala coast was produced by, among others, G. Liesegang (1972) and L. Barradas (1967). Further north, a number of Swahili towns and settlements have been recognized, particularly in the Querimba archipelago at Ilha de Mocambique, near Nacala (Duarte 1993), and at Angoche. Farming community sites of the coastal area and interior of Nampula have been extensively investigated, particularly by Adamowicz (Sinclair et al. 1993).

In Vilanculos Bay, the Bazaruto Islands provided safe settlement locations, such as at Ponta Dundo, while on the mainland, where the River Govuro runs parallel to the coast, a settlement and trading entrepôt developed at Chibuene. From at least about a.d. 650, Chibuene maintained contacts deep into the interior, furnishing imported pottery and glass beads from the Persian Gulf as far as Palapye in eastern Botswana and there is evidence of extensive ironworking activities at Chibuene (Kiyaga Mulindwa 1992; Sinclair 1982, 1987). Later, the settlements along the Mozambique coast played an important role in linking the states of the Zimbabwean plateau with Kilwa and other Swahili trading cities.

The Swahili settlements were established initially as small local farming and fishing villages at a number of different places along the coast and the offshore islands. With the growth of overseas trade and the consolidation of internal production sectors, they underwent major expansion until they culminated in the Muslim towns of the fourteenth and fifteenth centuries. Although most settlements remained small villages, several towns expanded greatly in size and population. The larger towns exceeded ten hectares and had buildings of coral rag stone and wood-and-daub houses. Examples of classic Swahili cut coral architecture are best known from spectacular major sites such as Kilwa and Gedi, but they occur more widely. The settlements were small by modern standards, and even at their peak, in the fifteenth century, few were larger than twenty hectares. Their populations must have been small; for example, in the fourteenth century, the important town of Shanga had 220 masonry houses within seven hectares and an estimated population of 3,000 (Horton 1996, 58).

The main towns developed into city-states and had very little political control over their hinterlands. These major towns, from the Lamu archipelago, Ungwana on Tana, Malindi, Gedi, Mombasa, and Tongoni, as well as the towns on the southern Tanzanian coast and islands of Zanzibar and Pemba, represented larger population centers on a quite densely populated coast with numerous smaller villages in between. Initial investigations of parameters of settlement location and a spatial analysis of settlement size by J. De V. Allen (1980) and T. Wilson (1982) established a site hierarchy, which is still in use today, consisting of isolated structures, hamlets, and small settlements of less than 2.5 hectares; medium-sized sites occupying about 2.5 to 5 hectares; larger stone town sites 5-15 hectares in size; and town sites greater than 15 hectares. The Comoros apparently had similar urban networks, and in northern Madagascar, at least one of the coastal settlements, Mahilaka, grew into a large, walled urban

settlement with extensive trading contacts with other parts of the western Indian Ocean system.

Current Issues

In general, controlled stratigraphic excavations at major settlements on the East African coast, dated by imported ceramics, go some way toward providing a general framework for stone town urban development. They still fall short, however, of providing clear estimates of the volume and spatial extent of nonstone-built residential areas and the relation of the country towns to the archaeologically better known stone towns, for example, Shanga (Horton 1996). The recognition of clusters of coastal settlements, for example, by Abungu (1998), points to the need for a detailed investigation of an area larger than an individual site. The need is to establish the contemporary size and spatial layout of the sites that made up the settlement clusters, which might provide significant insights into subsistence, craft specialization, and the political organization of the Swahili city-states.

Trade and Urban Development

Interregional trade knowledge, which is often based on evidence of imported ceramics, has been seen as fundamental for the growth of towns in East Africa (Horton 1987; Kusimba 1999; Middleton 1992; Wright 1993). The limited concept of "the Swahili corridor" as a conduit of trade has been expanded with the recognition of a lattice of trading hubs linking the offshore islands and the East African coast extending far into the various interiors (Sinclair 1995). Wilson (1982) pointed out that Swahili town sites were situated, not only to facilitate trade, but also in terms of local agricultural potential. The distinction between coast and interior has begun to crumble with the progress of historical and archaeological research that focuses on local production and exchange (Haaland 1994-1995; Horton and Mudida 1993; Kusimba 1993; Mutoro 1998; Radimilahy 1998; Wright 1984). New methods of retrieval of evidence from archaeological excavations and computer-aided remote-sensing applications such as geographic information systems (GIS) are being developed to better address these issues.

Socioeconomic and Political Organization

Although archaeological and documentary evidence tell us something about the physical characteristics of the Swahili towns, we still know very little about their socioeconomic and political organization prior to the nineteenth century. Using scattered travelers' accounts from the tenth century on, supplemented by Portuguese sources from the sixteenth and seventeenth centuries and ethnographic sources, numerous authors have attempted to reconstruct the sociopolitical and local and regional economic relationships of the Swahili (Allen 1993; Mazrui 1995; Middleton 1992; Nurse and Spear 1985; Pouwel 1987).

Current discussion focuses upon the difficulties encountered in trying to provide dynamic models of culture change and urban development. The roles of external-forcing mechanisms and human-induced environmental change in system collapse have also been the focus of recent discussion (e.g., Kusimba 1999; Sinclair 1995) as has been the suitability of different concepts of city and state in describing Swahili political organization (Kusimba 1999).

Swartkrans

Swartkrans is a cave in South Africa with deposits dating from 1.7 to 1 million years ago that contain hominid fossils. The first of these

PREV NEXT

fossils was recovered by R. Broom and J.T. Robinson in 1948. Work has continued at the site (most notably by C.K. Brain since 1965), and more than 100 representatives of *Australopithecus robustus* have been identified. This human ancestor is substantially more "robust" than the smaller gracile East African *A. afarensis* and *A. africanus,* although it is younger than them at one million years old. The site has gained additional significance through the discovery of fossils of *Homo erectus* in the same deposits as those of the australopithecines, which indicates that at some time in the early Pleistocene period, both hominids were contemporaneous.

Sweden

Not only is Sweden's antiquarian/archaeological history closely related to that of the other Scandinavian countries, but the subject has also been influenced by theories from other disciplines as well as by currents of thought in Europe. Sociopolitical changes in Sweden have also contributed to this history. The antiquarian/archaeological discourse thus consists of a multitude of more or less connected assertions that must be understood against this background. A summary of such a multitude is made at the expense of other material, and this article is an attempt to show how the subject successively changed and finally developed. The history is therefore more a question of discontinuities rather than one of continuous development, and the changes can only be understood in relation to earlier ways of thinking.

The 1500s

In the mid-fifteenth century, the first chronicle was written about the history of the Swedish state until the reign of Karl VIII (1448-1457). The author is unknown but was most likely a monk closely connected to the regent. Thus, history was closely tied to power. The chronicle began with the Flood, and Swedish history was associated with myths about Noah. Scyths and Geats, historically known peoples from around the Black Sea and ancient Thrace, are mentioned. This chronicle was also the first example of the Gothic interpretation of history. The author used older sources, which fueled speculations, and the chronicle's influence on sixteenth-century historians is very apparent.

On 6 June 1523, Gustav I (1496?-1560) was crowned king, and a new era began in Sweden. The country converted to Protestantism, and the entire Swedish society was reformed, including the interpretation of history. One of the more influential reformers was Olaus Petri (1493?-1552), who wrote, at the end of the 1530s, *Svenska krönika* [Swedish Chronicle] as a reaction against the biased nature of the older chronicles. Characterized by a certain freedom from national prejudice, Petri's chronicle was the first original work to be written in the modern Swedish language, and thousands of copies were printed and distributed. According to Petri, the historian should be impartial and seek the truth, but in spite of this claim, the chronicle should be judged in the context of political and religious changes. Petri expressed, for example, doubts about the Goths' migration from Sweden, but he also found fault with Gustav I's church politics and government. Didactic intentions can also be discerned.

Petri believed there was very little knowledge available about Swedish history between the birth of Christ and the introduction of Christianity. Only medieval history was completely clear, because written evidence, such as sealed letters and documents, existed from that time. Petri was also interested in runes, which resulted in a separate work.

If Petri tried to shorten historical perspective, the opposite is true of Johannes Magnus (1488-1544), Sweden's last Catholic bishop. His view of Swedish history in his *Historia de omnibus gothorum sueonumque regibus,* published in 1553 in Rome, was from the perspective of 4,000 years. Although it was supposed to reflect a desire for truth, rather than a desire for eloquence, it hardly succeeded. Instead, the work was characterized by uncritical views of history and pure fabrication. Magnus saw, for

Petri expressed, for example, doubts about the Goths' migration from Sweden, but he also found fault with Gustav I's church politics and government. Didactic intentions can also be discerned.

Petri believed there was very little knowledge available about Swedish history between the birth of Christ and the introduction of Christianity. Only medieval history was completely clear, because written evidence, such as sealed letters and documents, existed from that time. Petri was also interested in runes, which resulted in a separate work.

If Petri tried to shorten historical perspective, the opposite is true of Johannes Magnus (1488-1544), Sweden's last Catholic bishop. His view of Swedish history in his *Historia de omnibus gothorum sueonumque regibus,* published in 1553 in Rome, was from the perspective of 4,000 years. Although it was supposed to reflect a desire for truth, rather than a desire for eloquence, it hardly succeeded. Instead, the work was characterized by uncritical views of history and pure fabrication. Magnus saw, for

example, a connection between the European Goths and the Swedish “Göter,” a mythological people, and traced Swedish history back to Japhet's son Magog.

The chronicle was nevertheless a significant work, and the only publications that can compete with it in influence are Petri's reformatory works. Successive Swedish kings and statesmen directly or indirectly obtained their historical knowledge from the chronicle, and Gothicism greatly influenced the sixteenth- and seventeenth-century view of history.

The 1600s

During the 1600s, Sweden became a great power through its victories during the Thirty Years' War, and in that context, antiquarian research went in a direction that had little in common with what had preceded. Sweden's first antiquarian and, moreover, director of national antiquities was johan bure (1568-1652). In 1599, he devised a system to interpret runes, and in the same year he received a permit from King Karl IX (1550-1611) to travel around Sweden and document rune stones and locate ancient monuments. Bure was a pioneer in rune research, as Petri's documentation had been fairly insignificant.

Although Bure's contributions were limited, his close contact with the kings of Sweden drew their attention to antiquarian research, and as a result, official antiquarian research took shape. On the advice of Bure, King Gustav II Adolf (1594-1632) issued, for example, an “antiquities instruction” whereby he ordered the nation's antiquarians to collect antiquities, and consequently, the Central Board of National Antiquities developed.

Bure's successor, Johan Hadorph (1630- 1693) traveled throughout the countryside with draftsmen and scribes and documented about 1,000 runic inscriptions. One of the draftsmen was Elias Brenner (1647-1717), a student of Olof Verelius (1618-1682), who was professor of antiquities at Uppsala. It was, however, from Johannes Schefferus (1621-1679) that Brenner received his first insights into numismatics, which he elevated to a science in the 1690s. Hadorph researched both ancient monuments and artifacts as well as folk traditions. During the mid-1680s, he also conducted archaeological excavations in the Viking town of Birka. Verelius had also undertaken fieldwork, and so had Olof Rudbeck (1630-1702), who investigated royal Iron Age burial mounds in Old Uppsala.

Place-name research by Petter Dijkman (1647?-1717) developed alongside antiquarian research. Dijkman communicated with Schefferus about his numismatic studies under Brenner, and Dijkman's *Bua Haiti,* one of the first attempts at place-name research, was published in 1711. Dijkman was influenced by Kilian Stobaeus's uncle Anders Stobaeus (1642-1714), a historian, Latin scholar, and poet. One of Dijkman's more important works was published posthumously in 1723. It contained a selection of material from seventeenth-century rune research and was particularly concerned with the Christian faith's influence on the inscriptions. Dijkman made use of previously published material, and of the ninety inscriptions he discussed, some seventy are found in Bure and Verelius.

Hadorph was primarily an organizer and viewed himself as a materialist. In 1666, he was appointed director of national antiquities, and he became powerful within the Antiquities Committee, which was established during the same year. The committee's tasks were to preserve the country's ancient monuments; publish Icelandic sagas and ancient Swedish laws; create a Swedish dictionary; document rune stones, coins, and seals; and carry out archaeological excavations. The committee was first based in Uppsala but was moved in 1690 to Stockholm. Gradually, its organization was tightened, and it was renamed the Antiquities Archive. The chairman had the title of secretary and functioned as the director of national antiquities.

Hadorph also became secretary of the Antiquities Archive but died soon afterward. After the demise of

the last secretary in 1777 there was no appointment of a new one, and in 1780, the archive was dissolved. After the reorganization of Queen Lovisa Ulrika's (1720-1782) Literary Academy in 1786, the Academy of Literature, History, and Antiquities took over the duties of the Antiquities Archive, and its secretary became the director of national antiquities.

PREV NEXT

Archaeological excavations were consequently carried out, and Schefferus wrote Sweden's first archaeological dissertation, a work that discussed a bronze sword found in Scania and three gold bracteates. In spite of this work, most of the academy's interests were focused on literary sources and, in particular, on Icelandic ones. During the late seventeenth century, patriotism and Gothicism reached the height of their popularity. Gothicism identified the Goths with the *hyperborés,* an ancient mythological people, a theory that was supported by some evidence from Icelandic material. Olof Rudbeck, in his monumental work *Atlantican* (1679-1702), claimed that Sweden was the lost civilization of Atlantis. Although the work was received with enthusiasm outside of Sweden, it soon lost its standing and was criticized by Schefferus and Hadorph, who had little sympathy for such speculation. Perhaps the most interesting critique of *Atlantican* was by the German philosopher Gottfried Wilhelm von Leibniz (1646- 1716), who was one of the forerunners of the scientific revolution. Leibniz's critique was ironic and was an indication that new scientific viewpoints were developing in Europe.

Various bills to protect ancient monuments were issued in 1666 and renewed in 1669, 1676, and 1684, and they laid the groundwork for more organized antiquarian research. Priests and public officials were ordered to participate in field surveys and to send the results of any pillaging of monuments to the Antiquities Committee, and ancient monuments were more closely linked to royal power. During the 1600s, there was still no organized research that focused on the material culture and artifacts associated with ancient monuments. Artifacts were collected and documented but then compared to literary sources. It was unthinkable to view them as something outside the literary historical field.

The 1700s

In 1718, King Karl XII died, and Sweden's period as a great power came to an end. During the following years, known as “the period of liberty,” parliamentary power took shape. An unsuccessful war against russia (1741-1743), bureaucracy, and a disorganized monetary system caused many problems for Sweden during this period. Later, after a successful reorganization of the monetary system, closer ties with England, and the establishment of ties with Russia, the first Swedish law concerning freedom of the press was instigated.

During this period, antiquarian research was still faulty and descriptive, its results were mainly compilations, and any conclusions it drew were speculative and lacked cohesion. Historians continued to interpret Sweden's earliest times. Jacob Wilde (1679-1755) was one of Sweden's first modern historians, and he often dealt with problems with source material. Wilde demolished Johannes Magnus's list of regents and criticized Olof Rudbeck's fantasies. Wilde's work dealt with three historical periods-ancient times, the Middle Ages, and modern times-and his divisions were later accepted by several historiographers. The ancient period was divided into two ages: a “dark age,” knowledge of which must be sought among classical authors, and a “mythological age,” ca. 120 b.c.-ca. a.d. 1150. Within the latter age, three phases were identified: the cairn age, the cremation age, and the mound age. It was a historical division, based on Icelandic sagas and not on archaeological material. There was no comprehension of a prehistory that demanded an independent chronology. Wilde was followed by Olof von Dalin (1708- 1763), Anders af Botin (1724-1790), and Sven Lagerbring (1707-1787).

The doctor and antiquarian Kilian Stobaeus (1690-1742) and the philosopher Andreas Rydelius (1671-1738) taught Dalin in Lund. Stobaeus occupied Lund University's first chair of natural science in 1728 but exchanged it for a professorship in history in 1732. The great philosopher Carolus Linnaeus was one of his many pupils. Stobaeus taught natural science, history, numismatics, and antiquarian research. He donated his significant collection of artifacts and natural objects, known as Museum Stobaeanum, to Lund University in 1735.

Dalin began a state administrative career in Stockholm in 1727 and at the same time, together with Johan Ihre (1707-1780), competed for the position of state historiographer. Although

had far more impact than Dalin. He contributed to the publication of thirty-six dissertations on Scania's medieval archaeology, and he was also the first to discuss the historical source value of Icelandic literature in a modern way. Lagerbring taught geography, a significant subject for archaeology, and he helped ensure that the eighteenth century was a golden age for recording the details of provinces, towns, and parishes, a descriptive tradition begun by Dijkman and Stobaeus. Lagerbring also made lasting contributions to the organization of the Cabinet of Coins, which was kept for a long time inside his house. He saw truth, founded in historical criticism, as the historian's guiding star. His method of delivery was original in that it was not organized chronologically, as all earlier histories had been. In accordance with Voltaire, and in a manner similar to that of Botin, Lagerbring arranged source materials by subject matter.

Contrary to Dalin, Lagerbring drew a sharp distinction between source and literature, and he made two new demands on the historian: source references and source evaluation. With source references, statements or suppositions could be checked. For source evaluation, the cardinal rule was that the more certain the contemporary nature of the document, the greater its reliability. Agreement among several sources was important as a criterion of truth. But Lagerbring had a didactic and pedagogical delivery, and he viewed history in the light of his contemporary society's political conditions and according to the rational critique of the eighteenth century. He evaluated ancient and medieval religious conditions in the same way as most scholars of the Enlightenment, with little sympathy for medieval people and a belief that monks were frauds.

The 1800s: Period of Transition

The beginning of the nineteenth century was full of change. Sweden surrendered finland to Russia, a new constitution was written in 1809, and foreign policy was changed. The French field-marshal Jean-Baptiste-Jules Bernadotte, one of Napoleon's generals, ascended the Swedish throne as King Karl XIV Johan in 1818, and during the 1830s, liberal political forces grew stronger.

It is this context Nils Henrik Sjöborg (1767- 1838) outlined a three-age system in 1797 even though its structure remained unclear. Sjöborg used a comparative ethnographic perspective, inspired by Anders Jahan Retzius (1742-1821), to help formulate his system. Stobaeus had also used ethnographic analogies to confirm that stone artifacts were used as tools before iron artifacts. Retzius, an early natural science student and a pupil of Linnaeus, donated his collection of prehistoric stone tools and natural history to Lund's museum between 1805 and 1811. He also divided the Museum Stobaeanum into separate natural history, art history, and history departments.

Natural-scientific systematization gradually overtook the historical view. Magnus Bruzelius (1786-1855) began as a physical anthropologist but turned to antiquarian research. Modern European geology, which traced nature's successive development, was also a significant influence, contrasting catastrophe theory with biblical chronology, which had dominated historical research since the sixteenth century.

First Half of the 1800s

A new chronological and ethnographical perspective on history took shape during the early nineteenth century. Its founders were christian jürgensen thomsen (1788-1865) from denmark and the Swede sven nilsson (1787- 1883). Thomsen's three-age system replaced a chronology that was just a step above confusion. The Swede Magnus Bruzelius had formulated a similar system in the 1820s, based on archaeological find-contexts. Thomsen's system was, however, more composite and it schematized find observations. He was also the first to publicize the system, partly in museological form and partly through communication with colleagues (Gräslund 1987, 18). Nilsson later gave this system a culture-historic shape.

As a scientist, Nilsson was a systematizer, but he was also educated in history and philosophy. He made significant contributions not only to archaeology but also to several subjects within the natural sciences. He collaborated with the English geologist sir charles lyell, the English archaeologist Sir John Lubbock (lord avebury), and their compatriot Charles Darwin. Nilsson

carried out fieldwork and collected archaeological and ethnographical objects, and through his experiments in flint knapping he was able to confirm the function of knapping stones.

The idea of primitive people had existed since the seventeenth century, and during the nineteenth century, it became the object of classification and development theories within the natural sciences. Nilsson preferred natural science and comparative, ethnographic archaeology, which he formulated on the basis of the French paleontologist and geologist Georges Cuvier's (1769-1832) natural-scientific method, with archaeological methods above historical analogies. Nilsson was the first scholar in Sweden to use the term *prehistory* (Welinder 1991).

This change in the discourse was, among other things, linked to the Enlightenment's division of society into different subject areas, a way of thinking that both Botin and Lagerbring had borrowed from Voltaire. The need to view society from an evolutionary and holistic perspective developed and was related to the popularity of German Romanticism and its advocates Johann Gottfried Herder (1744-1803) and Georg Wilhelm Friedrich Hegel (1770-1831). Thus, Nilsson viewed development as a whole, with everything in nature, including man's culture, evolving from the lowest stages to the highest. Hidden behind the material world was the development of reason. The process was predetermined.

At first (in 1835), he divided the development of mankind into three economic periods: savage, nomad, and agriculturalist. This system and its divisions were completely separate from Thomsen's three-age system, as the two men were not familiar with each other's work at the time. Later, however, they were in close contact. In the late 1830s, Nilsson added a fourth stage: the agriculturalist, with a written language, production, and a division of labor among the members of society (Nilsson 1838-1843).

The three-age system, on the other hand, was not based on an a priori interpretation of cultural development but neither was it socioeconomic. It was chronological, and since it was related to archaeological find-contexts, it had a great impact because it had empirical and scientific proof. It was not an intuitive, practical method of arranging finds but rather the chronological means of assistance for further investigations (Gräslund 1987, 27).

Mid-1800s

It was through Thomsen and Nilsson that antiquarian research became separate from history and modern archaeology took shape. Gradually, comparative ethnography lost its influence because of its alienation from find-contexts. Instead, it became important to improve on Thomsen's three-age system.

The Dane jens jacob worsaae (1821-1886) laid significant groundwork for archaeology during the mid-nineteenth century. European cave finds of extinct animal species discovered in stratigraphic connection with cultural remains, finds that Lubbock later called Paleolithic, may have been important for Worsaae's initial division of the Stone Age into two periods. Later Worsaae divided the Stone Age into three periods, with cave finds constituting the earliest period, kitchen middens the middle period, and stone chamber graves the youngest period. Today, these periods are called Paleolithic, Mesolithic, and Neolithic.

The division of the Bronze Age into two parts was first expressed in 1854 by the Swede Nils Gustaf Bruzelius (1826-1895). The division was based on stratigraphy and on the fact that cremation burials overlay inhumations. Through various bog finds, Worsaae formulated a division of the Iron Age into two parts, which was successively confirmed by new finds, and the concept of the Iron Age became common in the Scandinavian countries during the 1850s and 1860s.

After a visit to Hallstatt, austria, in 1858, Bruzelius asserted that the Iron Age in southern and central

Europe must have begun a couple centuries before the birth of Christ. He also noted a sharp border between the Bronze Age and the Iron Age. He did not, however, compare this observation with conditions in Scandinavia. Instead, it was the Dane Emil Vedel (1824- 1909) who asserted that the transition between the Bronze and Iron Ages in Scandinavia occurred before the birth of Christ. He drew this conclusion after investigations at Bornholm between

PREV NEXT

1868 and 1872. Thereafter came a division of the so-called Roman Iron Age (a.d. 0- 450) into two parts, formulated mainly by the Danish archaeologist sophus müller (1846- 1934).

Antiquarian/archaeological research changed from being a political and didactic instrument to an empirical, critical science, and archaeology was finally free from the literary historical analogies. It was no longer a matter of writing a country's history; instead, it was important to organize and systematize the country's nonhistorical source material, and the leaders in the change were Thomsen and Nilsson.

