In pre-Columbian Mesoamerica at this time the nature of the labor force was somewhat more complex. Large numbers of Mesoamerican workers were necessary for the building of cities on a large scale. Construction projects like pyramids, public monuments, and apartment compounds of the cosmopolitan urban center of Teotihuacán (ca. 1–700), for example, bound people to the community and linked outlying agricultural workers to a central hub. Large labor forces also took part in the construction of the city's ceremonial centers, palaces, administrative buildings as well as irrigation systems. Additionally, large numbers of people were employed in crafts production, including jewelry, ceramics, and similar goods. Many of these goods were produced for the elite class. Most production was organized at the household level and carried out by specialists. Entire neighborhoods could be devoted to a single craft specialization.

Manufacturing employed a larger number of laborers in Mesoamerica. One major industry was the production of tools made of obsidian, a glasslike volcanic rock. Teotihuacán was a major obsidian production center. The obsidian trade required the labor of skilled workers, who forged raw obsidian into machetes, knives, points, and weapons. It also required a large class of laborers to mine the obsidian, transport it to manufacturing hubs, and then carry finished products away, all without benefit of wheeled vehicles or pack animals. In

support of this manufacturing activity was a large and affluent class of traders, who imported the raw obsidian and other commodities when necessary and served as middlemen in the exchange of tools for other commodities. One of those commodities was salt, which was extracted from coastal lowlands and then traded to the interior in exchange for tools, foods, textiles, and similar goods.

In connection with trade, a lower-class occupation developed—that of the porter. Surviving manuscript paintings show children being trained for this type of labor. These porters were based in towns along trade routes. Merchants would arrive in town and hire them to carry loads, typically of about 50 pounds, to the next town, usually a journey of a day. There the goods would be handed off to another porter, who carried the goods for another day to the next town, and so on.

The elite long-distance traders (*pochteca*) were an essential part of the Aztec economy. While the Aztec civilization (ca. 1200–1521) relied on agriculture and the labor of peasants and slaves, much of its economic activity revolved around craft production, including ceramics, jewelry, and metallurgy. But trade was a crucial economic activity. In the capital city, as many as 60,000 people gathered to trade goods in markets.

Textile production was a major labor activity throughout Mesoamerica, particularly the production of embroidered cotton cloth used to make luxury clothing for social elites. Most of this textile production was done by women working out of their homes, but it too could become a trade or tribute item, particularly under the Aztecs. Numerous crafts workers in some areas produced other luxury goods made of metal, particularly copper, including such objects as tweezers, bells, rings, necklaces, buttons, and needles.

Archaeological evidence shows that there was a considerable amount of craft specialization, which took place under the authority of social elites. Among these craft specializations was papermaking, which provided a paper made of bark that was used for administrative and ceremonial purposes. Mesoamerican society was hierarchical, and elites legitimated their power and control by sponsoring specialized craft production. One measure of the regard in which certain crafts were held is their proximity to the homes of the elite. Textile production and production of luxury goods, including goods made of gold and other metals, as well as of stone, often took place in homes very near elite residences and ceremonial centers. The feather workers and other elite craftsmen resided in the palace of the ruler Montezuma II (r. 1502–20). The Aztecs produced books of tribute showing the various kinds of raw materials and worked items requisitioned from subject peoples.

In all cases laborers were not paid with currency, largely because currency did not really exist. Sometimes, cacao

beans, the source of chocolate, were used as currency, but usually people were paid in kind. Thus, rural agricultural workers transported their surplus production to the cities. Similarly, craft goods became, in effect, the property of rulers among the Aztecs, to be distributed to other rulers and elite members of society as gifts. It was in this way that the rulers cemented their power and authority. Elite members of society and merchants also held lavish banquets, which also involved a great deal of gift giving.

During this period in South America domestic production was the norm. Households tended to cultivate their own land; make their own tools and utensils; domesticate animals; produce clay pots and other storage vessels; make clothing out of cotton, wool, and hides; and engage in other, similar activities. Thus, households were relatively self-sufficient. Extended family units provided labor for tasks that required larger labor forces, including clearing fields and harvesting crops, terracing fields, gathering lumber, and constructing houses. In the Amazon basin, for example, extended families and clans constructed earthen dikes to keep floodwaters out of their fields.

Like their Mesoamerican neighbors, South Americans relied on redistribution of goods to meet most of their needs. That is, goods such as agricultural surpluses were transported to city centers, where they became the property of rulers and other elites. In turn, these goods were distributed during times when food was in short supply in households. This type of exchange of resources as payment for labor became more commonplace as South American societies became more complex and as populations grew. By the time the Inca emerged in South America (ca. 1450), the notion that all resources—land, agricultural production, textiles, wool, cotton, metal products—belonged to the state had become entrenched. In effect, the state was supported by a labor “tax.” On a revolving basis, all citizens, including children, were required to provide labor for the state, working in agriculture, construction of public works, and crafts production of metal products, textile, and pottery. As much as two-thirds of a farmer’s output was taken by the state. In exchange, people received food, clothing, and other necessities when they needed them.

Craft specialization evolved from household production to specialized production for markets. In particular, many laborers were involved in metalwork production. Metals worked included gold, silver, copper, and *tumbaga*, an alloy of the three. These metals were used to make both utilitarian and luxury goods. However, most utilitarian goods were exchanged locally; luxury goods, in contrast, were exchanged over much longer distances. A major reason for this had to do with transportation costs. Another had to do with the role of imported luxury goods in defining the status and power of

elites. Therefore, laborers made utilitarian goods for the local market, while they made luxury goods from whatever exotic materials they could obtain—ceramics, stingray spines, turtle shells, shark teeth, conch shells, exotic woods, scarce minerals—for the long-distance trade market. Their activities were directed by those who occupied the upper strata of society.

Agricultural specialization, too, became the norm. South America is marked by a large number of climate zones and elevations. Different crops grew best at different elevations. Thus, the people of South America specialized in the production of certain crops that were suited to their microclimate, relying on local exchange to diversify their goods. As an example, up to 20 varieties of corn and 240 varieties of potatoes were grown, each adapted to the climate where they grew.

## ASIA AND THE PACIFIC

BY KENNETH HALL

Asia’s medieval rural laborers worked in village-based communal or family-centered groups. Extended family households were the norm in India and China, nuclear households in Japan, and a mixture of communal and family-centered work units in Southeast Asia and the Pacific islands. Men and women performed daily chores according to local tradition, but everyone participated in food production. Local work might be assigned by local leaders (“big men” or “big women,” chiefs, or priests) who did not perform physical labor but instead delegated it to their social subordinates as well as to prisoners of war, slaves, and indebted bond servants.

Where land was plentiful and additional labor was always in demand, women enjoyed a high degree of economic and social status, which contrasts with the low economic and social esteem of Chinese and Indian women in regions of population density. In everyday life the work of men included field preparation, plowing, felling trees, hunting, metalwork, tool repair, house building, statecraft, and formal (Indian- or Chinese-based) religion. Women transplanted crops, harvested, grew vegetables, prepared food, spun thread, wove cloth, made pottery, marketed local produce, and, because of their association with fertility, participated in traditional animistic cults meant to ensure favorable weather, good harvests, and the fertility of the land and family. Both men and women shared in planting, harvesting, animal care, food storage, and field maintenance, including the construction and care of irrigation canals.

There were a number of rural labor arrangements relative to land use and the resulting income rights. Ownership and entitlements to income depended on overlapping familial, communal, and political claims, many of which had their origin in the clearance of land, the building of irrigation

dikes and reservoirs, and the resettlement of free cultivators and bondsmen on previously uncultivated lands. In addition to obligatory divisions of annual production among those holding income rights, local cultivators were subject to the revenue demands of government officials, which were payable in kind, cash, or labor services. Outside of China, population shortages and increased productivity encouraged private-family or communal village holdings of property, but by the 12th century in densely populated China, 80 percent of the rural population worked on land controlled by less than half the population.

While food production was the primary element of the economy, commercial developments beginning in the 10th century increased the market for craft products throughout the Asian region. Agricultural communities responded to the potential presented by this change because income from supplemental craft production increased the local standard of living, and it blunted the ever-increasing tax and rental demands of the elite. In India, China, and Java farmers also balanced grain and vegetable agriculture with the cultivation, processing, and weaving of cotton. In China, Japan, Korea, and mainland Southeast Asia people raised mulberry trees to feed silkworms and processed the silkworm cocoons into thread. They then wove the thread into luxurious silk fabrics for local use or export or passed the thread along to rural and urban households who devoted themselves exclusively to weaving. Farmers throughout Asia also grew hemp and ramie stalks, which provided coarser fibers for weaving less-expensive textiles for local use. Rural tax collectors frequently doubled as commercial wholesalers or brokers, who gathered local agricultural surpluses as well as the government's share of local production and sold the surplus to transport merchants or urban shopkeepers.

As a result of improved market demand and commercial transport beginning in the 10th century, some enterprising farmers migrated from the countryside to cities to supplement their family's income, leaving their subsistence farming for full-time craft work. This urbanization of labor corresponded to labor specialization in the production of textiles and other crafts such as metalwork and ceramics. Urban textile production in China took place in private, temple, and imperial workshops, which produced more sophisticated and expensive weaves than those produced in the countryside. Workshops depended on the labor of artisans and their families, supplemented by day laborers, who were hired as individuals or as contracted laborers. Full-time shop artisans organized into guilds, which separated weavers of various varieties of cloth.

Artisan and merchant specialists throughout Asia initially resided in designated sectors of a community, perhaps a

## SPINNING

Spinning is the process of converting combed or carded fibers into long threads or yarns to produce cloth. In spinning, fibers are pulled from the mass of fibers, twisted to make them cling together, and wound onto a spindle. Spinning is traditionally women's work.

In the original process of spinning, fibers were pulled and twisted them by hand. In time, a spindle was developed to help with the process. The original spindle was a narrow stick about 12 inches long with the dual purpose of holding the mass of fibers at its upper end and containing the spun yarn at its lower end. A more advanced instrument, the drop spindle, was a rod that had been narrowed at both ends and inserted through a disk-shaped whorl. The whorl, made of stone, clay, or another hard substance, served as a flywheel to make the spindle drop toward the ground and rotate rapidly in one direction. Spindles and their attached whorls differed in size and weight according to the type of fiber being spun.

The Chinese were the first to invent the spinning wheel. The spinning wheel is essentially the mechanization of the drop spindle. The spindle itself was mounted horizontally between two short, slotted uprights, with bearings, to serve as an axle. The spindle tip protruded beyond the upright to accept the fibers. The whorl was grooved to act as a pulley that received a continuous stream of wound fiber from the wheel. The driving wheel would be attached by an axle to uprights on the same floorboard. A small wheel would be used for cotton or silk spinning with a larger wheel used for wool. One turn of the wheel produced many revolutions of the spindle, thereby permitting greater labor productivity in spinning yards of yarn. However, in contrast to the drop spindle, the early spinning wheel was clearly an inferior product. It too often produced yarns that were weak, uneven, with insufficient twist, and with too many knots to properly form cloth on a loom. The defects resulted chiefly from the wheel's speed. Such production defects did not matter with all yarns, particularly those that were combined with hand-spun yarns to produce cloth.

merchant/artisan quarter or specified streets. In the 12th century, in response to the generalized growth in Song-era private trade and economic specialization, China's trade guilds

and licensed firms grew out of earlier merchant associations grouped by trades in various streets and self-contained walled blocks within a city. The new guilds were organized under one member, selected as headman, who was responsible to the government for the collection of all the members' taxes or payments of collective quotas of local craft production. Guilds also were an institutional means by which the Chinese government could hold merchants and artisans accountable in a society in which merchant and artisan behavior was by nature counter to the Confucian ideal of the collective community, and they were vital in their inclusive representation of merchant and artisan interests relative to those of the Chinese imperial regime.

By the 13th century the Chinese and other developing Asian imperial regimes were demanding textiles to clothe state troops, courts, and bureaucrats and to make assorted payments in kind as rewards and gifts. Heavy state taxation forced laborers in the silk- and cotton-producing regions to commit their available labor to textile production instead of the surplus production of crops, which brought less profit and were less able to meet the state's revenue demands. Operating an urban workshop required amounts of capital that rural families lacked and allowed them to better balance the demands of the government and the opportunities of the urban marketplace. In China, as elsewhere in Asia, there was so much demand for cloth that rural weavers who created higher-quality and more sophisticated patterns had ample opportunity to make a comfortable living. The growing number of successful textile-producing workshops broke down the former distinct rural and urban division of labor in the textile-producing regions.

Other types of laborers who earned their livelihood in occupations associated with craft production included carpenters, blacksmiths, workers in gems, goldsmiths, printers, image makers (such as those who made statuary and temple carvings), and painters. There was open competition to receive the services of particularly skilled architects. Since master artisans were forbidden by custom or law to do menial tasks, others below them performed the actual work. Accomplished craftsmen built temples and palaces and were praised by name in local inscriptions and dynastic records and chronicles. In payment for their services notable artisans received honorific titles and designated income assignments from assigned land. Wealthy artisans and commercial specialists received other privileges, including the honor of having double conches blown and drums beaten at their marriages and funerals, wearing specified types of clothing, covering their houses with plaster and other decorations, and being transported in a litter.

Artisans were recognized for their contributions to a community's well-being. Blacksmiths were especially appreciated, as their work fashioning and repairing metal plows and iron farm tools was vital to local agricultural productivity. Inscriptional and dynastic records report local efforts to recruit artisans with guarantees of tax remissions, land grants, and special privileges. Laws were passed making it unlawful for valued artisans to move away from their homes, which would threaten the local economy and societal cohesion. While artisans of the highest stature received substantial rewards, lesser artisans were subject to these local restrictions, mandatory labor assessments, and the remission of craft objects to members of the secular and religious elite.

The increased economic stature of artisans, along with their local privileges relative to the traditional agricultural community, created the potential for social and political discord. Agriculturalists and members of the elite traditionally had occupied the top of the social hierarchy, while artisans and merchants, whose goal was profit over community service, occupied the bottom. Indian sources show particular concern with artisans' and merchants' legal and social status relative to Hindu religious obligations. Only artisans of the highest status among the laboring castes (Vaishya and Shudra) could perform the religious rites associated with sacred elements and structures, such as consecrating a temple site, preparing the foundation for a temple's sacred altar, or creating the central temple icon. To qualify, elite artisans were required to study the sacred texts in addition to learning the essential skills of building.

Seagoing populations the Chinese collectively called Kunlun specialized in economic activities related to the sea and coastal regions of Asia and the Pacific. In the medieval era Malay and Polynesian crews sailed the islands of Southeast Asia and the Pacific in ingeniously designed and built double-outrigger canoes and larger seagoing vessels. Men spent most of their productive time fishing the sea for fish, sea turtles, and octopus for their own and others' consumption; they also harvested coconut and breadfruit and hunted native animals, notably land snails and tropical birds. Women grew taro, a cash crop highly in demand regionally; gathered wild foods from the jungle; fished inland ponds; and wove cloth and mats from tree and plant fibers. In the absence of regular trade, local seafarers commonly turned to open piracy to acquire the commodities necessary for their own subsistence.

Labor in the eastern Indonesian archipelago during the Sung and Yuan eras is highlighted in Chinese literary sources, which discuss the local laborer's role in the provision of cloves from the Moluccas, nutmeg from the Banda Islands, camphor from Borneo, sandalwood from Timor, and tor-

toiseshells, sea slugs, and pearls from a variety of eastern archipelago sources. These products were in demand in China as medicinals and aromatics that were classified as either fine goods subject to government monopoly or coarse goods available for open-market exchange. Beginning around 1200 there was sufficient international demand for sea and island products that local labor specialized in their collection and export, to the exclusion of their piracy and cultivation of subsistence grains. Instead, they accepted volumes of imported rice from Java in exchange for their specialty crops. Mixtures of upstream and downstream island populations cultivated these desirable marketplace commodities in partnership with sojourning maritime traders who provided their connection to the international marketplace.

Numerous urban-based corporate trading communities existed in the medieval era, including those who specialized in international trade. In the Middle East, India, Southeast Asia, and China they were often centered in firms formed by merchant families who sent their members to Asia's ports of trade and caravan centers to transact business. These family agents might have several bases of operation. For example, sojourning merchants traveling from one Indian Ocean port to another had to follow the shifting seasonal monsoon winds. Having reached their destination, they would have to stay several months until the reversal of the monsoon season's wind allowed them to make their return voyage. In their absence, local-resident trading partners or perhaps the family of the woman they took as their local wife looked after the interests of the transient merchants.

International trade guilds based in southern India, at their height from 1000 to 1400, were a notable alternative to the family firm in their ability to represent the collective interests of their members, whose commercial goals ran counter to local communalism. These international guilds were inclusive of local and foreign members and trade associations, collectively represented in an executive council. Individual merchants were free to enter trade partnerships with other organization members or with nonmembers. Members swore a code of mercantile conduct that set them apart from other itinerant traders. The most prosperous members became so-called merchant princes who held monopoly privileges over certain goods, and they were allowed by local authorities to display the symbols of the wealthy and powerful, such as carrying umbrellas against the heat of the day, riding on elephants, and living in multi-storied houses. In an age in which there was periodic political insecurity, the international trade guilds employed mercenary troops to safeguard their business interests, caravans, ships, and warehouses and to be lent in support of local rulers who favored their commercial interests.

## EUROPE

BY JUSTIN CORFIELD

People in medieval Europe were involved in farming, for the large part growing their own food and tending to use barter rather than exchanging any money during the early Middle Ages. Barter also was used by people working in villages in a wide range of tasks involving agriculture. But for the sale of agricultural goods in towns and cities and also for specialized services in urban areas there was a need for payment, with certain occupations becoming lucrative because of the income they were able to generate. To restrict the number of people who could do particular tasks, regulations were enacted to control the quality of work, which led to the guild system and also the training of apprentices.

The vast majority of people in Europe in medieval times lived in or near villages. There is a wide range of surviving source documentation about the spread of the population, the most well known being the English Domesday Book, a sort of census completed in 1086 on the order of William the Conqueror (r. 1066–87). Parts of the record have not survived, but the original document listed every village in the country and detailed the number of people living in each village. Byzantine records for eastern Europe also list the number of men whose service could be called upon in times of war, showing that most people lived in villages. These written records are mirrored by archaeological data from other parts of Europe which show a large rise in population up until the Black Death of the fourteenth century. In some parts of Europe, especially in the east, the existence of serfdom precluded serfs from leaving the land for work in the city. However, even when movement was not restricted by law, many families lived in villages for generations.

Most villages were formed into parishes, around a parish church. In countries where there was constant fighting, the houses themselves would be set close together, often with a wall around them for protection. This created a strong sense of community, and allowed for a system of barter when work done by one person might be repaid by another at a later stage. Hence a shoemaker in a village could be paid for his shoes at harvest time. Similarly, many parish priests were maintained entirely by the parish, with goods provided by parishioners during the year. In feudal Europe even the lord of the manor might take much of his payment in kind, either in crops or in labor.

In towns and especially in cities, where there was far greater specialization in work and less control over the population, the system of barter was not as effective. As a result, if somebody needed to pay an artisan with coins, that person

also would have to collect payment for his own work. With no exact measure of time, payment was made for a day's work; the term *day laborer* was commonly used to describe people who were hired for such work. These were probably some of the first people to be paid a "wage," but there were other ways to calculate payment. Most artisans charged for individual items, for example, and lawyers drafting documents charged by the word.

From the 1300s on trade brought considerable wealth to much of Europe, with craftsmen and artisans working in towns and cities, which they had done since Roman times. To try to regulate these craft workers, from the early Middle Ages specialized guilds emerged and flourished in such cities as London, Florence, and Genoa. Often known as "liveried guilds" because of the distinctive clothes (liveries) worn by practitioners of various trades, these associations were able to restrict the number of people entering a particular field of business, with the dual aims of ensuring the quality of the product or service and keeping prices high. In order to join a guild, a boy typically would have to serve a fixed period as an apprentice, after which he would become a full member of

the guild. During the period of apprenticeship the master had the responsibility for caring for the youth, feeding him and providing him lodgings, educating him, and also teaching him the particular craft. Although there were cases of masters who took advantage of their apprentices, most masters established good working relationships; there are instances of masters, on retirement, handing over or selling their businesses to their former apprentices.

Extensive apprenticeship records are available for England, parts of Italy, and Germany, showing that similar patterns tended to emerge. Most records indicate that a large number of boys from villages in the countryside became apprenticed at local towns. There were also a number who were apprenticed in distant cities—often the master having had some connection with the village from which the apprentice came or sometimes being a distant relative. Some guilds even imposed strict rules on who could be an apprentice. In Paris no boy could be apprenticed as a weaver unless he was the son of a weaver.

For the making of food there were guilds for bakers, butchers, and fishmongers. Although bakers tended to be found throughout a town or city, butchers and fishmongers often congregated in particular places. Butchers had to be near the location where animals were slaughtered, since it was done soon before sale; fishmongers needed to be close to the wharfs where the catch would be landed. The skimmers, tanners, and curriers (who dressed leather), as well as other people involved in leatherwork, usually worked close to the location of the butchers. Girdlers and saddlers had their businesses near the horse markets.

Butchers and cooks existed throughout Europe from ancient times, but their guilds did not emerge until the late 12th century. The earliest reference to the Butchers' Guild in London dates to 1179, and the first cook's shop, in Cookes Row, London, is mentioned in a roll from nine years earlier. Most of the guilds, however, started at a later date. Their emergence was connected with particular crafts, among them, chandlers (makers of candles and soap), cobblers (shoemakers and shoe menders), and drapers (dealers in cloth and dry goods). Competition could arise between members of different guilds. To circumvent this, directives in some cities such as Paris regulated the guilds not by what they produced but by the material with which it was made, thus, for example, separating robe makers using cloth from those who made robes from fur.

Traditionally regulations were placed on the sale of alcohol, often because of the collection of taxes; for this reason, inns and taverns had to be registered. Some of these establishments were tied to particular brewers. Coopers (who made and repaired wooden casks in which the beer was stored) typically were located close to breweries. Vintners in many

*Corbel in the form of an angel holding a shield with the arms of the Grocers' Company, London, 1466* (© Museum of London)

cities imported wine from southern France and northern Italy. For cities and towns located near bodies of water, watermen and ferrymen transported people and goods—usually operating in very strictly regulated guilds that fiercely saw off any opposition. Carters did the same for land transport. As in villages, blacksmiths and ironmongers worked throughout a city, along with builders and carpenters. In cities there was also more use of glass, which increased dramatically during the Middle Ages; glaziers were working in every city by the end of the medieval period.

Within houses candles were the only method of illumination at night, and some cities, such as London, had rival guilds of tallow chandlers and wax chandlers. Bowyers made bows, a particularly important occupation in England, which heavily relied upon them in battle. Armorers had workshops throughout medieval Europe, and the best craftsmen usually were located around the palaces of kings and other rulers, whom they supplied with armor. Although cutlers could produce knives, they tended to specialize in the making of cutlery; the fork was first used in Byzantium in the 10th century.

Many women made clothes for the family at home, so there were relatively few clothes shops. Shops tended to sell lengths of cloth to be made into clothing, and cloth workers, drapers, and dyers often were situated close to each other. At the higher end of the market were haberdashers (dealers specializing in men's clothing), merchant tailors, and mercers (dealers in expensive, high-quality fabric such as silk). Some of these guilds, such as that of the mercers in London, became extremely powerful; Mercer's Hall became a center of city intrigue. The mercers required an apprenticeship of nine years, and there were many famous members of their guild, including Sir Richard Whittington (d. 1423)—the “Dick Whittington” of children's stories—who was Lord Mayor of London on three occasions. Such was the wealth of some of these guilds that the haberdashers', merchant tailors' and mercers' guilds in London were all wealthy enough to found their own schools.

The four most specialized occupations were those of goldsmiths, barber-surgeons, apothecaries (people who sold drugs and medicinal preparations), and lawyers. Many of the medical associations and law societies in Europe today have their origin in guilds that operated in medieval times. The making of spectacles was concentrated in Antwerp from the mid-14th century on and led to the formation of a guild there that also jealously guarded entry to the profession. With each of these guilds closely shielding access to membership, it was not long before people came to realize that membership of a particular guild could be an easy path of personal enrichment.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

Employment and labor were very complex social issues in the medieval Islamic world, as the spread of Islam incorporated many different cultures with different employment and labor practices into the Islamic sphere. New rulers in conquered territories faced two problems. One was the occasional shortage of labor, as war sometimes resulted in the deaths of laborers or in their flight to escape the Muslim invasion. The other problem was that of determining how to apply Islamic laws to local employment and labor practices. Throughout the medieval era matters of employment and labor generally were resolved through markets and the balanced application of state laws and regulations; the maintaining of this balance allowed for the development of the most prosperous economic era the world had known until then, often called the “golden age” of Islam.

Labor shortages seem to have been most acute in two regions: the western Near East, particularly the Levant, and northern India. In the case of the western Near East, the Arab invasions resulted in the loss of farmers and the fleeing from cities of Greeks and others who took along their wealth and skills. In India the burning of cities and the occasional wholesale slaughter of locals resulted in the loss of craftspeople and their employees, with many people likewise escaping from the conquered lands and taking along their skills and labor. In general, once Islamic rule was imposed, the new rulers engaged the local populations in work and tolerated local employment and labor practices. This was probably a practical matter, because making sweeping changes in local labor practices could have created unmanageable chaos in local economies. Further, Islamic laws were perhaps difficult to apply specifically to employment practices.

In rural areas farmers often were allowed to pursue their work as they wished. Muslim leaders usually focused their efforts to control and organize labor in the cities. The conquests of Islam typically resulted in the growth of cities, with laborers leaving the countryside to find work in the many building projects and other enterprises sponsored by Islamic governments. Rural populations were often heavily taxed—though generally less so than under previous rulers—making employment in the city seem a preferable avenue toward earning a living.

A chronic problem in the cities of the early Islamic world was the general unrest of unskilled laborers. Islamic cities tended to be slightly different in layout from modern cities. The urban area itself was defined by its marketplaces, mosques, shops, and houses. At the edges the city was surrounded by gardens, where many laborers living in the city went to work during the day, producing fruits and vegetables for the city's markets. The gardens eventually blended into

the countryside, where farms could be found. The region of the gardens included places for caravans to stop and trade their wares, and near these were areas where unskilled laborers could gather, hoping to find employment in the gardens, with the caravans, or in workshops. These semiemployed laborers sometimes rioted. Sometimes a charismatic imam's fiery oratory against the supposed immorality and unfairness of rulers would inspire outright revolts among unskilled laborers. A persistently aggravating factor among laborers was that while merchants were regarded with respect, those who worked with their hands were held in contempt and frequently were treated accordingly.

Marketplaces in Islamic cities were among the wonders of the medieval world. In them could be found fresh food, clothing, shoes, furniture, tools, and beautiful jewelry. To regulate the marketplaces and those who made the goods, governments employed two people, the *sayafi* and the *muhtasib*. The word *sayafi* is often translated as “money changer,” but this term is not entirely accurate; a *sayafi* would indeed exchange local money for foreign money, thus enabling visiting traders to do business in the city, but he would also assess the values of coins. The *sayafi* was in charge of determining the percentage of silver or gold in individual coins and then weighing the coins to determine exactly how much actual silver or gold was present. Coins were sometimes damaged through use or shaved on their edges by unscrupulous people. By determining the actual content and weight of coins, the *sayafi* played an important role in ensuring that workers were paid exactly what they were owed by their employers.

The *muhtasib*—the equivalent of the modern-day ombudsman—was one of the most important figures in the business life of a city. The word *muhtasib* translates fairly well as “market inspector,” even though the authority of the *muhtasib* extended beyond the functioning of the markets. The *muhtasib* was responsible for ensuring that the rules of Islamic ethics and morality were followed in the marketplaces and workshops of the city. He also was charged with ensuring that markets functioned smoothly, for the state viewed the integrity of the marketplace as critical to its foundation as well as with ensuring social justice. This meant that he and the law enforcement officers who worked for him would force shop owners to clear the streets of their displays—shop owners constantly tried to set their wares outside their storefronts where the goods could be easily seen, thus blocking traffic. The use of the wheel for transportation was largely abandoned in Islamic lands, with donkeys, mules, and horses bearing riders and burdens. As such, streets needed to be wide enough only for two donkeys to pass side by side; narrow byways were often jammed with traffic.

The *muhtasib* ensured that all weights and measures were accurate, including those used by the *sayafi*. Further, he made sure that people were paid what they were supposed to be paid,

the market-determined “prevailing wage.” In addition, he enforced public morality; for instance, public drunkenness was not tolerated. The *muhtasib* had the authority to punish anyone who violated the rules. He also collected the poll tax from *dhimmis*, a term for non-Muslim “People of the Book,” that is, those people who adhered to the religions that recognize the god of Abraham—Jews and Christians. In exchange, the state would extend hospitality and protection to members of the other revealed religions (religions whose scriptures had been received through the word of God), including freedom to practice their faith and exemption from military obligations. Jews often filled the roles of sea merchants that had been held by Greeks under the Byzantine Empire. They also were allowed to hold jobs Muslims regarded as inferior. Both Jews and Christians often held government posts, sometimes as a practical necessity for the functioning of the state, and the experienced bureaucrats of newly conquered lands were often Jews and Christians. Nonetheless, Jews had to wear yellow bands on their shoulders and Christians had to wear blue belts, just as Jews and Muslims were subjected to similar humiliations in Catholic Europe, particularly post-Islamic Spain. Despite their inferior status, however, Jews and Christians were not consigned to ghettos, as Jews were in parts of medieval Christian Europe.

Workers in the Islamic world were not organized into formal guilds. Even in former Byzantine territories, existing guilds disappeared, perhaps because under the Byzantine Empire guilds had been part of the government's system for controlling workers, and few people would have sought to retain them. Instead, various groups of employers had leaders who spoke on their behalf to government officials. Workers engaged in similar crafts and traders selling similar wares typically aggregated in separate sections of the market in order to promote competition and comparative shopping. A community might have several loosely organized groups of furniture makers, bakers, stonemasons, and other such workers, each with its own leader. Another way of organizing under a leader was by territory in a city, with all workers of any kind represented on the basis of where they worked or where they lived. Often, the leaders would choose a head to speak for all of them on important matters.

Workplaces often were owned by governments or religious institutions. As such, palaces and mosques could have workshops attached to them. For instance, in the 1300s the sultan in Delhi, India, had 36 workshops that employed thousands of workers. The most prestigious craftspeople, such as metalworkers, were located near the palaces of rulers. Other jobs were closely associated with mosques and the marketplaces near mosques, including papermakers, lawyers, and booksellers. Sometimes a city became organized around the kinds of work done in it. In the medieval city of Fez al-Bali, in Morocco, for example, a stream flowed through the city,

with the main mosque upstream and the papermakers, lawyers, and booksellers nearby. Near the palace were the metalworkers. Downstream were the millers and dyers, as dyeing was smelly and created pollution, making it a trade to be kept downstream from most of the city. (In many parts of the early Islamic world, one of the tasks of the *muhtasib* was to check and minimize the effects of pollution in communities; for example, brick-manufacturing factories could not be located near textile markets.) Farther downstream, at the edge of the city, were the butchers, who generally were regarded as the most unclean of all workers. Sometimes the sheer number of workers in a city made organizing crafts by territory nearly impossible. For instance, craftspeople had about 200,000 residences in Cordoba, Spain, with about 80,000 shops scattered throughout the city, near marketplaces and along streets.