Typology

The chief characteristic of the last half of the nineteenth century was the division of the three-age system into subperiods and the formulation of culture-historic guidelines. Find-contexts played an important role. Within Iron Age research, historical analogies were used in the sense that historically datable, Continental material was comparable with Scandinavian conditions. Numismatics also had a high priority in Iron Age research. Around the year 1870, the nature of archaeological discourse changed again, with chronological work directed toward making shorter time divisions while the intensity of research and the amount of source material increased. The increase in material was seen to be connected with the intensification of agriculture, as well as with increased industrialization in general. By this time, researchers and museum scholars both had a specialized university education. It was in this context that a new archaeological discourse on typology was formulated.

The background of typology was empirical. Changes in form had been described by oscar montelius (1843-1921) and hans hildebrand (1842-1913) as “development” in accordance with the language of the time. The idea that development was continuous and unbroken was thus the basis of typology. This meant that development could also be observed and traced without the support of find-contexts. With the aid of typology, correct chronological conclusions could be drawn entirely on the basis of changes in form, and in this area, statistics were an important aid. Typology was, however, formulated in a diffuse way and the term consequently has a broad definition.

It was to mark these new methodological directions that Hildebrand formulated the typological method, but typology was of less importance for him than it was for Montelius (Gräslund 1987, 97). Montelius's famous *Tidsbestämning* [Dating in the Bronze Age] (1885, English edition in 1986) was based, to a greater extent, on different find-contexts than on typology. Determining time sequences in the Bronze Age did not require the development of typological analysis. Thus, Montelius worked not only typologically but also, and especially, by empirically combining different find-contexts.

Müller criticized Montelius for neglecting the relationship between the context of artifacts and the typological series and implied that it was impossible to classify artifacts typologically without taking these contexts into account. In other words, Montelius did not differentiate between typology and find-context analysis.

Yet it was Montelius himself who popularized his image as a typologist. After Darwin's works were published in Swedish, Hildebrand and Montelius began to hint at a connection between typology and Darwinism. However, unlike Hildebrand, Montelius never referred to the theory of natural selection, and as a result, the relationship to Darwinism is vague (Gräslund 1987, 104). Typology belonged more to a pre-Darwin theory of development, a way of thinking that had existed during the eighteenth century, a fact that Nilsson emphasized strongly. But typology also belonged to neo-Kantism and to the advance of positivism within historical research. Hildebrand and Montelius never claimed that Darwinism had given rise to typology (Gräslund 1987, 105). Rather, typology was associated with Darwinism only after the relationship became apparent, and it should therefore be viewed as a scientific-political move.

The most decisive “discovery” of the time was, however, Montelius's dating of the Bronze Age and indirectly also providing dating for the Stone and Iron Ages. A more exact dating of the Stone Age had to wait, however, for the scientific methods that first became possible during

the 1970s. The Iron Age in Scandinavia acquired the dates of the sixth century b.c. to eleventh century a.d.

In *Tidsbestämning,* Montelius synchronized historically datable comparative finds from the Mediterranean and Middle East with Scandinavian conditions. In so doing, he could set the span of the Bronze Age from 1500 to 500 b.c. In comparison with the eighteenth-century Bible-based datings and the nineteenth-century vague chronological interpretation (Worsaae, for example, maintained in the 1850s that the Bronze Age reached its peak at around the birth of Christ), this was an enormous step forward.

Early 1900s

During the first half of the twentieth century, archaeological source materials increased considerably, new perspectives opened up, and old methods were refined. In general, research was directed toward settlement history and the history of style.

Settlement history had existed during the nineteenth century, but during the first decades of the twentieth, it became more focused and systematic, and better known to a wider circle of researchers. Investigations of regional complexes of settlement remains also began at this time. Oscar Almgren (1869-1945), together with the botanist and Quaternary geologist Rutger Sernander (1866-1944), made early advances in this field. In 1901, they investigated Uppland's settlement history, encouraged by the discovery of the first Middle Neolithic settlement (ca. 2800 b.c.) in central Sweden.

In 1907, Knut Stjerna (1874-1909) initiated extensive archaeological provincial investigations in southern and central Sweden, focusing on the Stone and Bronze Ages. It was hoped that the project would eventually encompass all of Sweden, and the intention was to study the typology and chronology of the artifacts found as well as their topographical distribution. The project resulted in several dissertations and publications, but never encompassed all of Sweden.

Geographical, geological, and ecological factors were all important to an understanding of settlement development. Place-name research and historical and ethnological analogies were applied to the Iron Age. The Royal Place-Name Committee began to publish *Sveriges Ortnamn* [Swedish Place-Names] during the early twentieth century. Within the history of style, typology was more important, visible, for example, in Hanna Rydh's (1891-1964) doctoral dissertation of 1919, the first thesis in archaeology to be written by a woman.

The term *primitive* was used regularly. Within the history of style it was used to characterize the development of different elements of style, and there were also reference to prototypes, manufacturing processes, and industries. These terms coincided with typological and chronological questions. The term *settlement history* was used in debates on ethnicity and race. The basic question to answer was how different Mesolithic cultures developed into Neolithic cultures. A dualistic relationship was sought, which implied either that immigrating people, or people of other races, who had a higher technological and intellectual level had suppressed the first cultural phases or that the Neolithic level had been achieved within the country's boundaries and that more-primitive hunting cultures had been suppressed or assimilated.

In that context, ethnographical and ethnological analogies had some importance. The choice of language revealed uncertainty in the relationship to the “primitive” Mesolithic peoples, which gave rise to theories that implicitly, or occasionally explicitly, expressed a reluctance to accept the idea that such comparative “primitive” cultures had existed in Scandinavia at the same time as the cultures of the Bronze and Iron Ages. On the other hand, the more “developed” and artistically more “talented” cultures of the Bronze

and Iron Ages did not have the same problems concerning identification. One could accept and even identify with Neolithic cultures because they depended on agriculture and livestock. The means of distancing oneself from the “primitive” cultures of the Mesolithic was to transfer them into being part of the natural world, and thus to being governed by the laws of nature. In the case of the Bronze and Iron Ages, one could easily identify with the creative powers and great initiatives of these cultures. This pattern has certain parallels with

ideas of the eighteenth century and their erratic views of earliest history.

During the early twentieth century, archaeology lacked composite theories about the composition of and changes in different cultures. This lack does not mean that such questions were ignored-now and then references were made to religious and social conditions-but above all it was a case of diffusionist explanations and an implicit view of man and society. In general, the scientific ideal was empirically inductive with a natural-scientific undertone. Most works were descriptive and pragmatic in character.

A prehistoric petroglyph or vase painting from a Bronze Age site in Tanum, Bohuslan, Sweden, depicting three figures standing on the deck of a boat

(Hulton Getty)

Later 1900s

From the end of the 1930s until the 1950s, style-historical research (the use of style in material culture to determine the direction of historical change) in archaeology predominated. During the 1950s, several human geographers took an interest in settlement-history questions, and at the same time, several large field projects were initiated. These resulted in extensive and detailed publications of material. The inductive tendency of these works, as well as the lack of more explicit theories about human society, led to a crisis that developed into a debate on method and theory.

Criticisms burgeoned during the 1950s and 1960s, and especially influential at this time was criticism by Bertil Almgren and mats malmer. Generally speaking, their arguments pointed in two different directions: Almgren took an art-historical, hermeneutics/phenomenological direction while Malmer upheld a rationalistic, positivistic, and scientific ideal or direction. Berta Stjernquist represented a third approach. She worked with traditional typology and also with ecology and ethnicity, and she argued that it was important to give greater emphasis to factors that had influenced the material. This approach demanded theoretical and anthropological knowledge as well as situation studies like those of anthropologist Bronislaw Malinowski (Stjernquist 1955, 2).

The renaissance of settlement historical archaeology during the 1960s is linked to that crisis/debate. Through extensive archaeological excavations, historical maps, and surveys of ancient monuments, an attempt was made to acquire knowledge of the colonization process, settlement structure, and economic conditions during, above all, the Iron Age in Sweden. Attention was given especially to economic variables. Collaboration between archaeologists and human geographers was strengthened, and even place-names and medieval fiscal material were used.

Greater emphasis was placed on local economic factors than on diffusionist factors. Economic aspects were considered to be the basis for man's production possibilities and for living conditions. These could be studied geographically, zoologically, and geologically. Since the beginning of the twentieth century, settlement historical archaeology had been influenced by advances within quantitative methodology. In the area of analysis that has “hardware” as its point of departure, statistics were important along with diagrams and models. These were some of the preconditions for the introduction of the new archeology into Sweden during the 1970s.

As early as 1963, Carl-Axel Moberg (1915- 1987) had been in contact with lewis r. binford (b. 1929). By the end of the 1960s, Moberg was arguing that a rationalization of archaeology was necessary since the constant increase of material had given rise to a collecting and publishing crisis. In this context, he

pointed out the possibilities of processual archaeology as

well as the practical revolution that computerized data implied (Moberg 1969, 16-18).

In so doing, Moberg put his finger on the crisis that has been the subject of discussion since the 1960s. He maintained that the cause was a crisis in education, that new directions were needed within archaeology, and that, in the long run, new archaeologists were needed. It was necessary to educate archaeologists in theoretical knowledge and change the goals of archaeology, which implied that an archaeology based on inductive knowledge would be replaced by more objective observations. Technological development would contribute to the globalization of archaeology and the fusing of different archaeologies into one. There were two possible paths: the regional picture could be broadened to include the history of mankind in both time and space; alternatively, world archaeology could be achieved via anthropology. The idea was to determine general laws of human behavior by using deductive methods (Moberg 1969, 21).

Thus, the deductive, scientific ideal was formulated for the first time within Swedish archaeology, and Moberg's future expectations would be realized during the 1970s. At this point, however, we should consider one of the more theoretically knowledgeable and independently active researchers in Sweden during that decade. In Stig Welinder's dissertation on the Scanian Mesolithic (1971), there is no reference to processual archaeology and its aim to trace changes in the environment by conducting natural-historical investigations. In a later work (1975), on the other hand, there are several references to processual archaeology, or "the new archeology." Welinder even eliminated the "a" in the combination "ae" in archaeology and was working explicitly with models and system-theoretical questions. His point of departure was the axiom that the surrounding milieu and technology were society's base. In order to prove this axiom, it was necessary to work system theoretically. Welinder's thinking was similar to that expressed by the English archaeologist david clarke's ecological paradigm (Clarke 1972), and Welinder was also interested in Clarke's view of the sociocultural system (Welinder 1975, 22). Economic, ecological, and demographic aspects composed the foundations of his model. In the long perspective of prehistory, war, trade, religion, social organization, etc. were of secondary importance. Settlement historical conditions could only be understood from an ecological perspective, and societies were interpreted as composite economic/technological complexes (Welinder 1975, 20).

Welinder sometimes doubted the possibility of creating laws for diffusion and social structures, since culture-historical processes and human societies are not repeated in time and space. In his opinion, the model sometimes deviated from the models normally used by the new archeologists (Welinder 1977, 15). Neither could it be used as an explanatory model. Instead, its strength lay in its description of basic structures in the cultural landscape. On a later occasion (Welinder 1979, 24), however, he implied that if it were possible to formulate such laws, then the preconditions could be found within demography. This archaeology could be called "human paleoecology," "ecological archaeology," or "population anthropology" (Welinder 1979, 25). Welinder's thinking has been used as an example of the tendencies of the 1970s, but it should be noted that they are not representative of the subject as a whole. Alongside them there was a traditional, inductive, and typological archaeology. However, Welinder's archaeology, to a certain extent, was representative of a more theoretically oriented archaeology.

Thus, archaeology during the 1970s became more natural-scientific in character. Attempts were made to reduce the preconditions for the formation of society to a single basic norm. The decisive factor was the relationship between man and his surrounding environment, with the latter constituting the basic variable. This line of thinking was linked to the positivistic ideals that were predominant within Swedish society as a whole. Generally speaking, the political model for Swedish society has been characterized by standardization in a positivistic spirit.

Archaeology Since the 1980s

During the 1980s, the reductionist viewpoint was called into question, not only within the

sciences but also within Swedish politics. Multiplicity became the political slogan. But this questioning has not implied, and will not cause, the disappearance of the deductive and inductive ideals. Rather, archaeology's relative homogeneity began to break down, and in the future a broad front of disparate archaeologies will probably develop. On scientific-theoretical grounds, it is difficult to give priority to one archaeology above another. It is therefore no longer clear how Swedish archaeology should be defined.

The possibility, or risk, is that research will be divided up into more and more problem areas. This idea may sound like an exaggeration, but it should be remembered that archaeology has always depended on different auxiliary sciences. In practice, a closer relationship can be established with any subject. We can therefore expect a wide spectrum of archaeologies. The risk is that barriers may be erected among them and each may fight the others' existence. There is the possibility that certain scientific-ethical grounds will be established so that the flood of ideas runs freely and various alternatives develop not only in different directions but also in close relationship with one another. It will be decisive in this context that discourses are not hindered by supposed scientific ideals.

Swedish Cyprus Expedition

See Gjerstad, Einar

Switzerland

As long ago as a.d. 1490, excavations financed by the authorities were reported in Switzerland. An early Middle Age cemetery had been fortuitously uncovered during the alterations of Saint Maurice Church in Schotz (Lucerne). The skeletons, seemingly holding their skulls in their hands, were considered to be the martyrs of the Theban legion, put to death with their leader, Saint Maurice, because of their Christian faith.

sciences but also within Swedish politics. Multiplicity became the political slogan. But this questioning has not implied, and will not cause, the disappearance of the deductive and inductive ideals. Rather, archaeology's relative homogeneity began to break down, and in the future a broad front of disparate archaeologies will probably develop. On scientific-theoretical grounds, it is difficult to give priority to one archaeology above another. It is therefore no longer clear how Swedish archaeology should be defined.

The possibility, or risk, is that research will be divided up into more and more problem areas. This idea may sound like an exaggeration, but it should be remembered that archaeology has always depended on different auxiliary sciences. In practice, a closer relationship can be established with any subject. We can therefore expect a wide spectrum of archaeologies. The risk is that barriers may be erected among them and each may fight the others' existence. There is the possibility that certain scientific-ethical grounds will be established so that the flood of ideas runs freely and various alternatives develop not only in different directions but also in close relationship with one another. It will be decisive in this context that discourses are not hindered by supposed scientific ideals.

Syro-Palestinian and Biblical Archaeology

The history of Syro-Palestinian archaeology, or the archaeology of the southern Levant (ancient Canaan; modern coastal and southern Syria, Lebanon, jordan, and israel), and the history of the specialized branch of this discipline, usually called “biblical archaeology,” will be examined.

Roots in the Nineteenth Century: The Exploratory Era

The archaeology of the Holy Land, in the broad sense of the exploration of biblical topography and antiquities, goes back centuries to hundreds of pilgrims' accounts since the Byzantine period. The modern discipline of Palestinian archaeology, however, can be said to have begun with the pioneering visits of the U.S. biblical scholar Edward Robinson to the Holy Land in 1838 and 1852, an account of which was published as *Biblical Researches in Palestine and the Adjacent Regions* (1853). Robinson and his traveling companion Eli Smith correctly identified dozens of long-lost ancient sites. The first modern maps, however, after those made by Napoleon's cartographers, were drawn up by C.R. Conder and H.H. Kitchener for the great *Survey of Western Palestine* (1872-1878; published in six volumes in 1884). This work was sponsored by the British Palestine Exploration Society (1865-), which also undertook the first actual fieldwork, C.W. Wilson and C. Warren's soundings around the Temple Mount in Jerusalem (1867-1870).

In Egypt and mesopotamia, dramatic archaeological discoveries, which began in the 1840s partly by chance and because of the results of the first deliberate excavations, soon drew attention to Palestine, largely because of its biblical connections. Several foreign societies soon joined the British Palestine Exploration Fund: the German Deutsches Palastina-Vereins (1878-); the French Ecole Biblique et Archéologique in Jerusalem (1892-); and the american schools of oriental research (1900-).

Despite mounting interest, however, true excavations did not begin in Palestine until the brief campaign of the legendary English archaeologist sir william matthew flinders petrie at Tell el Hesy in the Gaza area (possibly biblical Eglon) in 1890, which was soon followed by American work there under F.J. Bliss in 1893. It was Petrie who laid the foundations of all subsequent fieldwork and research by demonstrating, however briefly and intuitively, the importance of detailed stratigraphy of Palestine's complex multilayered tells, or mounds, and the potential of comparative ceramic typology and chronology.

This first, formative era of archaeological exploration and discovery in Palestine in the nineteenth

Syro-Palestinian and Biblical Archaeology

The history of Syro-Palestinian archaeology, or the archaeology of the southern Levant (ancient Canaan; modern coastal and southern Syria, Lebanon, jordan, and israel), and the history of the specialized branch of this discipline, usually called “biblical archaeology,” will be examined.

Roots in the Nineteenth Century: The Exploratory Era

The archaeology of the Holy Land, in the broad sense of the exploration of biblical topography and antiquities, goes back centuries to hundreds of pilgrims' accounts since the Byzantine period. The modern discipline of Palestinian archaeology, however, can be said to have begun with the pioneering visits of the U.S. biblical scholar Edward Robinson to the Holy Land in 1838 and 1852, an account of which was published as *Biblical Researches in Palestine and the Adjacent Regions* (1853). Robinson and his traveling companion Eli Smith correctly identified dozens of long-lost ancient sites. The first modern maps, however, after those made by Napoleon's cartographers, were drawn up by C.R. Conder and H.H. Kitchener for the great *Survey of Western Palestine* (1872-1878; published in six volumes in 1884). This work was sponsored by the British Palestine Exploration Society (1865-), which also undertook the first actual fieldwork, C.W. Wilson and C. Warren's soundings around the Temple Mount in Jerusalem (1867-1870).

In Egypt and mesopotamia, dramatic archaeological discoveries, which began in the 1840s partly by chance and because of the results of the first deliberate excavations, soon drew attention to Palestine, largely because of its biblical connections. Several foreign societies soon joined the British Palestine Exploration Fund: the German Deutsches Palastina-Vereins (1878-); the French Ecole Biblique et Archéologique in Jerusalem (1892-); and the american schools of oriental research (1900-).

Despite mounting interest, however, true excavations did not begin in Palestine until the brief campaign of the legendary English archaeologist sir william matthew flinders petrie at Tell el Hesy in the Gaza area (possibly biblical Eglon) in 1890, which was soon followed by American work there under F.J. Bliss in 1893. It was Petrie who laid the foundations of all subsequent fieldwork and research by demonstrating, however briefly and intuitively, the importance of detailed stratigraphy of Palestine's complex multilayered tells, or mounds, and the potential of comparative ceramic typology and chronology.

This first, formative era of archaeological exploration and discovery in Palestine in the nineteenth

century was characterized by adventurism, by nationalism and competition among the colonial powers, and by growing expectations that archaeology would shed a unique light upon the biblical world. Yet ancient Syria had scarcely been touched, although some archaeological exploration there had begun as early as the 1860s under French scholars like Ernest Renan.

From the Turn of the Century until World War I: The Formative Period

The first two decades of the twentieth century constituted a sort of "golden age" in Syro-Palestinian archaeology, one that saw the first large-scale, reasonably well-staffed and well-funded field projects. These included the work of the Americans at Samaria (1908-1910); of the British at Tell Gezer (1902-1909); and of the Germans at TaCanach (1902-1904), Megiddo (1903-1905), Jericho (1907-1909), and the Galilean synagogues (1905). In Syria, Howard Crosby Butler's splendid surveys of Byzantine Christian sites (1904-1909) for Princeton University deserve mention, but by and large, Syria was ignored as being peripheral to the Holy Land. None of these excavations, however, with the exception of george a. reisner's work at Samaria (results of which were not published until 1924), demonstrated more than the rudiments of stratigraphy. Pottery chronology was off by centuries, and the publication volumes, although sometimes lavishly illustrated, are largely useless today. An almost exclusively architectural orientation, and/or biblical biases, marred most of the work.

All of these and other projects were brought to a halt by the onset of World War I, but the foundations of both Syro-Palestinian and biblical archaeology had been laid. Nevertheless, neither an academic discipline nor a profession had yet emerged in this second, formative period.

Between the Great Wars: The Classification Period

Following the corrupt bureaucracy of Ottoman Turkish rule, Palestine became a British mandate in 1918 at the close of World War I. The British government opened a Department of Antiquities, promulgated modern antiquities laws, and undertook the first systematic, comprehensive program of archaeological investigation of the entire area, including Transjordan. During the ensuing period, the foreign schools in Jerusalem flourished, particularly the American School of Oriental Research, which now dominated the field under the direction of william f. albright (1920-1929; 1933-1936). Albright, one of the most eminent orientalists of the twentieth century, was then followed by his protégé Nelson Glueck, who was famous for his explorations in Transjordan.

It was Albright who became known as "the father of biblical archaeology" through his unparalleled mastery of the pottery of Palestine, of the broad ancient Near Eastern context in which the results of Palestinian archaeology needed to be placed to illuminate them properly, and of the vast scope of biblical history with which individual discoveries often seemed to correlate. Although Albright himself sometimes used the term *Syro-Palestinian archaeology*, his overriding concern was with the biblical world. Through his genius; his towering status; his own excavations at Tell el-Fûl (1922), Bethel (1934), and especially at Tell Beit Mirsim (1926-1932); and his innumerable disciples, Albright dominated "biblical archaeology" from the early 1920s through the 1960s. One of his protégés, G. Ernest Wright of Harvard, carried on the tradition by coupling "biblical archaeology" more specifically with the "biblical theology" movement that flourished in the 1950s-1970s. A transitional figure, Wright trained most of the older American generation still working in the field today.

Many of the U.S. excavations in Palestine between the two world wars, under Albright's influence, were at biblical sites, staffed by Protestant seminarians and clergymen, and supported by funds from church circles. These included Albright's own excavations and those at Tell en-Nasbeh (1926-1935), Beth-shemesh (1928- 1933), and many smaller sites. Nevertheless, there was a parallel, secular U.S.

tradition, especially in the large projects of the University of Pennsylvania at Beth-Shan (1926-1933); of the Oriental Institute of the University of Chicago at Megiddo (1925-1939), well funded by the Rockefellers; and of Yale University at Jerash in Transjordan

century was characterized by adventurism, by nationalism and competition among the colonial powers, and by growing expectations that archaeology would shed a unique light upon the biblical world. Yet ancient Syria had scarcely been touched, although some archaeological exploration there had begun as early as the 1860s under French scholars like Ernest Renan.

All of these and other projects were brought to a halt by the onset of World War I, but the foundations of both Syro-Palestinian and biblical archaeology had been laid. Nevertheless, neither an academic discipline nor a profession had yet emerged in this second, formative period.

Between the Great Wars: The Classification Period

Following the corrupt bureaucracy of Ottoman Turkish rule, Palestine became a British mandate in 1918 at the close of World War I. The British government opened a Department of Antiquities, promulgated modern antiquities laws, and undertook the first systematic, comprehensive program of archaeological investigation of the entire area, including Transjordan. During the ensuing period, the foreign schools in Jerusalem flourished, particularly the American School of Oriental Research, which now dominated the field under the direction of william f. albright (1920-1929; 1933-1936). Albright, one of the most eminent orientalists of the twentieth century, was then followed by his protégé Nelson Glueck, who was famous for his explorations in Transjordan.

It was Albright who became known as "the father of biblical archaeology" through his unparalleled mastery of the pottery of Palestine, of the broad ancient Near Eastern context in which the results of Palestinian archaeology needed to be placed to illuminate them properly, and of the vast scope of biblical history with which individual discoveries often seemed to correlate. Although Albright himself sometimes used the term *Syro-Palestinian archaeology*, his overriding concern was with the biblical world. Through his genius; his towering status; his own excavations at Tell el-Fûl (1922), Bethel (1934), and especially at Tell Beit Mirsim (1926-1932); and his innumerable disciples, Albright dominated "biblical archaeology" from the early 1920s through the 1960s. One of his protégés, G. Ernest Wright of Harvard, carried on the tradition by coupling "biblical archaeology" more specifically with the "biblical theology" movement that flourished in the 1950s-1970s. A transitional figure, Wright trained most of the older American generation still working in the field today.

Many of the U.S. excavations in Palestine between the two world wars, under Albright's influence, were at biblical sites, staffed by Protestant seminarians and clergymen, and supported by funds from church circles. These included Albright's own excavations and those at Tell en-Nasbeh (1926-1935), Beth-shemesh (1928- 1933), and many smaller sites. Nevertheless, there was a parallel, secular U.S.

tradition, especially in the large projects of the University of Pennsylvania at Beth-Shan (1926-1933); of the Oriental Institute of the University of Chicago at Megiddo (1925-1939), well funded by the Rockefellers; and of Yale University at Jerash in Transjordan

(1928-1934). These, too, were biblical sites, but the secular stream of U.S. Palestinian archaeology never captured the imagination of the public or succeeded in perpetuating itself as the Albright school did. In retrospect, it seems that, in the United States at least, archaeology in “poor Palestine” was not thought to be able to justify itself without the biblical connection.

British work in Palestine between the two wars combined biblical and nonbiblical interests. The principal excavations were those at Ashkelon (1920-1922); Dor (1923, 1924); Petrie's at Tell Jemmeh (1926, 1927), Tell el Fara (1927-1929), and Tell el Ajjul (1930-1934); the Mt. Carmel prehistoric caves (1925-1934); Petra (1929-1936); Athlit (1930-1933); Samaria (1930-1935); Jericho (1930-1936); Lachish (1932-1940); Kh. Mefjer (1935-1948); and, of course, many projects in Jerusalem.

The French approach between the wars was similar, the major excavations in Palestine being those at Ai (1933-1935), Teleilat al-Ghassul (1929-1938), and several prehistoric sites. The same combination of secular and religious interests characterized the German school, with excavations at Mambre (1926-1928) and Kh. el-Minyeh (1932-1939). However, neither the British, French, German, or any other international school combined Palestinian and biblical archaeology in the deliberate, almost exclusively biblical, and often theological way that much of the American work did.

British advantages during the Mandate period notwithstanding, biblical archaeology in Albright's unique style seemed triumphant on the eve of World War II when all fieldwork came to a halt. Nevertheless, despite differences in approach among the various schools, archaeology in Palestine had made enormous strides in this third era, which may be characterized as “the classification period,” when the stratigraphy of the major sites was first worked out and the chronological-cultural history was outlined for the first time from the Paleolithic to the Islamic periods.

The Heyday and the Decline of Biblical Archaeology: 1950-1970

American-style biblical archaeology reached its zenith soon after the resumption of post-World War II fieldwork in Palestine in the early 1950s. Principal excavations were those of Wright at Shechem (1957-1968), J.B. Pritchard at Gibeon (1956-1962), J.A. Callaway at Ai (1964-1969), P.W. Lapp at Teller Rumeith, Tell el Fûl, and TaCanach (1964-1968), and Pritchard at Tell esSaCaidiyeh (1964-1967). All of those excavations, which were affiliated with the American school in Jerusalem, were at biblical sites; the directors in every case were clergymen and professors of theology or religion; the agenda was often drawn from issues in biblical studies; and funds came largely from religious circles. In addition, the generation of younger American archaeologists who would come to the fore in the 1970s was trained at these sites.

In addition, a series of publications by Albright, Wright, and others attracted international attention to American biblical archaeology and provoked heated controversy in Europe. At issue were both fundamental questions of method in general (biblically biased or not) and certain specific historical questions in biblical studies (the historicity of the patriarchs and the Israelite conquest, Moses and monotheism, Israelite religion and cult, etc.). Neither Albright nor Wright was a fundamentalist (although certainly conservative by more recent standards), yet outside of the United States suspicions prevailed. The misgivings were prescient, for by the early 1970s, biblical archaeology (along with the biblical theology movement, an outgrowth of postwar neo-orthodoxy) was moribund, if not dead.

In retrospect, the demise of biblical archaeology was probably inevitable, for many reasons. First, what may be called the internal weaknesses of the movement were numerous: its reputation for amateurish fieldwork, naive or biased scholarship, and poor publication; its parochial character, related as it was largely to the conservative (if not fundamentalist) character of so much of religious life in the United

States; its reactionary nature, locked into dated theological issues, which left its practitioners unable to respond creatively to new developments in or outside the field; its resistance to growing trends toward specialization and professionalism; and, above all, the fact that it failed

The French École Biblique et Archéologique in Jerusalem excavated at Tell el-FarCah (1946- 1960), Qumran (1951-1956), Munhata (1962- 1967), and Tell Keisan (1971-1976). Preliminary reports appeared in the "Chronique Archéologique" of the *Revue Biblique.* The Dutch, although without an in-country institute, carried out important excavations somewhat later at Tell Deir CAlla in the Jordan Valley (1976-1978).

The 1967 Arab-Israeli war had a considerable impact on archaeology, at least in Palestine if not in Syria. In effect, Palestine was now repartitioned, and the West Bank now fell under Israeli control. The Israelis initiated a surface survey of this area almost immediately as well as launching a large-scale clearance around the Temple Mount in Jerusalem and somewhat later in the restored Jewish Quarter in the Old City. Following the Israeli takeover of the Old City, the British, French, and German schools in Jerusalem maintained a nominal presence, but in practice they transferred their field operations to Jordan, where in time they opened new institutes in Amman. Only the Americans aligned themselves with the Israeli authorities, reconstituting the old American Schools of Oriental Research by changing its name in 1968 to the William Foxwell Albright Institute while at the same time opening a new branch in Amman under the name American Center for Oriental Research.

The result of the shifts was to leave archaeology in "Palestine" after 1967 in the hands of the Israelis, with some American participation; in the occupied territories on the West Bank (now called "Samaria" and "Judea") in the exclusive hands of the Israelis; and in Jordan in the hands of the foreign archaeologists but with growing Jordanian control. In Syria and Lebanon, most foreign work diminished as political instability increased, and at the same time, the nascent national schools found themselves beleaguered.

The Maturation of the Discipline: The 1970s-1980s

In the development of archaeology in Palestine we have noted two parallel streams, as it were, sacred and secular, particularly as the discipline(s) evolved in the United States. Beginning about 1970, however, the new archaeology began to eclipse the old-style biblical archaeology. The latter had always been merely an enterprise, a kind of "applied" archaeology, or what Wright called "armchair archaeology," but it had never evolved into a profession or an academic discipline. Indeed, biblical archaeologists had often resisted specialization, apparently cherishing their amateur status and content for their work to remain an adjunct of biblical studies. By the 1970s, however, both the internal weaknesses of biblical archaeology and the challenge of the new archaeology and other external threats resulted in a separation of the "two archaeologies," gradual at first, but soon virtually complete. And with the ascendancy of Syro-Palestinian archaeology, more in the style of the 1920s and 1930s, biblical archaeology was soon passé. Even the name was largely abandoned, Albright's original term *Syro-Palestinian archaeology* now being generally preferred.

The debate that continued throughout the 1970s was not, as some thought, merely a semantic quarrel. What really happened was the separation of Syro-Palestinian archaeology from its parent, biblical studies, so that the entire enterprise became, for the first time, an independent academic discipline with its own methods and specific aims. This discipline was no longer just a branch of biblical history (much less theology) or even the "handmaiden of history" generally. Syro-Palestinian archaeology now began to be considered as a regional-cultural branch of Near Eastern archaeology, like Anatolian, Egyptian, Mesopotamian, or Iranian archaeology. Its adherents also wished, without denying the natural connections with the history of the ancient Near East, including the biblical period, to allay themselves more with other disciplines. Paramount was anthropology, for its more sophisticated theory and use of cross-cultural comparisons. But the natural sciences were also seen as valuable allies for their analytical methods, even if archaeology, still a discipline within the humanities, could not attain the precision of the

so-called hard sciences.

The newer theoretical approaches first began

versus new archaeology, which raged for a decade or more in the United States, was not replicated in Europe.

The situation in Israel is in many ways unique and thus deserves separate comment. The Israelis claim that they connect with the biblical past not necessarily by means of formal religion and certainly not theologically, since most of the archaeologists are neither personally observant nor academically trained in the Bible and religion, but emotionally and directly. They maintain that the Hebrew Bible is, after all, the virtual constitution of the modern state of Israel and, furthermore, that for Jews displaced for centuries, even secular Jews, digging for their past in the soil of the Holy Land and searching for their roots is a vital matter of identity, an existential quest that no one has the right to deny them. They have a point, although the argument is somewhat disingenuous and can lead to nationalist extremes. In any case, Israeli archaeologists who use the phrase "biblical archaeology" for popular consumption, or for an English-speaking audience, do so with a meaning that differs from typical American usage, and partly to avoid the awkward term "Palestinian." (In Hebrew, the common designation is simply "the archaeology of Eretz Israel," or the state of Israel, exactly parallel to the archaeology of Jordan or Syria.)

National Schools Come to the Fore

The 1970s and 1980s saw not only the maturation of Syro-Palestinian archaeology as an overall discipline but also the ascendancy of national schools in the Middle East, the Israeli school being the prime example. This school, which had its roots in Jewish archaeology in mandatory Palestine in the 1930s, was rooted in the European academic tradition of ancient Near Eastern studies in history, philology, and art but also deeply influenced by Albright and his long years in Palestine. It is grounded in the realia of the landscape, sites, material culture, and long history of the country and is pragmatic in approach, with scant use for theory, including that of the new archaeology. It is characterized less by stratigraphic detail than by large-scale architectural exposure and stress on assemblages of pottery from living surfaces. It is, and always has been, secular and professional, largely separated from other departments in universities and organized in institutes of archaeology, and often in conflict with the religious establishment rather than allied with it. In recent years, surface surveys and regional projects have become prominent emphases.

The Israeli school really grew out of Yigael Yadin's excavations at Hazor in 1955-1958, where the first generation of Israeli archaeologists was trained. In the 1960s and 1970s, many large projects were carried out, producing another new generation of archaeologists. Archaeological enterprise in Israel is well supported by the Israel Antiquities Authority, institutes of archaeology at four universities, the Israel Exploration Society, many publication series, including the periodicals *Israel Exploration Journal* and *Tel Aviv,* and the national Israel Museum as well as dozens of municipal and regional museums. Not surprisingly, the Israeli school dominates the local scene and has done so almost from the beginning. American field projects (often joint projects) still continue under the auspices of the American school in Jerusalem, but the British, French, German, and other schools transferred most of their operations to Jordan after the founding of the state of Israel in 1948. The latest syntheses by Israeli archaeologists are Amihai Mazar's *Archaeology of the Land of the Bible 10,000- 586 b.c.* (1990) and Amnon Ben-Tor's edited volume *The Archaeology of Ancient Israel* (1992).

In the modern Hashemite kingdom of Jordan, which inherited eastern Palestine or Transjordan after the end of the British Mandate, another national school flourishes. There is a vigorous Department of Antiquities, which publishes annually; programs of archaeology at the University of Jordan and Yarmuk University; a large group of professional archaeologists, most with doctorates from European universities; and dozens of field projects. Foreign archaeological work is much more prominent here than in Israel and is sponsored chiefly by American, British, German, and other institutes in Amman. Although

the archaeology of Jordan still lags somewhat behind archaeology in Israel, some idea of its rapid progress may be gleaned

from such works as the four-volume *Studies in the History and Archaeology of Jordan* (1982-1992). There is no biblical archaeology of any persuasion in Jordan.

Archaeology in Syria has scarcely been covered because Palestine has loomed relatively larger in terms of interest and fieldwork. Yet coastal, central, and southern Syria (plus modern Lebanon) constitute the major part of ancient Canaan, or the southern Levant. The relative neglect is probably because of the area's isolation from Albright's original concept of Syro-Palestinian archaeology because of modern Middle Eastern politics and the instability of the region. Nevertheless, large and important excavations have been carried out in the above areas of Syria and Lebanon since the 1920s. The sites include American work in the Amûq and at Sarafand (the latter in Lebanon); Italian work at Tell Mardikh/Ebla; French work at Ugarit, Byblos (now in Lebanon), Qatna, Qadesh, and many other sites; Danish work at Hama; German work at Kamid el-Lôz and the Bega Valley (in Lebanon); and more recent Syrian-sponsored excavations, especially at Islamic sites. American work has been undertaken recently only on a small scale, principally in connection with the international salvage campaign when the Al-Thawra dam was being built on the Upper Euphrates (1963-1971).

The Syrian Directorate General of Antiquities and Museums continues the traditions of the long French Mandate. There are major museums in Aleppo and Damascus, and important publications include the periodicals *Syria* and *Annales Archéologiques Arabes Syriennes.* Potentially far richer in archaeological remains than Palestine, Syria may well have spectacular prospects in future. In any case, Albright's early intuition that Syria and Palestine were part of the same cultural sphere in antiquity, and should be studied in conjunction, appears to have been well founded, despite the modern political fragmentation of the area. The same may yet be true of Lebanon (part of ancient greater Syria or Canaan), where disruption of the country since the early 1970s has hampered almost all archaeological activities.

Current Status of the Discipline

In the post-biblical archaeology era, the fact that Syro-Palestinian archaeology is no longer a province of biblical studies but a discipline in its own right poses a challenge that must be faced. The only way to relate this new/old discipline and its results to biblical studies is through an interdisciplinary dialogue among professionals. That prospect may seem threatening to some, but there is no acceptable alternative. Certainly the professionalization of Syro-Palestinian archaeology is the only way to guarantee the survival of the field in the United States (as has long since been recognized in the Middle East), and it is also the only means of ensuring healthy growth in all the interrelated disciplines.

What, then, remains of biblical archaeology? What is it, or What can it be? Biblical archaeology, or, to put it more accurately, “the archaeology of Palestine in the biblical period,” is not a surrogate for Syro-Palestinian archaeology, or even a discipline at all in the academic sense. It is only a branch of biblical studies, an interdisciplinary pursuit that seeks to utilize the pertinent results of archaeological research to elucidate the historical and cultural setting of the Bible. In short, biblical archaeology is what it always was, except for its brief bid for dominance of Syro-Palestinian archaeology during the Albright-Wright era. The crucial issue for biblical archaeology, properly conceived as a dialogue, has always been (and is even more so now) an understanding and use of archaeology on the one hand, an understanding of the issues in biblical studies that are fitting subjects for archaeological illumination on the other, and the proper relationship between the two.

What are the prospects for the discipline of Syro-Palestinian archaeology now that it has come of age? First, it is obvious that with the colonial era long since past, the various national schools in the Middle East will increasingly dominate the scene. That is already true in Israel, and with the maturation of the

national schools in Jordan and Syria it will soon be true in those countries as well. European and North American archaeology will thus inevitably become somewhat peripheral, based less on fieldwork and firsthand materials and becoming more synthetic

1990s, much of the pretense of science and the positivism of the new archaeology had faltered, although the ecological orientation and interdisciplinary thrust seemed likely to become permanent fixtures. Out of this frustration, came "postprocessual archaeology," which is more particularistic and focuses once again on culture-history. It is also more eclectic and less dogmatic than the previous approaches. Not surprisingly, the historical orientation of postprocessual archaeology is more congenial to Near Eastern archaeologists, who possess a long and textually documented history with which to deal.

Another aspect of the theoretical flux of the early 1990s is a spin-off of postmodernist, poststructuralist critical theory. In this perspective, archaeology should no longer be seen as "antiquarianism" but as a means of applying archaeological reconstructions to current social environmental, socioeconomic, and other problems, an archaeology as "cultural critique" or even political ideology.

Conclusion

Syro-Palestinian archaeology has had a long and checkered history, but it remains a uniquely interesting and significant branch of Near Eastern archaeology. It contributes to our understanding of the Bible by illuminating the context in which it originated, thus giving it tangibility and a certain kind of credibility. Perhaps more important, however, is the contribution that Syro-Palestinian archaeology can make to elucidating the origins of civilization and the long process of social and cultural change along the periphery of the Fertile Crescent between its two principal foci in ancient Mesopotamia and Egypt. The "archaeological revolution" predicted by our forerunners is not over; it has scarcely begun.

Tabon Caves

From 1962 through 1966, staff members from the Philippine National Museum led by Robert B. Fox excavated a number of caves located at the limestone formation of Lipuun Point, Quezon, on the southwestern coast of Palawan Island in the philippines. Collectively called the Tabon Caves, the excavations and the subsequent analyses of excavated materials revealed a wealth of archaeological data that have extended and detailed the frontiers of Philippine prehistory up until 50,000 years ago.

The findings have profound implications for the Philippine, Southeast Asian, and Pacific region's archaeology because they reveal that “the ancient Filipinos were not only the recipients of cultural complexes from Asia but contributed to the historical developments of neighboring areas” (Fox 1968, 2).

Tabon Cave is the most important cave in the area, revealing a date range from 30,500±1100 b.p. and 9,250±250 b.p., well within the late Paleolithic period in the Philippines. It is large, with the cave mouth measuring sixteen meters wide and eight meters high. Located on higher ground, over thirty meters above the present sea level, the cave is nearly forty-one meters in length. It is bathed by sunlight throughout the day and is generally dry even during the rainy monsoon seasons, making it ideal for extended habitation.

Excavations have established the presence of Pleistocene man in the archipelago and revealed six levels with Paleolithic assemblages. The cave was inhabited continuously during the last glacial period, a time when the sea level was low and the shore, presently just below the cave, was about thirty kilometers away. The presence of a land shelf in this area, as revealed by geological and geomorphological findings, is validated by the total absence of marine shells from all the levels excavated at Tabon Cave.

The habitation levels indicate the ubiquitous presence of chert-flaked tools and waste materials. Attesting to the manufacture and use of stones for tools by the former inhabitants of the cave, thousands of waste flakes and unused cores were recovered in the course of the excavation work at Tabon Cave. One important result of the excavations was the recovery of human fossil bones of at least three individuals. The finds include a large fragment of a frontal bone, including the brow and parts of nasal bones. Although found in a disturbed area of the cave, available comparative data indicate that the fossil finds may be tentatively dated between 22,000 and 24,000 years ago. The late phase at Tabon Cave indicates a jar-burial complex. Archaeological excavations “also yielded jade and stone beads, bracelets, earrings, a few glass beads, and bronze, but no iron” (Fox 1970, 44). Tabon Cave was used for jar burial from about 200 to 500 b.p.

Manunggul Cave was discovered nearly two years after the excavations of Tabon Cave had started. This jar-burial cave was found tucked into the face of a sheer cliff with a majestic view of the South China Sea. It is over 115 meters high from present sea level and has four chambers. The cave has three openings but only two of the chambers, A and B, were used for jar burials. Chamber A contained large jars and covers, smaller decorated and painted vessels, human skulls, and parts of hematite-painted human

The cave has three openings but only two of the chambers, A and B, were used for jar burials. Chamber A contained large jars and covers, smaller decorated and painted vessels, human skulls, and parts of hematite-painted human

tradeware ceramics from China dating to the Song and Yuan dynasties (from the tenth through the fourteenth centuries a.d.) were found.

Archaeological work in the Tabon Caves has revealed more than 50,000 years of Philippine prehistory. The excavations of the caves were a boost to archaeology in the area and have contributed significantly to a better understanding of the prehistory of Southeast Asia and the Pacific region.

Tallgren, Aarne Michaël

(1885-1945)

Born in Ruovesi, finland, Aarne Tallgren was a professor of archaeology at the University of Tartu (Dorpat), Estonia, from 1920 to 1923, a professor of archaeology at the University of Helsinki from 1923 to 1945, chairman of the Finnish Society of Archaeology (later the Finnish Antiquarian Society) from 1930 to 1942, and a specialist in east European and north Asian prehistory. Tallgren was also the editor of *Eurasia Septentrionalis Antiqua* (published in Helsinki from 1926 to 1938, with a supplementary volume in 1954).

Tallgren can be regarded as the most renowned Finnish archaeologist of the twentieth century. His international fame was largely due to his achievements in the systematization and cultural synthesis of east European and Siberian Bronze Age and early Metal period materials and his involvement in the publication and editing of the journal *Eurasia,* a unique international forum for archaeological discussion in the interwar years.

In 1903 Tallgren enrolled at the University of Helsinki to study history and receive instruction in archaeology, which was not yet an official academic subject. Graduating in 1905, he continued his studies in Stockholm and Uppsala under oscar montelius and O. Almgren. Tallgren's early research concerned the so-called Ural-Altaic Bronze Age as outlined by J. R. Aspelin, the founding figure of Finnish archaeology in the 1870s and 1880s. Aspelin's Bronze Age was in fact ultimately related to the semiromantic quest for the prehistoric homeland of the “Finnish race”-the ancestors of the Finno-Ugrians-which had defined the orientation of early archaeological scholarship and prehistoric research in Finland. Tallgren reformulated the problems set out by Aspelin, pointing out that the assumed Ural-Altaic Bronze Age culture did not exist as a single entity; he stressed that the original ethnic interpretation had to be reconsidered.

Before the October Revolution, Tallgren visited russia in 1908, 1909, 1915, and 1917. (He

Tanum

Tanum, an area of northern Bohuslän, southern sweden, has a tremendous wealth of rock art sites, most of them attributed to the Bronze Age, about 3,000 years ago. At that time, the sea level was twenty-five meters higher than at present, and many of the images were carved very close to water. There are thousands of petroglyphs (rock carvings), most of which are figures of warriors (armed men), circles, boats, vehicles, oxen, or plows at Tanum.

Many of the decorated rock surfaces face the sun, and the most visited have now been painted in for easy viewing and photography by the public, a practice that is now frowned on by most specialists-it is possible that they were painted in the Bronze Age, but there is no evidence for this. The so-called Cobbler figure at Backa was the subject of the earliest known rock-art drawing in Europe (seventeenth century b.c.).

Tanum was also the place where Carl Georg Brunius (1792-1869), son of the local parson, made his pioneering drawings of the petroglyphs, a major milestone in rock-art studies that remains almost unknown outside Scandinavia. Today, the best-known and most-visited site is the huge rock of Vitlycke, which has almost 300 figures including the famous “bridal couple.”

Tanum

Tanum, an area of northern Bohuslän, southern sweden, has a tremendous wealth of rock art sites, most of them attributed to the Bronze Age, about 3,000 years ago. At that time, the sea level was twenty-five meters higher than at present, and many of the images were carved very close to water. There are thousands of petroglyphs (rock carvings), most of which are figures of warriors (armed men), circles, boats, vehicles, oxen, or plows at Tanum.

Many of the decorated rock surfaces face the sun, and the most visited have now been painted in for easy viewing and photography by the public, a practice that is now frowned on by most specialists-it is possible that they were painted in the Bronze Age, but there is no evidence for this. The so-called Cobbler figure at Backa was the subject of the earliest known rock-art drawing in Europe (seventeenth century b.c.).

Tanum was also the place where Carl Georg Brunius (1792-1869), son of the local parson, made his pioneering drawings of the petroglyphs, a major milestone in rock-art studies that remains almost unknown outside Scandinavia. Today, the best-known and most-visited site is the huge rock of Vitlycke, which has almost 300 figures including the famous “bridal couple.”

Rock Art

Taylor, Joan du Plat

After earlier involvement in archaeology in Great Britain, Joan du Plat Taylor became assistant curator of the Cyprus Museum in 1932, a post she held until the outbreak of World War II, when she served in the Ministry of Information. She was later, for twenty-five years, librarian in the Institute of Archaeology, London University. She undertook numerous minor excavations in cyprus, but her most important work was at two late-Bronze Age sites: Apliki (excavated in 1939) and Myrtou-Pighades (1950-1951).

Apliki, in the northern foothills of the Mount Troodos, remains the only good example of a mining village of the late Cypriot Bronze Age. The excavations at Myrtou-Pighades (a joint project of the ashmolean museum, Oxford, and the University of Cyprus) exposed the earliest intramural cult center known in Cyprus within one of the most extensive settlements in the northwestern part of the island.