The nomads and farmers who lived outside the cities made much of what they needed themselves. Itinerant craftsmen roamed rural areas providing their services to those who paid for them; prominent among these were smiths who repaired tools. People in rural areas would select sites for small markets where they could exchange goods. Sometimes these sites became villages or towns, where craftsmen would set up permanent workshops to serve the people who came to the market.

The interests of the workers in cities and those in rural areas often conflicted. In the market-exchange environment that prevailed in the Islamic world, farmers wanted to earn profits on what they grew, while workers in cities wanted cheap food. Notable efforts were made by rulers to balance the needs of the rural workers who produced food and the need of city workers for food they could afford. Ala-ud-Din Khalji, the sultan of Delhi in the late 1200s and early 1300s, paid particular attention to this matter. In accord with the Islamic emphasis on social justice, he instituted price controls on goods viewed as necessities, such as food and clothing. To

enforce these price controls he employed public inspectors and auditors. Further, various types of grains were identified and made subject to sales at fixed prices. In order to ensure adequate supply at fixed prices even during poor crop seasons, the sultan oversaw the stockpiling of grains. Ala-ud-Din Khalji became celebrated for keeping basic necessities affordable for even the lowliest of laborers.

A negative result of such price controls—one that could arise in any market-exchange setting—was that many farmers, not earning enough profits, abandoned farming. They then became part of the semiemployed labor force in cities. Another problem was that low prices often kept wages low, such that even if food and other goods were inexpensive, some workers did not earn enough money to pay for them. However, a system of public assistance was typically organized, as funded by revenues from the institution of *zakah*, whereby Muslims are obligated to contribute to public charity; *zakah* is one of the five pillars of Islam.

Europe

~ Ordinance of Laborers (England, 1349) ~

The king to the sheriff of Kent, greeting. Because a great part of the people, and especially of workmen and servants, late died of the pestilence, many seeing the necessity of masters, and great scarcity of servants, will not serve unless they may receive excessive wages, and some rather willing to beg in idleness, than by labor to get their living; we, considering the grievous incommunities, which of the lack especially of ploughmen and such laborers may hereafter come, have

upon deliberation and treaty with the prelates and the nobles, and learned men assisting us, of their mutual counsel ordained:

That every man and woman of our realm of England, of what condition he be, free or bond, able in body, and within the age of threescore years, not living in merchandise, nor exercising any craft, nor having of his own whereof he may live, nor proper land, about whose

(continued)

*(continues)*

tillage he may himself occupy, and not serving any other, if he in convenient service, his estate considered, be required to serve, he shall be bounden to serve him which so shall him require; and take only the wages, livery, meed, or salary, which were accustomed to be given in the places where he oweth to serve, the twentieth year of our reign of England, or five or six other commone years next before. Provided always, that the lords be preferred before other in their bondmen or their land tenants, so in their service to be retained; so that nevertheless the said

lords shall retain no more than be necessary for them; and if any such man or woman, being so required to serve, will not the same do, that proved by two true men before the sheriff or the constables of the town where the same shall happen to be done, he shall anon be taken by them or any of them, and committed to the next gaol, there to remain under strait keeping, till he find surety to serve in the form aforesaid.

### Europe

#### ~ Abbey of Stavelot: Corvée of Labor (France, 1126) ~

In the name of the Holy and Indivisible Trinity. Cuonon, by the grace of God, Abbot of Stavelot. Just as it is right to keep alive those things which have been well and truly decreed to be inviolate and holy, so there is no question at all that those things which have been corrupted by perversion ought to be returned to their proper use. Therefore, let it be known to your posterity that we have discovered a certain corrupt and altogether reprehensible use, or rather abuse, which we on the advice of our monastery and of our faithful people have corrected by this present charter. For since it was the ancient custom that all, who have a rural possession within the boundaries of the villa of Stavelot, should bring lime three times a year to the monastery, negligent officials, having accepted money for the cartage, worked two evils, i.e., they oppressed the people by this exaction and they neglected both the walls of our buildings and the crumbling walls of the inner cloister. And so we, resisting this two-fold evil, have decreed, and by this present charter have confirmed our decree, that, for the future, serfs will

bring lime or stone for burning to our monastery, and if they are not commanded to transport the lime, they need not pay any commutation or redemption at all, except that if there be an abundance of lime, they may pay for one cartload of lime six loads of timber for building purposes or two for fuel. Moreover, they will go three times a year, first in the month of May, then between the feast of St. John and that of St. Peter, at the end of the month of June, and thirdly between the feast of St. Remaclus and that of St. Remigius. Let them bring this lime or stone prepared for burning from our manors, that is Louveigné, or Xhoris, or Filot, or Ozo.

Done at Stavelot in the year of the Incarnation 1126, Lothar being King of the Romans, Alberon Bishop of Liège, and Cuonon Abbot of Stavelot.

## ► exploration

### INTRODUCTION

During the millennium that defines the medieval period, peoples throughout the world continued the explorations they had begun in ancient times. Portions of the world were relatively densely populated. Cities in the Middle East were large and highly developed, as were those in China and other parts of Asia. Central Mexico's population was dense, the cities of northern and western Europe were growing, and the region surrounding the Mediterranean Sea had long been the home of dense civilizations such as Rome, Greece, and Constantinople. Other parts of the world, however, were still sparsely populated: the Great Plains of North America, the non-Andean portions of South America, swaths of sub-Saharan Africa, the frozen steppes of the Eurasian landmass, and islands in the Pacific, the Caribbean, and other parts of the world. These and other areas of the world were ripe for exploration.

Exploration during the Middle Ages was motivated by a number of factors. One was the search for resources. As people became increasingly sedentary, settling in towns and cities rather than leading a nomadic existence, they exhausted their physical environment. Forests were cut down for lumber and firewood, land was converted to agricultural uses, and mines were emptied of their ores. As populations continued to grow, nations explored surrounding regions with a view to replenishing their resources and providing room for more and more people. A related motivation was defense. By extending the reach of the territory under its control, a medieval state or kingdom could better defend itself against foreign invaders. Again, such territory had to be explored before it could be brought under a state's influence.

Trade, too, was a motivating factor behind medieval exploration. Trading requires someone to trade with. A culture that evolved beyond subsistence agriculture developed classes of specialists who were able to produce surpluses of goods, and many of these goods were traded internally and with border regions. But to acquire other types of goods unavailable in the local region—pottery, glassware and mirrors, precious stones and metals, tools, ivory, lumber, spices, animal

hides, wine, feathers, and a host of other goods—communities had to establish trade routes with other cultures, which necessarily implied exploration of these routes, sometimes over vast distances. As the medieval period unfolded, vibrant trading networks developed, linking, for example, Asia with the Middle East and from there to Europe or linking the cultures of sub-Saharan Africa with the Mediterranean region, the Middle East, and Europe or linking the cultures of Mesoamerica as well as those up and down the Andes region of South America.

While the development of seafaring technology did not motivate exploration, it certainly facilitated it. In ancient times seafarers were limited in the distances they could travel. Lacking rudders, navigational tools, and sails that allowed sailing against the wind, sea explorers tended to remain within sight of land. But as the technology of sea travel evolved, new vistas were opened, such as the southwestern coast of Africa or the innumerable islands, inlets, peninsulas, and coves of the Asian coastline, explored in a series of seven voyages the Chinese launched in the early 15th century. Of course, seafaring technology enabled contact between the Americas and Europe, as European explorers, driven by "gold, glory, and God," spread throughout the New World in search of wealth, fame, and the desire to spread their religion. The first of these explorers were the Spanish conquistadors following the voyages of Christopher Columbus, though strong evidence suggests that the Scandinavians had explored the northeastern coast of North America centuries before, and claims have been made that African explorers reached the New World before Columbus did. Late in the medieval period it became possible for the first time for seagoing explorers to circumnavigate the globe, rounding the southern tips of Africa and South America.

Another factor that led to exploration was warfare, and during the medieval period warfare and religion were often two sides of the same coin. The most prominent example was the Crusades, which spanned the 12th and 13th centuries. The Crusades originated in a desire on the part of Christian Europeans to protect Christians and holy sites of the Middle East from what they regarded as the depredations of Islam. Accordingly, in 1095 Crusaders departed from Europe, primarily what is now France, for the Holy Land, inaugurating the first of seven Crusades. The endeavor ended in 1291, with the fall of the last crusader stronghold at the Mediterranean city of Acre.

While the Crusades led to considerable bloodshed, they also had positive outcomes. Europeans returned to their homes with new ideas, new foods, and new words in their vocabulary. They gained exposure to Arabic knowledge of engineering, mathematics, and astronomy. The Crusades inspired a desire for westerners to translate Arabic texts and to

explore the vast regions of the Middle East and western Asia. Missionaries were sent to explore these regions and win converts, and schools were established in Europe to teach the languages of these regions. Travelers, many of them dispatched by the Christian pope, returned with a new understanding of geography.

The movement of people and ideas was not one way. At the same time, Asian explorers and conquerors were exploring the lands to their west. Arabic Muslims made voyages of exploration into eastern Europe and India, and African Muslims made similar voyages, usually in the form of pilgrimages, to the Middle East. All of this exploratory activity led to the diffusion of people and ideas, contacts with new cultures and ideas, and a general shrinking of the world as people were beginning to understand, often for the first time, that new lands, new cultures, and new peoples could be found over the horizons.

## AFRICA

BY BRADLEY A. SKEEN

Africans from south of the Sahara did not engage in the kind of systematic exploration conducted, for instance, by the European state of Portugal. Beginning in the 1440s Portugal sent fleets of ships to reconnoiter the African coast and eventually find a new route to Asia around the Cape of Good Hope on the southern tip of the continent. Undoubtedly, many Africans were trailblazers who were led by restlessness or circumstances to discover fresh pastures and farmlands and new trade routes. During the Middle Ages the Bantu peoples especially spread out across Africa, but those explorers remain unknown to us. Africans did, however, become caught up in Portugal's network of exploration and trade that extended along the coasts of their nations, and African ambassadors traveled to Lisbon and Rome for the first time. Ethiopia was isolated as the only traditionally Christian country in Africa surrounded by hostile Muslim states. The Ethiopian government and the Catholic Church, therefore, found it expedient to send representatives to Europe, seeking a new horizon of diplomacy and learning.

In the Middle Ages the first Africans brought to Europe were slaves, traded across the Sahara and then from Islamic ports on the Mediterranean to cities in Spain and Italy. As in most slaveholding cultures, a small number of the enslaved Africans in Europe managed to obtain their freedom. For them their traumatic journey ended with the discovery of a personal new world that brought them lives and experiences far different from anything they could have experienced in Africa. The Holy Roman Emperor Frederick II (r. 1212–50) had a corps of black trumpeters at his court that

made a display of the cosmopolitan character and power of his rule, though the trumpeters' status as slaves or free men is unknown.

The spread of Islam to northwestern Africa and Arabia isolated Ethiopia as a Christian country, bringing to an end its monopoly on the Indian Ocean trade between Europe and Asia. As a result, Ethiopian culture and politics turned inward. In the later Middle Ages, however, Ethiopia began to make efforts to contact the Christian world of western Europe, especially after the Crusades displayed European military power in the Near East. Ethiopia began to look to Christian Europe as an ally against Islam and so sent envoys into an unknown wider world.

Emperor Lalibela of Ethiopia (r. 1185–1225) was posthumously made a saint in the Ethiopian Orthodox Church. Several centuries after his death the *Gadla Lalibla*, a hagiography of the emperor, was composed. According to that tract, he made a pilgrimage to Jerusalem in his youth, perhaps during a period of political exile, before Muslim forces took the city from the crusaders. According to the same source, after hearing of the loss of the city by the Christians, Lalibela was ordered by God in a dream to build a new Jerusalem on the site of his home city of Roha and rename it after himself. In the city of Lalibela he built the famous rock-hewn churches of Ethiopia, drawing on his exploration of the wider Christian world beyond Ethiopia.

Emperor Lalibela's pilgrimage was a precursor to a tradition of religious pilgrimages and diplomatic journeys by Ethiopians that became more prevalent after the founding of a new dynasty in 1270 (which claimed descent from King Solomon through the Queen of Sheba) and reached a peak in the 15th century. The first Ethiopian diplomatic mission to Europe toured Rome, Genoa, and Avignon in 1306. (It is uncertain whether they also visited any of the Spanish kingdoms.) Ethiopia had already sought a military alliance with European powers against the common enemy of the Islamic states on the Mediterranean. Ethiopian representatives attended the Council of Florence in 1441, invited by the pope to help in unifying Christendom. Thereafter the tempo of Ethiopian diplomatic activity increased.

In the mid- to late 15th century Emperor Zara Yakob sent ambassadors to the Vatican, Venice, Milan, and Florence as well as to Lisbon. The emperor directed the ambassadors to act as diplomats and to increase his prestige at home and abroad. In addition, he charged the ambassadors with soliciting scholars and technical experts to join the Ethiopian court and with asking European rulers to donate sophisticated weapons and other technological devices for Ethiopians to copy as well as technical books and texts describing advances in scholarly disciplines, such as geography and theology. Em-

peror Zara Yakob was attempting to bring to Ethiopia what had become a very new world.

The Santo Stefano degli Abissini in Rome was converted from a church into a monastery for Ethiopian monks around 1179. Pope Sixtus IV expanded the monastery in 1479 as Ethiopian envoys became more common. Aside from hosting diplomatic missions, it provided a residence for Ethiopian clergy living and studying in Rome (usually between two and 30 individuals). With their Western educations and new contacts made in the wider world, priests trained in Rome brought new learning and new technical developments back to Ethiopia. By the late 15th century an Ethiopian monastic community was permanently settled in Jerusalem and acted as a source of information about political and military developments in Islamic states with whom Ethiopia was frequently at war.

The Portuguese expanded into the Atlantic islands and down the African coast beginning in the mid-15th century. They were interested in favorable trade contacts and could obtain gold and slaves profitably in western Africa. In Senegal and other areas they built forts as a basis for their trade network. The first organized African state they encountered (other than the Islamic kingdoms of North Africa) was Benin (modern-day Ghana and western Nigeria). Oba Esigie, the king of Benin, encouraged the establishment of a Portuguese trading post at Quantum (1485) and began to rely on Portuguese mercenaries in his conflicts with local African states. In 1486 Esigie sent his son as an accredited ambassador to the Portuguese court in Lisbon, the first African to hold such a position in Europe. Carried there on Portuguese ships, Esigie's son would have been the first African to return home from Europe with reports on conditions there, refining and expanding the Benin monarchy's knowledge of their new ally.

Portuguese involvement in the kingdom of Kongo (modern-day Congo) was more extensive. The Kongo monarchy was elective and limited in its powers. The king at the time of the Portuguese contact (1483), Nzinga a Nkuwu, quickly saw that a close alliance with the European newcomers (who established a station on the island of São Tomé) would help him consolidate his own power. He converted to Christianity and took the name João I (the Portuguese form of John) in 1491. He encouraged Portugal to send missionaries and build churches at its own expense, which it was happy to do. Constrained by the example of the king, many Kongolese noblemen converted. The Christian ideology of the divine right of kings allowed João to increase his authority. As a reward for conversion, the Portuguese made a gift to João of firearms, naval vessels, and mercenaries and later supported his son Alfonso in a civil war over the succession against a non-Christian opponent.

João was anxious to strengthen his ties with Portugal further and also sent a diplomatic mission to Lisbon. Another of João's sons, known to the Portuguese as Dom João da Silva, arrived in Lisbon as an ambassador in 1484. He made a second embassy from 1488 to 1490. Another of the king's relatives, Dom Pedro, was made ambassador to Portugal in 1493 and was soon joined by yet another family member, Dom Henrique, who was ordained the first bishop from the kingdom of Kongo.

In 1484 the Portuguese established the Convento de Santo Elói in Lisbon to house the diplomatic missions from Kongo. It also became a center for educating missionaries and clergy, mostly members of the royal family and other nobility. In this way the kingdom of Kongo was provided with a corps of citizens trained in European languages (especially Latin) and European diplomatic protocol. King Alfonso's son, Henry, became one of the brightest students at this institution and later became bishop of Kongo. The Portuguese crown was happy to pay for this institution because it provided a ready source of translators for its own officials in the kingdom.

João I went beyond this, however, and persuaded the Portuguese to establish a school in Lisbon where the sons of Kongolese noblemen could be trained as missionaries. Graduates of this school later were dispatched to Rome to form a Kongolese diplomatic mission to the pope as well. Particularly after the return from Lisbon of the first students who could report on conditions there, members of the Kongo court and the households of other great noblemen began to adopt Portuguese dress and manners. This was facilitated by the return of Kongolese diplomats, all of whom were given gifts of Portuguese court dress. This elite display increased their status within the kingdom of Kongo.

The Kongo diplomatic mission in Portugal brought to the kings of the Kongo and the elite class that supported them increased power and status in their homeland (especially through the institution of the Catholic Church), an introduction to the wider Atlantic world, profitable trade relations, and a militarily valuable ally. Although the Portuguese initiated the contact that resulted in these benefits, the Africans facilitated it by venturing beyond their homeland to the new world of European culture and politics.

## THE AMERICAS

BY J. J. GEORGE

The climax of the period from 500 to 1500 in the Americas is defined by the arrival of European colonialists. As Europeans settled on native lands, a hemisphere already in a state of continual flux witnessed its most permanent and decisive

changes, including the transformation from native, autonomous development to its colonial antecedent. The final outcome unfolded over many generations and in some sense continues as researchers uncover native artifacts buried either long before the conquest or as a direct result of it. Data are genuinely scant regarding the concept of exploration—how it was carried out and what the consequences were—and deductions necessarily speculative. Exploration in the style of the Age of Exploration or the Enlightenment—as in the maritime journeys of Ferdinand Magellan (ca. 1480–ca. 1521), Christopher Columbus (1451–1506), Vasco da Gama (1460–1524), and Captain James Cook (1728–79)—is essentially unknown in the Americas, although some surprising similarities arise when comparing the Native Americans with their colonial counterparts through the lens of the exploratory impulse.

The idea of exploration carries with it a few basic assumptions. In its broadest context Native American exploration extends from prehistoric antecedents marked by diffusion and migration. Considered in this early context, exploration was a defining aspect of daily existence. Even when occurring within well-defined areas, the wandering that is indicative of nomadic, seminomadic, and hunter-gatherer cultures, which continued into the 16th century and beyond in areas such as the North American plains, is inherently tied to exploration. In this sense exploration is more or less a permanent facet of existence.

From another viewpoint exploration is a consequence or extension of sedentarism. Settlement pattern data and diffusion statistics indicate that by 500 the Americas were populated—heavily in some areas, such as central Mexico, and moderately to scarcely in others, such as vast regions of the Arctic and Canada, the North American plains, the intermediate zones of the Caribbean, and non-Andean areas of South America. As sedentarism increased, land and resources within a particular localized area sometimes grew scarce. In certain areas, such as the Mayan lowland regions of the Yucatán, Belize, Guatemala, and Honduras, where land had to lay fallow between plantings, additional agricultural plots precipitated expansion. Increasing territorial needs, at least initially, coincided with the exploratory impulse.

Similarly, as population densities increased, greater demand for agricultural and other products necessitated not only the consolidation of existing land but also the expansion of agriculture into peripheral areas as well as a search for new sources of sustainability. The trend toward urbanism, even rudimentary urbanism, coincided with greater social and political complexity. The greater complexity of these settlements—whether village or hamlet, city or city-state, or empire—necessitated the growth of exchange sys-

tems to maintain an entrenched population and to support its growth. Thus itinerant traders shuttled outward toward markets, by definition a form of exploration.

State-level or city-state-level organization was evident by 500 in central Mexico at Teotihuacán, Mayan settlements such as Tikal, and South American polities like Moche. Perhaps unavoidably, forms of exploration tied to trade became state sanctioned in these areas, often with a militaristic counterpart. Later, in the civic and imperial examples of the 15th- and 16th-century Aztec and Inca empires, the state monopolized all internal and external workings, including trade and exchange, such that exploratory impulses were inherently tied to consolidation of resources and expanding territory and influence.

The example of European and American exploration from the 15th to the 19th centuries suggests that exploration is rarely, if ever, into purely empty land; the same was true for intraregional exploration by Native Americans. Traveling within any country in the Americas would result, sooner or later, in stumbling on some form of settlement or nomadic group. Of course, that was the situation Spanish and Portuguese explorers stepped into, beginning with Christopher Columbus's arrival in the West Indies in 1492, which signaled the beginning of the end of Native American culture as an autonomous development. Sailing on preconditions of securing both financial backing and royal sanctioning, the Spanish and Portuguese expeditions generally were state adventures, especially considering that few persons of the time outside royalty could afford the initial capital expenditure necessary to outfit an entire expedition. The traditional reasons given for the conquistadors' motivation has always been threefold: gold, glory, and God—and not necessarily in that order.

It might seem strange, then, to say that to a surprising degree, within its own localized context, the Native American exploratory impulse is similar to its European counterpart. Yet spreading religion, acquiring wealth, securing advancing borders or pushing outward into frontier regions, and establishing trade and exchange over long distances are reasons that the two cultures share and that inform their respective exploratory impulses.

Caught up in expensive regional affairs tied to national defense, sustainability, and expansion, Europeans considered procuring wealth abroad a primary, if not necessary, motivation for royally sanctioned explorations. Gold acquired abroad for the state financed and sustained the monarchy back home. It should be said that patriotism had its limits. Private motivations must also be considered, and for the European explorer acquiring gold for the state usually translated into some form of personal wealth, if not in gold then either

in royalties or land, of which the conquistadors often claimed vast amounts as their own private estates.

While the individual conquistadors went in search of gold to aid the state with the explicit desire of attaining vast personal wealth, their private impulses were also inextricable from the acquisition of glory and personal fame. The third portion of the “gold, glory, and God” proposition was the moral sanctioning provided by the Catholic Church, whose own motivations were intricately intertwined with the expanding state. In general, beside each conquistador was a priest whose objective was converting the native population to Christianity, thereby providing the colonial impulse with its moral foundation.

Whereas the impulses, reasons, and motivations for European exploration are a matter of historical record, similar data for Native American examples are matters of archaeology and reconstructing imperfect prehistorical conditions. In this scenario impulse is often indecipherable, or an inferential deduction, from the material remains. For Native Americans religion, or cult, and state were often inseparable; consequently, spreading religion was a form of conscious imperialism. Throughout the Americas iconographic evidence gleaned from ceramic distribution indicates that the dispersal of imagery was akin to spreading a message, quite often of a religious nature, suggesting that territorial gain was accompanied and facilitated by religious imagery of the dominant or conquering polity.

For example, in South America images associated with the Wari and Tiwanaku cultures (ca. 500–ca. 1000) found far from their civic origin indicate expansion and control of an imperial nature. That the images are associated with cult religious trends indicates a level of coordination between empire and religion that is at least equal to the European example. However the campaigns ensued, it is clear that the exploratory impulse eventually resulted in consolidated religious influence. Similarly, far-reaching trade networks spread the new iconography over vast areas of the altiplano, or high plains.

For the state the accumulation of wealth carries both practical and symbolic connections. Accumulating wealth through conquest or through trade and exchange demands some form of exploration, both internally and externally. Whereas the wealth derived from European exploration was shipped overseas, exploration in the Americas was a more localized enterprise, even though energy expenditures remained high given that beasts of burden were unknown in Mesoamerica and North America and the llama was used as a pack animal in Andean South American.

Exploration for the Native American seems to have existed in contrary forms, either predicated by state expansion

and its increasing demand for goods acquired through trade or as a condition of a nomadic or seminomadic way of life. As with the Europeans, exploration for Native Americans was often inextricable from religious imperatives.

## ASIA AND THE PACIFIC

BY TOM STREISSGUTH

Island dwellers of Southeast Asia were in constant need of land for settlement and cultivation. In search of new homelands, they had been exploring the western limits of the Pacific Ocean since the second millennium B.C.E. From the northern coast of New Guinea and nearby islands they set out in several waves of exploration across the Pacific Ocean. By the early medieval period they had reached Tonga and Samoa by sailing east through the islands of Melanesia (the island group lying immediately northeast of Australia). In the meantime a distinctively Polynesian culture was emerging, with its own social hierarchies, methods of cultivation, stone and wood carving methods, and languages.

Despite less favorable winds and currents, Polynesian explorers pushed eastward to the Mariana Islands and the Society Islands, which include the island of Tahiti. Eventually they reached Easter Island, at the western limits of the Pacific Ocean, as well as Hawaii and the two main islands of New Zealand, which were settled around 1000.

For these voyages the Polynesians developed sturdy, double-hulled canoes that were capable of navigating long voyages across the Pacific. These craft were 50 to 60 feet in length and held one or two masts for sails made of reed matting. Navigation was by observation of the clouds, stars, ocean waves and currents, and the flight patterns of migratory birds. A platform of beams lashed between the two hulls provided living space and storage. These ships were large enough to accommodate as many as two dozen colonists as well as food, weapons, domesticated animals, and a stock of plants and seedlings that provided a base for agriculture in a new homeland.

Historians trace the Polynesian migrations mainly through a study of oral tradition and linguistics. Legends on New Zealand tell of colonists who arrived from the Society Islands and the Cook Islands, while Hawaiian tradition relates that original settlers of that archipelago came from the island of Tahiti. The Polynesian tongues have been related to languages spoken in Southeast Asia, particularly the Indonesian archipelago. This language family also reached Madagascar, indicating that Southeast Asian explorers also sailed west across the Indian Ocean.

The philosophy of Buddhism spread through Asia mainly by the voyages of long-distance merchants, who called at ports

in Southeast Asia and traveled overland via the Himalayan passes to Tibet and the plains of southern China. Buddhism also inspired an epic voyage by a Chinese monk named Xuanzang, born in about 602. Troubled by the contradictions posed by Buddhist doctrines, Xuanzang resolved to search for original Buddhist texts in the homeland of the faith—India. At the age of 28, he set out from the town of Liangzhou. Two companions soon abandoned the journey, leaving Xuanzang to face the dangers alone. He survived a capture by river pirates and the attentions of a khan of western China, who was so taken with Xuanzang's ability that he ordered the young man to remain and join his court as a scholar. When the monk, in protest, refused to eat, the khan relented and rewarded him with enough money to pursue his explorations for the next 20 years.

It took Xuanzang four years to cross the deserts of central Asia and finally reach northern India. He traveled the length and breadth of the Indian Subcontinent, but he spent most of his time in the city of Nalanda, where he studied Buddhist holy books in their original Sanskrit language. After a voyage of 16 years, he finally returned to China in 645 with more than 500 cases of books and writings and soon began translating the texts he had collected. The emperor called him to the capital and ordered a full report. In reply Xuanzang set down *Records of the Western Regions of the Great Tang Dynasty*, the first account of a foreign exploration by a Chinese traveler, which became a key resource for later scholars.

After the fall of the Yuan Dynasty (1279–1368) China entered the period of the Ming Dynasty (1368–1644). The Ming emperors ruled what the Chinese knew as the Middle Kingdom, the center of the world that lay between the earth and heaven. It was a realm self-sufficient in food, resources, and technology, the most advanced in the world throughout the medieval period. The Chinese emperors had command of a vast bureaucracy of governors and administrators who strictly controlled the movement and the place of residence of their subjects, while tributary states beyond the borders paid money and allegiance to the emperors.

A faction of the Ming government favored exploration and expanded trade, and with this purpose in mind the Yongle Emperor (Zhu Di) of the early 15th century dispatched a trusted officer, the admiral Zheng He (ca. 1371–ca. 1433), at the head of a series of expeditions to the East Indies, Southeast Asia, India, and the Indian Ocean coasts of the Arabian Peninsula and Africa. Zheng He employed the compass, a Chinese invention of the 11th century, as well as a sophisticated system of flags and bells used for signaling. His first voyage set out in 1405 and included 62 vessels built and gathered at Nanjing, a port on the Yangtze River. The fleet was led by four immense flagships measuring 400 feet long and 160 feet wide.

The ships were specialized craft, each with a purpose, holding food and water, arms, trading goods, or horses.

The fleet reached Southeast Asia (including the island of Java), the Strait of Malacca, and finally Calicut, a trading post on the southwestern coast of India. There the Chinese remained until the spring of 1407, when they set off for the voyage home; during this voyage Zheng He fended off a series of assaults by pirates in the waters off Sumatra. A second voyage, from which the admiral was absent, returned to Calicut and remained there until 1409.

The third voyage of the Ming Dynasty treasure fleet lasted from 1409 to 1411. This expedition furthered China's trade with India and also defeated the king of Sri Lanka, who was taken in chains back to the Ming capital of Nanjing. On the fourth voyage Zheng He took 63 ships past the Strait of Hormuz and into the Persian Gulf, where the Chinese obtained a treasure of gemstones, pearls, and other valuables. A detachment of ships continued to the African coast, calling at Arab trading posts and trading with African states of the interior.

Ambassadors brought to China returned to their homelands during the fifth voyage from 1417 until 1419, but the emperor was eager to pursue trade with Africa and so ordered a sixth expedition, which was launched in the spring of 1421. This was the largest treasure fleet dispatched by the emperor, numbering more than 500 ships. According to one hypothesis, the armada divided itself at several points, with admirals dispatched on smaller fleets with instructions to sail to the limits of the earth. From artifacts, ship remains, local legends, and a few rare charts, the proponents of the "1421 hypothesis" have attempted to reconstruct these voyages and have come to the astonishing conclusion that Chinese navigators preceded the Spanish and Portuguese to the Western Hemisphere as well as the farthest reaches of the Pacific Ocean, by several generations. The hypothesis postulates, in brief, that Admiral Hong Bao sailed around the Cape of Good Hope, down to the Strait of Magellan and the tip of Antarctica, then east to Australia; another admiral, Zhou Man, sailed around the southern tip of South America and across the Pacific Ocean to the East Indies and the coasts of Australia and New Zealand. In the most improbable feat of arctic navigation, Zhou Wen left the fleet at the Cape Verde Islands, sailed north to the coast of North America, around the northern limit of Greenland, and then through the Arctic Ocean along the northern coasts of Siberia before returning to China.

Whatever the true achievements of the sixth treasure fleet, its return marked the beginning of the end of Chinese exploration. The emperor's death brought to the throne his grandson Zhu Zhanji as the Xuande Emperor (r. 1425–35). This ruler ordered a seventh voyage that left in 1433 and

turned out to be the last for Zheng He, who is believed to have died in the course of it. After the ships returned, the emperor ordered them broken up and ended trade and contact with all foreigners. Fearing the contamination of new modes of thought, the Chinese emperors began to isolate their realm from the rest of the world. They put up strong resistance to explorers and merchants who were arriving off their coasts in ever-greater numbers from Europe. With trade restricted and China largely cut off from the technological improvements that were occurring in Europe, the later Ming emperors presided over a gradual decline in China's economic fortunes that lasted through the end of the 20th century.