David Frankel

Taylor, Walter W.

(1913-1997)

Walter Willard Taylor was born 17 October 1913 in Chicago, Illinois, and was raised in Greenwich,

Connecticut. A Yale University graduate (A.B., 1935), he conducted archaeological fieldwork in Georgia, Arizona, New Mexico, and Coahuila, mexico.

Taylor enlisted in the U.S. Marine Corps in 1942 and was sent to Algeria after earning his Ph.D. from Harvard University (1943). He served with distinction in Algeria, Italy, and France (receiving the Bronze Star with citation and the Purple Heart). Captured and interned by the Germans, he taught anthropology and geology in two prisoner of war camps; among the prisoners he taught was an Englishman, Philip J. C. Dark, who, with Taylor's help, earned his Ph.D. in anthropology from Yale in 1954 and became a noted authority on African and Melanesian art.

A furor erupted after the 1948 publication of *A Study of Archeology*, the revised version of Taylor's doctoral dissertation. Most of the reaction centered on Taylor's damning critique of pre-World War II American archaeology in which Taylor specifically criticized the work of six leading archaeologists: alfred v. kidder, E. W. Haury, F. H. H. Roberts, Jr., W. S. Webb, W. A. Ritchie, and james b. griffin. In response, Taylor always maintained that his critique was solely theoretical and methodological, but colleagues and students of the six leading archaeologists perceived Taylor's criticisms as prejudicial rather

than intellectual. Furthermore, because Taylor had not yet published the supporting materials for his "conjunctive approach" on how archaeology should be carried out, most readers were skeptical of his arguments. In the short term, the book generated far more heat than light.

Consequently, although Taylor received a Guggenheim Fellowship (1950-1951) and recognition as a scholar (made a Fellow of the American Anthropological Association in 1946 and a Fellow of the American Association for the Advancement of Science in 1954), he could not obtain a permanent academic position during the decade following the book's publication. Instead, he held a series of part-time visiting appointments at six institutions, mostly in Mexico.

In 1958, at age forty-five and with the help of his colleague and former Harvard classmate, J. Charles Kelley, Taylor was hired as professor and chair of the newly formed Department of Anthropology at Southern Illinois University- Carbondale (SIU). Over the next five years he developed a strong curriculum and created a highly regarded Ph.D. program at that institution. The death of his wife in 1960 and other personal problems led him to resign the chair in 1963, but he accepted a research professorship, which he held until his retirement from SIU in 1974 as professor emeritus.

Despite his recognized administrative abilities, Taylor was never nominated for an office in any major archaeological or anthropological society. Students found it difficult to work with Taylor, so although he must be considered a "founder" of the new archaeology, there is no cadre of Taylor's students to carry on his work, as there is for lewis binford, James Hill, and William Longacre. This fact, combined with a modest publication record (although there are some important papers and *A Study of Archeology* is now in its seventh printing), Taylor's failure to publish the long-awaited Coahuila report, and residual anger on the part of some people (after so many years), has meant that Taylor has been less influential in American archaeology than might otherwise have been expected.

Taylor's last public involvement with archaeology was at the Fiftieth Annual Meeting of the society for american archaeology, held in Denver, Colorado, in 1985, and his last publication was the mainly descriptive monograph *Contributions to Coahuila Archaeology* (Carbondale: Southern Illinois University Center for Archaeological Investigations, 1988). He resided on the Oregon coast until his death on 14 April 1997.

Tello, Julio Cesar

(1880-1947)

Julio Cesar Tello was born in peru of inca background, was educated in Lima, and began his Ph.D. studies in medicine in San Marcos, Peru, where he also worked in the National Library and the Raimondi Museum. In 1909, he won a scholarship to study anthropology at Harvard University in the United States, where he was taught by anthropologist Franz Boas and archaeologists ales hrdlikca and frederick ward putnam. He finished his M.A. in anthropology in 1911 and traveled to France, England, and Germany, where he studied the conservation and interpretation of archaeological materials at major museums.

He returned to Peru in 1913 as director of the archaeological department of the Museum of Anthropology and Archaeology (formerly the Museum of Natural History). He accompanied U.S. archaeologists, such as Hrdlicka and Alfred Kroeber, into the field, participated in many other expeditions, and was the first Peruvian archaeologist to excavate scientifically. Tello's early fieldwork was in the Peruvian highlands, where he was the first anthropologist to encounter and study the chavín culture and Chavinoid materials. The site of Chavín in the Peruvian northern highlands comprises a town and temple complex, built and inhabited between 900 and 400 b.c. The Chavín style of art-in sculpture, carvings, textiles, and metallurgy-is distributed across northern, coastal, and central Peru. By the 1930s Tello had worked all over Peru. This diversity in archaeological experience and expertise in the Chavín culture led to his theories about the autochthonous

highland origins of Andean civilization, which he published in *Origen y desarrollo de la civilizacion andina* (Origin and development of the Andean civilization) in 1942. He also wrote newspaper articles on archaeological topics, and these helped to popularize the subject and interest the Peruvian people in it.

Tello became director of the University Museum at San Marcos in 1923, director of the National Archaeological Museum in 1924, and professor of general archaeology at San Marcos in 1923; then at the same institution he became professor of American and Peruvian archaeology in 1928, a position he kept for the rest of his life. He was also briefly professor of anthropology at the Pontifical Catholic University (1931-1933). Through all of this work, Tello influenced and trained a generation of Peruvian archaeologists.

He was drawn into Peruvian politics, which proved ultimately to be to his personal and professional disadvantage, and he was a member of the National Congress from 1917 to 1928. He was honorary curator of archaeology at Harvard University; a fellow of the Royal Anthropological Institute, London; and an executive board member of the Institute of Andean Research.

Tenochtitlán

The capital city of the aztec empire, Tenochtitlán was founded in a.d. 1325 and fell to the Spaniards under Hernando Cortés on 13 August 1521. In less than 200 years, the island city had a remarkable growth and development, and by the time the Spaniards arrived it was one of the largest cities in the world. Certainly, it was one of the most beautiful: the Spaniards were in awe of it as they gazed upon the city shortly before meeting the Aztec emperor Motecuhzoma (Montezuma). In the words of one eyewitness, the Spanish foot-soldier Bernal Díaz del Castillo:

And in the morning we arrived at a wide causeway and we continued marching toward Iztapalapa. And from the causeway we saw so many cities and towns in the water, and other great towns on the lakeshore, and that straight and level causeway leading to Mexico [Tenochtitlán] made us marvel, and we said that it was like the enchantments that are written about in the tale of Amadis, on account of the great towers and pyramids and buildings that rise from the water, and all built of stone masonry. And some of our soldiers wondered aloud if the things that we saw were not a dream.

(Matthews 307-308)

Aztec descriptions of the city were understandably no less glowing: “The city is spread out in circles of jade, radiating flashes of light like quetzal plumes. Beside it the lords are borne in boats: over them extends a flowery mist,” elegized one poet.

According to legend, Tenochtitlán was founded at a nadir in Aztec history. The Aztecs had just been driven out of a city where they had served as mercenaries, having committed atrocities that disgusted their hosts. The Aztecs were forced to flee to a group of low, swampy islands that lay in the western part of Lake Texcoco, the largest of a series of lakes that formed the heart of the basin of mexico where

Mexico City now stands. It had long been prophesied that they would be given a divine sign by their patron god, Huitzilopochtli, when the time was right to build their city and become ancient Mexico's “chosen people.” This sign would be an eagle eating a snake and perched on a prickly-pear cactus, and the Aztec priests saw that sign on those swampy islands in Lake Texcoco.

The Aztecs settled on the islands, driving wooden stakes into the grounds as piles to anchor their building foundations, and gradually their fortunes improved. In a.d. 1428, they attacked and beat the most powerful city in the basin of Mexico, and from that time they were the most powerful nation in the region. The city grew rapidly in both grandeur and size, ultimately reaching a population of 150,000-200,000 people and covering perhaps twenty square miles.

By the time of the Spaniards' arrival, the city was a metropolis of gleaming white houses and temples interspersed by canals and linked to the mainland by a series of causeways. In the center

of the city was a sacred precinct, surrounded by a wall and containing the great temples of the city, a ball court, and a “skull-rack”-a structure that contained the skulls of tens of thousands of sacrificial victims skewered on wooden stakes. All buildings were dominated by a huge pyramid topped by twin temples: one was the house of the Aztec rain god, Tlaloc; the other, that of Huitzilopochtli, the war god and patron of the Aztec people.

Outside the precinct wall, but still at the heart of the city, were the palaces of the various Aztec emperors. Beyond these were the houses of the nobles and commoners laid out in a grid with canals serving as streets (many of the Spanish conquerors compared Tenochtitlán most favorably with Venice). The city was divided into quarters, each quarter was divided into smaller units called *calpulli,* and by all accounts, the city was very clean, orderly, and efficiently run. The great market of the Aztecs was in another city, Tlatelolco, immediately to the north of Tenochtitlán. There, some 60,000 people would pour into the market to exchange wares brought in from every corner of the empire.

After conquering the Aztecs, the Spaniards razed the city and began to build their own capital of New Spain-the city now called Mexico City. The Spaniards reduced most of the beautiful Aztec buildings to rubble, reusing many of the stones in their own constructions. Even so, the rubble reached in some parts to a height of three to four meters, which means that in many parts of Mexico City there are preserved remains of Tenochtitlán. Almost any deep excavation in the central part of the city will reveal such remains, and in 1968, excavations to extend Mexico City's subway system uncovered a perfectly preserved Aztec temple. It was kept as the centerpiece of the Pino Suárez subway station.

In 1978, a huge carved stone was found by electrical workers in central Mexico City. The stone was decorated with the relief of an Aztec moon goddess, Coyolxauhqui, sprawled dead and dismembered on the ground. In fact, the Coyolxauhqui stone was at the base of a stairway leading to the temple of Huitzilopochtli and recalled the Aztec myth telling how Huitzilopochtli killed his half-sister Coyolxauhqui, dismembered her, and threw her body down from Coatepec (Snake Hill). The Aztec Great Temple of Tenochtitlán, then, was the physical reconstruction of Coatepec, with the broken body of Coyolxauhqui at its base.

Subsequent excavation of the Great Temple has revealed the way in which the structure was enlarged over the years, each construction being larger and more elaborate in direct reflection of the growing fortune of the empire. The Great Temple was the ritual heart of the empire, and it was at the very center of Tenochtitlán.

Teotihuacán

A huge ancient city that dominated central mexico for most of the first millennium a.d., Teotihuacán is located in the northeastern part of the basin of Mexico, about forty kilometers northeast of modern Mexico City.

In 1500 b.c., the basin of Mexico was dotted with small agricultural villages. Gradually, some of these villages grew in size and local power, a process that culminated in the dominance of just one city, San Cuicuilco, which today lies underneath Mexico City's southern suburbs. By 300 b.c., San Cuicuilco had an estimated population of more than 10,000 people-perhaps one-third of the basin's entire population. At the time, the vast majority of the population of the basin of Mexico was in the south. The northern half of the basin (which was generally drier and more prone to frosts and which also had saltier lakes than those in the south) was relatively unpopulated, although some small agricultural villages were beginning to farm the Teotihuacán region in the northeast. The pattern was soon to change, however: the villages in the Teotihuacán region grew rapidly (in part perhaps owing to

the culprits were, they seemed to have shared Teotihuacán's belief system, for this was not wanton destruction by invading barbarians.

A restored painting found in Teotihuacán

(Gamma)

Although Teotihuacán's political power was gone after 750, the city had a sizable population for centuries. For instance, the city still had 40,000 inhabitants in 950. In Aztec times, although the population of Teotihuacán was much reduced, the city was a place of pilgrimage. It was revered by the Aztecs and their contemporaries as the home of the gods, and according to Aztec legend, the current world age was created by the self-sacrifice that the gods made at Teotihuacán. Ironically, that self-sacrifice was done by fire: the gods leaped into a sacred fire to create the sun and other elements of the cosmos.

Despite the tremendous amount that is now known about the great city of Teotihuacán, there is still a great amount that is not known. Even the language that the ancient people of Teotihuacán spoke is not known for certain. Although more is now known about the organization of the city, details of the sociopolitical organization of the city and of the nature of Teotihuacán rulership remain elusive. It is clear, however, that Teotihuacán was the largest and most powerful city in Mesoamerica until the rise of the Aztec capital tenochtitlán in the fourteenth and fifteenth centuries a.d.

Terracotta Warriors

One of the great archaeological discoveries of the twentieth century was made by accident in the spring of 1974. Peasants from the village of Xiyang in Lintong, Shaanxi Province, in the People's Republic of china, were engaged in digging a well and discovered pottery figures and tiles. The similarity between the tiles discovered in the village well and those unearthed by farmers in the vicinity of the tomb of Qin Shi Huang (China's first emperor) was noted. Excavation of the site by a team from the Shaanxi Provincial Relics Bureau began in July 1974, and within two years, it

had become clear that the terracotta warriors (and horses) were indeed part of a buried army related to the mausoleum of Qin Shi Huang.

Excavation at the site has continued ever since, with three major pits being opened, and further explorations in the area surrounding the great mausoleum have revealed new sites. Thus far, over 8,000 warriors and horses have been recovered, along with over 100 wooden war chariots. A major museum has been constructed at the site of Pit 2 displaying many of the weapons found with the warriors, and another housing the incomparable bronze chariot and horses has opened recently.

Part of a buried terracotta army related to the mausoleum of China's first emperor, Qin Shi Huang

Thompson, Sir J. Eric S.

(1898-1975)

One of the greatest scholars of the ancient maya civilization, J. Eric S. Thompson was born and educated in England. He fought in World War I, and in the early 1920s, he spent some time as a gaucho in Argentina.

In 1926, Thompson traveled to mexico to work at chichén itzá. From 1926 to 1935 he worked for the Chicago Natural History Museum, and in 1935 he joined the staff of the Carnegie Institution, where he spent the rest of his career. Thompson traveled widely in the Maya area and published works covering the archaeology, ethnography, history, mythology, and hieroglyphic writing of the Maya. He was a prolific scholar, writing over 200 books and articles that ranged over a wide array of subjects, from the uses of tobacco among the Maya to legends concerning the moon. Many of Thompson's books were written for the general public, and, along with his great contemporary sylvanus morley, he was largely responsible for popularizing the temples and sites of the Maya area. He also published several major scholarly books, one of which, *Maya Hieroglyphic Writing* (1950), was for its time as complete a statement about Maya hieroglyphics and calendars as could be made.

Maya hieroglyphs were Thompson's great love, and it is ironic that Thompson was wrong

concerning both of the two most important issues involving Maya writing. The first concerned the content of the thousands of surviving Maya carved stone monuments: Thompson believed that they were carved to commemorate the passage of time and that it would have been sacrilegious for any Maya to glorify individual achievements. This view was dramatically overturned in 1960 when tatiana proskouriakoff showed that the Maya monuments do indeed have historical content; to his credit, Thompson immediately and graciously accepted Proskouriakoff's arguments.

The second issue concerned the nature of the script. Thompson never wavered from his deeply held conviction that Maya hieroglyphic writing was a logographic system (in which signs represent entire words), but it has now been convincingly demonstrated that the script is a "mixed" one, containing both logographs and syllabic signs. Even though Thompson, were he alive today, might not approve of the methods of decipherment, he would be gratified to know that over 90 percent of Maya hieroglyphs have now been deciphered.

Thompson made many great contributions in the advancement of our understanding of the Maya culture. The correlation between Maya and Christian calendars is essentially the one proposed by him in the 1920s, he published a catalog of Maya hieroglyphs that is still widely used today, and one of his last publications was a detailed study of the most famous surviving Maya book, the Dresden Codex.

Thomsen, Christian Jürgensen

(1788-1865)

Born in Copenhagen the son of a wealthy businessman, Christian Jürgensen Thomsen worked in the family business while pursuing his antiquarian interests part-time. He began to collect coins and antiquities and in 1816 was appointed national antiquary and secretary of the Antiquaries Commission. As such, he began to expand and rearrange the collections of the Museum of National Antiquities in Copenhagen. To do this work Thomsen had to devise a chronology or method of explanation for the display of archaeological artifacts and material, and he chose the three-age system of stone, bronze, and iron to organize them and make them coherent. This chronology was put into place in the museum between 1818 and 1825 and appeared in print in the museum's guidebook *(Guide to Northern Antiquities)* eleven years later.

Thomsen was not the first to devise the three-age system, but he was the first archaeologist to formulate, define, and illustrate it with archaeological materials and the first to publish it. Thomsen defined the metal ages primarily on the basis of types of weapons and tools and, as importantly, on their find contexts. Like the great numismatists hans hildebrand, bror emil hildebrand, and sir john evans, Thomsen found that his numismatic background was of great benefit when investigating the typologies of other material. He was a formidable organizer and administrator, an innovative thinker, and a nationalist-keen to describe and celebrate the origins of denmark and the Danish people through the collections in the museum.

Owing to his extensive connections in scientific circles within Scandinavia, Thomsen advised Bror Emil Hildebrand on the arrangement of the collections of Lund University in sweden, which was also based on the three-age system. Hildebrand used the system again in the Stockholm Museum, and it had an impact on the collections in the museum at Christiana (Oslo), Norway, by 1835. By the time it was published the next year, the system had already been widely accepted in archaeological circles across Scandinavia. Consequently, Sandinavian archaeological collections were the first in Europe to be organized both regionally and culturally, and they were homogenous, large, and coherent enough to make the next stage in the development of archaeology-that of scientific analysis, periodization, and more detailed chronology-possible.

In 1839, Thomsen was appointed curator of the Art Museum and Collection of Paintings in

Three-Age System

Rightly regarded as being one of the most significant conceptual advances in prehistoric archaeology, the three-age system had a long gestation that drew on the writings of classical historians and geographers, Enlightenment philosophers, antiquarians in Scandinavia, and the large collections of the Museum of National Antiquities in Copenhagen. Historians of archaeology are fond of demonstrating that the idea of producing a sequence of human history tied to a gradual evolution in the complexity of technology and material culture (from Stone Age to Bronze Age and then to Iron Age) is as old as the ancient Greeks. Certainly, the discovery of contemporary peoples in the Americas (and the Arctic) who used stone tools and who were believed to be in a comparatively uncivilized state provided strong support for such ideas. It is also true, as Swedish archaeologist Bo Gräslund (1987) has argued, that other antiquarians such as the German Freidrich Lisch (1801-1883) were persuaded that the writings of the ancients, the philosophers, and the explorers might provide a valuable key to unlocking the secrets of European prehistory. Nonetheless, it was the Dane christian jürgensen thomsen (1788-1865) who did the most to develop and promote the three-age system.

It is significant that it is easier to discuss the impact of the three-age system through Thomsen's book-*Ledetraad til nordisk Oldkyndighed* (1836), published in a very bad English translation as *Guide to Northern Archaeology* (1848)-than it is to recount the steps Thomsen took to develop the system. Historians of archaeology have stressed that the system was the outcome of Thomsen's desire to rearrange the collections of the Museum of National Antiquities in Copenhagen in a strict chronological form. Gräslund has argued that this process occurred sometime between 1818 and 1825, when the exhibition was completed. He has also noted that this work was achieved at least ten years before the publication of the *Ledetraad* and that the system had been exported to Sweden and Norway by the early 1830s.

Thus, the *Ledetraad* is a museum guidebook that provides an explanation of the objects in the collection within the context of a broader exposition of how archaeologists create information and how artifacts can be dated. In this exposition, Thomsen went well beyond a description of technology to include discussions of a wide range of objects and site types, focusing particularly on the association of artifacts in sites. This more complex understanding of how archaeologists could define chronology in ways that could be directly confirmed by field discoveries was a significant reason for the early and widespread acceptance of the three-age system in Scandinavia and northern Germany. For an understanding of how the system was "exported" from the north to the rest of Europe we need to turn to the advocacy of Thomsen's successor, jens jacob worsaae, especially the English translation of his book *The Primeval Antiquities of Denmark* (1843), and German scholar ludwig lindenschmidt (1809-1893).

At its height, during the Maya classic period (a.d. 250-900), Tikal was a massive site, covering some sixty-five square kilometers and containing thousands of structures-the population of Tikal at its height was perhaps 100,000.

Tikal was rediscovered only 150 years ago, and for the second half of the nineteenth century it was visited by a succession of early researchers. It was not until the 1950s, however, that excavations began. From 1955 until 1969,

Tikal is famous for its lofty pyramid temples and other impressive architecture. The heart of Tikal, the so-called great plaza, is flanked on the east and west side by two great pyramids (Hasaw Chan K'awil was buried in the eastern pyramid); on the north side of the plaza is the ritual heart of the city, and on its south side is the great palace where the kings lived, received tribute, and held court.

Today, Tikal is surrounded by one of Guatemala's national parks, and there is dense tropical forest on all sides. The site has been well developed for tourism, and access to it is very easy-certainly quite different from the several days' ride on muleback that was the only way of access until the 1960s.

Tindale, Norman

(1900-1993)

The professional career of the Australian zoologist, anthropologist, and archaeologist Norman Tindale began in 1917 when he joined the staff of the South Australian Museum in Adelaide. After early zoological work in Cape York and the Gulf of Carpentaria, Tindale moved into anthropological fieldwork in the 1930s, first (1933) in the Mann Ranges of South Australia and subsequently (1935) in the Warburton Ranges of Western Australia.

Tindale is most famous for his work at Devon Downs, a rock shelter on the Murray River in South Australia where the first evidence of cultural change in Australian prehistory was collected. Tindale also gained notoriety for his explanation of these changes as being the product of movements of prehistoric populations.

Toltecs

Toltecs is the name given to a group of people who were considered by the aztecs and most of their contemporaries to have represented “the golden age” in Mesoamerican history. The name “Toltec” means “people of the place of reeds,” and Tollan (Tula), “the place of reeds,” figures in the origin myths of many Mesoamerican peoples from the Aztecs to the Maya. Descriptions of Tollan as a mountain surrounded by reedy swampland may well have been an evocation of the environment of mesoamerica's first civilization, the olmecs, and their human-made mountains in the swampy lowlands on the southern borders of the Gulf of Mexico.

Ruins of the Toltec city of Tula

(Corel)

Because of the widespread origin myths involving Tollan, there are actually many places in mexico that have used or incorporated the name (which was corrupted by the Spaniards to Tula). Archaeologically, the Toltecs have been identified specifically with the site of Tula, some seventy kilometers north of Mexico City. This site was first occupied during the eighth century a.d., as the ancient city of teotihuacán, which had dominated Mexico for the first millennium a.d., was declining. By a.d. 900, Tula was a major site, and in the following 300 years, it came to dominate central Mexico.

At its height during the eleventh and early twelfth centuries, Tula covered thirteen square kilometers, and had a population of up to 60,000 people. The central part of the site had broad plazas punctuated with temple pyramids, ball courts, and colonnaded palaces. Toltecs who were farther down on the social scale lived in flat-roofed houses with sleeping rooms arranged around open patios where many of the daily activities would be undertaken. Family altars and shrines have been found in the patios of several houses, and the houses themselves were connected by passageways and alleys. There is evidence that much of the city was laid out in a rough grid. Workshops abounded in Tula, especially for work in obsidian and ceramics. Agriculture was carried out with the aid of irrigation (rainfall is low and undependable in the area), and the dozens of small farming hamlets that have been found within fifteen kilometers of the city must have provided much of Tula's food supply. In the Mesoamerican tradition, additional food and other commodities would have flowed into the city as tribute from subject regions.

By the late twelfth century, Tula was in trouble. The central ceremonial part of the site was sacked and burned, and there are signs of destruction in the suburbs as well, for some courtyards and altars were looted. Later historical accounts mention a civil war in the city, but the final collapse of Tula may well have been at the hands of barbarians from the north, the "Chichimeca" peoples.