## EUROPE

BY TOM STREISSGUTH

The first ocean explorers of medieval Europe may have been Irish. After the fall of the Western Roman Empire, Irish monasteries preserved the writings of the early Christian church fathers as well as classical writings of the Greeks and Romans. Irish monks roved the cold seas of the North Atlantic Ocean in small carracks, sturdy craft that easily handled strong winds and steep waves. Carracks sailed to the Hebrides, the Orkneys, and the Faeroe Islands and may have reached the shores of Iceland as well. One tradition described in the 10th-century manuscript *Navigatio sancti Brendani Abbatis* (The Voyage of Saint Brendan) holds that Saint Brendan of the sixth century set out from Galway and roamed the North Atlantic for several years before returning home. Some historians believe that Brendan may have reached Newfoundland, though no evidence has been uncovered to prove it.

The Irish were precursors to the Vikings of Norway, skilled mariners who sent entire fleets of longboats into the Atlantic to colonize Iceland, Greenland, and North America. According to some traditions, one of these intrepid Norsemen, Gunnbjörn Ulfsson, was blown off course and became the first European to lay eyes on a mass of sheet ice, glacial valleys, and rocky coast in the far north. Erik the Red sailed to this region in the late 10th century, naming it Greenland to attract settlers to what he promised was a fertile new land of opportunity. Erik had fled Norway after being involved in violence, and his penchant for trouble followed him to Iceland; he was banished from that country, prompting his excursion west.

The Vikings gradually ceased their raids on the European continent after two centuries of mayhem. A treaty had been signed, and the king of France had ceded Normandy. Norway, however, provided marginal land for a rising population, and many Norse still had few prospects at home. To escape poverty, colonizing expeditions made their way westward into

unknown seas and territory. Erik the Red explored Greenland for three years and in 985 founded the Western Settlement and the Eastern Settlement, both on the southwestern coast. These sites traded with Iceland and the homeland for three centuries before succumbing to the cold climate and disease outbreaks in the 14th century.

Erik's son, Leif Eriksson, voyaged as far as the northern reaches of Newfoundland, which he called Vinland for the prospect of growing wine grapes in the region. The settlement at what is now L'Anse aux Meadows struggled for several years with a harsh climate and conflict with hostile *skraelings*, or Native Americans. Trade with Europe was hindered by

## EXPLORERS OF THE WHITE SEA

The ice-bound coasts of the Barents Sea and the White Sea was the last region in Europe to be explored and settled. The pioneers in this territory were settlers from medieval Novgorod, a principality of northern Russia and a center of shipbuilding and exploration. These seafarers, called Pomors, first arrived on the White Sea coast in the 12th century, when they founded the towns of Kholmogory and Kola. They explored northern Scandinavia, the Arctic Sea, the island of Novaya Zemlya, and the coasts and river mouths of northern Siberia. Expert navigators, they employed sundials, magnetic compasses, and star charts in finding their way along these featureless coasts.

The Pomors used a craft known as a *koch* that was adapted to travel in hazardous icebound seas. The *koch* had two masts for sails and an extra layer of oak planking to protect it from the ice. Its rounded hull allowed it to more easily escape the ice when surrounded. A false keel permitted the boat to be dragged across tundra or ice without damage to the hull. The *koch* carried two light anchors, which could be dropped on the ice or in the sea, as well as small iceboats, large sleds that could be used to transport people and cargo.

By the end of the medieval period the western European nations of England and Holland were sending expeditions to this region and seeking to open trade with Siberia, which in the 21st century is the last frontier of the Eurasian landmass. The Pomors survive as a distinct ethnic minority of northern Russia, living in and around Arkhangel'sk, the most northerly port in the world.

sea ice, storms, and long distances, which made the journey of several months in an open longboat a risky proposition, even for Norway's experienced navigators. Finally the site was abandoned, its people leaving behind scant but definitive evidence that the Norse were the first Europeans to colonize North America.

Italy's medieval explorers were motivated not by the prospect of settlement but by the promise of riches through trade with China and the other empires of Asia. In 1245 Giovanni da Pian del Carpine was the first to venture east, dispatched by Pope Innocent IV across the steppes and deserts of central Asia, to the Mongol khanates, the realms founded after the victorious campaigns of Genghis Khan in the 1220s. The pope sought information on the frightening horde of mounted archers who had ravaged central Asia, Persia, and the Middle East. He also may have wanted to form an alliance with the khans against the Muslims, with whom the Christians were still fighting for control of Jerusalem and fortifications in Palestine.

A disciple of Saint Francis of Assisi, Carpine left behind a record of his travels to the domain of Rus, founded by Swedish Vikings, and to the court of the Great Khan at Karakorum, in modern-day Mongolia. He detailed the journey to the court of Batu Khan, the ruler of the Golden Horde, which lay just north of the Caspian Sea. Carpine's party crossed the river of Syr Darya (the ancient Jaxartes), survived the deserts of what is now Xinjiang in western China and in the summer of 1246 reached Karakorum. Güyük Khan resisted the Christians' efforts to baptize him and instead sent a letter to the pope demanding that the Europeans submit to the authority of the Mongols.

Carpine was followed to the East by the Polo family, ambitious Italian merchants willing to risk the dangers of long-distance travel for a chance at opening trade with China. Niccolò and Maffeo Polo were traders from Constantinople who lived with the khan of the Golden Horde and later in the city of Bukhara (in modern-day Uzbekistan). In 1266 they reached Khanbalik (modern-day Beijing), a city of northern China that became the seat of Kublai Khan, a descendant of Genghis Khan. The Polos returned to Europe at Kublai Khan's request, to bring Christians east to educate his followers. On their second journey the Polos brought Niccolò's son Marco, who remained in the khan's service for several years as a diplomat and as the governor of the city of Yangzhou. Marco set down an account of his travels after returning to Europe, where he was briefly made a prisoner. *The Travels* gained a wide and admiring audience in Europe and inspired a lust for travel and exploration among many readers in the generations to follow.

The Iberian Peninsula was the base for important explorations of the distant reaches of the Atlantic Ocean begin-

ning in the 15th century. The Portuguese conquest of Ceuta, a Muslim port on the southern rim of the Mediterranean, brought information that a rich source of gold lay at the opposite end of trans-Saharan caravan trails, then controlled by Berber and Muslim merchants of North Africa. The common belief, however, was that sailing past Cape Bojador, at the western limit of the Sahara, was impossible. Winds and currents were contrary, and, it was thought, anyone foolish enough to venture past the cape would drop off the edge of the earth and never return.

Doubling Cape Bojador became possible with the caravel, a lighter and nimbler craft rigged to sail close to the wind if necessary. Hoping to bypass the overland trade routes and control a faster sea-lane to the gold fields of western Africa, Henry the Navigator, a son of the Portuguese king, began arranging voyages of exploration to the hazardous, uncharted waters. The Portuguese touched at Madeira, the Canary Islands, and the Azores; Gil Eanes passed Cape Bojador in 1434, and Diogo Gomes reached the Cape Verde Islands in 1455. The Portuguese built forts and trading posts at the river mouths and obtained gold, slaves, and ivory to sell in European markets.

After the death of Henry the Navigator, King João II continued royal patronage of sea exploration. The kingdom of Castile, Portugal's main rival, surrendered its rights to sail past Cape Bojador in 1479 and effectively gave up the Indian Ocean and the East Indies to the Portuguese. In 1487 Bartholomeu Dias became the first European to round the Cape of Good Hope, at the southern limit of Africa. Dias sailed for some distance up the eastern coast of Africa Vasco da Gama followed Dias's route in 1497, reaching India and opening the sea route to the East Indies. Returning to Portugal, da Gama's success inspired King Manuel to support another voyage by Pedro Álvares Cabral. Setting out in 1500, Cabral ran into a storm and was blown off course as far as the coast of Brazil. In the meantime, Portugal established fortified posts in India, Malaysia, and the Moluccas, or Spice Islands.

After the unification of Castile and Aragon by the marriage of Ferdinand and Isabella in 1492, Spain followed the lead of Portugal in exploration. After many years of trying and failing to win a patron, the Genoese mariner Christopher Columbus finally persuaded the Spanish monarchs to support his notion that the Indies could be reached by sailing west. Columbus reached San Salvador, a small island in the Bahamas, and returned with a report of success, not realizing that he had reached an entirely new hemisphere. Pope Alexander VI, the former Cardinal Rodrigo Borgia and a Spaniard, supported Spain's claims to the western islands. By signing the Treaty of Tordesillas in 1494, Portugal and Spain agreed to divide their discoveries along a meridian lying 370

leagues west of the Cape Verde Islands. Columbus returned three times to the Caribbean, discovering Hispaniola, Cuba, Jamaica, the northern coast of South America, and the eastern shores of Central America.

By the close of the medieval period a race was on among the European nations to explore and claim as much new land as possible in the hope of establishing settlements, mines, and farms that could be exploited as sources of raw materials and as consumer markets for home industries. Seeking a northerly route to Asia, the British hired the Italian captain Giovanni Caboto (also known as John Cabot), who made two voyages to the coasts of Canada before being lost at sea on his way home. During an expedition begun in 1501 Amerigo Vespucci, a member of a Spanish expedition under the command of Gonçalo Coelho, speculated that Europe had discovered a “new world,” and in honor of Vespucci the German mapmaker Martin Waldseemüller named the discovery America. The conquest and colonization of the Western Hemisphere by the Europeans would enrich the treasuries of the European kingdoms, ignite three centuries of intercontinental warfare, result in the death and enslavement of millions, and propel Europe to the forefront of the world economy.

## THE ISLAMIC WORLD

BY BRADLEY SKEEN

The essence of much of Islamic exploration is captured in the Sinbad tales from the *Arabian Nights*—a collection of mostly Persian folk stories that is one of the cornerstones of Islamic literature—with individual merchants venturing off known routes and returning with fantastic tales of foreign lands. Such exploration was often performed along trade routes that had existed since antiquity but had never before been followed by Arabs and Islamic culture. Exploration usually was undertaken either by individual merchants seeking out new markets or by missionaries trying to convert foreigners, particularly foreign rulers, to Islam. Islamic cartography, the scientific codification of the results of exploration in maps and descriptive narratives, was based on that of the Roman Empire but was greatly expanded, since Arab merchants were far more active in central Asia, the Indian Ocean, and even the Pacific Ocean than were the Romans.

One of the most famous Islamic voyages of exploration was an embassy from the caliph al-Muqtadir to the king of the Volga Bulgars. In 920 the Bulgar king, who ruled territories on the Volga River on the border between Asia and Europe, well north of the Caspian Sea, sent a letter to the caliph offering to convert to the orthodox Islam practiced in Baghdad if the caliph would send an ambassador to instruct him and

would build a mosque for him. An ambassador, Nadhir al-Harami, was duly sent, leaving Baghdad on June 21, 921. His secretary, Ahmad ibn Fadlan, kept a diary of the 2,500-mile overland journey, and substantial fragments of this survived in a later geographical Arabic text.

The route Fadlan describes is extremely circuitous, perhaps because the traveling party wished to avoid the more direct route across the Caucasus Mountains and along the shores of the Caspian Sea, which was controlled by the Jewish Khazars. They headed far to the east in following the Silk Road, a network of trade routes with China that crossed central Asia. At Bukhara, in modern-day Uzbekistan, they left the trade route to follow the course of the Amu Dar'ya north to the Aral Sea, where they wintered at the town of al-Jurjaniya. Fadlan, used to the intense heat of the Baghdad climate, was amazed at the cold, remarking that he had to sleep under furs and blankets and that his beard became caked with ice from the freezing of the water vapor in his breath. The winter temperature in that region is usually just below the freezing point but can sometimes drop to as low as  $-104$  degrees Fahrenheit; Fadlan reported that he learned there for the first time that men and animals alike can freeze to death.

The party finally reached the tents of the Bulgar king on May 12, 922. The effort to exploit the king's offer to convert to orthodox Islam ultimately failed because he also wished in exchange to be paid a large sum of money, to be used to build a fortress. In his journal, meanwhile, Fadlan continued to express amazement at the strangeness of the locale. The party was then around latitude 48 degrees north—about the same latitude as the U.S.-Canada border—and Fadlan saw for the first time the aurora borealis, also known as the northern lights. The king told him that the phenomena were manifestations of battles between tribes of jinn (supernatural creatures), with those that had converted to Islam fighting against those that had not. Fadlan observed that because of the short summer nights, the local Muslims combined the sunset and evening prayers, two of the five daily prayers required of all Muslims.

Modern Western interest in Fadlan's text has centered on his ethnographic description of traders from Kievan Rus at the Bulgar king's camp. This kingdom, centered in the area of modern-day Ukraine, was the precursor of Russia and is generally thought to have become organized by Vikings from Scandinavia who conquered the local Slavic population. Fadlan considered the Rus to be culturally—as well as racially—inferior to those from his native Baghdad. In his journal he dwells at great length on what he considers their drunkenness, poor hygiene, and sexual depravity, comparing them in these respects to donkeys. He similarly denigrates the “pagan” religion of the Rus in comparison to Islam.

Fadlan was an eyewitness to one of the elements of Viking society known best in modern times, the “Viking funeral,” as often featured in Hollywood films. An important Viking chieftain was cremated in a large ship, together with his grave goods, but the burning ship was not cast adrift on the water; rather, the entire ship was placed in a large grave dug in the ground and was covered over with a mound of earth, or barrow, after burning. The grave goods included expensive weapons, clothes, and furnishings, as the destruction of such costly objects was believed to honor the dead. Also, several domestic animals were sacrificed and placed in the ship to be burned. Fadlan demonstrates much interest in one of the dead chieftain’s slave girls who volunteered to be sacrificed as well. During the several days of necessary preparations, this girl was treated as a member of the aristocratic class and was given her own servants, with whom she prepared her master’s funeral clothing. On the day of the funeral, she had intercourse with several of the chieftain’s officers. At last she was hoisted on a sort of crane up into the sky, where she had an ecstatic vision of her master in paradise (Valhalla), where she believed she would shortly join him. She, too, was then ritually killed, and the entire assemblage was burned.

The first Muslims to voyage to India during the annual monsoon were missionaries. In 664 the Muslim scholars Malik ibn Dinar and Sharaf ibn Malik reached Kodungallur, on the southwest Indian coast, together with their students and families. They built the first mosque in India and thus initiated a series of missionary journeys that would continue through the Far East for the rest of the Middle Ages, with emissaries spreading out along the trade routes as far as southern China. Not long after the year 700, missionaries reached the city of Guangzhou, which became the center of Islamic culture and trade in southern China.

The tradition of Arabic geographical writing was originally based on the work of Greek geographical writers such as Aristotle and Ptolemy, with Arab travelers eventually pressing into areas unknown to the Greeks. Mohammed Abdul-Kassem ibn Hawqal (fl. 943–69) traveled the eastern African coast (probably with Arab merchants) as far as latitude 20 degrees south, to conclude in his book *Surat al-ardh* (The Face of the Earth) that Aristotle’s speculation that the equatorial regions were too hot for human life to exist was simply wrong. Abu Abd Allah Muhammad al-Idrisi (ca. 1100–65) worked for Roger II, a Christian king of Sicily, and produced updated versions of the maps in Ptolemy’s atlas using commercial and geographical learning from Islamic culture; these maps were still consulted as late as the time of Columbus. Ibn Jubayr (1145–1217) wrote an account of his travels around the Mediterranean that is more like modern travel literature than Is-

lamic geographical writing. Interestingly, he mostly traveled on Genoese (that is, Christian) merchant ships.

An unusual case with regard to exploration was that of Abu Abdullah Muhammad ibn Battuta who, strictly speaking, did not “explore” anything in the sense of discovering new geographical facts unknown to his civilization. He was, however, the most widely traveled man in the history of the world prior to the 19th century. Trained as a lawyer in his home city of Tangier, in Morocco, he set out at the age of 22 in 1325 on the hajj, the religious pilgrimage to Medina and Mecca. Once he had fulfilled this duty, Ibn Battuta did not stop traveling but, working as a merchant, judge, ambassador, or soldier and sometimes making repeated pilgrimages back to Mecca, he crisscrossed almost the entire Islamic world, from Spain to China, from southern Africa to the Balkans, and from central Asia to Timbuktu, covering a total distance of at least 75,000 miles. About 1353 he returned to Morocco, where he dictated his memoirs and lived without conducting any further travels, dying sometime after 1368.

A rare instance of exploration undertaken for the love of adventure is mentioned by al-Idrisi. He describes the voyage of a band of men from Lisbon who set out to find the Canary Islands (known from ancient Greek geographical writing), which lie in the Atlantic a few hundred miles off Morocco. They indeed found the islands, seemingly quite by chance, to discover an Arab already living there who could translate for them with the native Guanches; that man was the sole survivor of an early Arab voyage about which nothing more is known.

Perhaps the most outstanding Arab navigator and geographer at the end of the Middle Ages was Ahmad bin Majid (1421–ca. 1500). In his *Kitab al-fawaid fi usul ilm al-bahr wa l-qawaid* (Book of Useful Information on the Principles and Rules of Navigation) (1490), one of many geographical works, he describes the art of sailing upon the Indian Ocean, including the details of navigating the monsoon that made travel between the Red Sea and India possible. He also describes the technique of fixing a port’s latitude by observing the distance of Polaris, the North Star, above the horizon, a technique that was by then probably hundreds of years old in the Arab nautical tradition but was just being adopted by the Portuguese and other Europeans. Bin Majid was actually employed by the Portuguese explorer Vasco da Gama to navigate to India once the expedition had sailed around the southern cape of Africa. This renowned journey effectively ended the Islamic monopoly on trade between the Far East and Europe.

One last item worthy of mention was really more of an Arab cartographic experiment than a journey of exploration, but it bore the most important consequences for later exploration. In the early ninth century the Islamic astronomer al-Farghani (known in Western languages as Alfraganus; d. after

861) performed an experiment to determine the distance of one degree of longitude at the equator. Astronomical calculations were carried out to find two sets of two places in Iraq that were precisely 1 degree apart and were separated by flat, featureless land. The distances involved were physically measured with the equivalent of a yardstick. The result obtained indicated that 1 degree of longitude at the equator would be equal to 56⅔ Arab miles. Columbus happened to read this measurement in a Latin translation and therefore calculated that the distance going west by sea from Portugal to Japan, instead of the correct 12,000 miles, would be about 3,000 miles—in fact, the actual distance from Portugal to the West Indies. How was such an error made? Al-Farghani calculated in Arab miles; converted into modern units, the result of his calculations is a figure between 67 and 70 miles, and indeed

the actual figure is 69 miles. But Columbus made the mistake of interpreting the word *mile* in terms of the much shorter Italian nautical miles with which he was familiar, giving the badly incorrect figure on which he based his plans.

*Asia and the Pacific*

≈ *Ma Duanlin, Wen hsien t'ung k'ao*  
(*Encyclopedia of Government Institutions, late 13th century*) ≈

The Wai-kuo-t'u ["map of foreign countries"] says: From Yung-ch'en north there is a country called Ta-ts'in. These people are of great size; they measure five or six ch'ih [six to seven feet] in height. The Kuei-huan-hsing-ching-chi says: The Fu-lin country is in the west of Shan [Armenia], separated by hills several thousand li; it is also called Ta-ts'in. Its inhabitants have red and white faces. Men wear plain clothes, but women wear silk stuffs beset with pearls. They have many clever weavers of silk. Prisoners are kept in the frontier states till death without their being brought back to their home. In the manufacture of glass they are not equaled by any nation of the world. The royal city is eighty li square; the country in all directions measures several thousand li. Their army consists of about a million men. They have constantly to provide against the Ta-shih. On the west the country bounds on the western sea [the Mediterranean]; on the south, on the southern sea [Red Sea?]; in the north it connects with K'o-sa T'u-ch'ueh [the Khazars]. In the western sea there is a market where a silent agreement exists between buyer and seller that, if the one is coming the other will go, and vice-versa; the seller will first spread out his goods, and the purchaser will afterwards produce their equivalents, which have to wait by the side of the articles to be sold

till received by the seller, after which the purchase may be taken delivery of. They call this a spirit market.

There is also a report that in the west there is the country of women who, being affected by the influence of water, give birth to children. It is further said: the country of Mo-lin [Alwa, or Upper Nubia] is on the south-west of the country of Yang-sa-lo [Jerusalem?]; crossing the great desert 2,000 li you come to this country. Its inhabitants are black and of ferocious manners. Cereals are scarce, and there is no vegetation in the way of shrubs and trees; horses are fed on dried fish; men eat *hu-mang*, that is, the Persian date. The country is very malarious. The hill tribes which one has to pass in pursuing the overland road of these countries are of the same race. Of religions there are several kinds: there is the Ta-shih, the Ta-ts'in, and the Hsun-hsun religion; The Hsun-hsun have most frequent illicit intercourse with barbarians; while eating they do not speak. Those who belong to the religion of Ta-shih have a rule by which brothers, children and other relatives may be impeached for crime without implicating their kin, even if the crime be brought home to them. They do not eat the flesh of pigs, dogs, donkeys, and horses; they do not prostrate or kneel down before the king, nor before father or mother, to show their veneration;

(continued)

*(continues)*

they do not believe in spirits and sacrifice to heaven alone. Every seventh day is a holiday, when they will refrain from trade and not go in or out, but drink wine and yield to dissipation till the day is finished. The Ta-ts'in are good physicians in eye-diseases and diarrhea, whether by looking to matters before the disease has broken out or whether by extracting worms from the brain [trepanning].

In the south-east of this country you go to Chiao-chih [Cochin China]; there is also a water-road communicating with the I-chou and Yung-ch'ang principalities [both in the present Yunnan]. Many rare things come from there. It is said that in the west of Ta-ts'in there is the water of a sea; west of the seawater there is a river; the river flows south-west; west of the river there are hills extending from south to north; west of the hills there is the Red Water; west of this is the White Jade Hill; west of the Jade Hill is the Hill of the Hsi-wang-mu [western king's mother] who lives in a temple built of jadestone. Coming from the western boundary of Ar-hsi [Parthia], following the crooked shape of the sea, you also come to Ta-ts'in [at Aelana (modern Elat)], bending round over 10,000 li. Although in that country the sun, the moon, and the constellations appear not different from what they are in Zhongguo, former historians say that in the west of T'iao-chih [Babylonia] you go a hundred li to the place where the sun sets; this is far from being true. . . .

The Dwarfs. These are in the south of Ta-ts'in. They are scarcely three ch'ih [four feet] large. When they work in the fields they are afraid of being devoured by cranes. Whenever Ta-ts'in has rendered them any assistance, the Dwarfs give them all they can afford in the way of precious stones to show their gratitude. The Hsuan-ch'u. Their country contains many "birds of nine colors," with blue pecks, green necks, red-brown wings, red breasts, purple crests, vermilion feet, jade-colored bodies, yellowish backs, and blackish tails. Another name of this animal is "bird of nine tails," or chin-feng [the brocaded phoenix]. Those which have more blue than red on them are called Hsiu-luan [embroidered argus pheasant]. These birds usually come from the west of the Jo-shui [weak water]. Some say that it is the bird of the Hsi-wang-mu [western king's mother]. The coins of the country are the same as those of the country of San-t'ung. The San-t'ung are a thousand li south-west of Hsuan-ch'u. The inhabitants have three eyes, and sometimes four tongues by means of which they may produce one kind of sound and speak one language. They trade in plantains, also in rhinoceros' horns and ivory; they make golden coins on which they imitate the king's, also the queen's face [with the king's together.]; if the husband is changed, they use the king's face; if the king dies, they re-melt the coin. The above three countries border on Ta-ts'in whence they are here appended.

Europe

~ "The Voyages to Vinland," excerpt from  
The Saga of Eric the Red (1387) ~

Here Begins the Brief History of the Greenlanders

. . . There was now much talk about voyages of discovery. Leif, the son of Eric the Red, of Brattahlid, visited Biarni Heriulfsson and bought a ship of him, and collected a crew, until they formed altogether a company of thirty-five men. Leif invited his father, Eric, to become the leader of the expedition, but Eric declined, saying that he was then stricken in years, and adding that he was less able to endure the exposure of sea life than he had been. Leif

replied that he would nevertheless be the one who would be most apt to bring good luck and Eric yielded to Leif's solicitation, and rode from home when they were ready to sail. When he was but a short distance from the ship, the horse which Eric was riding stumbled, and he was thrown from his back and wounded his foot, whereupon he exclaimed, "It is not designed for me to discover more lands than the one in which we are now living, nor can we now continue longer together." Eric returned home to

Brattahlid, and Leif pursued his way to the ship with his companions, thirty-five men. One of the company was a German, named Tyrker. They put the ship in order; and, when they were ready, they sailed out to sea, and found first that land which Biarni and his shipmates found last. They sailed up to the land, and cast anchor, and launched a boat, and went ashore, and saw no grass there. Great ice mountains lay inland back from the sea, and it was as a [tableland of] flat rock all the way from the sea to the ice mountains; and the country seemed to them to be entirely devoid of good qualities. Then said Leif, "It has not come to pass with us in regard to this land as with Biarni, that we have not gone upon it. To this country I will now give a name, and call it Helluland." They returned to the ship, put out to sea, and found a second land. They sailed again to the land, and came to anchor, and launched the boat, and went ashore. This was a level wooded land; and there were broad stretches of white sand where they went, and the land was level by the sea. Then said Leif, "This land shall have a name after its nature; and we will call it Markland." They returned to the ship forthwith, and sailed away upon the main with north-east winds, and were out two "doegr" before they sighted land. They sailed toward this land, and came to an island which lay to the northward off the land. There they went ashore and looked about them, the weather being fine, and they observed that there was dew upon the grass, and it so happened that they touched the dew with their hands, and touched their hands to their mouths, and it seemed to them that they had never before tasted anything so sweet as this. They went aboard their ship again and sailed into a certain sound, which lay between the island and a cape, which jutted out from the land on the north, and they stood in westering past the cape. At ebb-tide, there were broad reaches of shallow water there, and they ran their ship aground there, and it was a long distance from the ship to the ocean; yet were they so anxious to go ashore that they could not wait until the tide should rise under their ship, but hastened to the land, where a certain river flows out from a lake. As soon as the tide rose beneath their ship, however, they took the boat and rowed to the ship, which they conveyed up the river, and so into the lake, where they cast anchor and carried their hammocks ashore from the ship, and built themselves booths there. They afterward determined to establish themselves there for the winter, and they accordingly built a large house. There was no lack of salmon there either in the river or in the lake, and larger salmon than they had ever seen

before. The country thereabouts seemed to be possessed of such good qualities that cattle would need no fodder there during the winters. There was no frost there in the winters, and the grass withered but little. The days and nights there were of more nearly equal length than in Greenland or Iceland. On the shortest day of winter, the sun was up between "eykarstad" and "dagmalastad." When they had completed their house, Leif said to his companions, "I propose now to divide our company into two groups, and to set about an exploration of the country. One-half of our party shall remain at home at the house, while the other half shall investigate the land; and they must not go beyond a point from which they can return home the same evening, and are not to separate [from each other]. Thus they did for a time. Leif, himself, by turns joined the exploring party, or remained behind at the house. Leif was a large a powerful man, and of a most imposing bearing—a man of sagacity, and a very just man in all things. . . .

It was discovered one evening that one of their company was missing; and this proved to be Tyrker, the German. Leif was sorely troubled by this, for Tyrker had lived with Leif and his father for a long time, and had been very devoted to Leif when he was a child. Leif severely reprimanded his companions, and prepared to go in search of him, taking twelve men with him. They had proceeded but a short distance from the house, when they were met by Tyrker, whom they received most cordially. . . . Leif addressed him, and asked, "Wherefore art thou so belated, foster-father mine, and astray from the others?" In the beginning Tyrker spoke for some time in German, rolling his eyes and grinning, and they could not understand him; but after a time he addressed them in the Northern tongue: "I did not go much further [than you], and yet I have something of novelty to relate. I have found vines and grapes." . . . They slept the night through, and on the morrow Leif said to his shipmates, "We will now divide our labors, and each day will either gather grapes or cut vines and fell trees, so as to obtain a cargo of these for my ship." They acted upon this advice, and it is said that their after-boat was filled with grapes. A cargo sufficient for the ship was cut, and when the spring came they made their ship ready, and sailed away; and from its products Leif gave the land a name, and called it Wineland.

~ Excerpt from "The First Voyage," *The Seven Voyages of Sinbad the Sailor* (ca. 800–ca. 1400) ~

I had inherited considerable wealth from my parents, and being young and foolish I at first squandered it recklessly upon every kind of pleasure, but presently, finding that riches speedily take to themselves wings if managed as badly as I was managing mine, and remembering also that to be old and poor is misery indeed, I began to bethink me of how I could make the best of what still remained to me. I sold all my household goods by public auction, and joined a company of merchants who traded by sea, embarking with them at Balsora in a ship which we had fitted out between us.

We set sail and took our course towards the East Indies by the Persian Gulf, having the coast of Persia upon our left hand and upon our right the shores of Arabia Felix. I was at first much troubled by the uneasy motion of the vessel, but speedily recovered my health, and since that hour have been no more plagued by sea-sickness.

From time to time we landed at various islands, where we sold or exchanged our merchandise, and one day, when the wind dropped suddenly, we found ourselves becalmed close to a small island like a green meadow, which only rose slightly above the surface of the water. Our sails were furled, and the captain gave permission to all who wished to land for a while and amuse themselves. I was among the number, but when after strolling about for some time we lighted a fire and sat down to enjoy the repast which we had brought with us, we were startled by a sudden and violent trembling of the island, while at the same moment those left upon the ship set up an outcry bidding us come on board for our lives, since what we had taken for an island was nothing but the back of a sleeping whale. Those who were nearest to the boat threw themselves into it, others sprang into the sea, but before I could save myself the whale plunged suddenly into the depths of the ocean, leaving me clinging to a piece of the wood which we had brought to make our fire. Meanwhile a breeze had sprung up, and in the confusion that ensued on board our vessel in hoisting the sails and taking up those who were in the boat and clinging to its sides, no one missed me and I was left at the mercy of the waves. All that day I floated up and down, now beaten this way, now that,

and when night fell I despaired for my life; but, weary and spent as I was, I clung to my frail support, and great was my joy when the morning light showed me that I had drifted against an island.

The cliffs were high and steep, but luckily for me some tree-roots protruded in places, and by their aid I climbed up at last, and stretched myself upon the turf at the top, where I lay, more dead than alive, till the sun was high in the heavens. By that time I was very hungry, but after some searching I came upon some eatable herbs, and a spring of clear water, and much refreshed I set out to explore the island. Presently I reached a great plain where a grazing horse was tethered, and as I stood looking at it I heard voices talking apparently underground, and in a moment a man appeared who asked me how I came upon the island. I told him my adventures, and heard in return that he was one of the grooms of Mihrage, the king of the island, and that each year they came to feed their master's horses in this plain. He took me to a cave where his companions were assembled, and when I had eaten of the food they set before me, they bade me think myself fortunate to have come upon them when I did, since they were going back to their master on the morrow, and without their aid I could certainly never have found my way to the inhabited part of the island.

Early the next morning we accordingly set out, and when we reached the capital I was graciously received by the king, to whom I related my adventures, upon which he ordered that I should be well cared for and provided with such things as I needed. Being a merchant I sought out men of my own profession, and particularly those who came from foreign countries, as I hoped in this way to hear news from Bagdad, and find out some means of returning thither, for the capital was situated upon the sea-shore, and visited by vessels from all parts of the world. In the meantime I heard many curious things, and answered many questions concerning my own country, for I talked willingly with all who came to me. Also to while away the time of waiting I explored a little island named Cassel, which belonged to King Mihrage, and which was supposed to be inhabited by a spirit named Deggial. Indeed, the sailors assured

me that often at night the playing of timbals could be heard upon it. However, I saw nothing strange upon my voyage, saving some fish that were full two hundred cubits long, but were fortunately more in dread of us than even we were of them, and fled from us if we did but strike upon a board to frighten them. Other fishes there were only a cubit long which had heads like owls.

One day after my return, as I went down to the quay, I saw a ship which had just cast anchor, and was discharging her cargo, while the merchants to whom it belonged were busily directing the removal of it to their warehouses. Drawing nearer I presently noticed that my own name was marked upon some of the packages, and after having carefully examined them, I felt sure that they were indeed those which I had put on board our ship at Balsora. I then recognised the captain of the vessel, but as I was certain that he believed me to be dead, I went up to him and asked who owned the packages that I was looking at.

“There was on board my ship,” he replied, “a merchant of Bagdad named Sindbad. One day he and several of my other passengers landed upon what we supposed to be an island, but which was really an enormous whale floating asleep upon the waves. No sooner did it feel upon its back the heat of the fire which had been kindled, than it plunged into the depths of the sea. Several of the people who were upon it perished in the waters, and among others this unlucky Sindbad. This merchandise is his, but I have resolved to dispose of it

for the benefit of his family if I should ever chance to meet with them.”

“Captain,” said I, “I am that Sindbad whom you believe to be dead, and these are my possessions!” . . .

Throwing himself upon my neck he exclaimed, “Heaven be praised that you have escaped from so great a danger. As to your goods, I pray you take them, and dispose of them as you please.” I thanked him, and praised his honesty, begging him to accept several bales of merchandise in token of my gratitude, but he would take nothing. Of the choicest of my goods I prepared a present for King Mihrage, who was at first amazed, having known that I had lost my all. However, when I had explained to him how my bales had been miraculously restored to me, he graciously accepted my gifts, and in return gave me many valuable things. I then took leave of him, and exchanging my merchandise for sandal and aloes wood, camphor, nutmegs, cloves, pepper, and ginger, I embarked upon the same vessel and traded so successfully upon our homeward voyage that I arrived in Balsora with about one hundred thousand sequins. My family received me with as much joy as I felt upon seeing them once more. I bought land and slaves, and built a great house in which I resolved to live happily, and in the enjoyment of all the pleasures of life to forget my past sufferings.

## ► family

### INTRODUCTION

The family has long been the ugly stepchild of history. Traditional history focuses on politics, wars, and revolutions but not the ordinary happenings of everyday life. The private world, one dominated by women, simply seemed too common to be of any scholarly interest. In the 1970s this situation began to change gradually as historians examined social and cultural history. However, all of the problems of family history have not been resolved. Emotional history and sexual history remain fields with major gaps of knowledge at the start of the 21st century. The very definition of a family also differs from region to region, thereby complicating studies of the family. While the medieval Europeans established nuclear families, Africans lived in clans, with family relationships extending far beyond the nuclear family. A father or mother to a medieval African was not the same as a father or mother to a medieval European or Asian.

Scholars of the family have been burdened with a lack of sources. For many regions, including the Americas, most evidence about family life must be drawn from archaeological sources. Attempts to do justice to women of the medieval period have encountered special difficulties owing to the character of the documentary sources that are typically used. The writings of church leaders and theologians have been repeatedly cited, with little consideration of the accuracy of their descriptions of conditions or of their audience.

By a similar method of investigation, a modern scholar might conclude that modern Catholics never practice birth control. Law books and manuals have also been misleading. William Blackstone's 18th-century pronouncement that European women lacked any legal rights in the medieval era enjoyed wide acceptance until the 1970s.

Childbearing is at the heart of the family. It is also one of the few aspects of medieval life that was not shaped by class standing or wealth. Rich or poor, women suffered and were injured in labor. Often, they died during birth, along with the child. Contraception by mechanical, medicinal, and magical means found limited use in all cultures, though it had little effectiveness. Abortion and infanticide apparently had been practiced since ancient times in all regions of the world and continued in the medieval era. Females were the targets of infanticide much more than males because the cost of raising a daughter and providing a dowry were more costly than the labor that she could provide to a family. However, females in the Americas and Africa seem to have been much more highly regarded than females in Europe, Asia, and the Islamic world. American and African women were valued for their childbearing and ability to link clans. This valuation probably reduced female infanticide rates in this region.

The gender roles of men and women influenced all aspects of the family. Males and females in Europe, Asia, and the Islamic world had different ages of consent, and a double standard gave sexual freedom to the man but not the woman. While the Islamic world emphasized polygamy (where either spouse could

have more than one mate), Europeans celebrated celibacy and practiced monogamy. In the Americas polygyny (where only the man could have more than one mate) was apparently common, and it clearly was established as a widespread practice in medieval Africa. In Europe, Asia, and the Islamic world women in general were secluded in harems or segregated at home away from the male worlds of business, politics, and religion. In the Americas and Africa women enjoyed both greater power and more freedom. Again, the inhabitants of the Americas and Africa seem to have had far more equality than men and women in other parts of the medieval world.

Throughout the world there has been a distinction between men's work and women's work. Activities within the household have been considered feminine, with a strong connotation of inferior importance except in the Americas. Men's work has involved the more socially valued tasks of governing, fighting, and providing family wealth. Accordingly, men generally have been provided with educations outside the home, while women have been restricted to learning how to cook and make clothing for the family and engage in other household-related tasks. Women had limited legal rights outside the home, including limits on taking legal action, such as suing, pleading in court, giving evidence, or witnessing wills.

The medieval world was largely a man's world. Women and children resided in a realm that had little relative importance. As a result, much evidence about the medieval family has been lost to the ages.

## AFRICA

BY AMY HACKNEY BLACKWELL

The family and family relations were at the center of all significant life events in medieval Africa. African peoples had many different family types, and it is impossible to provide one single definition of a medieval African family. In most African societies, however, people defined themselves in terms of their positions within their families.

The largest family unit was the clan, which comprised many people related by blood and marriage. The clan was one of the most important social units in African societies. Among the Bantu, for example, family relationships extended far beyond the nuclear family. Bantu children called all their father's brothers "father," all their mother's sisters "mother," and all the children of those two relatives "sister" or "brother." Children of the father's sisters were considered cousins. Among many Bantu peoples the clan made all important decisions, and individuals did not have much say in their own lives. For example, when a man died the clan would choose who would inherit his property.

African peoples had both patrilineal and matrilineal clan systems. In a patrilineal system people traced their ancestry through their fathers and the male line. The Bantu had a patrilineal system. People living under a matrilineal system traced ancestry through their mothers. Patrilineal systems were more common.

The clan often arranged marriages among members, choosing partners based on their family relationships and statuses. Incest between blood relatives was taboo and strictly avoided. Definitions of incest, however, varied from people to people. In some southern African cultures marriage between cousins was desirable, whereas in others it was abhorrent. Individuals might request particular partners and use go-betweens to negotiate between the families. Fathers might speak to one another to arrange a match between their children.

Throughout African grooms had to pay the bride's family a bride-price—property or money paid in exchange for the bride's presence, including her work and her children. The bride-price frequently was paid in livestock, such as goats or cattle, but it could also include pots, baskets, lengths of cloth, or metal goods. The higher the status of the bride's family the higher was her bride-price.

In most marriages brides were younger than their grooms, sometimes much younger. Many tribes commonly betrothed infants or children. In Somalia men could become engaged to women who were not yet born. Actual marriages and sexual intercourse did not usually take place until the bride reached puberty, though this was not always the case. Men were not allowed to marry until they were quite mature and owned enough property to support a wife.

In some cultures, usually hunter-gatherers such as the small people of the central African forests or the inhabitants of the southern deserts, weddings took place almost casually, when a man and woman decided to live together and produced a child. In most places, however, wedding ceremonies were joyous occasions involving the entire clan. The bride was the star of the wedding, accorded respect because she would provide the link between the families' ancestors and descendants. Weddings involved singing, dancing, feasting, and special costumes. The marriage might occur in several stages over a number of years, especially when children were betrothed. There might first be a betrothal ceremony to celebrate the marriage contract. When the bride was old enough, she might go to her husband's house for brief visits, during which she might sleep with her husband but would spend most of her time at her father's house. Among some peoples the bride might not live permanently with her husband until their first child was two or three years old.

Where the married couple lived was determined by whether the society was patrilineal or matrilineal. In a matri-

lineal society the groom would go to live with his wife's family in their village. In a patrilineal society the bride would live with her husband's family. Nuclear families were not the most common living arrangement in most of Africa. Instead, people thought of themselves as living in extended families. A couple might share a hut with their youngest baby, but in some places such as Senegal it was common for husbands and wives to sleep in separate huts. A wife might cook in her mother's or mother-in-law's house, sharing the food and the work with a group of relatives.

Clans decided what would happen to a family when a husband or wife died. Often if a man died, his brother or another close male relative became responsible for his widow and children. This man would adopt the children as his own and make no distinction between them and his own offspring. Even if the parents were not dead, it was not unusual for an uncle or other relative to adopt a child, especially from a family that had many children.

Polygyny, the practice of a man having more than one wife, was fairly common throughout Africa. It was allowed under many traditional religions. Islam also allowed men to have several wives, which meshed well with traditional practices in some areas. As a practical matter most men did not take more than one wife. Maintaining wives was expensive, and keeping more than one family happy could be complicated. Generally only chiefs and wealthy men practiced po-

lygyny, and some kings reportedly had hundreds of wives. In a polygynous household the first wife had the highest status and often had a say over whether the husband could introduce more wives. Although one man's wives might benefit by sharing work, often the women did not get along with one another and would try to make one another's lives difficult. Typically a husband favored the newer and usually younger wife, which caused feelings of jealousy among all his previous wives.

Extramarital affairs were fairly common among African peoples. It was not unusual for a man to sleep with the wives of his male relatives; a son was particularly prone to sleeping with his father's many wives (though not with his own mother). Taking lovers was often tolerated. In some societies, however, women caught in adultery were punished more harshly than men under the same circumstances.

Divorce occurred regularly among most African groups. Sometimes it was caused by extramarital affairs. Other causes were barrenness, witchcraft, and bad temper. Depending on the group, either sex could initiate divorce proceedings. Usually this would involve a public hearing in which the partners would list their grievances in front of elders. If a divorce was granted, the parties had to arrange their communal property. The woman's family might have to refund her bride-price, and the partner at fault could lose rights to the produce of a harvest or hunt.

## FAMILIES OF THE SMALL-STATURED PEOPLE OF CENTRAL AFRICA

The small people who inhabited the jungles of central Africa had a fairly simple family structure. The basic social unit was a nuclear family: a man, a woman, and their children. Marriages happened almost casually. A man and woman might live together for a time and then wander apart to search for other partners. The community would not acknowledge a marriage as complete until the couple had produced a child, but even then the pair might separate. Occasionally a man would end up with two wives; this could occur if he and his first partner separated and he found another spouse, only to have his first wife return.

The small-statured people of central Africa passed their property along gender lines. Mothers passed their baskets, knives, and pots to their daughters. Men passed their bows and arrows, spears, and hunting nets to their sons. If parents died young, their siblings or other relatives would hold their goods in trust for their children.

These people did not have the elaborate clan system of other African peoples. The small people hunted in bands of several families, but these groups were flexible and did not always include the same members. This allowed the hunting parties to share their game equally, with all members being treated the same for participating in the hunt, instead of being treated preferentially out of kin obligations. Each member of the party would be called by a specific kin name that determined which portion of the catch went to whom.

The small-statured people of central Africa addressed one another by family terms, such as *grandfather* or *brother*, but these terms did not correspond exactly to a person's position in a family. For instance, it was not unusual for a boy to call his older brother "father" if the difference in their ages was great. The term *sibling* could also mean "friend." Children would call all older women "mother" and all men "father." All men and all women would act as parents to all children in their group. Husbands and wives addressed one another as "man" or "woman."

Childbirth often occurred in some private setting, away from settlements and crowds. Women among the hunter-gatherers of the southern deserts and jungles would go off by themselves to give birth. In more settled groups women might go to a special hut to give birth with the aid of other women. Childbirth was dangerous, and many women and infants died in the process. Women whose genitals had been modified by cutting and sewing were particularly prone to complications such as bleeding and infection.

Women tried to space their births so that they would not have too many young babies at once. Their most effective methods of spacing births were extended breast-feeding, which can suppress fertility, and taboos on intercourse while breast-feeding. Infanticide immediately after birth was common, especially if a mother had another child who was still nursing and needed to be carried. Keeping a newborn could jeopardize the lives of both babies. If a woman decided not to keep her infant, she might smother it or bury it or simply leave it lying on the ground in the bush. When she returned to her village no one would question her.

If a woman did keep her newborn, she might spend several days in seclusion before rejoining her village or group. Newborns often died during their first days of life, so tribes would wait several days before acknowledging them. If the child was still alive after about three to seven days, it would be named, and the village would celebrate the birth with a feast and hold a naming ceremony. The child's name was very important. The parents might choose the name, but often a village elder performed this task, selecting a name that reflected the child's position in his or her lineage or communicated some desirable trait such as courage. Some villages performed tests before the naming ceremony to determine the child's legitimacy; for example, the grandmother might drop the umbilical cord into a container of milk to see if it floated. If it sank, the child would be considered illegitimate.

Within the household men and women performed different jobs determined by culture and tradition. Men typically did the hunting and might be in charge of a particular crop. Women might grow their own crops; in western Africa, for example, women often grew the rice. Women typically did the cooking and might cook for their grown sons even after they had moved into their own huts. Among pastoralists women did much of the work of milking the livestock. Both sexes might weave cloth, depending on the society. The presence of people within a family constituted part of its wealth. It enhanced a man's status to have several wives and many children. These people could all contribute work to the household, which increased its harvests and the size of its herds.

A person did not leave a clan simply by dying. African peoples believed that their ancestors continued to live near

them and influence their daily lives. Bantu people had poets who memorized lengthy lists of ancestors, going back many generations. At naming ceremonies these poets would perform, singing the story of the clan by reciting the names of its former members. Because ancestors were so important, families followed specific rituals when handling their dead. Every clan had its own funeral customs. Some buried their dead within the village; others had burial grounds some distance from living areas.

## THE AMERICAS

BY ANGELA HERREN

Throughout the Americas the period from 450 to 1500 marked the transition in many regions from scattered hamlets or villages to dense concentrations of residential groupings that sprang up around ceremonial centers and supported populations in the tens of thousands. While some groups continued nomadic or seminomadic ways of life supported by hunting, fishing, and gathering activities, others developed intensive agricultural production and trade activities that supported some of the largest metropolitan centers in the early Americas, changing the family experience forever.

In native North America many cultures maintained a nomadic hunting-gathering existence through the first millennium of the Common Era, congregating in small settlements with impermanent architecture. However, the cultivation of staple crops like corn, beans, and squash led to the establishment of permanent villages in the Four Corners region of the American Southwest, the area where the borders of Utah, Colorado, Arizona, and New Mexico meet. In the fifth century families lived in pit houses—underground single-room structures with earth-roofed domes. By the eighth and ninth centuries multiroom masonry structures dominated, giving way to compact villages like Pueblo Bonito, which housed more than 1,200 people at the beginning of the 10th century. The multifamily dwelling units of the Anasazi (ca. 900–ca. 1300) represent some of the earliest permanent architectural structures in North America. Often built into protective overhanging cliffs, these mud-brick structures integrated domestic family units, storage and working areas, and underground ritual spaces called kivas. The Hopi, the Zuni, and the Pueblo peoples of the Rio Grande are descendants of the Anasazi.

In Mesoamerica archaeological remains indicate that in areas of high population density many families lived in clusters surrounding a civic or ceremonial core. Skeletal remains document the practice of cranial deformation, the shaping of the soft skull of an infant with boards to achieve a desired profile, and indicate a high infant mortality rate. Information recorded at the time of European encounters in the 16th

Stone sculpture of Tlazolteotl, a goddess associated with fertility, Huastec culture, Mexico, ca. 900–1521 (© The Trustees of the British Museum)

century provides greater detail about family traditions surrounding marriage, pregnancy, and birth among the Mexican (Aztec) and Mayan cultures.

At Teotihuacán (ca. 100–ca. 700) families lived in approximately 2,200 apartment compounds, each housing 60 to 100 family members related to each other through patrilineage. Each compound had high walls and a single entrance that restricted access. Open courtyards and shrines serviced the residents. Elaborate murals and sculptural decor indicated that families of high status lived closest to the ceremonial center. Dominated by red pigments, the stucco murals in many compounds featured images of warriors, deities, and sacrifice, perhaps templates for proper worship by the

city's many inhabitants. A major urban center, this central Mexican city achieved populations estimated between 85,000 and 200,000 by the fifth century, making it the sixth-largest city in the world at that time. In addition to apartment compounds, the Pyramid of the Sun, Pyramid of the Moon, and Temple of the Feathered Serpent as well as various palace and administrative structures lined the roughly north-south axis of the 3-mile-long Avenue of the Dead. Families in this cosmopolitan city would have interacted with Zapotec, Mayan, and Veracruzian “foreigners” inhabiting various enclaves within the city.

Just as Teotihuacán reached its apogee, the Toltec people began to expand settlements at the central Mexican site of Tula. By the Tollan phase (ca. 950–ca. 1150 or 1200), Tula's rulers established a new ceremonial center, and a population of 30,000 to 40,000 inhabited surrounding apartment complexes. Each complex contained up to five square or rectangular rooms. Like the structures in Teotihuacán, these flat-roofed units were surrounded by high walls, while centrally located altars and courtyards facilitated domestic activities and ritual.

Although Mayan and Mexican peoples erected monumental stone pyramids, temples, palaces, and other civic and religious structures, perishable thatch-roofed dwellings continued to house most of the population. Mayan households of the Classic (ca. 200–ca. 900) and Postclassic (ca. 900–1521) periods, located in the regions of southern Mexico, Belize, Guatemala, and Honduras, cultivated vegetables and fruit trees in kitchen gardens. Like the Mexica of Tenochtitlán in central Mexico from the 14th to 16th centuries, the Maya hunted fish, fowl, and larger mammals like deer and peccary. Both Maya and Mexica raised small dogs and turkeys for food and sacrifice.

Among the Mexica, commoners married at around 20 years of age. The families of the bride and groom negotiated an arrangement, and then the couple chose an auspicious day for the ceremony. After a banquet at the home of the bride's family, the adorned and painted bride was borne to the groom's house, where the evening ceremony occurred. Seated on a straw mat before a lit hearth, the couple received gifts, and a matchmaker knotted the bride's blouse and the groom's cloak together, signifying the union. After the ritual events of the marriage ceremony, elderly relatives counseled and advised the couple during a four-day period of feasting.

In the Mayan and Mexican cultures women bore responsibility for child rearing and maintaining the home. Midwives assisted at the birth of a child and conducted ritual purification and naming ceremonies. The Yucatec Maya venerated Ix Chel as the supernatural patron of midwives, while the Mexica propitiated the purifying water deity Chalchi-

uhtlicue. Shortly after a Mexican birth, a diviner consulted a *tonalamatl*, or book of days, to determine the nature of the child's birthday and its future implications. If the day was deemed inauspicious, the diviner mediated by selecting a beneficent day for baptismal rites. During this ceremony Mexican boys received a symbolic shield and weapons along with tools of the profession they might engage in. Girls received a small tunic and weaving instruments. Women who endured the pain of childbirth were likened to warriors on the battlefield and were honored as such in death. Scholars believe that the 260-day ritual calendar may be based on a nine-month human gestation period.

Sixteenth-century Spanish accounts of the Taíno, a large ethnic group that inhabited the Greater Antilles, describe their house structures and village layout. Like their Caribbean ancestors, the Taíno built impermanent wood and fiber dwellings. Large thatch-roofed structures housed the members of an extended family. A long rectangular plaza or ball court, with the home of a lord at one end, formed the nucleus of the village; private homes surrounded it. Villages accommodated as many as 1,000 nuclear families.

In the Andean region of South America the highland site of Tiwanaku (ca. 100–ca. 1000 C.E.) contains residential groupings that may have accommodated populations as high as 30,000 to 60,000. Most families lived outside the moat that surrounded Tiwanaku's ceremonial core, while high-ranking political and religious practitioners may have occupied the city center. The Incan culture of the 14th to 16th centuries venerated this earlier site as a sacred place of origin and attempted to emulate the fine stone masonry of the site's ruined buildings in Cuzco. An impressive example of the mortarless stone architecture sits high atop the Andean mountain range, where elite residences made up the Incan site of Machu Picchu.

Sixteenth- and 17th-century accounts by Spanish and mestizo authors provide information about Incan social mores. This society valued duality and complementarity and was organized in kin groups called *ayllu*. The lineages of the kin groups were divided into two parts, called moieties. Marriage partners came from separate moieties, and Incan law forbade marriage to close relatives. The Inca often turned to omens to help select marriage partners. Incan society permitted rulers to take many wives, and the last two rulers are documented as taking their sisters as primary wives to emphasize the divinity of the ruling lineage and promote peaceful succession.

## ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Family was very important throughout medieval Asia. Family relationships dictated almost every aspect of a person's life,

from educational and marriage possibilities to how a person would spend any given day.

Contraception was not widely available or effective in medieval Asia. The most commonly used contraceptive techniques were withdrawal and douches with such substances as lemon juice, which were not reliable means of preventing births. Most women experienced many pregnancies and births during their lives. Every pregnancy was risky because there were few medical treatments for complications of pregnancy and birth. Many women died giving birth.

Once a child was born, it was almost invariably breastfed, either by the mother or by a wet nurse. In some societies, such as that of New Guinea, husbands did not sleep with their wives when they were nursing babies or toddlers; people believed that semen from the man would contaminate the woman's milk. Women often nursed their babies for two or three years, so this period of abstinence could space births several years apart.

Infant mortality rates were high throughout Asia and the Pacific. Although exact numbers are not known, historians estimate that between 30 and 50 percent of all babies born did not reach adulthood. Many infants died at birth. Some of them died of natural causes, while others died of infanticide, a typical method of reducing family size. Female infants were the most common victims of infanticide. In many Asian societies male offspring were desired and female children considered a burden. If a newborn's mother died in childbirth, the infant also stood a good chance of dying. Older babies and children died of illnesses and accidents.

Family was the foundation of Chinese society. Confucianism, one of the prevailing philosophies, placed great importance on relationships and the duties family members owed one another. Younger people were supposed to respect and serve their elders. Their elders, in return, were supposed to look out for the welfare of their juniors. Children had to revere their parents and other ancestors. Wives were expected to obey their husbands without protest.

Chinese people traced their lineage back several generations through the male line. In the Mandarin Chinese language, each position in a clan had its own name. For example, a paternal great-great-grandmother had a different name from a maternal great-great-grandmother. An aunt by blood and an aunt by marriage had different names. Different types of cousins had their own separate terms. Dead family members were still considered part of the family, and the living often consulted their dead ancestors about important matters. All children took their father's surname.

Females were considered inconsequential in China, useful only as workers and to produce children. A woman who married would move into her husband's home, where three to

five generations might all live together; the wife had to serve her mother-in-law. Women usually married outside their own villages. This separated women from their own relatives and friends and increased their disadvantages within their husband's homes. A man might take several wives and concubines, and these women would have their own dominance hierarchy, with the first wife or the mother of the oldest son holding the highest rank.

Chinese couples were expected to produce children; a failure to have offspring was considered a betrayal of both living parents and dead ancestors. Sons were the most desired children because they were the ones who would care for their parents in their old age. Parents arranged marriages for their

*Children at play, China, ca. 1368–1644; children were a favorite theme in Chinese art, symbolizing the desire of families to have many sons. (Freer Gallery of Art, Smithsonian Institution, Gift of Charles Lang Freer, F1916-60)*

children by consulting astrologers to find auspicious wedding partners and dates and by interrogating prospective in-laws about their financial situation. Weddings were festive occasions, with large numbers of guests and lavish banquets.

Medieval Hindus in India divided themselves into four *varnas*, or social categories: Brahmin, the priest-scholars; Kshatriya, warriors; Vaishya, merchants and artisans; and Shudra, laborers. These groupings were further subdivided into many castes that defined the kind of work a person did. Caste status was inherited from one's parents, and a person's caste name often functioned as his or her surname. Hindus married within their own castes.

The Hindu religion taught that marriage was a sacred relationship between the souls of the partners and that this union could extend beyond one lifetime. Most marriages were arranged by the parents of the new spouses, who would examine the caste, financial status, genealogy, and appearance of their prospective in-laws before agreeing to the union. Once the match was made, the families exchanged gifts, which were sometimes substantial. Wedding ceremonies were lengthy and involved the singing of many Vedic mantras. During the ceremony the bride's family formally handed their daughter over to the groom's family and asked them to care for her. The groom finalized the marriage by tying a symbolic thread around the bride's neck.

The wife was recognized as an important figure within the family—the symbolic goddess of the household. Ideally, husband, wife, and children all were supposed to love and care for one another. Spouses were expected to enjoy a sexual relationship with each other, an idea expressed in the Hindu text called the *Kama Sutra*. Polygamy did exist, and it was not uncommon for men to have concubines in addition to their wives.

Widows often found themselves at a disadvantage in the community. A widow's husband's family might not want to support her, which could leave her and her children destitute. Sometimes a widow would commit suicide at her husband's funeral in a ritual called *suttee*. In this practice, which became common between the fifth and 10th centuries, a widow would come to her husband's funeral dressed in wedding robes or other fine clothes, unlike the other mourners. She would then join her dead husband on the funeral pile and allow herself to burn to death.

In Japan families typically lived in small groups consisting of a married couple, their children, and sometimes the husband's parents and unmarried siblings. The husband was the head of the household, and the wife was expected to obey his orders. An oldest son would inherit his parents' home and farm; in return, he was expected to care for his parents until they died. When a woman married, she left her own family's

home and moved in with her husband. She was expected to care for the house, prepare meals, and serve her in-laws, which was often a source of strife and dissatisfaction.

Although Japanese parents wanted boys as offspring, they sometimes welcomed female children as a free source of labor. In fact, in some rural areas parents would hope that their first child would be a girl so that she could help the mother raise a younger son. All children, except for eldest sons, had to leave their family homes when they grew up. Parents arranged all marriages. They might try to find a younger son a wife with no brothers so that the son could take over his father-in-law's home and business. In such a case, the groom might take his wife's family name as his own, so that his father-in-law's name could continue.

Australian aboriginal society was organized around a complex web of extended family relationships. An Australian family was a collection of clans, which included males and females of all ages and all relationships. A person's role in the clan was defined by his or her position in relation to others. Kinship rules determined who could marry whom; in many groups a person had to marry someone who was related to him or her in a particular way, as defined by the group's genealogical rules. Family relationships also determined who could live where. Family groups fluctuated in size over the seasons as the nomadic people traveled around, hunting and gathering.

Men were primarily in charge of hunting. Women gathered nuts, roots, and fruits. Elders of the extended family kept the society's accumulated knowledge and passed it on to younger members through storytelling and advice. Everyone in the group contributed to the clan's well-being.

The entire community was responsible for raising children. A child would consider all of his mother's female relatives to be equivalent to his biological mother. Each woman watched all her relatives' children, feeding them or correcting them as needed. All members of the clan—men and women, young and old—considered all of their relatives to be both their responsibility and a source of help. Parents did not consider their biological children to be their exclusive responsibility.

Like the aboriginal Australians, Pacific islanders relied on the support of large extended families to feed themselves and raise their children. Extended families operated as single economic units, working together to raise crops and livestock and catch fish. The kin group organized family social events, such as wedding feasts and funerals. Clans extended across islands, and when an islander traveled to another island he could expect to find kin there who would let him stay with them. Hospitality was considered a natural part of clan membership and not a burden. Many transactions were the result of reciprocity, with every person taking and giving favors and goods to kinsmen.

Within the Pacific islander family group a man might be the head of his immediate household, including his wife and children, but he did not hold unquestioned authority over them. If he abused his wife, her father or brother would intervene. Uncles, grandfathers, aunts, grandmothers, and other relatives all participated in the rearing of children, fulfilling the same role as biological parents. Children thus thought of themselves as having several parents, not just two. As they grew up, they might live with various relatives in different households, not just with their parents.

Women's roles varied from island to island. In Yap (Micronesia) women were fairly powerless and could easily be disinherited by their husband's siblings. In Palau, by contrast, women helped choose new chiefs and even exercised veto power. Throughout the Pacific women usually had some say in how land was apportioned among clan members.

## EUROPE

BY AMY HACKNEY BLACKWELL

For most of the medieval period the majority of European families lived in small houses, often with only one room in which everyone ate, worked, and slept. Animals sometimes shared the space as well, separated from the human living area by a fence. Married couples did not have their own rooms, and privacy was virtually unknown.

Life expectancy was short. The average life expectancy was only 35 to 40 years, though these numbers reflect a high infant mortality rate. During the plague years of the 14th century, however, life expectancy dropped to less than 20 years. Death had many causes during the Middle Ages. Women often died in childbirth. Men died in wars. Children who lived past their precarious first two years could still die of illness and accidents. There is good evidence that medieval families were emotionally devastated by the loss of their family members, especially their children. Although death was common, people did not accept it with equanimity. Frequent deaths and a high birthrate meant that medieval families were often in flux, with members frequently dying and new ones entering by marriage or birth. Most marriages ended within a few years as the result of the death of one of the partners, and it was common for adults to marry more than once. The Christian church did not allow divorce, but it did not really have the power to prevent couples from separating if they wanted to. Celtic civil laws did allow divorce under a variety of circumstances, the most common of which were adultery or barrenness.

The medieval family functioned as an economic unit. Children were expected to help their parents with household work. There were almost no schools in western Europe

throughout most of the medieval period, so children did not attend school. Children of both sexes helped with daily tasks or large jobs, such as carrying water, fetching firewood, or harvesting crops. These tasks often were carried out by groups of people, as part of a larger community, such as a village. Girls performed housekeeping tasks and child care at home. Boys learned their fathers' trades with the expectation that they would carry on their family's business. In the later medieval period some boys were sent to live with the families of other tradesmen as apprentices.

Parents tried to launch their grown children into solid adult lives, if possible. Distribution of property varied, depending on the region. In some areas the oldest son inherited all of his father's property, and the younger sons inherited nothing. In other areas fathers divided their property among their children; this provided for more children, but it also reduced the sizes of parcels of land. Families of property had to furnish dowries for their daughters. A dowry was a gift of money, cloth, or property that the bride brought to her marriage. It usually remained the property of the woman, though her husband might have the use of it. Women could not inherit property, so the dowry was all they received from their own families. Providing property for sons and dowries for daughters was an endless problem for medieval families, and folklore and history are full of the stories of families who found themselves struggling financially because of these heavy burdens.

Wealthier families could not provide actual property for all their children. It was common for families to send their younger sons and some of their daughters to monasteries and convents, respectively. The monastic organizations would keep their children safe and fed, and the families in return could expect spiritual goodwill. A family member who belonged to the church could say extra prayers just for his or her relatives. Having a son in the priesthood was considered especially advantageous politically because priests had a great deal of power within their towns. Although monks and nuns were generally celibate and childless, priests often had mistresses and children of their own. The celibacy of the clergy had long been a matter of some debate, but it was not until 1074 that Pope Gregory VII decreed that priests should not be married.