Despite the devastation of the city, the Toltecs left an important legacy. Tollan was considered to be the metaphor in Mesoamerica for civilized life, and the Toltecs were eulogized as master craftsmen and artists. Later peoples went to great lengths to claim Toltec heritage. For example, the ruling families of the cities in the basin of Mexico all claimed descent from Toltec royal lines, and those groups that didn't have Toltec blood sought to marry into lineages that did: having royal Toltec ancestry was a major prerequisite of legitimacy. The Aztecs were one such group, and their leaders went to great pains to obtain Toltec ancestry through marriage. Once they had achieved that end, the Aztecs reinforced their "Toltec heritage" by looting the site of Tula and incorporating its sculptures and other relics into their own imperial capital's buildings and ritual offerings.

Troyon, Frederic

(1815-1866)

Frederic Troyon was one of the first and most important Swiss archaeologists of the nineteenth century. In 1838, when archaeology was still in its infancy in switzerland, Troyon discovered burial places on his family estate of Bel-Air in Cheseaux (in Vaud Canton), which he correctly determined as Burgundian. He soon abandoned theological studies and devoted himself to the new discipline of archaeology. Within three years, he had completely excavated the 162 tombs, and, remarkably, he published the richly illustrated results as early as 1841. That same year, Troyon took the almost revolutionary initiative of trying to make an archaeological map of the canton of Vaud by sending a precise questionnaire about antiquities and monuments observed in the region to all the local authorities, both public and religious.

As a tutor to the royal family of sweden (1843-1846), Troyon passed on his interest in archaeology to the future king Charles XV and helped to create a Swedish institution for the preservation of antiquities. He also took advantage of his stays abroad to acquire a vast archaeological knowledge, and he built up a considerable collection of drawings and watercolors, copies of artifacts in most of the museums of Germany, russia, and Scandinavia that he visited.

A keen advocate of the three-age system, of which he would be one of the main promoters in Switzerland and france, Troyon was moreover one of the pioneers of comparative ethnology, using data on "primitive peoples" (as observed in the New World) provided by contemporary travelers. He also

made an innovative study of the stylistic typology for Burgundian belt buckles (Troyon 1843).

Appointed curator of the Museum of Antiquities of Lausanne in 1852, Troyon undertook numerous excavations and explorations, including one of the first known underwater excavations in Morges (Vaud) in 1854 with fellow Swiss archaeologists Adolf Morlot and Forel (Ruoff 1990, 29). His interpretations, however, which were often integrated into a mystical and religious network of ideas, are now out of date. He considered the succession of prehistoric ages the result of brutal and successive invasions, and he meant to prove this theory by demonstrating changes in burial ritual: the incinerating celts were supposed to have arrived in Switzerland with bronze technology, then to have been supplanted by the mound-builder, iron-working Helvetians.

Nevertheless, Troyon did enjoy the sort of influence he deserved at the time because of his independent nature. Taking a stand against the tutelary figure of Swiss archaeologist ferdinand keller, with whom he fell out, Troyon refused to attribute all lake dwellings to the Celts. Finally, however, as a victim of a fraud, his reputation was besmirched, and some people went so far as to wrongly accuse him of perpetration and collaboration with the fraud's instigators (Vayson de Pradenne 1932). Troyon's work maintains great value today. He had the praiseworthy habit of writing careful and accurate reports and of recording elements that he did not understand, which makes the reinterpretation of his excavations easier.

Tsountas, Christos

(1857-1934)

Archaeologist Christos Tsountas succeeded heinrich schliemann at Mycenae after the latter decided to

return to the excavation of Troy in 1877. Tsountas, who was a far more gifted excavator than Schliemann, excavated the remains of the Bronze Age palace at the summit of the citadel at Mycenae between 1877 and 1902. Although this work was important, Tsountas went on to make significant contributions to our understanding of the Neolithic period in greece at the sites of Sesklo and Dimini and through his work *Prehistoric Acropolis of Dimini and Sesklo,* published in 1908. Tsountas then undertook pioneering work in the Cyclades Islands in the Aegean Sea.

Turkey

The most conspicuous geographic feature of Turkey is division, for it is a land of complex terrain partitioned by complicated mountain chains. Anatolia (as the land is known locally) is a mosaic of environmental zones, ranging from coastal fringes through a vast central plateau to the rugged geography of the eastern highlands, offering a range of ecological options for pastoralists (stockbreeders), farmers, and fishing communities alike. In antiquity this broken landscape engendered, for the most part, a spectrum of cultural diversity, which often displayed vigorous local traditions capable of absorbing new cultural stimuli that found their way along the many natural highways that cross the land.

Tsountas, Christos

(1857-1934)

Archaeologist Christos Tsountas succeeded heinrich schliemann at Mycenae after the latter decided to

return to the excavation of Troy in 1877. Tsountas, who was a far more gifted excavator than Schliemann, excavated the remains of the Bronze Age palace at the summit of the citadel at Mycenae between 1877 and 1902. Although this work was important, Tsountas went on to make significant contributions to our understanding of the Neolithic period in greece at the sites of Sesklo and Dimini and through his work *Prehistoric Acropolis of Dimini and Sesklo,* published in 1908. Tsountas then undertook pioneering work in the Cyclades Islands in the Aegean Sea.

Turkey

The most conspicuous geographic feature of Turkey is division, for it is a land of complex terrain partitioned by complicated mountain chains. Anatolia (as the land is known locally) is a mosaic of environmental zones, ranging from coastal fringes through a vast central plateau to the rugged geography of the eastern highlands, offering a range of ecological options for pastoralists (stockbreeders), farmers, and fishing communities alike. In antiquity this broken landscape engendered, for the most part, a spectrum of cultural diversity, which often displayed vigorous local traditions capable of absorbing new cultural stimuli that found their way along the many natural highways that cross the land.

PREV NEXT

In the nineteenth century an initial interest in Anatolia's past was fueled by the desire to uncover the remnants of civilizations mentioned in the Greco-Roman and biblical historical traditions. Accordingly, the Aegean coast received much attention from early archaeologists, who commenced excavations at ephesus, Pergamum, Miletus, and Troy (Hissarlık), perhaps the most celebrated site. Soon after, the Bronze Age cultures on the central plateau, homeland of the Hittites, attracted interest, most especially the extensive site at bogazköy (ancient Hattusha). In recent decades the tempo of archaeology in Turkey has increased considerably as dozens of international rescue projects record cultural heritage threatened with destruction by the waters of several dam lakes. Investigations began in the Keban region of east-central Turkey (running from 1964 to 1974), but the focus has shifted to the southeastern regions, where the ongoing development project known by the Turkish acronym GAP has necessitated rescue operations at many sites along the Euphrates and Tigris Rivers and their tributaries (*American Journal of Archaeology* 1955; Tuna and Öztürk 1999).

The Earliest Stages

Although Paleolithic and Mesolithic remains have been found at many sites, especially in the southwestern area, the earliest stages of human occupation of Anatolia are relatively unexplored. We gain a glimpse of the Lower Paleolithic at Yarımburgaz Cave, but the most complete Paleolithic sequence has been attested at Karain Cave near Antalya, noted for its Middle Paleolithic (Mousterian) industry and Upper Paleolithic rock art (Joukowsky 1996). Microlithic stone traditions of the Mesolithic (or Epipaleolithic) at Karain and nearby sites, including Beldibi Cave, bring us to the threshold of the earliest sedentary communities of the Neolithic around 11,000 b.c., when Anatolia experienced a period of climatic amelioration.

The Neolithic

As late as the mid-1950s no archaeologist was prepared to accord Anatolia a Neolithic period, believing that the formative processes that led to the domestication of plants and animals, which gradually changed the fundamental basis of subsistence economy in prehistory, took place south of the Taurus Mountains. Then, in 1961, James Mellaart began excavations at Çatal Huyük, which dazzled an unsuspecting discipline with its preservation and rich finds (Matthews 1998; Mellaart 1967). The largest site of its time (late seventh to mid-sixth millennium b.c.), covering 21 hectares, the settlement consisted of blocks of tightly clustered rooms, with rooftop access, and small courtyards. Some of the rooms, called shrines by Mellaart, were decorated with vivid wall paintings, plaster reliefs, and the skulls of horned animals fixed into the walls. Two broad categories of scenes are portrayed on the walls: representational scenes, featuring humans, animals, and birds, and geometric scenes, with patterns that perhaps imitate textile designs. Such exuberance and symbolism, unparalleled in a prehistoric building, likely reflect the community's belief system, which has been a focus of the renewed excavations at the site (Hodder 2000; Matthews 1998). Relatives were buried under the floors of both shrines and houses, and grave goods suggest a modest degree of social differentiation. The funerary gifts, among them Mediterranean shells, metal ores, obsidian, cinnabar, serpentine, and other exotic commodities, do confirm, however, the existence of a significant exchange network.

Today at least four distinct areas attest to intensive Neolithic settlement: the Urfa-Diyarbakır region of the southeast, the Konya-Aksaray region in the center, the Lake District of the southwest, and the Marmara region of the northwest (Özdogan and Başgelen 1999).

The funerary gifts, among them Mediterranean shells, metal ores, obsidian, cinnabar, serpentine, and other exotic commodities, do confirm, however, the existence of a significant exchange network.

Today at least four distinct areas attest to intensive Neolithic settlement: the Urfa-Diyarbakır region of the southeast, the Konya-Aksaray region in the center, the Lake District of the southwest, and the Marmara region of the northwest (Özdogan and Başgelen 1999).

yielded a sophisticated repertoire of pottery that was often painted with bold red patterns on a cream background. Clay figurines found at these sites may have been part of the accoutrements of domestic cult practices. Though hunted animals supplemented the diet, these communities had by that point developed an economy based on agriculture and stock breeding (Özdogan and Başgelen 1999).

The Chalcolithic

In terms of lifestyle, the transition from the Neolithic to the early stages of the subsequent cultural period, the Chalcolithic, was virtually seamless (Yakar 1985, 1991). But by the end of the Chalcolithic (ca. 3200 b.c.) there was an upsurge in technological innovations and cultural interaction. Although new sites were established in many parts of Anatolia, several large cultural zones can be discerned, largely on the basis of geography and contacts.

The Euphrates Valley and southeastern regions were much influenced by Mesopotamian and Syrian traditions, with the Taurus Mountains, mostly an obstacle to easy communication, determining the degree and nature of interaction with the northern districts (Joukowsky 1996). Although southern interconnections in these districts were pervasive throughout the Chalcolithic and subsequent early Bronze Age, they were more directional than uniform. Initial contact from the south, suggested by the presence of Halaf pottery at several sites, was followed by an expansion into the Middle Euphrates to exploit natural resources, where a late-Ubaid tradition is well documented at Degirmentepe. By the late Chalcolithic period the area below the Taurus Mountains, the northern reaches of mesopotamia, experienced intensive contact with southern merchant-venturers. Contact between indigenous communities and Uruk Mesopotamia is indicated at several places, especially at Hacınebi, whereas at Hassek Höyük there is evidence of an actual colony of late-Uruk type. Repercussions of this activity were felt north of the mountain range, especially in the Malatya and Elazıg regions, where local cultures adopted Mesopotamian forms of administration. At Arslantepe (Level VIA) centralized economic activity is reflected in a well-preserved complex that contained many bullae (seal impressions) and wheelmade pottery. Emerging connections with different cultural environments farther east, most notably with Transcaucasia, are also clearly indicated by the presence of handmade red-and-black burnished pottery.

West, north, and central Anatolia formed an independent culture province in the Chalcolithic period, with strong links to the Balkans and beyond to the Hungarian plains (Joukowsky 1996). Connections between the Karanova VI and Vinça D traditions of southeastern Europe and Anatolia are best seen at Ilıpinar, Alişar Höyük, Çadır Höyük, and I·kiztepe, where curvilinear-decorated and graphite-slipped pottery have been found. In the southwest, Beycsultan and sites in the Elamlı plain demonstrate continuity of late-Neolithic traditions. Architecture varied according to geography and climate. Mud brick was a ubiquitous building medium, though timber and wattle-and-daub houses, usually freestanding, were also common along the wet Pontic zone.

The Bronze Age

In the early Bronze Age (ca. 3200-2000 b.c.) sites displayed distinctive regional traits in every aspect of material culture (Yakar 1985). A unifying thread within this diversity was the impact of innovative metal technologies, especially in the third and final phase of the period, when even pottery imitated metallic vessels through highly burnished surfaces and angular shapes. Anatolian smiths made full use of their land's extensive mineral and polymetallic ore resources. Copper was the metal most widely used at the turn of the third millennium b.c., but attempts to combine it with tin (and in some cases with arsenic) were under way by early Bronze Age II. Despite an ever increasing amount of bronze production, actual sources of tin, perhaps the most highly prized metal at that time, have remained elusive, though crucibles

at Göltepe have traces of tin claimed by its excavators to have been mined at Kestel.

Bronze was not the only metal that was worked. Ceremonial artifacts and jewelry of silver,

yielded a sophisticated repertoire of pottery that was often painted with bold red patterns on a cream background. Mud brick was a ubiquitous building medium, though timber and wattle-and-daub houses, usually freestanding, were also common along the wet Pontic zone.

The Bronze Age

In the early Bronze Age (ca. 3200-2000 b.c.) sites displayed distinctive regional traits in every aspect of material culture (Yakar 1985). A unifying thread within this diversity was the impact of innovative metal technologies, especially in the third and final phase of the period, when even pottery imitated metallic vessels through highly burnished surfaces and angular shapes. Anatolian smiths made full use of their land's extensive mineral and polymetallic ore resources. Copper was the metal most widely used at the turn of the third millennium b.c., but attempts to combine it with tin (and in some cases with arsenic) were under way by early Bronze Age II. Despite an ever increasing amount of bronze production, actual sources of tin, perhaps the most highly prized metal at that time, have remained elusive, though crucibles

at Göltepe have traces of tin claimed by its excavators to have been mined at Kestel.

Bronze was not the only metal that was worked. Ceremonial artifacts and jewelry of silver,

indigenous (Hattic) and foreign cultures, especially Hurrian and Babylonian, producing its own distinctive blend. Their cities had two sectors surrounded by massive stone fortification walls: a citadel, with two- or three-story buildings (archive, storage and administrative buildings, and residence of the ruler) on stone foundations with a superstructure of mud brick and timber, and a lower, residential area (Seeher 1999). Access into the city was by a gate flanked by towers and protected by guardian creatures or by a postern gate-the best-known example of which at Bogazköy through the Yerkapī rampart, has a corbeled roof and is 71 meters long. Religious worship featured prominently among the Hittites. Bogazköy alone has revealed some thirty temples at this stage, and nearby is the rock sanctuary at Yazılıkaya with its relief panels. The temple complex was situated in a colonnaded courtyard that was surrounded by numerous storage rooms. Other important Hittite sites are Masat, Alaca, Kuşaklı, and Kaman-Kalehöyük.

In the clay tablets found in the archive at Bogazköy, mention is made of the Ahhiyawa, often cited as the Mycenaeans, whose presence is attested along the west coast of Anatolia at about this time. Indeed, the quest to identify Homer's Troy with either Level VI or VIIA, despite the difficulties of disentangling the complicated fabric of that great narrative, has continued unabated. One thing is certain-the internationalism between Anatolia, the Aegean, and Syria-Palestine is evident in the flourishing trading networks vividly reflected by the rich cargo found on board the Uluburun shipwreck.

East-central Anatolian sites in the Malatya-Elazıg region were heavily influenced by trends in the central plateau, as evidenced by the increase in the size of the sites, fortification systems at Arslantepe VB and Korucutepe F, and affinities in ceramic styles. Along the foothills of the southern Taurus Mountains, settlements such as Lidar Höyük (Levels 8-9) have an assemblage indistinguishable from those at sites in the Amuq Plain, including Alalakh VII, which was built by Yarimlim, a vassal of the Yamkhad kingdom based at modern Aleppo.

Still farther east, in the modern provinces of Erzurum, Kars, and Van, the scene in the second millennium b.c. was quite different, and the axis of influence was eastern rather than southern. No city-states were to be found in these highlands. At Sos Höyük there is clear evidence that the earlier Kura-Araxes cultural complex continued to endure in a modified form (Sagona 2000). Dwellings were different, now solidly built and multiroomed, but, significantly, the deceased were buried in deep shaft graves and supplied with grave goods that have marked similarities to the Trialeti kurgan barrow burials of Transcaucasia, which may point to the arrival of newcomers.

The Iron Age

The stable and prosperous late-Bronze Age kingdoms of Anatolia suffered sociopolitical and economic collapse between about 1250 and 1150 b.c., as did many of Anatolia's neighbors in the Aegean and the Near East. The impact of the invasions that brought about the decline in Anatolia had severely shaken the land and radically changed the map of the subsequent Iron Age. New ruling classes emerged in the centuries that followed, often described as a “dark age” because both archaeological and written records are meager, allowing scholars to sketch only the broadest political and social divisions of Anatolia in the Iron Age (Çilingiroglu and Matthews 1999; Joukowsky 1996).

Eastern Greeks established a number of city-states along the Aegean coast, among them Miletus and Ephesus. Western and central Anatolia was the domain of the Phrygians, the Mushki of the Assyrian records, who had formed a kingdom with centers at Gordion and Midas City by the ninth and eighth centuries b.c. The very few inscriptions in Phrygian, some in beeswax, were written in a new alphabetic script devised by the Phoenicians, which was also adopted by the Greeks, Carians, Lydians, and Lycians. Along the Pontic and in parts of the Hittite homeland, the Kaska, a feared mountainous folk,

reigned supreme, whereas the southeast was occupied by the East Luwians, who were ethnically and culturally related to the Hittites. These Luwian-speakers were organized into a number of small neo-Hittite

from Prehistory through the Lydian Period. Dubuque.

Tutankhamun, Tomb of

The discovery in 1922 of the intact tomb of the eighteenth Dynasty king Tutankhamun (ca. 1333-1323 b.c.) ranks as perhaps the single best-known event in archaeology during the twentieth century. The discovery was the culmination of a methodical search undertaken between 1917 and 1922 by howard carter with the patronage of the Earl of Carnarvon. The subsequent excavation of the tomb by Carter, assisted by a team from the Metropolitan Museum of Art in New York, received an unparalleled degree of attention from the international news media; it was the first archaeological project to be the subject of such press coverage. The debate over the fate of the artifacts was responsible for the rescinding of Egypt's until-then liberal antiquities laws, which had formerly permitted equal division of artifacts between the Egyptian Antiquities Service and foreign archaeological projects.

Tutankhamun's tomb is located in the Valley of the Kings, on the west bank of the Nile near the modern town of Luxor (ancient Thebes) in southern Egypt. The Valley of the Kings, a secluded desert wadi five kilometers west of the Nile, was the burial place of nearly all of the pharaohs of the New Kingdom (Dynasties 18-20, ca. 1550-1070 b.c.). The tomb of Tutankhamun was the only one of these to be preserved virtually intact. Most of the others had been plundered by local tomb robbers by the close of the New Kingdom. Although briefly penetrated within a century of the king's burial, the entrance to Tutankhamun's tomb was later obscured and protected by debris created during the construction of the

tomb of Ramses VI (Dynasty 20), located just above it.

Tutankhamun's tomb itself is modest in scale, consisting of only four rooms (antechamber, annexe, burial chamber and treasury). Objects that would normally have been deposited in an orderly fashion were piled together. The first two rooms contained an enormous volume of personal possessions including furniture, wooden caskets containing clothing, weapons, chariots, games, jewelry, and ritual couches, as well as containers of food, wine, oil, and other funerary offerings. The king's body was buried in a nested sequence of sarcophagi and shrines that filled most of the burial chamber. The fourth room, the treasury, contained the king's canopic shrine as well as an array of religious and ritual items closely connected to the person of the pharaoh.

Although Tutankhamun's life was comparatively short, his reign falls at the end of one of the most widely discussed periods of ancient Egyptian history: the period of the heretic king Akhenaten. The seventeen-year reign of Tutankhamun's father, Akhenaten (called the Amarna Period), witnessed the abandonment of traditional state religion and the sole veneration

of the sun-disc, the Aten. Court life was centered on a newly constructed royal city, Akhetaten (modern el amarna in Middle Egypt). Tutankhamun, originally named Tutankhaten, was responsible for the restoration of the traditional state religion and the abandonment of the short-lived royal capital at El Amarna. At the time of the discovery, it was hoped that Tutankhamun's tomb would shed light on the history of the Amarna period. The tomb, however, is devoid of written documents. The vast majority of material represents either funerary objects specifically produced for the royal burial or personal possessions of the king. Archaeologically, the tomb represents an unparalleled example of an intact royal burial from the height of Egypt's New Kingdom, but provides little historical information relevant to understanding Tutankhamun's reign.

Gold sarcophagus of Tutankhamun

(Image Select)

Despite the meticulous recording by Carter and the Metropolitan Museum team, as well as a series of popular books (Carter and Mace, 1923-1933), the full scholarly publication of the tomb of Tutankhamun was never completed. The records of the excavation, mostly unpublished, are at the ashmolean museum, Oxford. Today the body of Tutankhamun remains in his innermost coffin in his tomb in the Valley of the Kings. The artifacts are housed in the Cairo Museum.

Tylor, Sir Edward Burnett

(1832-1917)

Born in London, England, the son of a prominent Quaker manufacturer, Edward Burnett Tylor

U

Uhle, Max

(1856-1944)

Born in Dresden, Germany, Max Uhle studied languages at the Universities of Göttingen and Leipzig. He worked in the ethnological museums of Leipzig, Dresden, and Berlin, where he became interested in pre-Columbian archaeology.

In 1892, he traveled to South America for the Ethnographic Museum of Berlin to research the inca and the Indians of bolivia. He excavated in peru between 1897 and 1899 at Ancon and Pachacamac and between 1899 and 1901 in the moche and Chincha Valleys and at Huamachuco, Ica, and Pisco. Uhle found ceramics from pre-Spanish cultures at all of these sites-chavín at Ancon and Nazca at Chincha and Ica-and began to interpret the history, cultures, and chronologies of the ancient civilizations that produced them. From 1901 to 1903 he was employed by the University of California, Berkeley, and carried out further excavations of Peruvian coastal cultures and became involved in archaeological research on the shell mounds of California with the American archaeologist nels c. nelson.

From 1906 to 1909, Uhle was director of the National Historical Museum in Lima, Peru. Between 1909 and 1933, he excavated in chile and ecuador, helping to establish an archaeological museum in Santiago, Chile, and working as a professor at the University of Santiago (1912) working at the University of Quito (1919). He returned to Germany, where he was professor at the University of Berlin and worked on Andean archaeology at the Ibero-American Institute until his death during World War II.

United States of America, Prehistoric Archaeology

There is a tendency to treat the history of archaeology as a single development on the model of the sciences (Daniel 1950, 1963, 1975; Trigger 1988; Willey and Sabloff 1974, 1980). This is inappropriate. As theory-driven disciplines, the “hard sciences” are to a large degree “culture-free,” and they do share a more or less politically seamless history. Archaeology, despite wishes and claims to the contrary (Kuznar 1997; Watson, LeBlanc, and Redman 1971), is not science (Dunnell 1982, 1992a). Indeed, if there is a single thread to the history of U.S. archaeology, it has been its aspiration to become scientific for nearly all of its existence (Dunnell 1992a). Such motivation notwithstanding, the lack of scientific theory has permitted the cultural background of individual investigators, common sense, to take over most of the functions of theory (Kuzner 1997). One consequence is that archaeology, unlike science, is heavily influenced by its cultural context. Indeed, the postprocessualists seem to revel in this condition otherwise best construed as our most monstrous failing. Herein lies the fatal error

There is a tendency to treat the history of archaeology as a single development on the model of the sciences (Daniel 1950, 1963, 1975; Trigger 1988; Willey and Sabloff 1974, 1980). This is inappropriate. As theory-driven disciplines, the “hard sciences” are to a large degree “culture-free,” and they do share a more or less politically seamless history. Archaeology, despite wishes and claims to the contrary (Kuznar 1997; Watson, LeBlanc, and Redman 1971), is not science (Dunnell 1982, 1992a). Indeed, if there is a single thread to the history of U.S. archaeology, it has been its aspiration to become scientific for nearly all of its existence (Dunnell 1992a). Such motivation notwithstanding, the lack of scientific theory has permitted the cultural background of individual investigators, common sense, to take over most of the functions of theory (Kuzner 1997). One consequence is that archaeology, unlike science, is heavily influenced by its cultural context. Indeed, the postprocessualists seem to revel in this condition otherwise best construed as our most monstrous failing. Herein lies the fatal error

or both (“academic” archaeology), and that driven by conservation and, of recent, protective legislation, herein termed *cultural resource management* (CRM). Because these kinds of work are differently motivated, they have often developed along divergent lines.