Peasants had more latitude in the choice of a spouse than the nobility. They often married for love or because of an unintended pregnancy, although marriages to consolidate businesses also occurred. Among the nobility, marriages were a way of establishing or firming up alliances. Parents chose the spouses of their children for political reasons. It was not uncommon for children to be betrothed without ever having met one another. Medieval brides were typically quite young,

*Medieval illumination showing a family group, France, ca. 1275–99*  
(The Pierpont Morgan Library)

often in their teens or even as young as 12. Men tended to marry later, once they had established themselves in a trade and could support a family.

Many medieval Europeans married with no ceremony. In many societies, if the members of a couple declared to one another “I am yours” and then lived together as husband and wife, their town would accept them as a married couple. During the 11th century the church declared that a priest had to bless a marriage for it to be official, and gradually it became standard practice to have weddings in churches.

Some families took this formality further, having a priest officiate at betrothal ceremonies and holding large public feasts to celebrate engagements. For more formal marriages an engaged couple would post an announcement of the engagement on the church door several weeks before the scheduled wedding. This provided their friends and relatives an opportunity to announce any reason why the marriage should not proceed. Reasons could include blood relationship, monastic vows, or an existing marriage.

Wedding ceremonies and celebrations varied by social class and financial resources. Wealthy and noble families

held huge weddings with many guests, entertainers, and more food than anyone could eat. Peasant wedding feasts were simpler. The religious ceremony was very similar to the one used today in Christian churches. A couple who could afford rings would exchange them, placing them on the fourth finger of the left hand.

There was no reliable contraception in medieval Europe. The church disapproved of contraception and abortion, based partly on the writings of Saint Augustine of Hippo (354–430). It also tended to disapprove of sexual contact in general, even within marriage. Under church doctrine the only approved method of contraception was abstinence. Women, however, were not allowed to refuse sexual relations with their husbands. Couples tried to space births using primitive methods such as withdrawal. Some women used herbal potions to prevent pregnancy or to stop pregnancies already in progress. Infanticide was a common method of keeping family size manageable. If a newborn was unwanted, perhaps because the mother was unmarried or already had too many children, she might abandon it in the woods or on the street. Some of these children were rescued by strangers, but many of them died. Medieval people did not like the idea of infanticide, and certainly finding dead babies in the street was upsetting. In an effort to prevent newborns from dying, Pope Innocent III, in the 13th century, ordered churches to install devices known as foundling wheels. A foundling wheel was a turning drum in the wall of a church where a woman could place her baby and leave without being seen. A priest or nun would then retrieve the child, though raising abandoned babies was difficult and often unsuccessful.

Medieval infants depended on their mothers to feed them. The only safe food for newborns was breast milk, so most mothers nursed their own babies. A wealthy woman might hire a wet nurse to feed the child so that she could save herself the trouble and perhaps conceive again sooner. Nursing babies reduced fertility somewhat, which did help space out pregnancies. In some areas people believed that having sex while nursing would sour a woman's milk, so men stayed away from their wives until their babies were weaned at about the age of one or two. Noblewomen often were under particular pressure to produce a male heir for their husbands, so they did not necessarily want to postpone subsequent pregnancies.

Medieval laws recognized the importance of relationships by blood and marriage in matters of inheritance. Law codes defined several types of children based on the parents' legal and marital status. A child born of legally married freeborn parents was entitled to full inheritance rights. A natural child was one born of a relationship that was acknowledged but not legally binding in the community, such as the rela-

tionship between a lord and a concubine. Natural children could inherit less than legal offspring. The important factor here was that the father had to acknowledge his own natural children. A third category of children had no inheritance rights at all; these were children born to serfs or children of uncertain paternity.

Kinship was very important to medieval people. People could trace their genealogies back several generations and acknowledged a wide range of relatives, including distant cousins. Brothers were expected to support one another. Celtic peoples allied with their uncles and cousins in battle. Among the Germanic peoples and the Vikings the relationship between a man and his sister's son was especially close, partly because a man knew for certain that he was related to his sister's children but had to trust his wife that his sons were his. Poems written in Iceland in the 12th century are full of references to kinsmen, cousins, and uncles. Many Europeans used the fosterage system to strengthen relationships with relatives. They would send their children to live for a time with the family of a relative to be trained in battle or household skills. Thereafter the child would feel a close relationship with his or her foster family, and the family would have built up an alliance.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

Arabia had small cities, but much of the land was occupied by nomads. The laws of government had little reach in Arabia, and people had slight hope of being protected by laws. Thus, people relied on their families for help. Someone who was in need was supposed to be aided by family members. For instance, a woman who had been abandoned by her husband could expect to be taken in and cared for by brothers, sisters, uncles, aunts, or even cousins. A man who had been robbed would be aided by his family or his family's clan, a loose group of related families who shared common, often revered, ancestors. A family or a clan that did not help a family member lost status among the other families and clans of Arabia, and a failure to help a family member in need could be held against a family for several generations.

The relative status of men and women in pre-Islamic Arabian families is the subject of much dispute among modern historians, as it was among medieval Muslim historians. Some historians held that both men and women practiced polygamy, or marriage in which a spouse has several mates. Others believed that only men were allowed to practice polygamy. One relationship that later caused much disagreement among Muslim scholars was the temporary marriage, the *nikah mutah*, which was a marriage with a contractual time limit.

Documentation is slight with respect to the ways in which pre-Islamic Arab customs related to women, but most historians believe that Islamic law, the sharia, probably improved the lot of Arabian women but worsened the lot of women in the conquered lands of the Near East, North Africa, Spain, Afghanistan, Iran, and India. The sharia placed wives a step below husbands in marriage but gave wives rights to own property apart from their husbands' property and to seek redress in a court of law if they were mistreated.

Historians often refer to medieval Islam as an urban culture because the sharia was much more likely to be enforced in cities than in the countryside. Cities and some towns had courts. Anyone living within the city or town would have ready access to a court of law, and women were allowed to leave their homes and go out in public to take cases to court. The Koran is very clear about some aspects of marriage and vague about others, and throughout the medieval era legal scholars debated the meaning of sometimes obscure phrases in the Koran, creating a great deal of case law (law based on court interpretations of the law rather than taken directly from the Koran or government edicts).

Among the pre-Islamic Arabs a prospective groom had to pay the father or male guardian of the bride a bride-price, a sum of money or property, for the girl or woman. Under the sharia the money was be paid directly to the bride, and it was hers to keep and use as she saw fit. This gift to the bride was called the *mahr*. If her husband divorced her, the *mahr* still belonged to her. In cities of the Islamic world this law was enforced to varying degrees, depending on the integrity of the judges, but in most cases judges were honest men who took their tasks seriously and would find in favor of the wife should the husband attempt to take her property. The law said that the wife could voluntarily give some or all of her property to her husband, but her husband was expressly forbidden to force her to relinquish her property. If a husband forced his wife to surrender her property, courts would order the property returned to her. Further, almost all judges in cities had not only the authority but also the muscle, in the form of law enforcement officers, to ensure obedience to their rulings. On the other hand, in the countryside women were often sold into marriage and were forced to hand over their property to their husbands, brothers, uncles, or male cousins. Such a woman might find a court to hear her case in a regional town, but she frequently had no choice and no source of help.

The sharia plainly declared that both the man and the woman in a prospective marriage had to agree to be married. This moral point was central to the thinking of medieval Muslims: God expected both husband and wife to fulfill their obligations in marriage, and for those obligations to be valid, each of the marital partners must understand those ob-

ligations and freely accept them. In the countryside this view could be ignored, with girls and women forced into marriages that they would not choose for themselves. In cities agents of the courts could make sure that all aspects of the legal contract for marriage were properly understood and freely accepted by both bride and groom. If either the bride or the groom objected on the basis of being forced into an unwanted match, a judge could annul a marriage and order someone to care for the girl or woman.

One problem was the ages of brides and grooms. A groom tended to be older than a bride, sometimes decades older, because he was expected to have the income to pay completely for the maintenance of his wife and children, as required by the sharia. Sometimes a bride could be a small child. The third wife of the prophet Muhammad (ca. 570–632) was said to have been between six and nine years old when she was betrothed. However, the sharia was clear that such a young child was not legally responsible for her own actions and could not enter into a legally binding contract, seemingly making illegal a betrothal or a marriage at such an early age. Medieval legal scholars never resolved this problem, and in general the marriage of girls to much older men occurred throughout the Islamic world, especially in the countryside, where the power of reformist judges in cities and towns did not reach.

On the other hand, the bride was sometimes much older than the husband, as was Muhammad's first wife. One of the attractions of an older woman was that she often had considerable financial resources of her own, especially if she was the widow of a wealthy man. Such a woman could help a young husband set himself up in business. An older woman who had borne sons would have a powerful role in her extended family, providing her new husband with family connections that could immediately elevate his status in the world. The older woman often could improve her marriage contract. For instance, the widow Umm Salamah required her prospective husband, Abu al-Abbas, to promise not to take any other wives, even though a man could have up to four wives at the same time, and not to have sexual relations with any of his slaves. Even after he became al-Saffah, the first Abbasid caliph (r. 749–54), he remained true to his marriage contract, even while courtiers urged him to enjoy the females of his court.

For the whole of the medieval era it is hard to find information about the home life of ordinary people, partly because medieval Muslim writers believed it to be improper to discuss people's private lives. Marriage was principally for procreation. Both husband and wife entered into a marriage contract with the understanding that producing children was their primary obligation. Having children was paramount for maintaining a family's continuity and for contributing to

its future prestige. Many a Muslim writer notes that the best guarantee for love is for lovers to be married and that marrying for love is good but that being in love takes second place to the procreative potential of bride and groom. Having several wives could help a man have children. The wealthy and powerful, such as sultans, could have four wives and numerous concubines, but the sharia was usually interpreted to require that each wife be set up in her own household, equal to the household of each other wife. Few among the vast majority of men could afford to meet this requirement, so the practice was restricted to the small minority of very rich people.

In theory, a married woman was never to be unescorted among men not of her immediate family. She was to be watched carefully so that when she became pregnant, there could be no doubt that her husband was the father. In extreme cases wives were imprisoned under lock and key in the women's quarters, the harem. In the countryside and among the working class, cloistering a wife was impractical because wives took part in the family business, perhaps grinding grain or preparing goods for sale. Birth was attended by female family members, female friends, and midwives, and the process of birth apparently varied by local custom, from crouching down during labor to standing with legs spread apart. At birth the father whispered in the infant's ear the *adhan*, the call to prayer, and then the *shahada*, the first pillar of Islam, that there is no god but Allah and that Muhammad is his messenger.

Small children were the responsibility of their mothers, and a child would remain with the mother if she was divorced. When children reached the age of reason, which varied by regional custom, the father took responsibility for them, even

after divorcing their mother. A disciplined household was considered ideal, and the wife was supposed to obey her husband. The husband was expressly allowed to beat a wife into submission, although if a wife could prove that the beatings happened for no reason, she could gain a court-ordered annulment or divorce from her husband. In the majority of Muslim households the partnership of husband and wife in society, family life, and daily work was of great importance and may have discouraged abuse of women, at least in cities and towns, where courts were available. There are hints that the lives of women in the countryside of Arabia and North Africa could be hellish because of the lack of law enforcement.

Inheritance laws favored male family members because under the sharia, men bore the financial burden of caring for a family. The laws varied somewhat according to time and place, but in general if a man died first, then his will could leave one-third of his wealth to anyone he chose; another third would go to his wife, and the rest would go to his children, with sons receiving twice as much as daughters. If the wife died first, the wealth could go to her husband or to her children or male relatives, such as brothers.

### Asia and the Pacific

#### ≈ Taika Reform Edicts (Japan, 645) ≈

Again, there have been very many cases in which wives or concubines, when dismissed by their husbands, have, after the lapse of years, married other husbands, as ordinary morality allows. Then their former husbands, after three or four years, have made greedy demands on the second husband's property, seeking their own gain.

Again, there have been very many cases in which men, relying on their power, have rudely demanded people's daughters in marriage. In the interval, however, before going to his house, the girl has, of her own accord, married another, and the rude suitor has angrily made demands of the property of both families for his own gain.

Again, there have been numerous cases of this kind. Sometimes a wife who has lost her husband marries another man after the lapse of ten or twenty years and becomes his spouse, or an unmarried girl is married for the first time. Upon this, people, out of envy of the married pair, have made them perform purgation.

Again, there are cases in which women, who have become men's wives and who, being put away owing to their husbands' dislike of them, have, in their mortification at this injury, compelled themselves to become blemished slaves.

Again, there are cases in which the husband, having frequent occasion to be jealous of his wife's illicit intercourse with others, voluntarily appeals to the authorities to decide the matter. Let such persons not lay their information until they have obtained, let us say, three credible witnesses to join with them in making a declaration. Why should they bring forward ill-considered complaints? . . .

All such practices are habitual among the unenlightened vulgar. Let them now be discontinued without exception, and not permitted again.

Europe

≈ *The Contract of Marriage, in the Ecloga of Leo III (Byzantium, 726)* ≈

The marriage of Christians, man and woman, who have reached years of discretion, that is for a man at fifteen and for a woman at thirteen years of age, both being desirous and having obtained the consent of their parents, shall be contracted either by deed or by parol.

A written marriage contract shall be based upon a written agreement providing the wife's marriage portion; and it shall be made before three credible witnesses according to the new decrees auspiciously prescribed by us. The man on his part agreeing by it continually to protect and preserve undiminished the wife's marriage portion, and also such additions as he may naturally make thereto in augmentation thereof; and it shall be recorded in the agreement made on that in case there are no children, one-fourth part thereof shall be secured in settlement.

If the wife happens to predecease the husband and there are no children of the marriage, the husband shall

receive only one-fourth part of the wife's portion for himself, and the remainder thereof shall be given to the beneficiaries named in the wife's will or, if she be intestate, to the next of kin. If the husband predeceases the wife, and there are no children of the marriage, then all the wife's portion shall revert to her, and so much of her husband's estate as shall be equal to a fourth part of his portion shall also inure to her as her own, and the remainder of his estate shall revert either to his beneficiaries or, if he be intestate, to his next of kin.

If the husband predecease the wife and there are children of the marriage, the wife being their mother, she shall control her marriage portion and all her husband's property as becomes the head of the family and household.

**LIFE AT WALATA**

My stay at Iwalatan lasted about fifty days; and I was shown honour and entertained by its inhabitants. It is an excessively hot place, and boasts a few small date-palms, in the shade of which they sow

watermelons. Its water comes from underground waterbeds at that point, and there is plenty of mutton to be had. The garments of its inhabitants, most of whom belong to the Massufa tribe, are of fine Egyptian fabrics.

(continued)

*(continues)*

Their women are of surpassing beauty, and are shown more respect than the men. The state of affairs amongst these people is indeed extraordinary. Their men show no signs of jealousy whatever; no one claims descent from his father, but on the contrary from his mother's brother. A person's heirs are his sister's sons, not his own sons. This is a thing which I have seen nowhere in the world except among the Indians of Malabar. But those are heathens; these people are Muslims, punctilious in observing the hours of prayer, studying books of law, and memorizing the Koran. Yet their women show no bashfulness before men and do not veil themselves, though they are assiduous in attending the prayers. Any man who wishes to marry one of them may do so, but they do not travel with their husbands, and even if one desired to do so her family would not allow her to go.

The women there have "friends" and "companions" amongst the men outside their own families, and the men in the same way have "companions" amongst the women of other families. A man may go into his house and find his wife entertaining her "companion" but he takes no objection to it. One day at Iwalatan I went into the qadi's house, after asking his permission to enter, and found with him a young woman of remarkable beauty. When I saw her I was shocked and turned to go out, but she laughed at me, instead of being overcome by shame, and the qadi said to me "Why are you going out? She is my companion." I was amazed at their conduct, for he was a theologian and a pilgrim [to Mecca] to boot. I was told that he had asked the sultan's permission to make the pilgrimage that year with his "companion"—whether this one or not I cannot say—but the sultan would not grant it.

## ► festivals

### INTRODUCTION

The impulse for humans to gather together to celebrate important events, community milestones, and rites of passage runs as far back as human history itself. During the medieval period people toiled hard as they tried to scratch out a living,

Their lives were precarious. At any time disease could strike, rivers could flood, crops could fail, the ground and skies could dry up, and earthquakes, storms, and volcanic eruptions could disrupt and destroy their lives. People generally had few sources of entertainment, so community festivals were an important way of putting aside the hardships of life for a while.

While the nature of these festivals varied across the world, of course, a number of common themes can be identified. First, many festivals revolved around religious events. In Christian Europe numerous ancient festivals having to do with the arrival of spring or winter were transformed by the church into such religious festivals as Easter and Christmas, while Halloween evolved from an ancient Celtic Feast of the Dead to the church's All Souls' Day. Many modern traditions associated with holidays—Easter eggs and bunnies, Halloween costumes and "trick or treat," Christmas trees and Nativity scenes—are survivals from medieval religious celebrations, themselves survivals from more ancient pre-Christian Roman and Celtic traditions.

Additionally, communities in Christian Europe conducted festivals surrounding the life of a patron saint who was important to the area or country; Saint George of Scotland was a good example. These festivals could be marked by processions, during which statues of the saint were car-

ried through the streets; similarly, in Japan a portable shrine called a *mikoshi* would contain the spiritual essence of the local god, or *kami*. The chief festival of Islam is the month-long Ramadan, Islam's most sacred month, and Asian, African, and American nations conducted religious festivals as well. In the Americas, for instance, priest-rulers, dressed elaborately in feathers and headdresses, led processions to sacred sites, where sometimes blood sacrifices were offered to the gods. Accordingly, priests, shamans, rabbis, and other religious figures typically played a key role in guiding these events.

For some religious communities, religious festivals were a way of propitiating the gods or ensuring good fortune; for others they were a way of celebrating historical events in the history of the religion, such as the birth of Christ or Muhammad; in still others, such as China and Africa, it was believed that festivals were a way of making contact with ancestors. In some cultures, such as those of Mesoamerica but elsewhere as well, the king was regarded as a divine figure, so festivals were held to celebrate the king's accession to the throne or to acknowledge his birthday. In all cases, though, the cycle of festivals throughout the year formed, in effect, a calendar that marked the passage of both temporal and sacred time.

A second common theme is the nature of the festivals themselves. People used festivals to "blow off steam." Festivals became a way to invert the social order, so many cultures had festival days on which lower social classes adopted the roles of those in higher classes and vice versa or when servants were able to mock their masters without fearing punishment. Typically, festivals included music, singing, dancing, and in some cases, considerable consumption of alcoholic beverages. People dressed in costumes, held parades or candle-lit processions, feasted, lit bonfires, set off fireworks, and played pranks on one another. Festivals typically included popular forms of entertainment, depending on the culture. These entertainments might have included athletic contests (such as the ball games of Mesoamerica), plays (such as the liturgical dramas of Christian Europe), jugglers, recitation of epic stories celebrating the culture's history and its historical heroes, and so forth. Social rules were cast aside as the entire community participated in the organization of the event, contributing food, labor, and other resources.

A third common theme is the importance of the passing of the seasons. Nearly every world culture, particularly those in northern and southern climates, celebrated the arrival of the warmth of spring after the cold of winter. This was a major event, for it meant that the people had survived another season during which the ground froze, hunting was difficult, the fields lay under a blanket of snow, and people remained huddled in shelters merely trying to survive. Spring was a time for planting and renewal, which could take the form, as it did

in China, of cleaning the house from top to bottom and visiting the graves of ancestors. As the earth turned green with new life, spring became a symbol of fertility, procreation, and rebirth, so springtime festivals often were times when young people courted each other, and revelry could often have definite sexual overtones. Autumn was a time for the fulfillment of the promise of spring as crops were harvested, herds were moved to winter pasture, and people began to prepare for the winter. Autumnal festivals were a way for communities to celebrate the harvest. During the depths of winter, people held festivals to break up the boredom of confinement and look forward to spring. In many cases winter festivals had a religious dimension, for they were a call to the gods for the arrival of spring.

A fourth common theme is that festivals were held in connection with more personal events and rites of passage. Births and weddings were occasions for merrymaking, and many festivals surrounded rites of initiation. In Africa and the Americas, for example, numerous rituals were associated with the achieving of manhood, and a boy's rites of initiation could be a time of festivity. Similarly, the arrival of puberty for a young girl, when she became eligible for marriage and able to bear children, was surrounded by festivity. In parts of Africa the circumcision of a boy or a girl was a time of feasting and celebration. Even death could be an occasion for festivities, as people celebrated the passage of a person to a life beyond this one.

## AFRICA

BY AMY HACKNEY BLACKWELL

People throughout Africa celebrated festivals to mark rites of passage in peoples' lives. Births, deaths, weddings, and coming-of-age ceremonies all were occasions for music, dancing, feasting, and dressing up. Harvest festivals also were common as people celebrated the fact that they would be able to eat during the coming year. People who lived by hunting held festivals to mark successful hunts. There were also many religious festivals, including ones with Christian, Muslim, and indigenous rites.

Most African festivals featured dancing and drumming. People of all ages participated in the dancing. Traditional African dances told stories or had ritual significance, such as dances by warriors that showed their bravery and strength. Dances were also an occasion for people to show off to one another. Young people might dance to attract the opposite sex. Dancers often wore masks that represented particular animal spirits. The Dogon people of Mali were especially famous for their masks, which they started making during the early medieval period.

Many African festivals centered on age sets, groupings of people within a certain age range. At festivals people would sit and dance with their own age set. Age sets determined who could do what during festival events and afterward. Among the peoples of Uganda, for example, the elders might arrange rituals, set schedules, and find people to donate animals for feasts. The young men would prepare the site for the festival, clearing away branches, setting up seats for the elders, and cooking the meat. Groups would be served by age set, from the oldest to the youngest, and within the age sets the oldest members would be served first.

The members of the Ethiopian Orthodox Church held beliefs that were unique in Christianity and celebrated unique festivals. Ethiopian religious festivals were scheduled according to the Ethiopian calendar, which was based on the Coptic calendar and was slightly different from the Julian calendar then in use in Europe. This meant that even those Christian festivals commonly observed in Europe fell on different dates in Ethiopia. The Ethiopian New Year, for example, was celebrated in September rather than January, and Christmas fell in January instead of December.

At the end of September they celebrated Maskal, a festival marking the finding of the True Cross (the cross upon

which Christ was crucified), by lighting bonfires and dancing around them. In January they celebrated Timkat, the Ethiopian Orthodox version of Epiphany, commemorating the baptism of Christ. This festival included feasting, music, bathing in lakes or rivers, and religious processions carrying replicas of the Ark of the Covenant, said to have held the stone tablets of the Ten Commandments. Easter and Christmas were other important holidays.

Saints' festivals were important to Ethiopians. New Year celebrations were combined with the feast of John the Baptist. At the end of December, Ethiopians celebrated the feast of Saint Gabriel, guardian of homes and churches, by joining pilgrimages. They carried burdens to symbolize Christ's suffering and gave alms to the poor.

The fertility of humans and the land was a common reason to hold festivals. In Nigeria the Yoruba people held a festival called Gelede that celebrated motherhood and womanhood. This festival occurred during the spring rains, a time when the earth's bounty seemed assured for the coming year. In Yoruba mythology people originally lived in a matriarchal society that transformed into a patriarchal society, and the Gelede festival paid homage to mothers as female elders. The people would perform rituals to honor women's work and fertility and would dance wearing animal masks, sing, and play music.

Harvest festivals abounded in medieval Africa. Agriculture was always a chancy way of life, and a good harvest meant that the people could eat for another year. To show their appreciation to the gods and spirits who made the harvest possible, they celebrated with ritual dances and songs that thanked the spirits and ancestors for their help. The Ga people began holding a harvest festival known as Homowo sometime during the medieval period. The name Homowo means "making fun of hunger." The festival arose after a long drought had caused a deadly famine in the region; when the rains returned and the people could once again harvest crops, they invented a festival that mocked hunger with feasting and music. The festival took place in the late summer, around the time when the people harvested yams, the earliest crop and their primary source of sustenance. The people would offer yams to their ancestors and local gods, accompanied by dancing and singing. All people would return to their parents' homes to mourn that year's deaths, celebrate that year's births, eat special foods, and dance in the streets. Festivals were also an opportunity to address problems. If something had gone wrong that year, such as illness among the livestock or lack of rain, the people conducted rituals to attempt to solve the problem for the next year.

Herders celebrated their own festivals around the events of the year. In Mali every winter the herders congregated on

### THE FESTIVAL OF MASKAL

The religious basis of the festival Maskal was distinct to Ethiopia. According to legend, in 326 Helena (ca. 248–ca. 328), the mother of the Roman emperor Constantine I (r. 306–337), was looking for the cross upon which Jesus was crucified. She prayed for help and was told to set a bonfire in Jerusalem. She erected a large pile of wood, added frankincense to it, and set it afire. A stream of incense smoke directed her to the spot where the cross was hidden. Centuries later, during the 1400s, the patriarch of Alexandria, Egypt, gave an Ethiopian emperor half of the True Cross. This piece of the cross was placed in the Gishen Marien monastery on Mount Amba. The festival of Maskal evolved out of this story. The bonfires people burned symbolized the fire that Helen had burned to find the cross. Ethiopians added flowers to the pile to decorate it. Because the fire was holy, they would collect pieces of the charcoal left over once the fire finished burning and use this to draw crosses on their foreheads. According to church tradition the True Cross was found in March, but the Ethiopians moved the festival to September to avoid a conflict with Lent.

the banks of a river, meeting with family and friends before heading off to pasture again. Young men and women could meet one another, and the herders held cattle competitions, awarding prizes for the fattest animals. Cattle figured prominently in the festivals of the Masai. Cattle were ritually slaughtered for all major life-stage rituals, including birth, circumcision, marriage, and death. The elders blessed the meat, and the village consumed the meat together. The festivals to initiate young male warriors into adulthood included the ritual consumption of milk and meat.

Festivals celebrating circumcision were common throughout Africa. In Mali, for example, all boys were circumcised between the ages of nine and 12. Once they were healed, they reentered their villages playing musical instruments. Their families and neighbors greeted them with gifts. The new men remained naked for a month so that everyone could see their new status. Female circumcision was also an occasion for festivals. In Kenya girls might be circumcised in a group. Immediately after the operation they would join the guests who had assembled for the event. Among the Masai girls were married to older men on the same day as their circumcision.

African people had other festivals of initiation for men entering new stages of adulthood. The Fulani people of Nigeria conducted a festival in which bare-chested young men beat one another with whips to show their courage. Among

the Masai young men became true adults after 10 years as warriors. For the initiation their mothers would shave the heads of the young men, who then performed various acts of fasting and tests of courage. When the initiation was complete, the village celebrated with music, dancing, and feasting. The newly initiated men were then allowed to marry and become fathers.

Among the small-statured peoples of central Africa, such as the Mbuti, a girl's entering puberty was cause for a celebration known as the Elima festival. When a girl began to menstruate, she entered a special hut, the *elima* hut, and spent a month there with the other women and girls. The women taught the girl ritual dances and took her on forays into the forest to conduct rituals there. The girls made secret trips to bachelor camps to introduce themselves to the young men. The Elima ended gradually and informally, with the girl now assuming adult responsibilities and being recognized as a marriageable woman. The people also celebrated a festival called Molimo in which they invoked the power of a benevolent forest deity to help them in times of suffering, such as a period of bad hunting, illness, or death. During this festival the men sat together and sang all night long every night for a month.

Some African societies celebrated festivals to help young men and women meet one another. In Benin the harvest festival included rituals in which eligible young men and women were displayed to one another and their families in a sort of matchmaking ceremony. The young women wore no clothing, in order to display their beauty, but they did wear jewelry and elaborate hairstyles to showcase their wealth. The young men participated in feats of strength such as tug-of-war. Both sexes painted their bodies.

The hunter-gatherers of the Kalahari Desert did not have formal festivals in the way some other African peoples did. They did, however, occasionally have cause for celebration. If a man killed a large animal such as an ostrich, he would share the meat with a group of relatives. The cutting up and distribution of this meat was one of the more important social occasions for these hunter-gatherers. Because meat was a relative rarity in their diets, people might celebrate by making much of the hunter, dancing and singing around him to praise him. These people also held festivals to mark the advent of puberty in boys and girls. When a boy reached maturity, marked by the first time he killed a large animal, all the men would cook and eat the meat together, out of sight of the women. The boy's father would then cut lines in the boy's forehead to make decorative scars. When a girl reached puberty, she spent the duration of her first period in a special area, and the women and old men of her group would sing and dance around her every day.

Many African peoples held festivals during funerals. In indigenous religions dead ancestors remained an active spiritual presence among the living, so the living honored the newly deceased with elaborate rituals. In Ghana families would bankrupt themselves to hold extensive funerals with decorative coffins and days of feasting. In Nigeria villages would perform dances to drums and singing.

## THE AMERICAS

BY PENNY C. MORRILL

Through festivals and performance, shamanic lords and their followers attempted to transcend the present for another time and reality. Such transcendence was also represented in configurations of space or urban plans, architecture, tombs, sculpted reliefs, mural cycles, ceramics, jewelry, costumes, and masks in the Andes and throughout the Americas.

At Tiwanaku on the northern coast of Peru during the period 400 to 800, the sacred precinct was built of stone and encircled by a shallow moat. This site combines platforms and sunken temples on a grand scale that would have allowed for large gatherings. Access to the sunken court at the top of the 600-foot-high Akapana platform was restricted to the shamanic priest-ruler and his attendants. When it rained, water flowed from the top of Akapana down the sides of the platform, replicating the flow of rainwater from the surrounding mountains. This offered a setting in which the priest, in the transcendent guise of a puma, could reveal to his audience his power to provide much-needed rainfall.

Portals at Tiwanaku directed the crowd into the sacred precinct. Carved in relief on the main entrance, the Sun Gate, the priest-ruler stands in the center above the entrance, facing frontally and holding two staffs of office. He is surrounded by smaller images in profile and in lower relief. These figures, with their shamanic costumes and masks, were possibly the priest-attendants who participated in the ceremony in trance-like transcendent flight. One can only imagine the dramatic procession of shamanic priests, dressed as birds and pumas, entering through this portal into the sacred space where the audience awaited them.

The Mississippian communities were chiefdoms that flourished from 700 to 1400 at the crossroads of riverine trade routes. Religious structures in the form of large earthen mounds appear along the banks of rivers from the Atlantic to Arkansas and Oklahoma. Cahokia, a walled city encompassing 5 square miles near present-day Collinsville, Illinois, contained 120 pyramids and mounds. These large-scale structures and open plazas are thought to have provided the ruler with a dramatic setting in which to stage festivals that combined religion and trade.

In central Mexico, Teotihuacán's ceremonial Way of the Dead was the site of religious festivals that probably involved hundreds, even thousands, of participants. At the northern end the Moon Pyramid stands as a replica of the Cerro Gordo, the sacred mountain. The Pyramid of the Sun, built over a cave and springs, marks the center of the world and the locus of creation.

Priests wearing elaborate feather headdresses and rain-god masks are represented in procession in several murals throughout the city. Jaguars are depicted covered in netting, perhaps indicating how they were led along the Way of the Dead. The most significant figure is the Great Goddess, who pours forth from her outstretched hands the gifts of rain and green vegetation. This costumed figure, with her elaborate owl headdress and richly detailed costume, must have been one of the most spectacular participants in the religious ceremonies.

The Teotihuacán government probably carried the expense for the monumental architecture and elaborate costuming, as suggested by the layout of the Ciudadela at the southern end of the Way of the Dead. This large sunken court, featuring the platform Temple of Quetzalcoatl, may have been a large administrative palace complex. Historians speculate that the ruler of Teotihuacán was controlling the vast trade that was coming in and out of the city. Under those circumstances, it would have been most propitious to link market activity with religious ceremony.

The contemporaneous Zapotec site of Monte Albán in Oaxaca (200–650 C.E.) resembles that of Teotihuacán in some aspects but was, in actuality, a different kind of urban center. The architecture replicates its setting, as does the Moon Pyramid at Teotihuacán. The central plaza, surrounded by pyramids and platforms, is a direct reference to the valley of Oaxaca, ringed by mountains.

Unlike Teotihuacán, which was a city of more than 125,000 inhabitants, Monte Albán was the ceremonial gathering place for the people who resided in the valley below and who owed allegiance to the Zapotec ruler. Within palace compounds on the mountaintop at Monte Albán, Zapotec rulers were buried in tombs that were carved out of bedrock, ornamented with mural paintings and sculpture, and filled with offerings.

In Tomb 103 were found a group of ceramic figures elaborately costumed in bird masks and headdresses. They are accompanied by a seated old man and a group of musicians who do not wear costumes. In the center of the group is a carved mask set on a platform, probably an effigy. This scene suggests that the Zapotec ruler and the elite gained legitimacy through their direct connection to the ancestors who had preceded them in positions of power. Mural paintings in Tombs 104 and 105 indicate ceremonial processions related to an ancestor cult.

The worship of ancestors continued among the Mixtec and Zapotec in Oaxaca. After the Spanish conquest a priest discovered several corpses, lavishly dressed and draped with jewels, propped inside a mountain cave. The priest identified some of these as recently deceased local rulers. At Monte Albán, the elaborate costumes worn by male and female figures depicted in ceramic funerary urns and mural paintings imply a costly ceremony that would have taken place in the large plaza before a public audience. However, the actual entry into the tombs was considered a passage into another cosmic realm, a privilege enjoyed only by the elite—the ruler and priests.

The walls of the Zapotec Tomb 5 at Suchilquitongo, Oaxaca (ca. 500), are covered with mural paintings depicting costumed figures in procession, including a group of ballplayers. On the coast of the Gulf of Mexico at Las Higueras, Veracruz (600–800), various ceremonial processions and ritual scenes, some related to the ball game, are represented in mural paintings. At the site of El Tajín (800–1200) are 17 ball courts and carved stone reliefs depicting ballplayer sacrifice. Numerous images of the ballplayers and the ball game appear among the Mayan Jaina figurines, on Mayan vases, and in western Mexican ceramics. Ball courts occur in sacred precincts at Monte Albán, Copán, and Xochicalco.

The ball game was more than a spectator sport. In the scene carved on the wall of the largest ball court in Mesoamerica at Chichén Itzá (900–1200), snakes emerge from the neck of the decapitated ballplayer, along with a flowering vine. It is thought that players impersonated characters from a myth.

In most cases, the display and dispatching of captives took place before an audience. In northern Peru these sacrificial rituals were depicted on Moche pottery and revealed in the tombs at Sipán (ca. 300 C.E.). In Tomb 1, the priest-ruler who accepted the goblet of blood from the sacrifice was buried in extraordinary opulence.

An elaborate and full-scale depiction of an accession ceremony that includes a powerful image of ritual human sacrifice occurs in the mural cycle at the Mayan site of Bonampak (700–900). All activity revolves around the legitimization of the newborn heir to the throne. Days before the presentation ceremony the ruler participates in a successful battle for captives. In preparation for the event, musicians and dancers don wildly imaginative costumes. Dignitaries are assisted as they put on their headdresses and massive frames of feathers resembling wings. The family meets privately in a room to perform a bloodletting ritual. The baby is held up before the elite and presented to the crowd gathered below. At the dramatic moment on the steps of the pyramid, the captives are tortured and killed by decapitation or heart excision.

Ceremony the Americas is the dramatic metaphor for a vision of the cosmos that drew parallels among celestial, earthly, and human cycles. Priestly rulers attempted to control cosmic chaos through human intercession outside the bounds of time and place. The costumes they wore made them living symbols, and their architecture interpreted the movement of heavenly bodies.

## ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Medieval Asians celebrated a huge assortment of festivals. Festivals marked the new year, planting time, spring, summer, fall, and the harvest. Most festivals had religious significance and evolved out of peoples' wish to ensure good fortunes for themselves and their families. Each festival had unique traditions, but most were occasions for feasting, dressing up, dancing, singing, and visiting family.

Many Asian festivals had their beginnings in China. Most Chinese festivals originated during the Qin Dynasty in the third century B.C.E. During the Tang Dynasty (618–907 C.E.) these festivals had more or less taken the shape that they maintained for the next millennium. The Spring Festival, or Chinese New Year, took place on the first day of the first lunar month of the year, although festivities spread for several weeks on either side of that date. Chinese people journeyed back to their families' homes to make sacrifices to their ancestors. There they cleaned their houses from bottom to top, decorated their houses with poems celebrating the New Year, washed all clothes and bedding, made or bought new clothing, and acquired ample supplies for a feast. On New Year's Eve families ate together and stayed up late. The next day they dressed up, gave gifts to the children, ate special cakes or dumplings, and set off fireworks. Entire towns would dance in the streets.

On the 15th day of the first lunar month people celebrated the Lantern Festival, originally a religious festival to honor Buddha. People hung lanterns in the streets, set off fireworks, danced in the streets, and asked one another riddles. The Qingming Festival in early April celebrated the time for spring plowing and commemorated the deaths of ancestors. People visited cemeteries to clean the graves of their family members, burned incense, and flew kites. During the fifth month Chinese people commemorated the death of the poet Qu Yuan (ca. 340–278 B.C.E.) by holding the Dragon Boat Festival, at which they raced dragon-shaped canoes, ate rice dumplings, and drank wine.

In midsummer, the seventh day of the seventh month, Chinese people celebrated the Double Seventh Festival. This was a romantic festival commemorating the union of two

star-crossed mythical lovers, Niu Lang and Zhi Nu, who were symbolized by two bright stars that appeared in the sky at that time of year. The Mid-Autumn Festival fell in the middle of the eighth month. Chinese people celebrated the full moon by eating moon cakes and holding feasts to celebrate the harvest. On the ninth day of the ninth month people celebrated the Double Ninth Festival. On this day people climbed a mountain or a tower to prevent illness. They also ate special cakes decorated with chrysanthemum blooms and drank chrysanthemum wine. On the Winter Solstice, the shortest day of the year (December 22 or 23), everyone took the day off and offered sacrifices to their ancestors. People ate red beans and sticky rice dumplings to drive away devils. They also made rice cakes in the shapes of lucky animals, such as chickens, ducks, sheep, cows, pigs, or tortoises.

Chinese festival traditions spread throughout Southeast Asia and to Taiwan. The New Year was a particularly important festival throughout the region. In Vietnam the New Year was called Tet. People spent months preparing for it and days traveling home to visit their families for the holiday. There were regional festivals as well. In Korea, for example, people celebrated Daeboreum on the first full moon of the new year; they marked the festival by cracking nuts with their teeth and climbing mountains to see the moon rise.

In Japan people celebrated many festivals, called *matsuri*. Many *matsuri* were strictly local, restricted to a town, village, or even just a neighborhood. The festivals were centered on local Shinto shrines or Buddhist temples. During a local *matsuri* the people of the town or neighborhood might

*kami*. In other festivals local people would dress up in costumes and perform ritual dances. All local *matsuri* concluded with feasting and drinking sake.

Some *matsuris* were very large. The Gion Matsuri in Kyoto originated in 869 as a response to an outbreak of plague. It was decreed an annual festival in 970. Kyoto's Aoi Matsuri originated during the Heian Period (737–1185). During this *matsuri* members of the royal family made a pilgrimage to two major shrines in the city and watched competitions of sword fighting and archery.

Japanese people held large-scale festivals on particular dates. During the medieval period they celebrated the New Year on the date of the Chinese New Year. This was a time to clean houses, pay off debts, and eat special lucky foods that were prepared only for the New Year. People visited temples or shrines, and the emperor performed an annual ritual to bring good luck for the coming year. In March, Japanese people celebrated the Hinamatsuri, or girls' doll festival, which had originated during the Heian Period. For the Hinamatsuri girls dressed up, visited friends, and admired their collections of dolls representing the emperor's court. Boys' Day, or Kodomo no hi, marked the beginning of summer. Boys celebrated by flying flags shaped like carp. During the cherry blossom season people all over Japan held flower-viewing parties called *hanami*. They ate picnics under the falling cherry petals and wrote poems about the beautiful flowers. O-bon was a summer festival during which Buddhists prepared to welcome home the spirits of their dead ancestors. On November 15 Japanese nobles celebrated Shichi-go-san, or Seven-five-three, a festival to celebrate the health of three- and seven-year-old girls and three- and five-year-old boys.

Thousands of different festivals were celebrated in India. The New Year was celebrated throughout India, although it fell at different times throughout the subcontinent, depending on which calendar a region used. The Hindu and Muslim calendars were different. In the Deccan region people called the New Year Ugadi and celebrated the event by visiting family and feasting. They ate foods that blended the six tastes (bitter, sweet, salty, sour, spicy, and astringent) to symbolize the mix of fortunes in life and listened to predictions for the coming year.

Diwali, the festival of lights, was celebrated at the end of the Hindu month of Ashwayuja in mid-autumn. It lasted five days. Diwali commemorated the killing of demons by Hindu deities, the triumph of good over evil, and the continuity of life. People celebrated by bathing in the Ganges, wearing new clothes, eating sweets, setting off fireworks, and lighting millions of lamps and candles.

Holi was a Hindu spring festival that took place in February or March. People lit bonfires at night and threw

Stone sculpture of Durga Mahishasuramardini, Orissa, eastern India, 13th century; the sculpture depicts Durga defeating the buffalo-demon Mahisha, an event celebrated each year in Bengal at the festival of Durgapuja. (© The Trustees of the British Museum)

colored powder at one another during the day. The colored powder symbolized medicines used against disease. The festival of Vijayadashami was another occasion to celebrate the victory of good over evil. In southern India this festival celebrated the victory of the goddess Durga over a demon. In northern India it celebrated the god Rama's rescue of his wife, Sita Devi, after her abduction by a former suitor. In both regions this festival was the conclusion of nine days of festivities in honor of the goddesses. In much of India people celebrated a harvest festival. These festivals were an occasion to eat sweet foods, wear new clothes, and watch cockfights.

Australian Aborigines held festivals that came to be known as corroborees by European settlers long after the medieval period. These events were held when different groups

of people encountered one another. They played music with rattles, sticks, boomerangs, and didgeridoos. They also performed traditional dances that told the stories of hunts or battles or imitated the movements of animals.

The people of the Pacific islands had their own festivals. Polynesian people's festival traditions shared some similarities with one another because of their common origin in Asia, but during the medieval period islanders were isolated enough that their traditions took on unique qualities. Every island had its own forms of dance and music. Dance was very important to island festivals, and most island people used dance to celebrate their warrior cultures. In New Zealand the Maori men and women would perform the terrifying *haka* dance at festivals, dancing in a military formation, wielding spears, and showing off their tattoos. In Tahiti people held a festival to honor the god Maui. In Samoa and other islands drummers played a crucial role in keeping festivals moving. During festivals island people danced, played traditional sports such as canoe racing, decorated their homes and themselves with flowers, and prepared and ate huge amounts of food.

## EUROPE

BY MICHAEL J. O'NEAL

Medieval Europeans celebrated numerous festivals, and many holiday traditions in the modern world represent vestiges of medieval European traditions. Likewise, some festivals and traditions of the Middle Ages had persisted from the ancient Roman Empire or from local practices. Most festivals marked religious events, both Christian and pagan, but their importance to medieval Europeans was not only in their religiosity but also as opportunities for communities to come together to celebrate important milestones throughout the year, including the arrival of spring and planting time, the autumn harvest, and the winter solstice.

Two good examples of festivals with pagan origins were the Festival of the Madman, which carried on the ancient Roman festival of Saturnalia, and the Feast of the Ass. The chief characteristic of the Festival of the Madman, celebrated either on Christmas Day or on the feast of the Epiphany, was that for one day servants played the role of masters and masters played the role of servants, thus turning the social order upside down. Similarly, the Feast of the Ass was typically held on Christmas Eve. To commemorate the story of the birth of Christ, a young girl, playing the part of Christ's mother, Mary, rode into the church on a donkey, or ass. Churchgoers ended each prayer during the Mass with a "hee-haw." Church authorities, however, frowned on this celebration, which they considered sacrilegious.

More serious were the many other festivals associated with Christmas. In the early Middle Ages, Christmas was a quiet holiday, a time for sober reflection and prayer. In different regions of Christian Europe, Christmas was celebrated on different dates, sometimes in April or May, until 350 when Pope Julius I fixed the date as December 25. But Christmas was not celebrated with as much enthusiasm as was the Feast of the Epiphany, or Twelfth Night, which came 12 days after Christmas. Although some people considered it the day Christ was baptized, most people believed that Epiphany is when the three wise men delivered gifts to the infant Jesus. Thus the Feast of the Epiphany became the time for gift giving.

Some medieval Christmas holiday traditions survived from earlier pagan rituals. One good example is the Yule log, which evolved from the Druid tradition of blessing a log and burning it for 12 days during the winter solstice. The Vikings of Scandinavia also burned Yule logs on which they had carved inscriptions representing unwanted character traits; once the logs burned, the gods would take those traits away, and the people would be free of them. The burning of the Yule log was an important feature of the Scandinavian Julfest, a celebration of the winter solstice.

The modern Christmas tree is also a legacy from medieval festival practices, which themselves reflected ancient Roman beliefs. Because it retains its foliage throughout the year, the evergreen tree was held in high regard by the Romans and was often used in festival processions as a symbol of eternal life. Similarly, the Druids believed that holly and mistletoe are sources of good luck because they contain helpful spirits. Christians came to believe that the holly berry's change from white to red symbolizes the blood from Christ's crown of thorns when he was crucified. The use of ivy in Christian churches emerged when it was believed that ivy provides protection against witches and plagues. An important part of Christmas festivities that emerged during the Middle Ages was the performance of Christian liturgical dramas, particularly those representing the Nativity—a practice that survives in Nativity scenes on the grounds of modern-day Christian churches.

Other Christmas traditions dating back to medieval Europe include wassail, a usually alcoholic beverage served warm in a large bowl; the name comes from the Old English words *waes hael*, meaning "be hale" or "good health." Another traditional Christmas treat is mince pie. A medieval Christmas custom was to bake small mince pies in oblong baking pans. The pans represented Jesus's crib, and the three spices added to the pie—cinnamon, cloves, and nutmeg—represented the gifts of the three wise men. Eating a mince pie on each of the 12 days of Christmas, up to the Feast of the Epiphany, was thought to bring good luck. The modern phrase "eat humble pie" came from the Christmas tradition

of poor people and servants eating the “humbles” of a deer—the heart, brains, and liver—while wealthier people ate the choicer cuts of meat.

The arrival of spring represents a rebirth of the world, and in medieval Europe spring and summer were occasions for numerous festivals. One was Easter, which originated in pagan traditions of fertility and birth. The Easter egg symbolized the creation of the world, which many people believed emerged from an egg, and the Easter bunny reflects pagan notions of fertility and procreation. The Christian Church transformed these traditions into the celebration of Christ’s resurrection, or rebirth, on Easter Sunday.

Festivals surrounding the maypole and the first day of May likewise had their origins in pagan beliefs. The Saxons and Celts celebrated the first of May as Beltane, the day of fire; Bel was the Celtic god of the sun. In time it became common to celebrate the first of May as the end of the winter cold, and the date became associated with numerous planting festivals as well as festivals related to hunting and fertility. Europeans transformed the ancient Roman goddess Diana, the goddess of the hunt, into the Queen of the May; and Robin Goodfellow, who evolved into the legend of Robin Hood, was an adaptation of the English horned god Herne. Robin Goodfellow was the Lord of Misrule and made the nobility the butt of numerous jokes. Eventually the Queen of the May was associated with fertility of the fields, and Robin Goodfellow presided over the woods and forests.

Later in the medieval period trade guilds elected an eligible young woman as Queen of the May, who was thought to rule over the harvest. Out of this medieval tradition emerged modern beauty pageants as well as the tradition in many communities of electing a queen to preside over a festival associated with that community’s important crops. A common practice in medieval European communities was the raising of a maypole, a symbol of male fertility. Young men and women gathered to dance around the maypole, where courting rituals took place. The Christian Church frowned on these rituals, so the Queen of the May evolved into a celebration surrounding Mary, the mother of Christ, who was honored with processions and flowers.

In some areas of central and northern Europe people celebrated the eve of May 1 as Walpurgisnacht, or the night of the witches. A common ritual associated with Walpurgisnacht was the lighting of huge bonfires on the night of April 30. The event was the occasion of much revelry and drinking, feasts, pranks, and rowdy behavior—a celebration of release from the confinement of winter.

Equal in importance to the arrival of spring in the colder climates of Europe was autumn and the harvesting of crops. Many of the traditions of Halloween derive from medieval

autumnal festivals. Halloween has its origins in the ancient Celtic festival of Samhain. Samhain, or the Feast of the Dead, marked the end of autumn and the beginning of winter. Many ancient Celtic communities depended on herding for their living. As winter approached, they would move their herds down from their summer pastures on higher ground, and families would begin to huddle in their homes to work on handicrafts. It was also thought to be a time when fairies were especially active.

With the arrival of Christianity in the late ancient and early medieval periods the festival of Samhain evolved. It retained its origin as the Feast of the Dead but was celebrated by Christians as All Souls’ Day on November 2. Meanwhile Halloween, or Hallow E’en, was the night before the Christian feast of All Saints on November 1. The Celtic fairies were transformed into angels who wandered about the streets.

*Pilgrim badge of Saint George and the dragon (ca. 1400s); the cult of Saint George, with its associated festival day, gained popularity in England from 1098, when he was said to have appeared in the sky during the battle of Antioch in the First Crusade, causing the enemy to flee. (© Museum of London)*

Later in the medieval period people began to imitate the angels, wandering from house to house demanding treats and performing practical jokes, or “tricks,” on anyone who refused. Additionally, many of these people carried turnips carved to represent faces, the origin of the modern practice of carving Halloween pumpkins. Many modern Halloween traditions came to the United States in the 19th century with Irish immigrants who preserved the traditions in their folk beliefs.

In addition to celebrating the major festivals, medieval Europeans held festivities throughout the year whenever they believed there was something to celebrate. In February, Saint Valentine’s Day was marked by dancing, singing, and courtship rituals. People in the British Isles relived the legend of Saint George and the dragon on Saint George’s Day on April 23, and Midsummer Eve was celebrated in June with bonfires. Bones were burned in many of these fires, hence the word *bonfire*. August 1 was Lammass Day, or “loaf-mass” day, when Britons celebrated the first wheat harvest of the year by decorating their homes with garlands, holding candle-lit processions, and bobbing for apples. In September, Michaelmas Day, or the Feast of Saint Michael, was celebrated with feasting; the traditional food became a chicken or goose. Any of these festivals could feature mummies, tumblers, jugglers, jesters, troubadours, minstrels, acting troupes, bull or bear baiting, fairs, and other forms of entertainment.

## THE ISLAMIC WORLD

BY BABAK RAHIMI

The emergence of Islam in the Arabian Peninsula in the early seventh century introduced a body of religious festivals along with a new Islamic calendar, which began with the year Muhammad (ca. 570–632 C.E.) and his followers left the Saudi Arabian town of Mecca to form a new Muslim community in 622. The journey was called the Hegira, and the new calendar began with Year 1 A.H. (After Hegira). Most of these festivals took place to celebrate either a historical event of sacred importance or the end of a ritual performance, such as the month-long fast of Ramadan, which was divinely prescribed for the new Muslim community. During the pre-Islamic era of the Arabian Peninsula religious festivals were carried out to celebrate the birth of various gods, including Allah, the ancient god of the rain and sky who represented the supreme god of pre-Islamic Arabs. The rise of Islam as a new religious movement, however, brought to existence festivals that were chiefly meant to celebrate the accomplishment of pious deeds carried out by the new converts to show God their devotion and faith.

Since Islam recognizes correct conduct as the means to a good life in both this world and the afterlife, most Muslim festivities are performed to celebrate the accomplishment of pious actions through hardship and perseverance. However, Islamic festivals have mostly gained sacred significance not by their importance according to the Koranic laws but because of their popular appeal. Most of the Islamic festivities are collective events that allow the entire community, including the poor, women, and non-Muslims, to participate in the ceremonies. They offer an opportunity for Muslims to spend a festive time with their family and neighbors and to foster a sense of religious identity.

In the medieval period Muslim communities participated in religious festivals in various parts of the Umayyad Empire (661–750) and the Abbasid Empire (749–1258), regions spanning North Africa, the Middle East, and parts of central Asia. These religious festivals were organized primarily by Muslim governments to strengthen the religious identity of the Islamic empire, bringing together people of various ethnic and racial backgrounds. They also became unique cultural events where Muslims of various cults and sects, especially Shiite and Sunni, competed with one another for moral prestige and religious legitimacy.

According to Islamic law (sharia), one of the most significant ritual obligations for Muslims is to fast during the month of Ramadan, the ninth month in the Muslim lunar calendar. Excluding the young and ill and those who travel, Muslims are expected to refrain from eating, drinking, and sexual intercourse each day from sunrise to sunset. Although business can be conducted in the course of the day, the community is required to follow through the pious conduct of fasting as a way to worship God while the sun is out. The night, however, offers an opportunity for celebration, as those who fast the entire day are able to rejoice and feast at sunset for accomplishing a day of self-restraint through pious conduct.

The most important day of festivities begins at the end of Ramadan with the last sighting of the moon at the end of the month, on the first day of the month of Shawwal, marking the final day of fasting. After a light meal and a morning prayer the community begins a gluttonous celebration, a holiday that lasts from morning to night. On this holiday, known as the Id ul-Fitr or “festival of the breaking of the fast,” Muslims are also required to pay their annual religious alms as an expression of their piety and festive sharing that strengthens social solidarity. They also wear their best clothes, visit family and neighbors, and go to cemeteries.

The Id ul-Fitr represented the most communal of all the Muslim ceremonies. It was the most popular in medieval times because of the unique opportunity it provided for the common people, including non-Muslims, to celebrate a holi-

day that brought local people together. Although the type of festive activities performed on this holiday differed from one region to another, medieval Islamic communities celebrated this festival as a way to continue a religious tradition that was first celebrated by Muhammad and his companions in 624 in the town of Medina in Saudi Arabia, where Muhammad had traveled to create the first Muslim community.

According to the Koran, God required Abraham to sacrifice his son as a sign of his submission to God who existed beyond the world. When God offered a ram in place of the child as a sacrifice, Abraham was able to recognize the divinely ordained trial as a sign of God and to reaffirm his faith through the act of animal sacrifice as an expression of human ability to submit to God's will. This Koranic story has served as one of the most important sacred narratives to remind Muslims to celebrate an ideal act of devotion to God in recognizing his total authority and control over life.

During the four days of *Id ul-Adha*, which means "sacrificial festival" and begins on the 10th day of the month of *Dhul-Hijja* of the lunar calendar, communal festivities center on the ritual of animal sacrifice and the festive consumption of the animal's meat, which is believed to embody bliss. From the Umayyad to Abbasid rule and continuing into the Ilkhanid (1256–1353) and Timurid (1370–1506) periods, the provincial rulers organized feasts in various provinces that involved the slaughter of two types of domestic animals, mainly goats and sheep. But in the most festive display of the ceremonies in major urban places, such as Baghdad, the capital of the Abbasid Empire, camels were used as a sacrificial animal. The sacrifice and consumption of camel was important mostly because of the belief that the animal embodied a sacred spirit, which Muhammad first recognized when he followed a camel to choose a spot for the first Muslim mosque in a village outside the town of Medina in 622.

Although the most important Muslim festivities were built around certain ritual obligations, such as fasting or sacrifice, the *Mawlid*, or birthday and death day of Muhammad (occurring on the same day, June 8), is celebrated with great care and importance. The day marks an occasion when the faithful can express their devotion to the messenger of God. Under the Umayyads, when the Islamic empire was ruled under the nondescendants of Muhammad, the *Mawlid* was secondary to other holidays, such as *Id ul-Fitr* or *Id ul-Adha*. Under Abbasid rule, however, the festivities gained greater importance as Abbasid caliphs (leaders), who originally claimed family linkage to Muhammad, used the celebrations to legitimize their political power.

The term *mawlid* also applies to other festivities organized for the birthday of local saints and Sufi mystics who were revered by many Muslims, Christians, and Jews in

North Africa, particularly Morocco, and parts of the Middle East, especially Lebanon and Syria. These celebrations usually took place at the tomb of the saint, which many of the saint's devotees visited as an act of pilgrimage.

The first day of the month of Muharram is the beginning of the Islamic lunar calendar. For this occasion some Sunni Muslims, especially in Morocco, mark the day by organizing a special feast, performing music, and visiting the local cemetery to honor the dead. Shiite Muslims, however, recognize the first 10 days of the month as a period of mourning for the martyrdom of the grandson of Muhammad, Husayn (ca. 629–80), by the caliph Yazid I (r. 680–83) at the battle of Karbala in central Iraq.

During the first 10 days of Muharram, Shiite mourners perform a number of lamentation rituals, including poetic recitation, chest beating, and self-lamentation, which symbolically display the devotees' allegiance to the martyred grandson of Muhammad. On the 10th day of Muharram, known as *Ashura*, Shiite devotees congregate to exhibit the most passionate and bloody ceremonies of Islamic festivals, commemorating the beheading of Husayn by Yazid's army through various sorrowful rituals.

The early Shiite Muharram performers displayed these mourning ceremonies as a way to distinguish themselves from the majority Sunni communities. However, under the Sunni rule of al-Qaidr (991–1031) Muharram rituals were also organized by Sunnis to rival the Shiite ceremonies. In the 12th century, when Shiism and the cults of saints continued to spread in the Mesopotamia and the Plateau of Iran, Muharram festivals were observed by many Sunnis, performed even in the zealot Sunni city of Hamadan in western Iran. The rituals became increasingly violent with the rise of the Sufi brotherhood movements in the Islamic world from the 13th to the 14th centuries. In his famous journals, the Moroccan traveler Ibn Battuta (1304–68 or 69) describes a Sufi brotherhood in Anatolia that celebrated the Muharram ceremonies through acts of self-mutilation by knife and sword. These violent ceremonies were meant to signify a state of trance, which was said to enable the ritual participants to have access to a supernatural world through passionate lamentation for the martyred saint.

These forms of lamentation ceremonies also took place on the 40th day after *Ashura*, known as *Arbain*, when Shiites marked another grand occasion to mourn the martyrdom of Husayn. The most significant feature of *Arbain* festivals is the pilgrimage ceremony to the burial place of Husayn in Karbala, a tradition that came into practice under the Umayyad rule in the late seventh century. Both the Muharram and *Arbain* festivals became hugely popular in Iran in the 16th century when the Safavids (1501–1732) declared Shia the official religion of the state.

## ► food and diet

### INTRODUCTION

The food and diet of medieval peoples can be viewed as the fuel for the rise of empires. It can also be seen as the stuff that most concerned ordinary people during their lives. Happiness and unhappiness often depended more on the availability of food than on religion, good governments, and victory in war. Indeed, starving a population was a tactic of war, and any government that neglected the dietary needs of its people risked violent termination.

The earliest foodstuffs were wild plants and wild animals, and the earliest humans were almost certainly hunter-gatherers. Hunter-gatherers figured out what was good to eat and what was not good to eat, and there is no telling how many possibly starving people tried poisonous foods, discovering for their survivors which mushrooms or fruits would kill them. There were many hunter-gatherer societies during the medieval era, and to many of the people of agricultural societies, these hunter-gatherers seemed to be wandering the landscape, occasionally happening upon something to eat. In fact, hunter-gatherers, whether in central Africa, Argentina's grasslands, or the middle of Australia, were people who rarely set out not knowing where they were going or what they were

looking for. With the exception of islands in the Pacific, they had lived for thousands of years on their lands and knew what there was to eat at different times of the year and where to find it. Far from just wandering, they went to where they were likeliest to find food.

The vast majority of people lived in agricultural societies, mostly because agriculture allowed for larger populations than did hunting and gathering. Agriculturalists were limited in where they lived by the suitability of land for growing crops or grazing domesticated animals. Thus, places like the North American Arctic remained exclusively the realm of hunter-gatherers. Although agriculture had many advantages, particularly the advantage of being able to provide enough food to store for hard times, its limitations could result in malnourished populations. For instance, millet is not as nourishing as rice or wheat; it was thus possible in places such as northern China for people to eat millet and still suffer from nutritional diseases. The medieval Chinese went far to fix the problem by importing a strain of wheat that could grow in the northern Chinese climate. Other peoples did not have such options. For example, in New Guinea, people mixed the growing of gardens with hunting and gathering, because their domesticated plants could not provide them with the amount of protein they needed. Lacking large domesticated food animals, they could supplement their diet with meat only from spiders, insects, rats, and other small animals.

Meat in much of the medieval world was a luxury that the rich ate regularly and the poor ate only on special occasions. This resulted in one of the most interesting disparities among medieval people. The Khoi of the plains of southern Africa, who herded cattle but raised no crops of their own, instead gathering wild plants or trading with east coast cities for grains and fruits, may have had a richer, perhaps healthier diet than the common people in great cities in Europe, the Near East, and China.

Dietary laws also affected what people ate. Human beings do not eat just what nature or common sense would seem to demand, because they develop preferences, social customs, and religious restrictions that affect what they choose to eat and when they eat it. It is worth considering that many people would violate their preferences or social rules to avoid starving. Indeed, some anthropologists believe cannibalism was a response to diets deficient in protein. In some cases, people seemed willing to starve rather than eat a proscribed food such as pork or vermin such as mice.

Many a war began over food. In some cases, entire cultures depended for food on raiding other people, as happened with nomadic northern Asian tribes attacking China and the cities of the Silk Road, or in North Africa, where nomads attacked farming communities, stealing their food or exacting

tribute in food. A consequence of this behavior in northern China were wars with tens of thousands of casualties, with China trying to keep the products of its farms while outsiders tried to cut through the Chinese armies to take grain and other food. Deficiencies in food may have resulted in armed rebellions. Both the Byzantine Empire and nations of the Islamic world took measures to assure that bread was always available to even the poorest of their people, knowing that starving people had nothing to lose by overthrowing governments or trying to loot royal granaries. Among the theories for why the Maya of Mesoamerica shifted from a highly developed and ancient city-building culture with dense populations to a culture of scattered farming villages is that the Maya destroyed too much of their forest environment, resulting in an ecological catastrophe that severely reduced the protein from the wild animals they depended on to supplement their diet of maize, beans, and squash. Malnutrition may have brought a crash in population and forced the abandonment of a social structure that could no longer feed its people.