Histories themselves are usually driven by common sense-and that is why, until recently, the word *history* basically meant the history of western culture. One cannot get very far with that tack in examining a discipline that includes common sense as part of its subject. It is not necessary, however, to erect a detailed theoretical structure here. Elucidating but a few concepts will suffice to generate a sufficient framework to analyze American archaeological development. First, since science has played such a role in American developments, it is essential to be crystal clear on what the term *science* denotes. In this context science is an *explanatory system* that uses *theory* to explain phenomena and employs an *empirical epistemological standard,* that is, things don't explain things, events don't explain events, and whether something “works” in physical terms is the arbiter of correctness. All of the commonly cited features of science (i.e., the elements of scientific method) can be traced to these two features (Dunnell 1982).

Second, because of archaeology's particular focus, it is also critical to realize that there are two kinds of structures that meet these general criteria: essentialist (functionalist) science and materialist (historical) science, with the first identifying the ontological position on the significance of variation and the second recognizing different ontological positions on the significance of time. Essentialism sees the variable world as constituted by a finite number of fixed kinds (entities, classes, etc.) between which fixed relations (laws, “generalizations” in the social sciences) obtain. The methodological imperatives that flow from this view can be characterized as ones of “discovery.” Explanation in this view takes the form of timeless, spaceless laws that are often characterized as predictive. They are not, of course; they have this appearance and effect only because in this framework time is an elapsed quantity, not an age; thus, there is, strictly speaking, no past or future. Some sciences (e.g., physics, chemistry) operate wholly within this framework or nearly so. Materialism (not to be confused here with the term as used in anthropology) sees the same variable world as in a state of becoming. Because there are no empirical kinds in this view (kinds are analytic tools), there can be no fixed relations or laws, and without laws there is no appearance of prediction. Kinds are created, not discovered, in order to render variability explicable. Explanation takes the form of sets of contingencies interacting with content-free mechanisms to produce a special kind of “history.” Realistically, although these two approaches have often been opposed (e.g., Kroeber 1935, 1942; Spaulding 1968), there are no strictly materialistic sciences. Rather, disciplines such as evolutionary biology combine both, using the latter to organize the former so that, though there are no laws of history, all history is a consequence of the operation of laws (Popper 1961).

These aspects of our discipline have been discussed at length in other venues (e.g., Dunnell 1982, 1986a, 1992a), and interested readers can consult those items directly. But such aspects require recitation here because they are integral to an attempt to understand the conceptual development of archaeology in the Americas and its present condition in anything other than the most superficial way.

Coming to Grips with the U.S. Archaeological Record

U.S. archaeology is often taken to have begun with the prescient work of thomas jefferson in the excavation and reporting ([1784] 1801) of a small and, as it turned out, rather atypical burial mound at Monticello, Virginia (Heizer 1958; Lehmann-Hartleben 1943). His contribution was by no means isolated. Jefferson's observations and their reporting were certainly unique for the time, but he was in contact both with European scholarship, hardly advanced over his own work in most respects, and with Americans exploring the “west” in North America. For example, Henry Brakenridge, an important explorer of the southeastern (at that time the southwestern) United States, corresponded

PREV NEXT

that the museum became the first institution and intellectual seat of archaeology. More important, however, concern for conservation of the archaeological record led to the development of a particular kind of archaeology in the United States-CRM. But in the nineteenth century and indeed up until the 1970s, these concerns were pursued by the same people who were developing academic archaeology. Through lobbying by professional societies such as the American Anthropological Association and Section H of the American Association of the Advancement of Science, an active government role in preservation began with the creation of the casa grande National Monument in Arizona (1892). Legislation protecting archaeological materials on federal property was adopted shortly thereafter (the Antiquities Act of 1908).

The great amount of time it took for even these modest efforts to be realized can be related, at least in part, to the historical character of archaeology and its lack of scientific standing. The lack of scientific standing meant that archaeology did not enjoy the public support that science as a whole did in the late nineteenth and early twentieth centuries. It remained an esoteric activity without any obvious justification. Archaeology's historical character, however, served to prevent it from being embraced by physical scientists whose essentialist (sometimes obliquely characterized as “generalizing”) approach rejected all history as storytelling and seemingly precluded empirical testing. U.S. archaeologists would periodically be consumed by misguided efforts to make their field a generalizing discipline in pursuit of their scientific grail throughout the twentieth century. The same scenario has plagued biology (Mayr and Provine 1980).

The Emergence of Archaeology from Natural History

Although archaeology continues to be pursued as natural history today in the form of the various “amateur”societies of historical sciences, in which data have unique time-space coordinates, retain a role for amateurs long after their contributions to the ahistorical sciences cease. But the late nineteenth and early twentieth centuries saw the emergence of archaeology as a distinct discipline for the first time. Key was the development of a sense of professionalization, first through its incorporation into museums, most notably the smithsonian institution through the National Museum and the Bureau of Ethnology (later the Bureau of American Ethnology, or BAE). Universities, further contributing by training archaeologists, solidified this sense of profession.

These settings saw the first systematic efforts at artifact description. This, in turn, required the development of theory, that is, some principles or rules for how to conceive, tabulate, and discuss archaeological remains independently of common sense. The initial efforts were modeled on the physical sciences and focused on chipped-stone artifacts (e.g., Rau 1876; Wilson 1899; see Dunnell 1986b and references therein). Chipped-stone artifacts in North America meant “arrowheads, spearheads, and knives” (Wilson 1899); that they were tackled first when ceramics have since proved so much more efficacious reveals something of the inner working of the transition from common sense to archaeological theory. Object naming in English is largely functional, based on what the object does. Consequently, it “made sense” to organize only objects that had all their parts. Because sizable collections of whole chipped-stone tools were amassed in advance of more delicate whole ceramic pots, the former were deemed the “logical” starting place. Ceramics, which would come to dominate U.S. analytic efforts for those periods that produced them, followed somewhat later as, on the functional models, pots (and not shards) were deemed the relevant objects of typology (e.g., Holmes 1886a). Charles Rau and Thomas Wilson's efforts based on geometric shape did not bear any intellectual fruit (no temporal or spatial patterns) and thus gained no currency (Dunnell 1986b).

william henry holmes's ceramic analyses (1886a, 1886b) were more successful. His “philosophic approach” (Mason 1886) allowed him to crudely distinguish what today we would call functional and stylistic attributes, a distinction that would later prove critical to method

PREV NEXT

development. Furthermore, he identified most of the parameters now routinely used in ceramic analysis. His most enduring result, the geographic groups of ceramics (Holmes 1903), was largely a fluke, however, being accidental combinations of geography and the chronology of the custom of including vessels in graves. The first lasting accomplishment of U.S. archaeologists, beyond the recognition and accumulation of samples of the record itself, arose at this time as well-the appreciation and understanding of the technology of U.S. artifacts. Here, too, Holmes was a leader, as he "figured out" (via intuitive combinations of engineering, physics, and ethnographic accounts) how virtually all major classes of American artifacts were manufactured (e.g., 1886a, 1886b, 1890, 1897).

The First Paradigm: Culture History-Science at Last

Archaeology as an ad hoc assemblage of common sense and analogies with ethnographic observation was rather limited in its prospects despite the accumulation of descriptions and objects, even if they were systematic. Although trained as an artist, Holmes was a committed scientist in archaeological matters (Meltzer and Dunnell 1992), and his "philosophical" approach, a step in the right direction, still fell short of qualifying as a general theory. His guiding principles were clearly evolutionary, but, as is so often the case in archaeology, his evolution muddled scientific evolution (e.g., Holmes 1892) and with a more Spenserian evaluation, which was actually influenced by lewis henry morgan et al. (1877) progress-driven framework, little differentiated from Victorian optimism. As crucial as his work has proved to be, Holmes himself lived to see (but never really participated in) archaeology's first and closest approach to becoming science, his lifelong goal.

Three developments proved fundamental to developing a discipline-wide consensus on method, language, and, most important, problem-in short, what Thomas Kuhn (1962) characterized as a paradigm. This consensus has since become known as *culture history*. The first element was the development of a language of observation and an approach to the classification of artifacts. Although critically important, this revolution was confined largely to potsherds, with minor extensions to lithics (stone tools) and bone tools, and it remained restricted to the scale of the portable, discrete object. The second element was adopting a materialist ontology. Like classification, this innovation was far from general in application, being restricted to a narrow methodological role. The final critical ingredient was quantification. Prior to this time, although objects, monuments, and mounds might be enumerated, there was no effort to generate archaeologically meaningful numbers. This new effort entailed wholesale changes in the ways in which archaeologists generated data. What made it all come together as a consensus was that it worked-and for the first time archaeologists could produce conclusions that could be tested empirically like those of other scientists, and they gained a measure of respect that had thus far eluded them.

The so-called stratigraphic revolution (Willey and Sabloff 1980, 84-93) had little to do with stratigraphy per se. It was not an epiphany on the relevance of the geological notion of superposition; U.S. archaeologists from Jefferson on had routinely understood and made stratigraphic observations. Rather, it depended on the coincidence, largely accidental, of the three innovations just named: quantification, materialism, and classification. The success of Europeans using stratigraphy (e.g., de Mortillet 1883; Lubbock 1865; Worsaae 1848) to create archaeological chronologies was not unnoticed by U.S. Archaeologists. They specifically sought out the kinds of deposits that had been key to the European success (especially caves and rock shelters-e.g., Nelson 1917). Even when expanded to include such obviously stratified deposits as shell middens (e.g., Dall 1877; Nelson 1910; Uhle 1907; Wyman 1875), these efforts were unrewarded because they continued to look at the record in qualitative, essentialist terms. European sequences, because of the vastly greater amounts of time involved, yielded coarse chronological kinds or "periods" under such assumptions but not so the much shorter U.S. record.

Repeatedly, U.S. archaeologists would observe strata but then conclude they

were unchallenged. Even radiocarbon dating had little intellectual impact beyond putting absolute dates to archaeological chronologies and improving between-chronology correlation. Almost unnoticed, radiocarbon dating did confirm the accuracy of seriation-based chronology.

Cultural Resource Management

Field methods that could yield the kinds of data required to do culture-history were codified in the late 1930s. The context for codification was provided by an explosion in the number of field archaeologists needed to direct the large-scale excavations that were funded by the federal government to provide work for unskilled laborers during the depression. The ad hoc procedures employed by trained individuals who could be trusted to make the right decisions had to be replaced with a set of rules (in this case, forms) that could be counted on to generate usable data. One rationale for the federal programs lay in conservation (Quimby 1979), even if strategy was determined by political necessity. Still, the locations selected for excavation were usually chosen by professionals-typically to fill in time-space gaps and save spectacular sites-so this federal work contributed directly to the emerging culture-historical syntheses. The program came to an abrupt end with World War II.

Post-World War II conservation archaeology, now nearly synonymous with federal archaeology, restarted with the River Basin Survey program in the Missouri Valley, under the direction of the Smithsonian Institution. New legislation enlarged the federal mandate, especially during the 1960s. The Reservoir Archaeological Salvage and Archaeological and Historic Preservation Acts (1960) put the National Park Service (NPS) in charge of all federal archaeology, a position it maintained until 1974 when the Archaeological Resources Act (or the "Moss-Bennett" act of 1974) gave federal archaeology more stable funding and involved all federal land-managing agencies in archaeological conservation and research.

When the NPS oversaw federal archaeology, CRM was still done by academicians as a part-time activity. A benevolent and informal client-patron relationship between the NPS and universities existed. As the amount of money involved grew and the number of agencies increased, so did the formality of contractual arrangements. This expansion of federal funding and the involvement of less-benevolent agencies than the NPS coincided with a dramatic downturn in academic employment as the first of the bloated crops of Ph.D.'s created by the expansion of university archaeology programs in the 1960s entered the job market. For the first time a separate class of CRM archaeologists emerged, the for-profit contractors. And as luck would have it, this major organizational change took place at the very time that archaeology was in intellectual turmoil. The warranting legislation itself had been framed by culture-historians. That culture-history relied upon common sense was probably an essential ingredient in its passage, but by the time the impact was felt, culture-history was passé and in disrepute but had not yet been replaced by a paradigm of comparable robustness. During the critical years in which archaeologists ought to have been instructing new agencies in why cultural resources were valuable, what archaeology was, and how it was done, no leadership was forthcoming. In such an intellectual vacuum, procedure came to dominate process; compliance-compliance with the law-became the raison d'être. The amount of money spent on archaeology by federal agencies was staggering by previous standards, and soon the bulk of all archaeological fieldwork was CRM.

The Second Paradigm: Processualism-Theory without Practice

One of the distinctive features of U.S. archaeology is that, in spite of its natural history beginnings, it has been in close association with anthropology from the days of the BAE on. Indeed, nonclassical archaeology in the United States is usually called "anthropological archaeology" whenever its intellectual roots are called into question. Why this should have happened in the United States (and in the other

places it did) is not obscure. The early linkages were institutional and to some extent political. But the association was lasting and effective in large measure because the methodological problems facing

were unchallenged. Even radiocarbon dating had little intellectual impact beyond putting absolute dates to archaeological chronologies and improving between-chronology correlation. Almost unnoticed, radiocarbon dating did confirm the accuracy of seriation-based chronology.

The amount of money spent on archaeology by federal agencies was staggering by previous standards, and soon the bulk of all archaeological fieldwork was CRM.

The Second Paradigm: Processualism-Theory without Practice

One of the distinctive features of U.S. archaeology is that, in spite of its natural history beginnings, it has been in close association with anthropology from the days of the BAE on. Indeed, nonclassical archaeology in the United States is usually called "anthropological archaeology" whenever its intellectual roots are called into question. Why this should have happened in the United States (and in the other

places it did) is not obscure. The early linkages were institutional and to some extent political. But the association was lasting and effective in large measure because the methodological problems facing

functional ones. Partly because radiocarbon dating seemed to have relieved archaeologists of any chronological responsibility beyond the collection of dating samples and partly because archaeological chronologies were seemingly well established in most areas, the functional approach was cast as an alternative to, not a supplement of, culture-history's historicism.

Processualists handled epistemological problems (at least they recognized there were some-not an issue in U.S. archaeology for half a century at that point) by adopting a confirmationist rather than falsification strategy in hypothesis evaluation; analogy (ethnographic and otherwise) effectively replaced empirical testing (Binford 1966; Watson, LeBlanc, and Redman 1971). Deprived of empirical standards for hypothesis evaluation, a pretense of "scientific" rigor could be maintained only by focusing epistemological questions on methods. The correctness of a conclusion was to be judged not by how it worked in the empirical world but by how it was reached, which is a ritualistic view of science (e.g., compare Spaulding 1953 and Ford 1954). The processualist product did not replace culture-historical understandings of the past; those remain strongly in the culture camp (e.g., Fagan 2000; Wenke 1999), albeit with a functionalist-reconstructive overlay but still no better warranted (although infinitely more obscure) than before. In fact, the typical product was either an isolated, never-to-be-used-again demonstration of a method or an exemplary interpretation.

This revolution differed from the culture-historical one in another important respect. Culture-history emerged as a consensus from a natural history context. In fact, the key synthetic pieces (e.g., Ford 1954; Krieger 1944; Willey and Phillips 1958) occurred long after the consensus was in hand. Processualism had to contend with an extant program, and so it was, of necessity (Kuhn 1962), polemical. It had to start with programmatic assertion (Watson, LeBlanc, and Redman 1971). Culture-history was demonized (e.g., Binford 1966, 1968b; Flannery 1967) to make a space for processualism. And, importantly, processualist claims were explicit: science *and* anthropology. As a result, the failure of processualism to achieve its scientific objectives was equally apparent. With no product to show, the enormous burden-both intellectual (stuff you have to know) and empirical (data quality, quantity, and analytic methods)-imposed by adopting scientific procedure was too much to bear. Processualism was doomed from the outset.

The Modern Ennui: Isms and Schisms-Fatal Division?

One cannot be very analytical about contemporary U.S. archaeology; all analysts have vested interests. The foregoing does, however, provide something of a framework within which a few comments may give perspective. The death of processualism as a paradigm that can be defended in public (it, like culture-history, continues on in practice) is different from the preceding two revolutions. One saw the creation of a paradigm where there had been none; the other saw the replacement of one by the other. Both were rationalized by trying to become scientific and thus like the model of science prepared by the philosopher of science Thomas Kuhn in structure. But with the abandonment of this goal in some quarters, no discipline-wide epistemological basis for constructing a replacement exists. Three strands, some more tightly wound than others, have emerged.

One might be viewed as a continuation of the ideals of processualism but with a new methodology and explicit theory-evolutionary theory (e.g., Dunnell 1978, 1980, 1992c; O'Brien 1996; Teltser 1995). Although there is a growing literature, normal science is still some distance in the future. Use of an explicit theory makes it painfully obvious that facts are created by theories and that one has to start virtually from scratch in generating data that can be explained. After years of no product, this is too much for many who want to get on with the show. Many also have an almost hysterical reaction to the word *evolution;* regrettably, it is the only scientific theory that deals with change. Yet the basis for broad appeal exists. Evolution is undeniably science and can deliver testable hypotheses, allowing us to achieve

our historical goal, to say nothing of the benefits that might accrue from knowing why we are the way we

University of Pennsylvania Museum of Archaeology and Anthropology

One of the leading institutions of its kind in the world, the University of Pennsylvania Museum (UPM) has played an important role in the development of archaeology for more than a century. It was founded in 1887 and sent its first field expedition to Nippur, in what is now Iraq, in 1889 and recovered a significant number of cuneiform tablets. The first building of the current UPM complex was erected in 1899, and four additional buildings have been added since then, with a fifth addition soon to be constructed (Haller 1999). The UPM has had eight directors-Stewart Culin, George Byron Gordon, Horace H.F. Jayne, George Vaillant, Froelich G. Rainey, Martin Biddle, Robert H. Dyson, Jr., and Jeremy A. Sabloff-and three acting directors-Jane M. McHugh, Marian Angell Godfrey Boyer, and James B. Pritchard-since its founding. The UPM's collections number approximately 1 million objects, the large majority of which were obtained as a result of the museum's field research. The UPM has been an active sponsor of archaeological and ethnographic fieldwork since its

PREV NEXT

1996) and of U.S. archaeology in general. Although many of the museum's early expeditions were focused on the gathering of objects for its collections, the overall collections are distinguished by their abundant scholarly documentation. Furthermore, in the 1970s, the UPM was an early and visible proponent of the United Nations Educational, Scientific, and Cultural Organization's convention on looted archaeological materials.

More than a century after the museum's founding by a group of wealthy and civic-minded Philadelphians and enlightened university administrators under the leadership of William Pepper, it is interesting to note that the UPM, with geographically extensive field projects, cutting-edge laboratory research, a successful traveling exhibit program, active conservation and loan programs, an award-winning website, and a highly regarded education department, has retained the same general mission that its founders established in the late nineteenth century. That is to say, through research, care, and study of collections, and dissemination of knowledge to both the scholarly world and the public at large, the museum is still wedded to its original mission of advancing an understanding of the world's cultural heritage.

Ur

A major Sumerian city most closely connected with the excavations of sir leonard woolley, Ur was first explored in 1854 by J.E. Taylor, a representative of the british museum. sir henry rawlinson, the prominent nineteenth-century linguist, identified the name of the site from cuneiform cylinder seals that were brought

back to the museum. In 1918 and 1919 further explorations and some tests were carried out, but it was not until 1922 that the British Museum (in association with the university of pennsylvania museum) began serious work in the area, under Woolley's supervision. Between 1922 and 1934 Woolley recovered some of the most magnificent artworks of the ancient world from the cemeteries excavated at the site. Although Ur is justly famous for extraordinary objects made of gold and lapis lazuli, Woolley's excavations also revealed much about the changes in religious architecture and the evolution of the city and its elites.

Ussher, James

(1581-1665)

Born in Dublin, James Ussher was one of the first students of Trinity College, Dublin, which was founded with the help of his family. Ussher studied divinity, Greek, Hebrew, and Latin and became interested in chronology and ecclesiastical antiquarianism. He abandoned the study of law to become a minister in the protestant church of Ireland in 1601. He traveled to England to acquire books for Christ Church College, and while there he met many other Puritan and religious intellectuals and the antiquarians John Camden and Robert Cotton.

Ussher was appointed professor of divinity at Trinity College, Dublin, in 1607, but his title was later changed to professor of theological controversies in recognition of his stance against the Roman Catholic Church and his popularity as a preacher. He was involved in the organization of the Anglican Church in Ireland and came to the notice of King James I, who was impressed by his scholarly vindication of the Protestant and Reformed Church's position in defense against ongoing Roman Catholic attacks.

James Ussher-an engraving by George Vertue after the portrait by Sir Peter Lely

(Ann Ronan Picture Library)

Ussher was vice-chancellor of the Trinity College, Dublin, and was made a bishop in 1620 and archbishop of Amagh, the primate of Ireland, in 1625. From 1623 to 1626 he lived in London researching his projected work on the antiquities of the British church, which resulted in *A Discourse of the Religion Anciently Professed by the Irish and British* (1623 and 1631), a defense of the independence of the church in England and Ireland based on the history of the ancient Gallic, Celtic, and British churches before their “contamination” by Rome. In the same vein, he published *Britannicarum ecclesiarum antiquitates* in 1639, an account of the spread of Christianity in Britain until the seventh century a.d., when St. Augustine arrived in England.

In the last years of his life, Ussher became interested in establishing a universal chronology for the whole of human history, and in 1650, he published *Annales veteris et Novi Tesamenti* (the English edition, *Annals of the Old and New Testament; Or, The Annals of the World Deduced from the Origin of Time,* was published in 1658). This work involved research in different oriental languages, comparisons of ancient calendars, and the recalibration of different political and national years with astronomical years, and it was built on the work of other Reformation scholars in France and Holland. The work was a triumph of scholarship and it was *the* acknowledged universal chronology for as long as the Bible was regarded as absolutely true-until well into the

middle of the nineteenth century. Ussher's findings were so incontestable that his dates were printed in the margins of Bibles for the next few centuries. He is still remembered for precisely dating the flood to 1656 b.c. and the Creation to 6 p.m., Saturday, 22 October 4004 b.c.

Uvarov, Count Aleksei Sergeevich

(1828-1884)

Born into an aristocratic Russian family as the son of Czar Nicholas I's nationalist ideologue, Aleksei Sergeevich Uvarov promoted archaeological study and helped to organize scholarly associations of archaeologists in the Russian Empire of the nineteenth century. He helped to found the Russian Archaeological Society (in 1864), the first archaeological congress (in 1869), and the Historical Museum in Moscow.

In the 1850s, he excavated burial mounds around Moscow and Vladimir and at the site of the ancient Greek city of Olbia in the Chersonese. In 1877, he excavated the Upper Paleolithic site of Karacharovo on the Oka River. He was regarded as a dilettante by modern scholars of archaeology, but he greatly helped to establish the study of archaeology in Russia.