## AFRICA

BY CARYN E. NEUMANN

Africans in the medieval era ate many of the same foods that their ancient ancestors had dined upon. Bananas, fish, sheep, goat, chickens, cattle, yams, millet, sorghum, and insect larvae were popular meal choices in the sub-Saharan area. Africans supplemented their diets with wild animals. Beer remained a common drink of choice. Africans had not yet been influenced by foods from the American continent, and later dietary staples such as potatoes and tomatoes were unknown during the Middle Ages. Nonetheless, the African diet had already been significantly influenced by trade. Much of the African cuisine, including most of the domesticated animals, initially came from Asia or Egypt.

Sorghum is probably the most notable of the grain cereals native to Africa. It is a good source of carbohydrates and provides some protein. In one form or another, sorghum is grown all over Africa. *Sorghum bicolor*, the most primitive form and probably the first sorghum to be cultivated, formed a major part of African diets in the medieval era. Sorghum varieties are high in bitter-tasting tannin, and some possess more tannin than others. The *bicolor* form is sweet sorghum and was often chewed for its sweet taste. It also was eaten as porridge or used for bread. Some sorghums with a high tannin content are selected for food because birds will be deterred from feeding on the grain, leaving a greater food supply for people. The other sorghums proved better for beer making, since the high tannin levels removed the need to use hops.

Condiment tray, Egypt, ninth century (© The Trustees of the British Museum)

Sorghum beer is a brownish-pink beverage with a fruity, sour taste. Beer is an ancient beverage that probably originated both as a way to use grains before they spoiled and as a healthier drink than other available choices. For much of recorded history water has been a source of parasites that kill or disable. Milk, with pasteurization unknown until the mid-19th century, did not have a noticeably better safety record. Therefore most Africans, including infants and nursing mothers, drank beer in the morning, noon, and night. The boiling necessary to make beer neutralized most of tainted water's ill effects, although no one realized this for centuries; the cereals added protein to the diet. Sorghum beer, the prevalent African form of beer, was produced by women and contains an alcoholic content of 3.4 to 4 percent. It would have spoiled easily because hops were not used. The active ingredient in hops, lupulin, inhibits the growth of certain types of fungi and bacteria.

Millet was second to sorghum as a popular grain cereal in the medieval era. Like sorghum, it was used to make beer and would occasionally be combined with sorghum beer. Pearl millet (*Pennisetum glaucum*) generally was preferred to sorghum because it is a tastier cereal. It also has one of the best nutritional profiles among cereals. Pearl millet is found throughout sub-Saharan Africa. Wild forms of finger millet (*Eleusine coracana*) occur in the highlands of eastern Africa. Teff (*Eragrostis tef*) has the smallest seed of all the domesticated cereals and was used as the chief ingredient in a nutritious bread. Digitaria or fonio millet (*Digitaria exilis* or *fonio*) is a highly palatable grain that was used for ceremonial occasions. It was especially popular for couscous and has the additional advantage of being particularly resistant to drought. When other foods were scarce, Africans could eat fonio millet.

West Africans in the medieval era centered their diet on rice. To a rice-eating people, no meal is complete without rice. Accordingly, rice was the essential element of the medieval western African diet. African rice (*Oryza glaberrima*) is an annual grass of the savanna zone. Rice was combined with oil palm, white yam, or yellow yam for a meal. The preparation of yams is complicated and would commonly entail boiling, peeling, slicing, and pounding. Sometimes yams would be steeped in running water or, preferably, saltwater, a detoxification process that generally requires about three days. Yam tubers can be stored to ensure that yams are available for about six to nine months of the year. When yams were unavailable, people would instead eat African breadfruit (*Treculia Africana*). The oil palm, popular in western Africa, found its way into many meals. The sap of the oil palm formed an important source of wine, the fruit and kernel of the tree were eaten, and the fibers of its stem, palm fronds, and leaves were used as fishing lines and fish traps.

Rice also may have been combined with cowpeas, pigeon peas, sesame seeds, or peppers. Cowpeas, among the most popular African vegetables, grow in areas with considerable rainfall. Pigeon peas thrive on less water and would have been eaten either as green pods or ripe seeds. Sesame seeds and shea nuts were important sources of oil. African beans include lablab beans, sword beans, and locust beans. The pulp of the latter bean is eaten, and the seeds are roasted for a beverage. Leafy greens, frafra potatoes, and okra would add additional nutrition to a meal. Nuts of many kinds, including Bambara groundnuts and shea nuts, also were consumed. Kola seeds were used to make drinks.

Africans relied on wild game such as wildebeest, antelope, guinea fowl, and monkeys as supplementary sources of protein. The remains of the black rat (*Rattus rattus*) have been found at medieval sites in Zambia and the 12th-century site of Pont Drift in the northern Transvaal. While the rats may have been pets, they also may have been part of the diet. Dogs were kept as pets and as scavengers and also eaten for food and in ritual ceremonies. They apparently were introduced to Africa early in the Middle Ages and spread only to western and eastern Africa.

While Europeans have shied away from eating bugs, insects have always formed an integral part of the African diet. High in protein and low in fat, insects have the additional advantages of being numerous and inexpensive to obtain. Insect larvae, particularly caterpillars, have been the preferred form. Larvae were fried in palm oil and smothered with onions. Sesame oil, known to have been used in the medieval era, may have been mixed with insects. Some grubs may have been mixed with herbs and spices, but there has been little research into the use of herbs and spices in medieval Africa.

Some domestic animals were raised for consumption. Chickens were first domesticated in India and gradually spread throughout Africa. The earliest appearance of chickens in western Africa is at the Iron Age site of Jenne-jeno in Mali that dates from 500 to 800. In eastern Africa chicken remains have been found in Mozambique. Chickens also have been found in South Africa at an eighth-century archaeological site in Natal. The greylag goose (*Anser anser*), which is the common domestic goose of the present day, and the white-fronted goose (*Anser albifrons*) were first kept in captivity for consumption in the medieval era.

The history of cattle in Africa is better known than that of any other domestic species. Cattle came to the continent from Eurasia and India in the ancient era. By the medieval era cattle were consumed widely. Africans ate meat and drank blood and milk from cattle. However, lactose intolerance among western Africans and some Bantu-speaking people argues against the drinking of milk throughout the continent.

Goats and sheep were introduced from Asia to ancient Egypt and then spread southward. The Khoikhoi possessed a great number of goats, and goat remains have been found in the fourth-century site of the Happy Rest in the Transvaal and the eighth-century site of Ndongondwane in Natal. While goat was eaten, however, the vast majority of Africans preferred sheep because of the fat that could be obtained from the sheep's tails. The fat was semifluid, like thick oil. It was frequently used for oil and for butter. The meat of the sheep, like goat meat, was roasted or boiled.

Many of the meals that are popular in present-day Africa would not have been eaten by Africans of an earlier era. Sweet potatoes, tomatoes, potatoes, cocoyams (taro), corn (maize), cassava, and groundnuts were all introduced to Africa in the 16th century or later. Much of the African diet in the medieval era is unknown because of a shortage of evidence. Advances in science may eventually change this. The combined use of carbon and nitrogen isotopes permits the differentiation of pastoralists from farmers; eaters of camel from eaters of goats, sheep, and cattle; and grain farmers from nongrain farmers. Research on the biochemical analysis of human and animal bone may well eventually unravel the intricacies of the medieval African diet.

## THE AMERICAS

BY BRADLEY SKEEN

The main staple throughout North America and much of South America during the Middle Ages was maize. This cereal grain had been domesticated in central Mexico before 7000 B.C.E. Wild maize is inedible because of the hardness

of the husks surrounding the kernels, so the way in which the plant came to be domesticated has never been clear. One possibility is that it was originally used to produce popcorn, which would naturally discard the husks. Between 1500 B.C.E. and 1000 C.E. the plant spread to every part of North America and to the civilizations of the Andes. Frequently maize came together with beans and squash, since the system of agriculture developed in central Mexico used all three plants in a single field; the maize supported the beans, while the leaves of the squash provided an overall ground cover that discouraged weeds. Maize agriculture is far more efficient, in terms of the range of rainfall it will tolerate and the calories and nutrition produced per acre, than is the cultivation of rice or wheat, the common staples of Europe, Africa, and Asia. Amaranth, or pigweed, was another cereal crop that was part of the staple diet throughout the Americas.

The Aztec culture flourished in the valley of central Mexico in the 15th and 16th centuries until the Spanish conquest in 1521. The staple diet of the Aztec was the so-called three sisters of maize, beans, and squash. The ordinary peasant diet consisted mostly of maize, in the form of either tortillas or gruel. Salt and chilies (rich in vitamins) were widely used as flavorings. Tamales were also common, usually filled with beans. Fish and a kind of algae made into cakes, both harvested from Lake Texcoco (upon which the Aztec capital of Tenochtitlán was built), were additional important sources of protein. More protein was brought into the basic diet from shrimp caught in Texcoco and also from insects, especially crickets, ants, and grubs. The maguery worm, a kind of caterpillar, was a special delicacy and is still eaten today in some parts of Mexico.

Maize was processed to make both gruel and dough through nixtamalization. This process involved boiling the grain in limewater (prepared from calcium carbonate and ashes). It removed the outer husk of the grain to make vitamins and proteins more available in the finished food products.

Agave (a kind of succulent plant) provided a fermented drink, but without distillation the beverage was more like beer than modern-day tequila. Honey was collected from domestic bees and sometimes fermented. Other cacti and fruits were more rarely used to produce alcoholic beverages.

The aristocratic diet was more varied. Aztec warriors and wealthy merchants organized dining around formal banquets. These events usually would begin with smoking tobacco and end with drinking chocolate (a very bitter concoction without the milk and sugar routinely put into the product today). An important difference from ordinary meals would be the presence of meat from domestic and wild animals, including turkeys, dogs, gophers, iguanas, and salamanders. Ritual fasting was part of the aristocratic ethos, but in Aztec concep-

tion fasting merely meant doing without salt and chilies. In a densely populated urban area like Tenochtitlán hunting large wild animals must have been of little importance.

Another element of the aristocratic diet was the practice of cannibalism. The Aztec state religion sacrificed between 10,000 and 80,000 people a year, and their flesh was parceled out to the aristocratic warrior and priestly castes at public banquets. While cannibalism could not have been a staple means of acquiring protein in the Aztec diet in general, it must have been significant for the narrow groups who participated in it. The meat was prepared in only one way—stewed with nothing but salt and eaten on tortillas.

The Mayan diet was similar to that of the Aztec and was based on the “three sisters” of maize, beans, and squash. Although the modern name is derived from the Aztec language of Nahuatl, the process of nixtamalization was developed by the precursors of the Mayan civilization in Central America and continued to be used by the Maya down to modern times.

Dogs and turkeys may have been domesticated in Mayan society (which somewhat predates the Aztec, with its Classic Period ending about 900 C.E.) and used for meat. Since

*Lime-paste vessel in the form of a lion, white stoneware with ash glaze; Khmer, Thailand; Angorian Period; 12th–13th centuries* (Arthur M. Sackler Gallery, Smithsonian Institution, Gift of Osborne and Gratia Hauge, S1996.150)

honey was commonly used as a flavoring, the Maya probably also had domesticated bees. However, because the Mayan peasantry was more dispersed and lived throughout the countryside, game from hunting was a more important part of the diet. The main animals hunted were deer, tapirs, and peccaries (a wild relative of the pig). Maya living in coastal areas made extensive use of fishery resources to supplement their diet, not only with fish but especially with crustaceans (shrimp and lobster) and mollusks (the conch).

It was possible to grow maize in some areas of the Inca Empire in the Andes Mountains on the western coast of South America, but not very extensively, so the plant remained a delicacy. The coastal plain of Peru is essentially a desert where no agriculture is possible. Rather, the mountainous character of the Inca Empire meant that farming had to be carried on at higher altitudes. The main plants grown on the mountains were tubers, plants whose edible parts grow underground among the root system. The most important of these plants was the potato, which formed the staple diet of the Inca. The Inca grew hundreds of different varieties of potato suited to the varying altitudes at which cultivation took place. The domestication of the potato goes back long before the Inca, as far as 10,000 B.C.E. and the earliest human habitation of South America. The sweet potato was another important part of the Incan diet. The Inca ate other tubers that have never been cultivated outside Peru, such as the oca, the ullucu, and the arracacha. For peoples living on the coast, seaweed provided considerable nutrition.

Food eaten by the Incan aristocracy was vastly different from that eaten by the common classes. The main meat animal eaten by most Inca was the domestic guinea pig (whose origin goes back to prehistoric times). These animals often were prepared by scooping out the organs and filling the body cavity with heated stones to cook the meat. The organs would then be stewed with potatoes. Coarse fruits, such as the pepino, were part of the common diet as well. The poor frequently were forced to eat preserved rather than fresh food. If ordinary Inca did eat llama or game, it would likely have been freeze-dried into a form like jerky. Another source of protein for commoners, especially the army, was salted fish. The Inca were not great fishers, however, and were mostly able to take only sharks and mullet, bottom-feeding fish like skates, and shellfish. In addition, ordinary Inca would gather whatever wild animals were available in their localities, including penguins, beached dolphins and whales, amphibians, and a wide variety of insects. Wild ducks were eaten too.

The main domestic animal eaten by the elite class was the llama. The elite class, especially the royal household, also engaged in hunting as a pastime. The main animals taken were wild llama and deer, but the viscacha, a kind of chinchilla,

also was hunted with lassos. Large hunts would sometimes be organized in which beaters would drive vast numbers of wild animals into an enclosure, and then every kind of animal, even predators, such as bears and jaguars, would be killed by the elite hunters. The disposition of all meat taken by Incan hunters was at the discretion of the king, and most of it was sent to the royal storehouses. Various kinds of clays native to the Andes were eaten by the Inca. Some, rich in mineral salts, were used as a kind of sauce. Others were used to substitute for other foods altogether by people fasting for religious purposes.

The area of the Inca Empire was subject to wide varieties of rainfall because of the El Niño weather pattern, regularly resulting in famine conditions. Therefore, the government maintained storehouses with enough food to feed the entire population of the empire for several years if necessary. Some of the food was salted fish, but storage of food on this scale was possible only because the high elevations of the Andes enabled the Inca naturally to freeze-dry meat, potatoes, and other plants. The carcasses of llamas that had served as pack animals were contributed to this store when the animals died of natural causes, as were most game animals taken by hunting. Because it was meant to be part of royal patronage, food from the storehouses was doled out in the form of grand public feasts.

Civilization is possible only with the surplus allowed by the farming of domesticated plants and animals. It is no exaggeration to say that civilizations spread north from central Mexico along with domesticated maize. By the end of the medieval period (first contact with Europeans) maize cultivation had spread throughout temperate North America, giving rise to the civilizations of the southwestern United States (such as the Anasazi and the Hopi), the Cahokia and other mound-building (Mississippian) states in the middle of the continent, and the Iroquois Confederacy (the term *three sisters* may come from the Iroquois), among other Indian nations. The very landscape was cleared by the spread of farming as huge tracts of forest were cleared for the first time. Farmers naturally domesticated local North American foods as well, such as wild rice in the northern marshes or cassava on the Caribbean islands. Not all areas were suitable for cultivation, among them, the Great Plains (the thick sods embedded with prairie grass could not be cut with wooden plows), so some tribes retained their older hunter-gather existence. The Sioux, for instance, followed the herds of buffalo across the plains, taking almost all of their food and other necessities of life from these animals.

Maize-based agriculture spread from Mexico through the Caribbean and into the northern territories of South America, along with the cultivation of the cassava tuber that originated

in the Caribbean islands. Very little is known about the interior of the South American continent before contact with Europeans because of the lack of written records and of skeletal or other remains in the acidic soils of the Amazon rain forest. Probably most people lived by hunting and gathering, eating whatever plants or animals they could find, including roots, seeds, monkeys, insects, and fish. One of the few types of remains available is large deposits of seashells in many coastal areas, indicating that mollusks were an important food item where they were available. There are indications that settlements in the Amazon region could have contained thousands of households, a size that could have been supported only by a form of agriculture.

## ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Asia was home to a plethora of culinary styles. Owing to climate and the influence of China, rice was the principal source of carbohydrates throughout much of Asia, though there were areas where starches such as wheat or sweet potatoes took its place. Most Asian meals were simple affairs composed of rice or another starch, vegetables, and little or no meat. People used a vast array of spices to enliven these otherwise simple dishes.

Rice was the staple grain in southern China. It was served either boiled or as a soupy porridge. In northern China, around and to the north of the Huang River, people ate millet, wheat, and sorghum instead, also boiled into porridge. The Italian explorer Marco Polo (1254–1324) noted that people made porridge by boiling millet in milk. Both rice and millet could be made into dough and cut into noodles, which cooks put in soup or served dressed with sauce. Throughout most of the medieval period Chinese people did not make bread of any kind. Rice, millet, and sorghum all could be fermented into alcoholic beverages.

Many medieval Chinese people were too poor to eat anything besides their staple grains. Those who could afford it supplemented rice, wheat, sorghum, or millet with vegetables and meat. Chicken and pork were the most common meats. Beef and mutton were rarer. People who kept chickens also could eat the eggs.

The most common source of vegetable protein was the soybean, which could be prepared many ways. Tofu, a white, cheeselike substance, was made by coagulating soy milk with gypsum and pressing the moisture out of the curds to form soft blocks. Tofu was invented in China; no one is exactly sure when or where, although it is certain that tofu was widely available by the start of the medieval period. Some historians have suggested that Chinese cooks borrowed

milk-curdling techniques from the Mongols. Others believe that mixing soy milk with sea salt could have created a tofu-like substance.

Chinese cooking featured a great many vegetables, including mushrooms, peanuts, eggplant, and bamboo shoots. Chinese cooks devised stir-frying as a way to conserve fuel. Firewood was in short supply, so they tried to cook using as little fire as possible. To enliven their stir-fries, cooks added various spices, including ginger, garlic, daylily buds, and several kinds of pepper. Tea was a ubiquitous drink by medieval times.

North of China the Mongols ate a much less varied diet. Most of their food came from their livestock. They ate a great deal of mutton, goat, camel, beef, and any other meat they could acquire. Dried meat was essential to surviving harsh winters. Cooks typically prepared meat by boiling it. Mongols also consumed many dairy products. They boiled milk, scraped the cream off the top, and dried curds in the sun on their tents; they also dried cheese and fermented mare's milk to make an alcoholic beverage.

The cooking of Southeast Asia resembled that of China. Rice was the main starch. Cooks followed the same practices as Chinese cooks, cutting vegetables and meats into small pieces and cooking them quickly. Many Southeast Asians were Buddhists and did not eat meat but substituted tofu as a source of protein. During the medieval period food in this region was heavily spiced with ginger, basil, pepper, tamarind, shrimp paste, and coconut milk. The chilies that characterize the region's cuisine in modern times are New World plants and did not exist in the region until the 1600s.

Koreans adopted many of the foodstuffs of China, including rice as a staple starch. Korean cooks sometimes added beans, nuts, or other grains to their rice. They also cooked rice into a porridge flavored with other ingredients, such as mushrooms, pumpkin, ginseng, or abalone. In addition to rice, cooks served soups, stews, and cooked meat, fish, tofu, or vegetables. As was the case throughout most of Asia, meat was an uncommon treat for most households.

One quintessentially Korean dish was kimchi, a fermented vegetable pickle served with nearly every meal. Historians believe Koreans started making kimchi several centuries before the start of the Common Era. In its earliest incarnation kimchi was just salted vegetables. In the 1100s cooks began adding different ingredients to make the kimchi sweet, sour, or spicy. The modern form of kimchi made from cabbage did not appear in Korea until the 1800s.

Ginseng, a root, thrived in Korea. Koreans and Chinese people sliced it thin and boiled it to make a tea. This tea was believed to improve the health by balancing the energy in the body.

Rice was the staple starch in medieval India, although people also ate millet, barley, and wheat. Each of the several different varieties of rice was prepared in a slightly different way. Many people strained the water from rice after it was boiled and then made the rice water into a sauce by adding ground spices to it. Sometimes cooks added spices to the water they used to wash rice before boiling it. Typical spices included cardamom, cumin, cloves, coriander, and pepper.

Many Indians were vegetarian by religion; high-caste Hindus and Jains never ate meat. Others were vegetarian by necessity, because they could not afford to buy meat. Vegetarianism was by no means universal, however. Nobles and members of the royalty were not vegetarian. There are reports that nobles ate meats roasted on spits and baked fish, which was considered very good for people suffering from illness. Depending on the region, people were forbidden to eat certain animals. The meat of cows was often avoided in Hindu regions, and Muslims refused to eat pork.

A typical Indian meal included rice, a soup, and raw and cooked fruits and vegetables. Legumes such as lentils, mung beans, peas, and other pulses were common ingredients in soup. When eaten with rice, they furnished complete protein to the vegetarian Indian diet. People ate many vegetables, including various types of greens, tubers, and radishes. Cooks combined these ingredients in various ways and added spices to enliven them. Indian people also ate a great deal of fresh fruit, including lemons, grapes, pomegranates, jackfruit, plantain, and mangoes, which were considered the king of fruits. Desserts were very popular. Favorite sweets included puddings of buffalo milk mixed with sugar and spices, a rice pudding called *payasam*, and sweet noodles. People often brought *payasam* to temples as an offering to deities.

The staple food in Japan was rice. Many people ate rice at every meal, and for some people rice constituted the entire meal. The word for “meal” in Japanese, *gohan*, means “rice.” Cooks supplemented their rice with vegetables, fish, and a few simple sauces.

Seafood was an essential source of protein for many Japanese people. Japan has a very long coastline, so many Japanese people went fishing or gathered shellfish every day. Raw fish was considered the most delicious and healthful. Japanese cooks sliced their fresh fish thin and served it with bowls of rice. They also cooked seafood over fires, put it in soup, or dried it in the sun. Dried fish provided protein when fresh fish was unavailable. The Japanese dried fish in a variety of shapes, slicing fillets from large fish and drying tiny fish intact; the bones of these small fish were considered good for the health. Meat from mammals and poultry was much less common than fish on Japanese tables. Some farmers raised chickens and other fowl, and people ate eggs in addition to

meat. It was impractical to raise large animals such as cows in Japan’s environment, so beef and dairy products were virtually unknown.

Zen Buddhist philosophy taught that it was wrong to kill any creature, and for this reason many Japanese people were vegetarian. Tofu first appeared in Japan in the late eighth century, around the time Zen Buddhism took root in the area. Japanese Buddhists obtained most of their protein from soybeans and soy products, such as tofu, miso (fermented soybean paste), and *natto* (fermented, steamed soybeans). Soy sauce was the main salty seasoning, and soy products were popular even among people who did eat meat. Most meals included a bowl of miso soup that was served as a drink to wash down solid food.

All Japanese people ate many vegetables. Even the simplest meal of rice would usually include pickles made from daikon radishes, cucumbers, or other vegetables. Other common vegetables included cucumbers, eggplants, bok choy (a leafy vegetable), burdock root, lotus root, and various kinds of cabbage. Tiny pickled plums were a common salty addition to rice. People ate many different types of seaweed, either dried or reconstituted in soup.

Zen Buddhism taught that people should find pleasure and spiritual satisfaction through everyday activities, such as farming and the preparation of food. This led Japanese people to elevate the preparation of simple meals into an art form, with the presentation of dishes in attractive bowls an essential part of the meal.

Pacific islanders were somewhat limited in their available foodstuffs. Those who lived on larger islands in tropical climates could grow or gather a wider variety of plant foods than those in colder climates or more remote regions. Common fruits and nuts included coconut, breadfruit, macadamia nuts, bananas, and pineapple. The staple starches were sweet potato, taro, and cassava. Some islanders raised chickens and pigs for meat and eggs. Fish and shellfish were the primary source of protein for many islanders, though they also hunted wild birds.

The aboriginal people of Australia were very good at finding food in their harsh environment. They ate grubs, moths, honeypot ants, honeybag bees, and other insects, and they gathered eggs from birds’ nests. Men hunted kangaroo, wallaby, echidna, opossum, koala, and any other animal they could catch. Women gathered a variety of plant foods, including yams, fern roots, palm hearts, nuts, seeds, leaves, figs, and berries and other fruits. In coastal areas the people gathered shellfish from the shallows. The nuts of bunya pines were a popular food. Wild honey was their main sweetener.

Australians cooked meat over fires, sometimes wrapping it first in leaves. Preparing plant foods was very time-con-

suming; women had to extract seeds, remove inedible portions, and sometimes pound the foods for hours before they could be eaten.

## EUROPE

BY CARYN E. NEUMANN

Most of the surviving written records of medieval food consumption in Europe are accounts of fabulous feasts prepared by court cooks. The accounts emphasize the power of the ruler. Food is secondary. It is assumed that recipes were rarely recorded, because only a few survive. The most numerous people in Europe, the poor, did not use recipes at all. Food preparation techniques were handed down from mother to daughter and changed little through the years.

Political and economic connections often allowed foods to travel from one country to another. This foreign influence is indicated by the names of such medieval French dishes as Saracen Broth, German Broth, Subtle English Broth, and Norse Pasties. The medieval French professional cook appears to have been particularly fond of broths, jellies, deep-fried dough, roasted meat garnished with an assortment of sauces, and strained dishes of meats or vegetables. The bull or ox was far too valuable as a draft animal, while the cow was prized more as a bearer of calves and a producer of milk for cheese than it was for its meat. Only when these animals had aged beyond their useful life were they considered for food, but by this time their meat had lost much of quality. All classes consumed beef, mutton, and pork. Cuts of mutton generally were boiled or salted for later consumption. Suckling animals such as veal, lamb, and kid were quite popular. The upper classes ate venison, but restrictions kept the other classes from legally hunting deer. Similarly the consumption of birds was restricted by custom, law, and expense. Townsfolk and peasants ate few wild birds or chickens. The nobility consumed the most poultry, with many illustrations portraying kings and noblemen carrying hawks for use in falconry. Archaeological remains provide evidence for the relative numbers of the different species that were eaten. Among the favorites were chickens, ducks, guinea fowl, and geese as well as wild game birds such as partridge, pheasants, doves, cranes, and herons.

French cuisine emphasized the appearance of the dish and, most especially, its color. Saffron, extensively used, seems to have been preferred more for its reddish-yellow color than its taste. While the Italians displayed a love for a range of pasta, the French rarely used dough in this form. Omelets, common in Italy, were unusual in France, with eggs rarely used in dishes as either the sole or the main ingredient. Candied foods were rare in medieval France. Fruits, except for

raisins, were not often cooked. Pears, plums, prunes, peaches, quince, cherries, gooseberries, and red currants could be found commonly in markets.

The staple of the French diet, particularly for the poor, was bread. Wheat, semolina, bran, millet, rye, oats, and barley all had a role in various types of French bread, which came in all shapes and sizes. French cooks generally stewed leafy greens such as leeks and cabbages. They boiled and pureed peas, white beans, and other legumes. Bulbs of the onion family (leeks, onions, garlic, scallions, and shallots) were fried to add flavor to dishes. Brussels sprouts, watercress, and turnips were grown in quantity but are rarely mentioned in recipes. Turnips were used as animal fodder, but it is unclear if they were widely consumed by people. While carrots, beets, and parsnips are noted in recipes, they seem to have been consumed only rarely. Honey was the most common sweetener until cane sugar replaced it in the 14th century. The liquid products of the grape—must, verjuice, wine, and vinegar—all played a vital role in prepared dishes. Beer and ale had virtually no place in medieval French cookery, but they were widely consumed in other parts of medieval Europe.

While purees and porridges were common elsewhere in Europe, medieval Italians rarely ate them. However, vegetables were given a prominent place in Italian cuisine. A number of the dishes prepared for the upper classes show an Arabic influence in the use of sugar and cinnamon sprinkled over a dish or in the use of sauces flavored with raisins as well as prunes. Pasta made with rice flour, pizza, polenta, sausages, risotto, and soups were among the common foods. Veal was the most common meat among the wealthy, while everyone ate cheese. Sweet preferences included spiced cakes and biscotti.

The food of peasants was determined by the natural resources that were available locally. In the north of Russia, where the main grain was rye, the peasants generally ate dark rye bread, known as black bread. In the south of the country and in Ukraine, where wheat dominated the crops, white bread was more common. Bread was the main staple and was present at every meal on the tables of the people. Grains were not only baked but also cooked with water into different kinds of kasha, a mixture reminiscent of porridge but with varying consistency. In addition to grains, an important part of the diet came from the woods: gathering mushrooms, wild berries, and nuts was the pastime of children and grandparents, who lacked the strength to toil the land. Fish and meat were highly appreciated but scarce in Russia and reserved for special occasions.

The traditional Russian beverage, *beriozovitsa*, was made from the sap of birch trees, which was kept in large tubs to achieve natural fermentation. A similar drink, *medovukha*,

Copper alloy cauldron for cooking, Britain, 1200s or later (© Museum of London)

was made of honey, hops, and yeast fermented together. These beverages were later replaced by kvass, a fermented wheat drink. Russians did not regularly eat uncooked food. Even fruits and vegetables at harvest time were processed in some way, mainly to be eaten during the long winter. In Slavic countries the stove served as a dryer for all kinds of fresh produce—herbs, mushrooms, fruit, and berries. During the day it kept food warm and provided the requisite temperature to speed up the fermentation of kvass and other drinks

Religion had a significant impact upon food consumption. During the Middle Ages the church in Poland strictly enforced meatless fast days (Wednesday and Friday) as well as fasts on certain holy days. During Lent, Poles were expected to abstain not only from meat but also from butter. The Orthodox Church heavily influenced the eating habits of Russians. Orthodox believers were required to fast 178 to 200 days of the 365 in the year. Since meat and meat fat were prohibited during all fasting days (in addition to being prohibitively expensive), Russians adopted mushrooms as a meat substitute. Wealthier peasants might eat fish pies and salted herring for Lent.

The *Primary Chronicle*, the major source of information about the eastern Slavic state of Kievan Rus' of the ninth to the 12th centuries, reveals that food and drink as sources of pleasure were to be shunned. Sustenance was a benefit granted by a ruler to demonstrate his power and Christian piety. Banquets for military leaders served to reward past services and to ensure continued loyalty, and providing food and

drink for the poor and sick was the duty of a devout Christian. The Kievan Rus' commonly ate oats, wheat, bran, lentils, chickpeas, and honey, often in the form of the beverage mead. The *Primary Chronicle* does not mention any specific fruit or vegetable, other than *zel'e vareno*, or "boiled greens."

Medieval documents indicate that mead remained quite expensive in Poland. It appeared only at lavish feasts. Some monasteries produced wine, but the beverage was expensive because it was typically imported. A beer made from fermented toasted millet reached Poland in the sixth or seventh century. Beer fermented from a number of grains, typically millet, barley, wheat, rye, and oats, subsequently became the most popular drink among all classes. It even found its way into soup in combination with egg yolks and cheese. Pots from the 12th century containing traces of honey and small crocks of carbonized millet were unearthed from a medieval house at Gniezno. The animal-shaped *redykalki* cheeses from the hill country of Podolia apparently date to the medieval period. Luxury foods, such as almond milk and sugar, were enjoyed only by a privileged few.