Valcamonica

Valcamonica is a glaciated valley in the Alpine foothills of Lombardy, italy, that contains a rich collection of prehistoric rock art conventionally divided into four chronological phases (Neolithic, Copper Age, Bronze Age, and Iron Age) with subdivisions. Thousands of images were pecked into the glacially smoothed rock surfaces, and they include daggers, chariots, warriors and warfare, sun motifs, hunting and plowing scenes, men and animals, and geometric designs. Certain images are interpreted as huts while some at the site of Bedolina in Valcamonica are usually thought to be maps of settlements.

The known rock art comprises around 300,000 petroglyphs, although hundreds of decorated rocks probably remain buried. The art was first pointed out by a shepherd in 1914, but serious study really began decades later. This was the first rock art in Europe to be named a World Heritage Site by the United Nations Educational, Scientific, and Cultural Organization (UNESCO). The major set of decorated rock surfaces that is arranged for public visitation, with walkways, etc., is that of Naquane (another part of this site).

Van Giffen, Albert Egges

(1884-1973)

Born in Holland, Albert Egges Van Giffen graduated from the University of Groningen, where he studied biology and theology. He became interested in archaeology through his analysis of the faunal remains from prehistoric dwelling mounds or *terps.* He was appointed a keeper in the National Museum of Antiquities in Leiden in 1912, and he began to excavate and publish the results of a number of important sites. He finished his Ph.D. in 1913.

Van Giffen is best known for his skill as an excavator, to which he rigorously applied biological methods. In his early work, structure, periodization, and environmental data took priority over archaeological artifacts. He specialized in coastal geology and archaeozoology and always sought the expertise of paleobotanists, soil scientists, physical anthropologists, and chemists. His multidisciplinary approach to archaeology served widely as a model.

He founded the Biological-Archaeological Institute in 1920 at Groningen University and the Institute of Pre- and Protohistory at Amsterdam University in 1950. In 1947, he became the first head of the State Service for Archaeological Research, and he was responsible for archaeological collections at the Assen (1916- 1955) and Groningen Museums (1917-1955). From 1929 to 1973, he was responsible for the protective governmental acquisition, maintenance, and restoration of megalithic tombs in the netherlands. The quantity and chronological range of his excavations-from prehistoric *terps,* barrows, and urnfields to provincial Roman *castellum* (forts) and medieval Cistercian abbeys-have ensured that his scientific legacy continues to play a major role in Dutch archaeology.

Vatican Museums

Although the papal museums and galleries were based on the earlier work of Popes Clement IX and Pius VI, it was Pope Gregory XVI who founded the Etruscan Museum in 1837 and the Egytian Museum in 1839. The Vatican used the Etruscan Museum to house material recovered from excavations in southern Etruria, which were begun around 1828. The Egyptian Museum housed not only materials acquired by the Vatican from Egypt but also pieces from its collection of classical (Greek and Roman) artifacts. Since that time, the vast archaeological and ethnographic collections of the Vatican have grown in richness and complexity and are open to the public.

Ventris, Michael

(1922-1956)

Although trained as an architect, Michael Ventris was an accomplished cryptographer who played a significant role in the decipherment of the Linear B script. Ventris published his first paper on the issue at the age of eighteen, but because of war service, he had to wait until 1949 to resume work on the decipherment. In 1952, he announced that he had cracked the secrets of Linear B and had established that it was based on an archaic form of Greek. That same year he was introduced by sir john l. myres to the Cambridge philologist John Chadwick, and together they collected further evidence that Ventris's approach was correct. The 1953 publication of “Evidence for Greek Dialect in the Mycenaean Archives” was a clear and effective statement of their work.

Vergil, Polydore

(ca. 1470-1555)

Polydore Vergil was born in Italy at Urbino about 1470 and studied at the Universities of Bologna and Padua. He became secretary to the duke of Urbino and went on to become chamberlain to Pope Alexander VI. Made famous by two early works, *Proverbiorum libellus* and *De inventoribus rerum,* he was sent by the Pope to England in 1501 as a subcollector of Peter's pence (an annual tribute of a penny paid by each householder in England to the Pope). Vergil so impressed the English king, Henry VII, that in 1505 he was commissioned to write the history of England-the *Anglica Historia,* which was finished by 1512 but not published until 1534. Vergil was made archdeacon of Wells, and on 22

October 1510, he was naturalized as an English subject. Falling out with Cardinal Wolsey in 1514, he was imprisoned in the Tower of London and was not released until the Pope personally intervened.

Polydore Vergil has often been described as the first of the modern historians who placed great store on detailed source criticism and rational argument woven into a continuous narrative. It was Polydore Vergil who first seriously questioned the value of geoffrey of monmouth's legends of the role of the Trojan Brutus in the foundation of England. Vergil left England after the death of King Edward VI in 1553 and returned to Urbino, where he died.

Vergil, Polydore

(ca. 1470-1555)

Polydore Vergil was born in Italy at Urbino about 1470 and studied at the Universities of Bologna and Padua. He became secretary to the duke of Urbino and went on to become chamberlain to Pope Alexander VI. Made famous by two early works, *Proverbiorum libellus* and *De inventoribus rerum,* he was sent by the Pope to England in 1501 as a subcollector of Peter's pence (an annual tribute of a penny paid by each householder in England to the Pope). Vergil so impressed the English king, Henry VII, that in 1505 he was commissioned to write the history of England-the *Anglica Historia,* which was finished by 1512 but not published until 1534. Vergil was made archdeacon of Wells, and on 22

October 1510, he was naturalized as an English subject. Falling out with Cardinal Wolsey in 1514, he was imprisoned in the Tower of London and was not released until the Pope personally intervened.

Polydore Vergil has often been described as the first of the modern historians who placed great store on detailed source criticism and rational argument woven into a continuous narrative. It was Polydore Vergil who first seriously questioned the value of geoffrey of monmouth's legends of the role of the Trojan Brutus in the foundation of England. Vergil left England after the death of King Edward VI in 1553 and returned to Urbino, where he died.

Vilanova y Piera, Juan

(1821-1893)

Juan Vilanova y Piera's father was a lawyer, and the son received his primary education in Alcalá de Chisvert in Valencia, spain. Also in Valencia, he read humanities in the Jesuit Real Colegio de San Pablo, and later, he studied medicine, surgery, and sciences. In 1845, he graduated in medicine. In Madrid, he worked toward a doctorate in the Museo de Ciencias Naturales (Museum of Natural Sciences), which is part of the Universidad Central (Central University), and

the nineteenth century. On the international level, he was one of the promoters of international geological congresses.

However, it was in prehistory that Vilanova y Piera's research was its most innovative. He was the first naturalist full member of the Royal Academy of History, through his research activities and his diffusion of prehistory. His interest sprang from discussions with European geologists and through the association of Paleolithic industries with extinct fauna, which was also observed by Casiano del Prado on the banks of the river Manzanares in San Isidro, Madrid (1862). Vilanova y Piera was the author of two unique treaties on the prehistory of the Iberian Peninsula: *Origen, naturaleza, y antigüedad del Hombre* (The Origen, Nature, and Antiquity of Man)(1872) and, with Juan de Dios de la Rada Delgado, *Geología y Protohistoria Ibéricas* (The Geology and Protohistory of Iberia)(1894) in the Historia General de España edited by the Royal Academy of History. He also took part in all the congresses on archaeology and prehistoric anthropology that took place in Europe and in the associations aimed at achieving their institutionalization. By 1869, he was, along with J. F. M. Tubino, the official Spanish representative at the Copenhagen International Archaeology Congress.

In prehistory, Vilanova y Piera is associated with the introduction of a first Copper Age within the Metal Age and with the defense, even at the cost of his scientific credibility, of the authenticity of the altamira cave paintings discovered by Marcelino Sanz de Sautuola in 1879.

Throughout his life, Vilanova y Piera endeavored to incorporate European knowledge on the subjects with which he was involved into Spanish science and to present Spanish contributions to this knowledge at the different meetings and congresses that he attended abroad. His task had two main limitations. First, as a naturalist, the very extension of his work involved significant information gaps. Second, his religious attitudes, extreme on certain subjects such as evolution, reduced his objectivity in spite of his attempts to keep within the limits of science.

Virchow, Rudolf

(1821-1902)

Rudolf Virchow was born in Germany and educated at the University of Berlin, where he received his Ph.D. in medicine in 1843 and where he established an archive of anatomy and physiology. In 1849, Virchow became professor of pathological anatomy at the University of Würzburg, and in 1856, he returned to Berlin as professor of pathological anatomy and director of the newly created Pathological Institute, where he included lectures in prehistory in his courses.

Rudolf Virchow

(Ann Ronan Picture Library)

PREV NEXT

He encouraged the development of the discipline of anthropology in Germany by helping to found the National Anthropological Association (1870) at the same time as Germany unified politically and the Berlin Museum für Volkstrachten was founded (1888). He also contibuted to the development of the collections of the Berlin Museum für Volkerkunde (Berlin Museum of Folk Studies) and edited a national journal of ethnology. He excavated in Pomerania and took an interest in the work of heinrich schliemann, traveling to Hisarlik in turkey in 1879 to advise Schliemann on the excavating.

Unlike his student Ernst Haeckel, Virchow was not a Darwinist. He was involved in debates about developments in human paleontology, and he regarded the first Neanderthal discovery at the Feldhofer Cave in the Neander Valley in Germany as a pathological specimen and not a new species of hominid. He also refused to accept Dutch paleontologist eugene dubois's discovery of a fossil hominid in Java as evidence of human evolution.

Virú Valley

The small Virú Valley on the coast of peru was the site of a landmark study in the development of archaeological survey methodology. Research in the valley began in 1946 with the cooperation of U.S. and Peruvian scholars, but it was the innovative work of gordon willey in the field of settlement archaeology that lifted the program from being yet another site survey. Although Willey (who was much influenced by anthropologist julian steward) was certainly interested in exploring the ecology of 1,500 years of human settlement in the region, he chose to do so against a background of a detailed analysis of the location and distribution of sites within the region. Using both surface and subsurface survey techniques, Willey was able to chart the distribution of sites in the region over time, and he demonstrated the fact that the environmental (both natural and cultural) context of human settlement was also time-dependent and not simply “read off” from surface indications.

Waverly Plantation, Mississippi

George Hampton Young founded Waverly Plantation in 1841, and it remained in the Young family until 1963. This National Historic Landmark contains one of the South's finest plantation houses, complete with its own gas plant and swimming pool, built in the 1850s. Young founded the University of Mississippi and was a prominent political figure in Mississippi. He owned 3,420 acres and controlled much more; with 217 slaves, he was a big planter. In 1893, the National Fox Hunters Association was organized at Waverly.

After the American Civil War, a tenant and sharecropping system was established, which lasted until the 1930s. In 1979, archaeological excavations were conducted at six tenant farmer sites, a general store, a brick kiln, and a steam-powered cotton gin and sawmill under the direction of William H. Adams, Timothy B. Riordan, and Steven D. Smith. Historical geographer Howard Adkins researched the documentary history of this tenant-farming community. Folklorists David F. Barton and Betty J. Belanus interviewed eighty-nine informants, forty-three extensively, and their recordings are in the Library of Congress, the Mississippi Department of Archives and History, and the Indiana University Folklore Archives. This study marked the first archaeological investigation of tenant farming in the South. The community approach used to study tenant farmers and planters provided a broader historical context for the material recovered. Adams and Smith compared the purchases recorded in the general-store ledger with the artifacts from those tenant sites to evaluate what kinds of items were not being recovered archaeologically.

His “Indian” writings were published mainly in Ancient India, an official publication of the Archaeological Survey of India, which he himself edited.

His major achievements in the field of South Asian archaeology were the establishment of a training school at Taxila in 1946 to make Indian students familiar with his layer-based method of digging and the basic academic results of his excavations, which included, among other things,

the discovery of and a cross-section through the Harappan defenses at Harappa; the identification of a Roman trading station at Arikamedu; and the establishment, on the basis of ceramic correlations with the dated ceramic sequence at Arikamedu, of a chronological sequence for southern Indian archaeology from the Neolithic stage upward. Among other issues, he emphasized the need for prehistoric and proto-historic studies, establishing a separate prehistory branch in the survey, and he underlined the importance of spreading archaeological studies beyond the confines of a government department to the portals of universities in India. Within the short span of time available to him for archaeological researches in the subcontinent, what he achieved and influenced must be considered remarkable.

Tim Murray (Santa Barbara, CA: ABC-CLIO, 1999), pp. 371-383, and in *Mortimer Wheeler: Adventurer in Archaeology* by Jacquetta Hawkes (London: Weidenfeld and Nicolson, 1982).

Who Owns the Past?

It is a commonplace that archaeological knowledge is not and never has been produced in a cultural and political vacuum. Yet this fact was not formally recognized by archaeologists until the twentieth century. In the 1800s, when the fundamental structures of the discipline were created, the bulk of practitioners (and the general public, which avidly followed their work) firmly believed that archaeologists produced rational, objective, scientific knowledge about the past. Further, the search for knowledge about human history, at least as undertaken by archaeologists, was of sufficient cultural significance to be self-evidently worthwhile. A scientific archaeology was to provide an objective history of humanity, and this history (in the eyes of commentators such as Sir John Lubbock [lord avebury]) should become the foundation upon which rational societies of the future would be built.

This same search for universal edification (undertaken or controlled by Europeans or, later, North Americans) had been a major factor in fostering the work of collecting expeditions to italy, greece, and Asia Minor in the eighteenth and nineteenth centuries, which were followed by major expeditions in Egypt and the Middle East. In an important sense the pasts of countries that lay outside the borders of metropolitan Europe were considered to be resources that could be articulated by archaeologists and antiquarians in the search for an understanding of human (read European) history. Thus the great excavations in mesopotamia, Egypt, Asia Minor, and Greece that began in the nineteenth century and continue to this day were initially launched to explore the roots of Judeo-Christian civilization and to bring back to London, Paris, Berlin, or New York the material representations of that great journey toward civilization.

It is also no coincidence that these explorations outside Europe (especially in Africa, the Americas, and Australia) fulfilled two roles at the same time-providing a reconnaissance of contemporary human diversity and fostering a consideration of the relationship between the histories of such places or people and the history of Europe. The museums of “man” or “natural history” that sprang up all over the western

predecessors) have consequences for the peoples whose pasts they investigate.

Outside Europe the "loss of innocence" has been even more dramatic since World War II. Indeed, since the 1960s, much of our modern thinking about matters related to the ownership and control of pasts has developed in North America, Australasia, and, more recently, in Africa. In these regions recognition by governments and by archaeologists of the rights and interests of indigenous peoples has completely transformed the archaeological landscape. The practice of archaeology in these places is now highly regulated by legislation (such as the U.S. legislation Native American Graves Protection and Repatriation Act), and former collection and excavation practices have been replaced by models of negotiation and consultation. It is also now far more widely accepted that archaeologists cannot consider the scientific importance of their inquiries to be of such significance as to make their interests automatically more valuable than those of any other group. In Australia, as in some other countries, it is explicitly acknowledged that indigenous people "own" their pasts-an acknowledgment that requires that work can only proceed on the basis of informed consent. Archaeologists now spend a good deal of time developing research projects that produce knowledge of interest and value to indigenous communities, not just to nonindigenous institutions such as museums, universities, or academic disciplines. But again, notwithstanding the great changes that have occurred in the practice of archaeology in these contexts, significant challenges remain.

Against this background of transformation in the social, cultural, and political contexts of archaeological knowledge, at least three matters remain unchanged. Foremost is continued looting of archaeological sites and the theft of cultural properties for sale on the illegal antiquities market. Efforts persist to restrict if not stamp out this trade, but its power to destroy the past remains undiminished. Second, the preservation or conservation of archaeological sites and landscapes requires that all members of society (not just archaeologists) acknowledge the many values of such properties-an acknowledgment that accepts that those values can be diverse and that they must be balanced against other rights and interests existing in society. Third, archaeologists in all countries still need to recognize that interpretation must never be completely free from empirical demonstration and that it is up to them to clearly distinguish between interpretation and demonstration in their writings. It is imperative that archaeologists be honest with their readers-honest about the limits of their interpretations and honest about their biases and presuppositions. Some archaeologists have (wrongly) supposed that if archaeological knowledge is a social and cultural product, then this must mean the end of science as a model for the production of knowledge. Indeed, the history of archaeology aptly demonstrates that no science is or ever has been practiced in a vacuum, but this does not mean (and never has meant) that all opinions about archaeology are equally valid.

Willey, Gordon Randolph

(1913-)

Gordon Randolph Willey, the foremost Americanist among archaeologists, was born in Chariton, Iowa, and grew up in Long Beach, California. He took his undergraduate and masters degrees at the University of Arizona and pursued doctoral work at Columbia University, completing his dissertation in 1942. A year later, he joined the Bureau of American Ethnology at the smithsonian institution. In 1950, he accepted the Bowditch Professorship in Central

American Archaeology and Ethnology at Harvard University, which he held until 1987. During his productive career, he directed major fieldwork projects in belize, guatemala, Honduras, mexico, Nicaragua, panama, and peru. Within the united states, he has worked in Arizona, Georgia, Louisiana, and Florida.

Willey is perhaps best known for creating the subfield of "settlement pattern" archaeology. For him, the distribution of human settlements provided a natural starting point for the functional interpretation of archaeological cultures. Different sites were best understood, not in isolation, but as part of complex economic, social, and political landscapes. Willey devised his settlement pattern approach under the aegis of the virú valley project, one of the first multidisciplinary research programs in the New World. The widespread popularity of Willey's approach is due to its workable methodology for addressing questions of social structure, demography, and subsistence patterning.

Willey is the preeminent "grand synthesizer" of American archaeology. From 1953 to 1955, in a series of publications with Philip Phillips, he laid out the baseline for the prehistory of the New World. In 1965, he revised this framework in a comprehensive survey of North and Middle American archaeology. Spanning some 40,000 years of prehistory, his book covers the continent from Alaska to Panama. This project was quickly followed by a second volume on South American archaeology. More than any other work by a professional archaeologist, these lavishly illustrated books served to acquaint a popular audience with the broad diversity of past cultures and their rhythms of horizonal integration and regional florescence.

Willey has maintained a strong interest in the professional development of American archaeology. He prepared his first historical essay in commemoration of the one-hundredth anniversary of the peabody museum of archaeology and ethnology in 1966, and this essay emphasizes the growing professionalization of the field and its increasing claim to scientific status. In 1973, collaborating with Jeremy Sabloff, Willey completed his first major book-length history. This volume differs from Willey's earlier essay by embracing much of the new archaeology, an explicitly scientific approach grounded in positivism. In the third edition, Willey and Sabloff substantially revised their appraisal of the new archaeology and pointed out some of its excesses.

The influence of Gordon Willey on American archaeology is immense. His work on settlement archaeology is regarded as the starting point for all investigations of culture process and social change, his syntheses of New World prehistory and the history of American archaeology are considered classics and are widely used as textbooks, and his writings on functionalism, culture process, and ideology have anticipated many of the recent trends in archaeology since the 1980s. One of Willey's most distinguishing characteristics is his balanced view of archaeological explanation, and throughout his career, he has consistently sought to bridge the tensions between humanist and scientific traditions.

Williamsburg, Colonial

Williamsburg, the eighteenth-century capital of Virginia, earned its place in the annals of archaeology through the pioneering techniques used there to uncover the remains of British colonial buildings and then reconstruct them. In 1928, by excavating and rebuilding the colony's capitol, architects employed by

John D. Rockefeller began to turn Williamsburg into a living museum in an ongoing archaeological, architectural, and curatorial process that has continued into the twenty-first century.

The methods developed by the architects and their draftsmen that exposed foundations but ignored stratigraphy and the potential testimony of artifacts were replaced in 1957 after the arrival of British archaeologists who used methods employed in the Old World by the great stratigraphers sir mortimer wheeler and kathleen kenyon. Emphasis on site cleanliness

and the introduction of a process that came to be known as artifact cross-mending greatly improved the excavators' ability to interpret the sequential interrelationships between structures and other on-site features. Through the following quarter century, Colonial Williamsburg publications demonstrating the importance of potsherds and a wide range of other artifacts as a means of reading the colonial past had a lasting impact on the birth and growth of the discipline now globally known as historical archaeology.

Reconstructed dwelling at Colonial Williamsburg

(Spectrum Colour Library)

In 1969, the Colonial Williamsburg Foundation expanded its interpretive interests to include the nearby Carter's Grove plantation, where archaeologists found the remains of the Martin's Hundred settlement (1619-1645), much of which had been destroyed in an Indian uprising in 1622. The settlement's administrative center, Wolstenholme Towne, has been partially reconstructed, and a subterranean museum displays the arms, armor, and other artifacts found there.

Ivor Noël Hume

Wilson, Daniel

(1816-1892)

Daniel Wilson was the first person outside Scandinavia to practice the prehistoric archaeology that had been pioneered by christian j. thomsen and jens jacob worsaae. He also elucidated, if he did not invent, the term *prehistory*. Wilson was born in Edinburgh, Scotland, 5 January 1816. Between 1837 and 1852 he worked as an engraver, writer, and shopkeeper. The romanticism of Sir Walter Scott motivated him to use his considerable artistic skills to record old buildings that were being demolished in the course of Edinburgh's urban renewal. *Memorials of Edinburgh in the Olden Times* (1848), which contained many of his more interesting sketches accompanied by a rambling account of the history of the city, consolidated his reputation as a leading Scottish antiquarian.

Wilson was invited to rearrange the collections of the society of antiquaries of scotland according to the three-age system that Thomsen had devised for the National Museum of Antiquities in Copenhagen. His work on this collection and study of prehistoric monuments led him to publish *The Archaeology and Prehistoric Annals of Scotland* (1851), the first comprehensive work of prehistoric archaeology in the English

language. It is not clear whether Wilson understood the seriational principles on which Thomsen's work was based or merely copied his sequence. Wilson's major achievements were to distinguish history and prehistory not merely as time periods but as different approaches to the past, and to realize the potential of material objects as a rounded source of information about how human beings lived in the past.

In 1853, Wilson became professor of history and English literature at University College in Toronto, Canada, where in 1857, he began offering a course on ancient and modern ethnology. His encounters with Indians still living in a traditional fashion convinced him that the New World constituted a "laboratory" for studying European prehistory and understanding better the "essential characteristics" of all human beings. In *Prehistoric Man* (1862), Wilson used physical anthropological data to refute claims that American Indians constituted a separate species; interpreted archaeological findings as evidence of parallel, if unequal, cultural development in the Old and New Worlds; and interpreted what had happened to Europeans, Africans, and aboriginal peoples in the Western Hemisphere since 1492 as evidence that all peoples possess the same basic drives and abilities and, hence, could participate in cultural development. Wilson continued to uphold the principles of the eighteenth-century Enlightenment as they had been understood in the Edinburgh of his youth.

Wilson also continued to adhere to a biblical chronology. It was not until the 1870s that he was prepared to admit that human beings might have evolved from other animals, and even then he refused to consider an evolutionary origin for human reason or moral sense. Wilson continued to publish anthropological papers, but the problems he had in coming to terms with Darwinian evolution prevented him from becoming one of the leading anthropologists of the late nineteenth century. In his later years, Wilson continued to publish important works of literary criticism and was increasingly preoccupied with academic administration, which culminated in his becoming president of the University of Toronto in 1887. He died in Toronto 6 August 1892.

Winckelmann, Johann Joachim

Winckelmann was born on 9 December 1717 in Stendal, Germany. He went to the local grammar school and later spent a few months at the Collnisch Gymnasium in Berlin. For two years (1737-1739) he studied theology in Halle and then moved to Jena in 1741, where he enrolled for classes in mathematics and medicine. In 1743 he took a post as associate rector at a school in Seehausen, which he held for five years, a period of intensive study of the classics. He was taken on by Heinrich von Bünau as librarian in Nothnitz near Dresden in 1748; here he did research on the Ottonian emperors for Bünau's *History of the Empire.*

Winckelmann's earliest unpublished writing was notes from a lecture on recent general history in which he brought out the close connections between art and history. He moved to Dresden and published *On the Imitation of the Painting and Sculpture of the Greeks* in 1755, a depiction of classical Greece in which art could develop freely and free citizens could live in a state that was founded on liberty and democracy. Enthusiastic descriptions of the Laocoon group and the Herculanean Vestals form a contrast to the way he conceived his own times. In his theory of imitation he established the need to copy the natural and ideal beauty of Greek sculpture, its "noble simplicity and calm grandeur." He converted to

Catholicism and, helped by a stipend from the Saxon court, went to Rome in 1755. He began an inventory of Roman works of art, commenting on them both as iconography and in terms of restoration and described the Belvedere statues in the Vatican. At the same time he was striving for a language that would be appropriate to art and would reflect the essence of the works of art in question. His descriptions had a great influence on German scholarly prose. From his inventory there emerged a new system of historical classification, based on the criteria and the style of nations,

periods, and artists, of the rise, development, flourishing, and decline of the art of different nations, the whole connected with the attempt to classify each individual work of art. He exemplified this theory in his great work, his *History of the Art of Antiquity* in 1764, the work that marked the height of his fame. He described the art of the Egyptians, Phoenicians, Persians, and Parthians; of the Etruscans and Italians; as well as the style of Greek art, which he divided into four separate styles, the more ancient style, the grand, the beautiful, and the style of the imitators. He maintained that, besides nature, climate, and education, it was freedom that had produced the artistic flowering of Greece. In 1757 he became librarian at the Vatican and a year later entered the service of Alessandro Albani. In 1758 he visited Naples, Portici, herculaneum, and pompeii for the first time and went to the temple at Paestum. In 1762 his *Remarks on the Architecture of the Ancients* appeared and was instrumental in bringing the temple of Paestum to European attention. He saw that Vitruvius had not gone far enough in answering the question of the origins of Greek architecture and that its uniqueness and development could only be made clear through drawings and reproduction. In later writings, *Open Letters from the Discoveries at Herculaneum* (1762) and *News of the Most Recent Herculanean Discoveries* (1764), he reported on significant finds at Herculaneum and Pompeii. He also described in detail the Roman frescoes and artifacts from daily life and pointed out the artistic and aesthetic aspects of Roman handicrafts. In 1760 he published his *Description of Ancient Gems* by the late Baron de Stosch in Florence, which introduced methodologically significant elements into archaeology as he recognized that many of the themes or images taken from Greek mythology needed to be explained. In 1767 were published two volumes of *Monumenti antichi inediti,* in which he tested out his archaeological-hermeneutic methodology and tried to decipher the mystifying content of classical works, as well as attempting to determine their style and thus their date. In another work, *Attempt at an Allegory, Particularly for Art* (1766) Winckelmann undertook to provide artists with a supply of significant classical themes as a stimulus for their own works. Its impact was to help fertilize the intellectual ground for the rise of Neoclassicism in Europe. On 8 June 1768 he was murdered in Trieste.

Woolley, Sir (Charles) Leonard

(1880-1960)

Charles Leonard Woolley was born in London and won a scholarship to New College, Oxford, where he studied humanities and theology. He graduated in 1904 and then traveled to Germany to study modern languages. In 1905, Woolley was appointed assistant to sir arthur evans, keeper of the ashmolean museum in Oxford.

Woolley traveled to the Near East in 1907 to excavate in nubia with D. Randall-MacIver from the university of pennsylvania museum. He excavated the Meroitic cemetery at Karanog, unearthing rich finds and receiving an excellent training in field archaeological methods and the management of

excavations. In 1912, Woolley was appointed to lead a british museum expedition to Carchemish where he discovered Neo-Hittite

PREV NEXT

temples, palaces, and fortifications. He also worked closely with another young archaeologist, T. E. Lawrence, who was to become famous later as “Lawrence of Arabia.” Together, after the digging season had finished, they made an archaeological survey of Palestine north of Aqaba toward the southern end of the Dead Sea and managed to observe and note the Turkish government's military strengths and weaknesses in the area at the same time.

Sir Leonard Woolley

(Image Select)

The excavation at Carchemish was interrupted by the outbreak of World War I, during which Woolley was an intelligence officer in Egypt and spent two years in a Turkish prison camp after surviving being blown up at sea off the coast of Asia Minor. In 1919, he returned to Carchemish, where completing the excavation was made difficult because of its location between the French and Kurdish armies. Funded by the egypt exploration society, Woolley moved to Egypt and excavated the house quarter of el amarna.

In 1922, Woolley began thirteen years of excavation in mesopotamia at the mound of ur, where he unearthed a long sequence of cities going back to the Ubaid period of the fifth millenium b.c. He unearthed Sumerian temples, palaces, and whole towns, and the most famous discovery of the expedition-the royal cemetery of Ur and its wonderful treasures from before 2500 b.c. He also unearthed some of the earliest literature in the world, many remarkable small finds, sculptures, and metal work. He published *The Sumerians* (1928), *The Development of Sumerian Art* (1935), *Abraham* (1936), *The Royal Cemetery* (1934), and *The Ziggurat and Its Surroundings* (1939) on the excavations at Ur. His popular books, such as *Digging Up the Past* (1930), *Ur of the Chaldees* (1929), and *Excavations at Ur: A Record of Twelve Years' Work* (1954), were best-sellers.

Woolley continued to excavate. At Al Mina, an ancient port city near Antioch in Syria, he found ten levels of occupation from between the eighth and third centuries b.c., which shed light on the nature of the trade between Syria and the Aegean. At Tell Atchana, the site of ancient Alakakh in northwestern Syria (1937-1939 and 1946-1949), he discovered seventeen phases of middle and late-Bronze Age occupation, exposing residential, palace, and religious monuments and material culture and archives dating to the fifteenth century b.c.

In 1938, Woolley traveled to India to advise the government on a program of archaeological work for the subcontinent. During World War II, he served as a lieutenant-colonel, and in this capacity he managed to save many of the monuments, art works, museums, archives, and libraries of Europe from invading armies and bombs. He was knighted in 1935, received honorary degrees from the Universities of Dublin and St. Andrews, was awarded the Flinders Petrie Medal in 1957, and unfortunately died just before he received the gold medal of the Royal Society of Antiquaries.

World Archaeology

The first edition of the journal *World Archaeology* appeared in June 1969, and the opening issue set out the journal's objectives concisely: “to synthesize the best contemporary thought on matters of common interest to archaeologists the world over. It is the voice, essentially, of a fresh generation of professional archaeologists.” With those words, the founders of the journal allied themselves with the methodological revolution that was affecting Anglo-American archaeology during the late 1960s. This stance is particularly clear because they described *World Archaeology* as “designedly a journal of debate” and sought to organize the contents of most issues around a clearly defined theme.

From the start, the journal was run from England, and only occasionally has it drawn on editors outside the British Isles. Until recently, most of the editors have been associated with the Universities of Oxford, Cambridge, or London and have represented the archaeology of those parts of the world in which they have had special interests.

The journal has retained its thematic character, although the nature of the topics selected for particular issues have changed over the years. Early issues tackled broad themes such as subsistence, population, and trade, and sometimes they were concerned with questions that only became really topical some years later, such as archaeology and linguistics. After the first decade, however, the topics became rather more specific, and there was greater emphasis on empirical data and on particular analytical techniques. On the one hand, there were issues concerned with such topics as waste management, ceramics, or archaeology and musical instruments; on the other hand, there were groups of papers on early chemical technology and photogrammetry.

More recent editions of the journal show a subtle change of direction. There is less emphasis on appointing editors to represent particular areas of the world, and some issues have returned to the broader themes first explored in the early years of the journal, such as architectural innovation, craft production, and specialization or concepts of time and the ancient world.

There have also been changes in the authors writing articles for *World Archaeology*. Although contributors who were relative newcomers to archaeology were always encouraged, the early issues contain the names of many people whose careers were already well established. For example, françois bordes, j. desmond clark, mary leakey, Colin Renfrew, Jeremy Sabloff, and Bruce Trigger all contributed to *World Archaeology* during its first five years. Others were soon to make international reputations for themselves, indeed, the very first issue contained an early article by African prehistoric archaeologist glyn isaac. Relatively few of the contributors to the early editions of *World Archaeology* are still writing for the journal, although there are exceptions such as Charles Higham and Bruce Trigger. More of the articles are submitted by graduate students or by archaeologists who are just beginning their careers.

Last, there have been striking changes in the regions discussed in the journal. Not surprisingly, more articles are concerned with Europe than with other areas (approximately a third), but in the first ten years *World Archaeology* was published, a substantial number of articles also discussed material concerning Africa, mesoamerica, and South America. Over the next decade, however, the proportion of articles concerned with the New World declined, probably because other journals had been established dealing with just those areas, and *World Archaeology* carried significantly more articles discussing material from the Near East and Southeast Asia. Throughout its history, the journal has published relatively few articles concerning India, Australia, the united states, or the Pacific, although there are signs that the balance may have started to shift. No doubt there will be many more changes over the next quarter century, for the “journal of debate,” which was such a radical venture in 1969, still has a role to fulfill.

Worm, Ole

(1588-1654)

Ole Worm was born in denmark and educated at the University of Copenhagen. He was successively professor of pedagogy, Greek, physics,

and medicine before becoming personal physician to Christian IV, king of Denmark. Worm was a contemporary and colleague of the Swedish antiquarian johan bure and had similar interests in rune stones and collecting archaeological and ethnographic artifacts and other antiquities. He corresponded widely with other antiquarians across Europe, learned Old Norse from Icelanders in order to translate runes, and speculated about tumuli with the English antiquarian Sir Henry Spelman. In 1626, he organized a royal circular to be sent to all of the clergy throughout Denmark to submit reports on any rune stones, burial sites, or other historic remains and then sent draftsmen out to record them. The resulting mass of information was the basis of Worm's six volumes on Danish monuments published in 1644, the antiquarian record of Denmark with illustrations and maps.

Ole Worm

(Ann Ronan Picture Library)

He also established the Museum Wormianum, a kind of extended cabinet of curiosities, to display his collections and the donations of others. This collection was passed on to King Frederick III after Worm's death. It was installed in the old castle in Copenhagen and then moved in 1680 to a new building in Christiansborg, where it was opened to the public as the Kunstkammer (Royal Collection), which in time became a part of the Danish National Museum of Antiquities.

Wormington, Hannah Marie

(1914-1994)

One of the first female archaeologists in North America, Hannah Marie Wormington made significant contributions to Paleo-Indian archaeology. She was born and attended schools in Denver, Colorado, and she would live and work in this city as an adult for over thirty years. Wormington began studying medicine and zoology at the University of Denver, but under the influence of French archaeologist E. B. Renaud, she became interested in the prehistory of the Americas and participated in fieldwork in Colorado and New Mexico.

In 1935 she traveled to Europe, where she met and was greatly impressed by the renowned English archaeologist dorothy garrod. Wormington, whose mother was of French origin, studied in Paris and joined Paleolithic excavations in the Dordogne. She returned to work at the Colorado Museum of Natural History (later the Denver Museum of Nature and Science), where she began studying Paleo-Indian material in the collection. This typological work was the subject of her first paper, presented in 1937 at the International Symposium of Early Man in Philadelphia, Pennsylvania. It was so well received that it established her as a major contributor to the current debate around and study of Paleo-Indians.

Her later publication, *Ancient Man in North America* (1939); was based on this paper and was the first summary and synthesis by an archaeologist of the evidence for Pleistocene and early-Holocene occupations in North America. The book went through four editions (the last in 1957) and is still

regarded as a classic in Paleo-Indian studies.

In 1937 Wormington began postgraduate study at Radcliffe College, where she was the first doctoral student in anthropology. She also attended classes at Harvard University and was

only the second woman to study in the Department of Anthropology. Over the next seven years Wormington continued to work at the museum, and she undertook fieldwork, studied for her Ph.D., married, and volunteered with the Red Cross during World War II. She excavated sites in Alberta, Canada, for her doctoral fieldwork and received her Ph.D. in 1954.

Four years later Wormington traveled to the USSR, and in 1961 and 1964 she returned there to study Siberian archaeological collections, looking for similarities to and differences from Clovis material in the United States. There were none, and she came to believe that the Clovis people were not the earliest North Americans. Her final fieldwork in the mid-1960s was at the Frazier site near Greeley, Colorado. Many of the next generation of prehistoric archaeologists worked with her at this important Paleo-Indian site, dated to 9500 b.p.

In 1968 Marie Wormington was elected the first female president of the Society for American Archaeology, having served two terms as a vice-president (1950-1951 and 1955-1956). After thirty-one years she left the Denver Museum in 1968 to teach at Arizona State University (1968-1969); she then taught at Colorado College (1969-1970) and the University of Minnesota (1973), and from 1972 to 1986 she was an adjunct professor at Colorado College. In 1983 she became the first female archaeologist to win the society for american archaeology's Distinguished Service Award.

Worsaae, Jens Jacob

(1821-1886)

As a boy in denmark, Jens Jacob Worsaae carried out excavations and published his first archaeological study at the age of seventeen. Worsaae came into contact with christian thomsen at the National Museum of Antiquities in Copenhagen and worked as his assistant while studying law.

In 1843, Worsaae wrote and published *The Primeval Antiquities of Denmark* (published in 1849 in English), a result of his work with Thomsen, in which he observed that the three-age system was particularly dependent on the find associations of artifacts (ie. the stratigraphic contexts of the artifacts-where and with what other materials they were found). Unlike Thomsen, Worsaae did not just work in museums-his great strength was that he also worked in the field and was an excavator. In 1844, Worsaae became a full-time antiquarian, and in 1847, he became the inspector of ancient monument preservation in Denmark.

Between 1846 and 1847, Worsaae traveled extensively in Europe, England, and Ireland. He was the first archaeologist to undertake a survey of German archaeological material-which was scattered among dozens of provincial museums, reflecting the fragmentation of Germany's politics. He saw that the preoccupation of English and French archaeologists with Roman monuments had led them to neglect their prehistory and that Thomsen's three-age system could be used across Europe. He understood that

as a result of reorganization and their national character, the Scandinavian archaeological collections were unique and provided an opportunity to develop a “scientific” archaeology -and that in this regard they were well ahead of the rest of Europe.

There is no doubt that without Thomsen's and Swedish antiquarian bror emil hildebrand's collections, Worsaae would not have formulated his important chronological advances-his divisions of the Stone Age and the Bronze Age into two periods and the Iron Age into three. On the basis of these collections and his great knowledge of European archaeological material, Worsaae became the first archaeologist to place prehistoric monuments in a wider and comparative context, both socially and historically-as a result, he received the title of “founder of comparative archaeology.” In 1854, Worsaae became a professor, and in 1865, he became director of both the Museum of Nordic Antiquities and the Ethnographic Museum in Copenhagen.

Xia Nai

(1910-1985)

The British-trained Xia Nai was the premier archaeologist of Communist china. Born in 1910 at Wenzhou (Zhejiang Province), Xia graduated in history from Qinghua University in Beijing in 1934 and subsequently participated in the excavations at anyang. Studying at the University of London from 1935 to 1940, he majored in Egyptology and participated in British excavations in egypt and Palestine. He returned to China in 1941, joining the Institute of History and Philology, part of the Academia Sinica, in 1943. In spite of wartime conditions, Xia undertook important excavations at Neolithic sites in Gansu Province in 1944 and 1945. He was awarded a Ph.D. from the University of London in 1946.

In 1950, one year after the Communist takeover of his homeland, Xia was appointed deputy director of the newly founded Institute of Archaeology of the Chinese Academy of Sciences (since 1977 the Chinese Academy of Social Sciences) in Beijing. From the outset, Xia almost single-handedly ran the institute, which he led as its director from 1962 to 1982. A member of the Communist Party since 1959, Xia was criticized and sent to the countryside during the Cultural Revolution (1966-1976) but allowed to resume scholarly activities as early as 1971. From 1982 until his death in 1985, he served as deputy director of the Chinese Academy of Social Sciences.

A brilliant organizer and administrator, Xia established the institute as the paramount archaeological institution in China during a time of tremendous state-sponsored expansion. He was instrumental in creating structures for training, fieldwork, and publication and in framing relevant laws and regulations. During the 1950s Xia launched many major fieldwork projects, personally directing the excavations at Hui Xian (1950) and Changsha (1951), the salvage excavations near the Yellow River dam near Sanmenxia (1956-58), and the 1956 excavation of an imperial Ming tomb near Beijing.

Xia kept abreast of the archaeological discoveries of all periods everywhere in China, editing two syntheses. As the editor of several archaeological journals and a monograph series, he was concerned with divorcing scientific archaeology from antiquarian treasure hunting, and he insisted that excavated evidence should be treated as a separate class of data and scrutinized extensively before being integrated into historical frameworks. Xia's own publications mainly concern the history of technology and Sino-western connections, two areas in which he could capitalize on his knowledge of foreign languages, rare among Chinese archaeologists. Though not completely eschewing a nationalistic agenda or Marxist rhetoric, his work adhered to the highest scholarly standards. In it Xia tried to demonstrate the relevance of archaeology to the scientifically minded Communist elite, as well as strengthen his own position as the representative of Chinese archaeology in the international arena.

Because post-Cultural Revolution Chinese diplomacy used archaeology to generate international goodwill, Xia was frequently sent abroad, where he was showered with academic honors. Although his manner of running Chinese archaeology centrally through the Institute of Archaeology has become impractical since

York

York is a prominent city in northeastern England with a long history of invasion, settlement, and trade. Known as Roman Eboracum in the first century a.d., York became the Anglo-Saxon capital of Northumbria in the seventh century and was conquered by the Danes in a.d. 866-867. In both a.d. 700 and 1050 York was the premier settlement in northeast England in political, ecclesiastical, and economic arenas. The archaeological history of York follows the history of archaeology itself. Early studies focused on grave goods; early methods included creating typological series, relative dating, distribution in settlement patterns, and comparison of artistic motifs. The study of artifacts and environment in York continues at present and detailed studies are published in *The Archaeology of York*.

No direct historical documentation exists on the early history of York, although there are some coinage and runic inscriptions. Heathen Vikings lacked writing, but the neighboring people wrote observations of the Vikings. Most written records are from contemporary Anglo-Saxons and Irish. Other sources include West Saxon writers hostile to the Scandinavians; English monastic writers who include Scandinavian descendants; and the Icelandic sagas that blend fact, fiction, and folklore, but contain detailed records of the twelfth to fourteenth centuries. Recent archaeological evidence now supports the historical sources.

The early fifth century was a period of political, economic, and social change in Britain. At York, the archaeological evidence shows the end of town life after Roman withdrawals, between the fifth and eighth centuries (O'Connor 1990). Long-term excavations show the same at London (Vince 1990) and at Winchester (Biddle 1973). The early Anglo-Saxon settlements that followed were small rural villages. One of the difficulties in York is the problem of the palimpsest factor (approximately all of the site's stratigraphic elements), which creates a confusion of close dates between late Anglian and early Anglo-Scandinavian. The archaeological record does show continuity in land use, agriculture, and animal husbandry practices. Crabtree's work (1982, 1984, 1989a, 1990) and analysis of faunal remains shows continuity in the patterns of raising cattle, sheep, and pigs from the Iron Age to the Anglo-Saxon period.

Viking activity in the British Isles was part of the struggle between Danes and Norwegians for territorial expansion and control of the trade route from the Irish Sea to southwest Norway. The *Anglo-Saxon Chronicle* recorded the first Viking raids in a.d. 793. Archaeological research and place names show that Shetland, the Orkneys, and the Hebrides were colonized by Norwegian pirates by a.d. 800. Danish sailor-raiders known as Vikings attacked churches, farms, towns, and villages. With their shallow-draft boats of fifty men, the Vikings could travel up rivers. They established winter camps at the conquered sites; eventually they settled, converted to Christianity, and brought in family or married into local families. York became a trading center.

One of the difficulties in York is the problem of the palimpsest factor (approximately all of the site's stratigraphic elements), which creates a confusion of close dates between late Anglian and early Anglo-Scandinavian. The archaeological record does show continuity in land use, agriculture, and animal husbandry practices. Crabtree's work (1982, 1984, 1989a, 1990) and analysis of faunal remains shows continuity in the patterns of raising cattle, sheep, and pigs from the Iron Age to the Anglo-Saxon period.

Viking activity in the British Isles was part of the struggle between Danes and Norwegians for territorial expansion and control of the trade route from the Irish Sea to southwest Norway. The *Anglo-Saxon Chronicle* recorded the first Viking raids in a.d. 793. Archaeological research and place names show that Shetland, the Orkneys, and the Hebrides were colonized by Norwegian pirates by a.d. 800. Danish sailor-raiders known as Vikings attacked churches, farms, towns, and villages. With their shallow-draft boats of fifty men, the Vikings could travel up rivers. They established winter camps at the conquered sites; eventually they settled, converted to Christianity, and brought in family or married into local families. York became a trading center.

Glossary

Acheulean

Lower Paleolithic technology based around the production of bifacially flaked chopping tools. Acheulean industries are found on sites in Africa, Central and Eastern Europe, and in Asia east to India.

actualistic studies

Studies undertaken by archaeologists on contemporary materials and processes so that they might gain a clearer understanding of the processes that form the archaeological record.

Age of metal

That time succeeding the Stone Agewhich first saw the introduction of metal artifacts into prehistoric assemblages.

agropastoral

Referring to prehistoric agricultural economies.

amino acid racemization

An experimental technology used to date bone that can be up to 100,000 years old. It is based on determining the rate of transformation in amino acids from living bone to dead bone.

amphorae

Large two-handled jars used to store liquids.

anthropology

The discipline that is devoted to the study of human beings (particularly their cultural, physical, and social forms).

antiquarian

A person interested in many of the issues and perspectives that coalesced in the mid-nineteenth century as the disciplines of history and archaeology. Antiquarians used documents, oral histories, and artifacts to write about the history of humanity.

applied transformism

In Gabriel de Mortillet's terms, the use of archaeology to demonstrate the reality of transformationist ideas in human evolution.

arboriculture

The use of fruit and nut trees as part of prehistoric economies.

archaeomagnetic

A dating technology based on the fact that hearths or kilns (as heat sources) are sources of paleomagnetism.

archaeometric

Relating to archaeometry.

Archaic, early, late, terminal

North American sites and contexts that exhibit broad-spectrum foraging, ground stone artifacts, and evidence of increasing sedentism.

assemblage

A collection of artifacts that are thought to constitute a single unit of analysis-either by site or by period.

Aterian

Group of Upper Paleolithic tool assemblages with little flakes, some blades, and tanged points that was spread throughout northern Africa and the Sahara, dating roughly from 170,000 to around 30,000-20,000 b.p.

Aurignacian

An Upper Paleolithic industry that spread from the Levant to Spain and France.

Australopithecine

An ancestral genus to *Homo* found in East and South Africa. Skeletal remains (which date from about 3.7 million years ago) are classified into species such as *Australopithecus afarensis* (found in Ethiopia) or *Australopithecus africanus* (found in South Africa).

Austronesian

A family of languages found in island southeast Asia, Polynesia, Micronesia, and Melanesia (with the exception of most of Papua New Guinea).

autochthony

Referring to something native, indigenous, or “home-grown.”

backed blades

A stone tool that is a blade shape with one of the longer edges deliberately blunted.

Bandkeramik culture

The earliest Neolithic culture of Central Europe (between 4500 b.c. and 3900 b.c.).

Baradostian

An Upper Paleolithic stone industry found in Iran.

barrow

A mound of earth and stones that in most cases covers a burial or a number of burials.

Bell beaker barrow

A burial mound associated