The Poles believed that the amount of food was more useful to the body than the particular type of food, although meat was seen as the ultimate source of protein. A dinner for nobility would include not only a large quantity of meat but also huge amounts of bread and rolls. The bread was used to make trenchers on which each person ate. A purchase order for a royal dinner in 1394 itemized fish, lamprey, crayfish, green peas, dried peas, walnuts, pears, plums, cucumbers, parsley, beer, 360 loaves of rye bread, and 60 loaves of white bread. Each person was expected to consume about two quarts of beer. The food was eaten with the fingers. Meat was seasoned with pepper, saffron, parsley, and mustard. Mustard was the most common Polish condiment for flavoring meat sauces. In both western Europe and Poland pork lard was the primary cooking fat. Whereas the French used olive oil, the Poles used hemp or poppy seed oils.

English peasants apparently grew wheat, oats, barley, rye, peas, and beans. While much of the grain was eaten or set aside for sowing the following year, barley often was used to make ale. Women were the major brewers. Barley also formed a popular type of bread. Apples and pears were the major fruits grown for the market, with the large Costard as the most popular apple and the large and very hard Warden as the favorite variety of pear. Cherries could be found at market, but strawberries and vegetables typically were grown only for home use. Very large quantities of almonds were imported for use in almond milk, while pomegranates, oranges, and lemons were among the exotic foods that were often brought to England. All of the ports of England imported wine, although it was also produced locally.

Cattle and sheep, with pigs, were the main meat-providing animals in England. However, cows and sheep had more value as producers of milk, manure, wool, and traction for plowing and pulling. The English preferred beef, although they ate mutton, lamb, chicken, and goose. Rural people ate more mutton than did urban residents. For preservation, the English preferred smoking meat to salting meat. They relied heavily on stews, possibly because boiling counteracted the taste of tainted meat while reducing the salty flavor and leathery texture of preserved beef and mutton. Roasting, which consumes large amounts of fuel and labor, was a sign of wealth. All classes of English society ate chickens and geese. The nobility ate large numbers of doves, bred in dovecotes that held hundreds of pairs of birds. Peasants were forbidden by law to hunt larger animals, but the nobles commonly ate venison and boar. Demand for fish, especially saltwater varieties, remained high throughout England. The English favored herring, smoked, salted, or fresh.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

The concepts of *halal* and *haram* are important to understanding the dietary practices of medieval Muslims. The term *halal* refers to something permitted by Islamic law or by Islamic morality, whereas the term *haram* refers to something not permitted by Islamic law or Islamic morality; each term can be applied to many aspects of life other than food. Any foods or beverages that Muslims were allowed to eat on a regular basis were *halal*. Foods or beverages that were *haram* included not only foods that were forbidden almost all of the time but also foods or beverages that were forbidden at certain times. The most important difference applied to wild game. In general, if a wild animal was killed by a hunter, its meat was *halal*. But when a person was on the hajj, the pilgrimage to Mecca that was required by the Muslim faith, that person was not allowed to eat or hunt any wild game. This restriction did not apply to fish.

Intoxicating beverages were *haram*, but numerous records, stories, and poems from the medieval Islamic world make it clear that many Muslims drank alcoholic beverages, often past the point of intoxication. Punishment for public intoxication involved being whipped with a switch in public, and accounts of such instances make it clear that even aristocrats were not exempt from the punishment, which was usually administered the moment the miscreant was apprehended. Blood was also *haram* because it was thought to be dirty, even toxic. Likewise, bloody meat was forbidden. Meat from an animal killed by another animal was considered *carion* (rotting flesh that is unfit for human consumption), and

it was *haram*. Any food over which the name of any god other than Allah had been spoken was considered consecrated to a pagan god, and eating it was an almost unforgivable act.

The best known of the forbidden foods of Islam is meat from pigs. In the arid regions of the Near East, where clean water was scarce, pigs would wallow in mud, often including their own feces, to cool down. Thus, pigs were considered particularly unclean and unhealthy. Some Muslim scholars believed that a Muslim must not touch any part of a pig, not even in transporting preserved pig flesh. Muslims were not supposed to eat meat from any animal that had cloven hooves, and one way to recognize such an animal was by its chewing cud. Pigs have the forbidden hooves but do not chew their cud; hence they became a symbol of hypocrisy and a common image for hypocrites. People who professed to be Muslim but transgressed against laws set forth in the Koran were like pigs: Their appearances were deceptive.

Most medieval Muslim experts on dietary laws seem to have been pragmatists. People who would otherwise starve to death were permitted to eat forbidden foods; likewise, people dying of thirst could break restrictions against intoxicating beverages. Even so, there seem to have been Muslims who would choose to die rather than to consume something that was *haram*. A person who ate or drank an item forbidden by Islamic law or who broke the fast of Ramadan (the ninth and holiest month of the Islamic year) was expected to fast in penance. In the case of breaking the fast of Ramadan a violator was expected to fast two extra days for each offense.

Most people in the medieval Islamic world, whatever their faith, rarely ate meat, which was reserved for special occasions. The wealthy or well connected might have eaten meat more often than others. The meat of gazelles and deer was preferred over that of other game animals, except for birds, such as partridges. Meat from domesticated sheep, wherever it was available, was almost universally preferred over that of any other domesticated animal. There may have been some disagreement among experts on dietary laws about what sorts of fish were preferable to eat, although most agreed that fish in general were acceptable. Most fish came from lakes, from streams, and from the sea near shore.

Meat was supposed to be purified ritually. Ritual purity was called *tahara*. All meat had to be prepared by Muslims or by People of the Book (those who worship the god of Abraham), such as Jews and Christians. The slaughterer of an animal was required to say "In the name of God, God is the greatest" just before slaughter. The animal was not to be slaughtered in front of other animals. An animal had to be killed by an unserrated knife in one motion, slitting its throat so that the arteries, trachea, and esophagus were opened, cutting to the spinal cord without severing it. Then the animal

had to be upended to drain its blood. A wild animal that was killed by hunters usually was also halal. *Haram* was the meat from animals that were drowned, strangled, or struck a blow or from animals that had fallen to their deaths or been killed by wild animals. Muslims considered butchering to be dirty and unwholesome, so in much of the medieval Islamic world the butchers were Jews. In some cities the shops of butchers were segregated from the rest of the city, probably because the smell of butcher shops was considered offensive.

Throughout the medieval Islamic world bread was considered an essential food. Unavailability of bread or flour for making bread could lead to riots in cities and towns. Bread was usually made of wheat, although in places where wheat was rare, sorghum or barley was used. Travelers would carry flour and water with them. When camped outdoors, they would build fires that they encircled with stones. When the

stones were hot, they would brush off the cinders from the stones, mix flour and water, and place dollops of dough on each stone, then covering the dough with ashes. The dough would bake into a flat bread, which would be brushed off and eaten. This bread could be especially important during the hajj, when hunting wild game was forbidden. In the countryside homes usually had ovens in which bread could be baked; in cities houses often had no ovens, but bread could be purchased from bakers. A common meal would consist of bread covered with olive oil, eggplant, garlic, onions, or other vegetables. The other important grain of the medieval Islamic world was rice, which was common along the Nile and in parts of India. In many places rice was an expensive import eaten primarily by the rich.

Most medieval Islamic cities had two important areas of activity, mosques and markets. Outside of cities farmers often chose an unused spot to set up markets, which sometimes grew into towns. Except for privation caused by warfare or natural disasters, such as droughts, the markets were filled with the colorful bounty of gardens and farms. A city usually had gardens and orchards around it, from which fruits and vegetables were brought to city markets daily. Further, fruits and vegetables were imported from faraway places, preserved by cooling with snow, drying, salting, pickling in vinegar and salt, or cooking. Dates, oranges, raisins, apricots, and peaches were commonly available fresh, except to the north in central Asia, where they sometimes had to be imported. Nuts, molasses, honey, sugar, olive oil, mustard, and spices were found in markets. From India and North Africa came sugarcane, watermelons, mangos, bananas, and eggplants.

Pure water was esteemed in the medieval Islamic world. At markets were peddlers who carried on their backs jugs of water, from which they would pour water for their customers. In some places unadulterated water was rare and affordable only for the wealthy. The people of the medieval Islamic world were fond of fruit-flavored drinks. These were mixtures of water and juices from such fruits as dates, pomegranates, tamarinds, apples, oranges, lemons, and grapes. Muhammad was said to have been fond of drinking milk, but it was hard to keep fresh, so milk was usually made into yogurt or cheese, which would keep longer.

What drinks were halal or *haram* was debated by Muslim scholars. Some thought that soft beverages were acceptable; hence near beers were available. Slightly fermented fruit drinks were common throughout the Islamic world and were thought by some people to be halal. Wine and heavily alcoholic beverages were almost universally considered *haram* but were found almost everywhere too. Many vineyards that had produced grapes for wine in the Byzantine Empire were either abandoned or turned to producing grapes for raisins

Flask, rock crystal with enameled gold mount, Egypt, Fatimid Dynasty, mid-10th century (Freer Gallery of Art, Smithsonian Institution, Purchase, F1949-14)

and molasses after being taken over by Muslims. Even so, some Christians made wine, which was necessary for various Jewish and Christian rituals and which was also sold to Muslims. Wine and other alcoholic beverages were also imported from Europe.

Muhammad was supposed to have had a fondness for a dish called *tharid*, and as a consequence it was eaten throughout the Islamic world. It consisted of strips of meat stewed in broth and covered with crumbled bread near the end of the cooking time. The meat was chicken, goat, beef, or lamb, and the dish was prepared for lords as well as ordinary folk. Meat was cooked in spiced sesame oil or olive oil. Although many people could not afford meat, most other foods were available in nearly all places at most times during the medieval era in the Islamic world. Women usually prepared the dishes; a member of the household would take the dishes to a bakery to have them cooked, because few homes in cities had ovens.

In the majority of towns and cities shops carried a variety of breads and pastries as well as candy. In many cities there were restaurants. These establishments varied in quality and in clientele. Restaurants would likely have *tharid* available. According to what meats, fruits, and vegetables were on hand, the restaurants would serve a variety of foods, from meatless dishes to dishes with stewed or roasted meat.

## ► foreigners and barbarians

### INTRODUCTION

Most people in traditional cultures lived in small, relatively isolated farming communities or closely knit tribal groups and never saw strangers. Based on this experience, they reacted to the idea of the foreign with xenophobia, that is, suspicion and hostility toward any stranger or outside influence. Violence was a common reaction to meeting foreigners. A more cosmopolitan attitude accepting the foreign could develop only as trade and urbanization made contact with foreigners and familiarity with their cultures a more common experience.

Chinese culture, for example, was notably xenophobic in the Middle Ages. Exceptionally, the Tang Dynasty (618–907) was the most cosmopolitan in Chinese history, allowing foreign religions to enter China and developing trade along the Silk Road (the capital was moved to Xi'an in western China) and across the Indian Ocean as far as Cairo, and founding the Pearl River estuary port of Guangzhou for foreign merchants. But Chinese culture later reverted to older policies of isolation and a belief that China, particularly the Han Chinese ethnic group, was inherently superior to all foreign or barbarian cultures. The Chinese emperors thought that they were the rightful rulers of the entire world, and during the Ming Dynasty (1368–1644) they went so far as to send one of the greatest fleets of wooden sailing vessels ever assembled on a tour of the Indian Ocean to exact tribute from the local rulers. Foreigners were poorly treated in India as well because they were deemed inferior as having no caste in the Indian social system.

Because of the general attitude of xenophobia among traditional peoples, many words for foreigners are based on negative stereotypes. The normal Indian word for foreigner was *mleccha*, while the normal European term was *barbarian*. In both cases the word is an attempt to capture the supposed gibbering sounds of people who speak only foreign languages. The Aztec similarly referred to a foreign people with whom they were in conflict not by their own names but as *chichimecs*, “sons of dogs.”

One common response to the proximity of foreigners in medieval cultures was isolation. When the Arian Germanic

tribes conquered the western province of the Roman Empire in the fifth century, they generally lived apart from their Catholic subjects. The process of assimilation took a century. The same is true in the first generation of the Islamic Empire. Muslim Arab garrisons kept themselves strictly segregated from their Christian and Zoroastrian subjects, and there was not initially a rush to proselytize for Islam among the newly conquered peoples. But this policy of isolationism broke down in favor of assimilation. Even in more cosmopolitan centers that favored international trade, foreign merchants usually were governed and restricted by special laws to control and limit their influence.

Jews were outsiders in both the Christian and Islamic world, and their own traditions made conversion or assimilation unlikely. Islamic law made provision to give limited acceptance to the Jewish community along with Christians as “peoples of the Book” who were fellow monotheists; at some times and places they were well tolerated and could rise to professional and social prominence. The situation for Jews in the Christian world was conditioned by the increasing hostility of medieval Christianity to any outside group, whether eastern or heterodox Christians, “pagan” Baltic tribes, or Muslims. Jews were systematically isolated and eventually either expelled from entire kingdoms (as from England in 1290 or Spain in 1492) or segregated into ghettos. Ironically, Jews initially welcomed this segregation because they believed it would help protect them from the sectarian violence their communities frequently suffered in medieval Christian cities.

A quite different way that medieval people encountered foreigners was through international travel. This most often took the form of religious pilgrimage. Muslims, if they were otherwise able, were required to make the hajj to Medina and Mecca at least once in their lifetime, and pilgrimage to Jerusalem was if not obligatory then at least highly desirable in the Christian world. Indeed, one of the contributory causes of the Crusades was the interference of Islamic governments with the right of pilgrimage to Jerusalem.

Other journeys were taken as a sort of reconnaissance for trade, such as the trip of the Venetian Marco Polo to China (if indeed that journey was not a fictionalized account of other travelers’ memoirs). The Moroccan legal scholar Ibn Battuta (1304–ca. 1370), however, was the greatest traveler in the Middle Ages. He made the hajj as soon as he finished his education and continued traveling throughout Asia, Africa, and Europe for the next 30 years, covering an estimated 75,000 miles back and forth between Timbuktu in western Africa and Guangzhou in China. This kind of contact with foreign culture promoted a more cosmopolitan acceptance of the alien.

## AFRICA

BY KIRK H. BEETZ

The history of foreigners in medieval Africa is as varied as the cultures of Africa, with some cultures having social mechanisms for coping with outsiders and some seemingly lacking ways to deal with outsiders. More is known about the attitudes of those people on the fringes of the continent, and less is known farther toward the interior of medieval Africa. Much of what is known of medieval African cultures comes from the writings of foreign visitors; therefore, the point of view is that of outsiders rather than that of the Africans themselves. Further, the foreigners often recorded hearsay. For instance, the explorer Ibn Battuta notes that in the city of Yufi (perhaps known today as Nupe) white people were unwelcome, but he only heard this, not having actually visited the city, where he presumably would have been unwelcome. Indeed, as a foreigner he could not explain the origins of the attitude or why it was held.

There were Christian nations in Nubia as well as in Ethiopia for most of the medieval era. For centuries there was a powerful trading nation, Axum, with a great seaport, Adulis, about an eight-day trek from the capital city, also called Axum. This nation prospered as a way station for the exchange of goods from the interior of Africa for goods from Asia, North Africa, and Europe. Not much is yet known about their laws governing foreigners, but there seem to have been rules of conduct for foreign visitors, and all had to be inspected by government agents. Adulis may have had quarters in which foreigners could stay. There also may have been a local industry based on providing for the needs of visitors. It was apparently easy to find local people who spoke Greek or Arabic, major trading languages for the region.

Nubia had been receptive to Christian missionaries from the Byzantine Empire beginning in 543, resulting in long-term relations with the Byzantine Empire even after the Arab conquest of Egypt about a hundred years later. Visitors to the Nubian nations of Nobatia, Makuria, and Alodia noted that there were hundreds of churches. In general, foreigners were tolerated. The Nubians long had peaceful relations with Muslim Egypt, and Arab traders would have been seen frequently. It is hard to be certain what the Nubians thought of visitors, but they seem to have been comfortable with them. The invasion of Nubia from Egypt in the 1200s may have been a shock after centuries of peaceful relations. In 1276 the Saracens put their own candidate on the throne of Nobatia, in the 1300s Makuria fell, and in the 1400s Alodia fell. Although many local people converted to Islam, many did not, and many fled. For the rest of the medieval era there was enmity toward Muslims among those who did not convert.

Axum suffered from the hostility of its Muslim neighbors, and eventually its people withdrew to the Ethiopian highlands. Ethiopia and Egypt had a treaty that allowed Ethiopians to travel through Egypt on pilgrimages to Jerusalem in exchange for an annual tribute of slaves. Much of Ethiopia's contact with the outside world came through Egypt, and Egyptian traders visited frequently. People from Europe also visited and found Ethiopia to be an enigmatic place with strange social rules. Ethiopians were eager to show off their churches to visitors, but they were a society bound by complex rules of kinship, and foreigners who had no kin in Ethiopia were almost nonpersons. Foreigners could elevate their status by incurring obligations from Ethiopians, perhaps by doing favors or presenting gifts, and by accepting favors, because any kind of relationship in which there were obligations gave a person a place in society.

Before the beginning of the medieval era there were already trading communities along the coast of East Africa. Historians originally thought that cities were established by Arabs and Indians for trading with the interior of Africa, but recent archaeological discoveries show that the cities were founded by Africans. Moreover, rather than being controlled by foreigners, the cities were only influenced by foreigners.

These cities of East Africa grew in size and wealth while their people learned to deal with foreign traders. Egyptians, Arabians, Greeks, Indians, Sri Lankans, Indonesians, and Chinese thronged to their ports and mixed with the locals on city streets. Hotels and inns serviced foreign visitors, and the foreigners often would stay for months, waiting for the trade winds to shift with the seasons to enable them to sail north and east. Many foreigners chose to become permanent residents, indicating a welcoming atmosphere and increasing the cosmopolitan attitudes of local people.

The exact relationship of Arabs to the African peoples of the cities of East Africa is unclear. At one time it may have been easy to say that the Arabs founded the cities, but they did not, and it was possible that they used force to convert local people to Islam. At present the likeliest explanation is that people peacefully converted to Islam. Despite the conversions to Islam, there were still many pagans and Christians in the cities, and foreigners of many religious affiliations were welcome guests. The openness to foreigners of East African societies may have contributed to their downfall. When the Portuguese arrived in the 1440s, they were able to sail their ships into port and were met by government inspectors, like all other visitors, for the assessing of tariffs and taxes. Later, in the early 1500s, Portuguese ships were able to slip into East African ports by day, and at night the Portuguese attacked the cities, taking the trusting residents completely by sur-

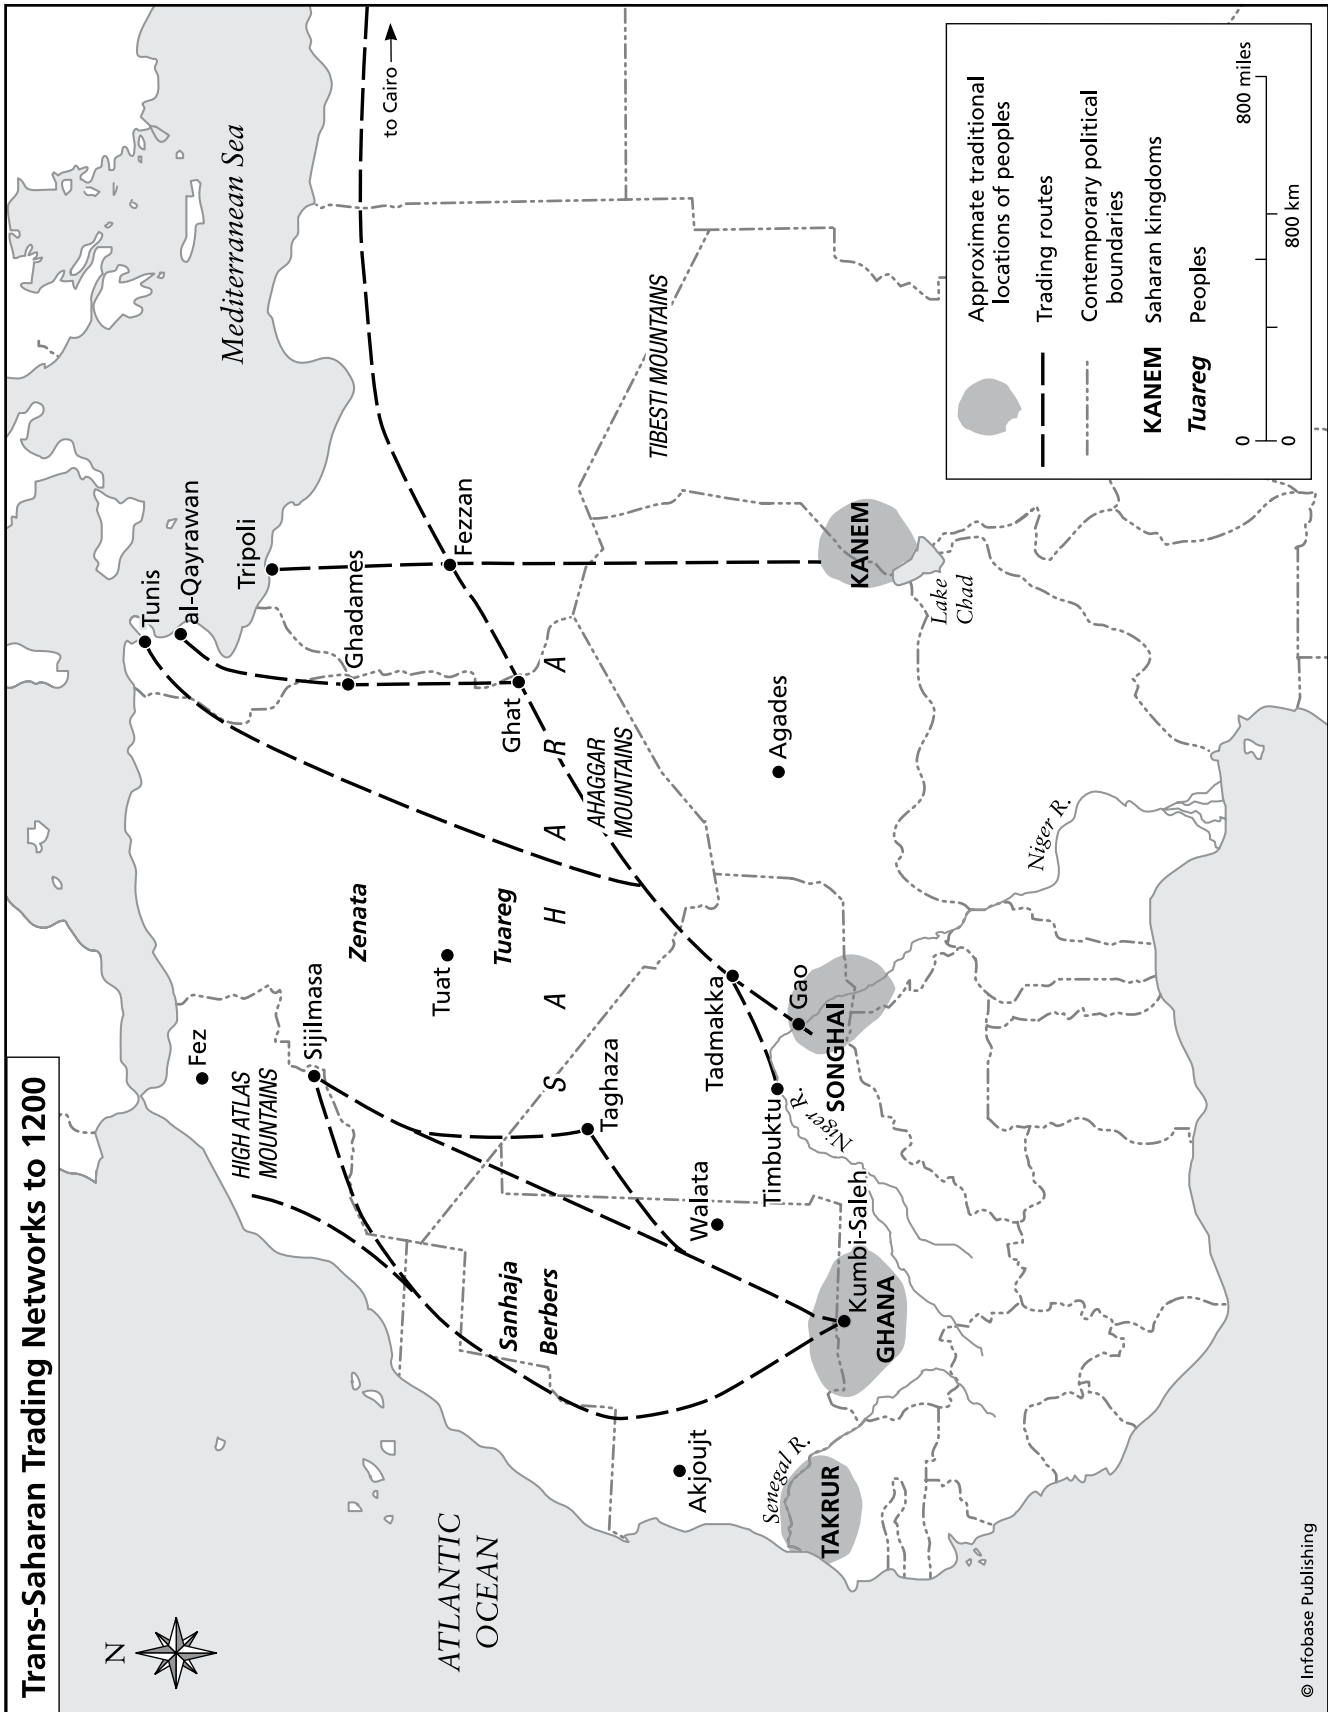

prise. Thousands were murdered, thousands more were taken as slaves, and some cities were burned.

In the rain forests of Africa there was a migration, begun in ancient times, of Bantu-speaking peoples from western Africa. They were farmers moving to find new land to cultivate or were bands of raiders seeking to conquer and loot. What the indigenous hunter-gatherers thought of this situation is unclear. They had traded with outsiders for centuries, but they lived nomadic lives, often without fixed villages. On occasion they tried to keep foreigners out of their lands, and their poisoned arrows killed many attackers. Their attitudes probably were not entirely hostile because they sometimes took up the ways of their settled neighbors and blended into the farming culture.

The San of southwestern Africa were also hunter-gatherers, occasionally living as nomads and occasionally in very small settlements. Much of the information about their attitudes comes from after the medieval era, but some aspects of their medieval responses to foreigners can be inferred. For example, they had strong views about what was their territory, and they resisted farmers and herders who tried to take the lands as their own. They formed small war parties and attacked people who moved into what they believed were their traditional lands. On the other hand, they often formed relationships with foreign cultures. When they were not fighting the Hausa, who were pastoralists, they worked for the Hausa and learned the Hausa language to help with trade between the San and the Hausa.

Between the southern East African coastal cities and the lands of the San were vast grasslands. The Khoi herded cattle across the lands and traded with the East African cities and with kingdoms in the interior, such as Great Zimbabwe. Archaeological research has shown that the Khoi and the settled states of the Zimbabwe plateau interacted. They traded goods and also fought over territory or more often over the Khoi's paying tribute. Foreign coins and beads found in Great Zimbabwe show that its people traded with the east coast, but whether foreigners actually visited Great Zimbabwe has yet to be established.

Among the farming peoples of western Africa and central Africa, attitudes toward foreigners varied greatly. For those living in the Sahel steppes, which stretch west to east across the southern edge of the Sahara, foreigners were probably common sights. Berbers, Arabs, and others made long treks south through the Sahara to reach several trading cities in the grasslands and the forests to the south. Some historians think that this situation changed some traditional western African societies, which had been stateless—with no kings, no chiefs, and indeed almost no one who could be called a leader. Some foreigners came not to trade but to steal and to

(opposite page) *Berbers, Arabs, and others made long treks south through the Sahara to reach several trading cities in the grasslands and the forests to the south. Thus, for the people living in the Sahel steppes foreigners were probably a common sight. The main purpose of the medieval trans-Saharan trade was an exchange of salt from the desert regions of the Sahara for gold from the sub-Saharan kingdoms of the Sudan. The trade linked the successive Sudan empires of Ghana, Mali, and Songhai with the Saharan states as well as with Middle Eastern and European merchants. In addition to providing foodstuffs and salt, the trade exposed the traditionally oral Sudan cultures to the Koran and the written language of Arabic. The leaders and businessmen of the Sudan kingdoms valued extensive trans-Saharan trade and often converted to Islam in order to ingratiate themselves with the Arab merchants.*

capture people to sell as slaves. The development of chiefs and then of governments may have been a way of trying to control the behavior of foreigners. Chiefs were people who could speak for several villages, and governments allowed for raising armies as well as for regulating trade and foreigners.

Many western and central African cultures remained stateless. These stateless societies organized themselves on the basis of obligations. The richest person in a village was the one who was owed the most favors by other people, not the person with the biggest house or the most luxuries. When a foreigner came to a village, there was rarely any organized greeting. There probably would have been women eager to sell foreigners millet or rice; women often set up near well-traveled roads to sell food to travelers. If foreigners indicated that they needed a place to live, even if they did not speak the local language, they could be assigned a piece of land to work. This assignment was a step toward acceptance, because the foreigners now had a debt of obligation to whoever previously had had the right to farm the land. Helping others weed their crops, repair their homes, and so on could turn them from foreigners into members of the village. Marrying a local person would help settle the issue.

Another kind of social organization was by gender and age. The Nyakyusa of the region of Tanzania were an example. Their culture could be called a society of strangers. In their culture an unmarried young man was believed to be a sexual threat to women, even to his sisters. To prevent his harming a woman, the boy was forced to leave his village and seek out other boys his age. Several boys, otherwise unknown to each other, would form a new village only for boys of about the same age. Boys of the right age, seeking new homes, were welcomed into the new village. When the boys became old enough to marry, no more outsiders would be allowed into their village, and they would change their village from a haven for homeless boys their own age to a place for wives and children.

## THE AMERICAS

BY PENELOPE OJEDA DE HUALA

Shortly after the arrival of the Spanish in the New World, stories of the foreign beings circulated throughout the region. In

the Aztec capital of Tenochtitlán, Montezuma II (r. 1502–20) heard descriptions of floating temples on the sea. In North America the Spanish presence was felt before the foreigners set foot on land, because disease traveled faster than they did. By the mid-16th century disease had practically wiped out all the indigenous people of the Caribbean. Farther south in the rugged Andes, time was also running out for the great empire of the Inca.

Around 1000 a Norse ship sailing from Iceland with Leif Eriksson at the helm landed on the shores of a land called Vinland. In 1960 a Norse settlement in L'Anse aux Meadows, Newfoundland, was discovered, confirming the Norse presence in North America. Nordic records report of their meeting and battling with an indigenous people, whom they refer to as *skraelingy*, meaning “native” or “barbarian.” Evidence suggests that the settlement survived until the 15th century, when it was abandoned abruptly, possibly as a result of the plague and several economic factors. However, at about the same time the Inuit people arrived in the area.

The Inuit, a nomadic people who populated the area of present-day Greenland as well as parts of Alaska and Canada, arrived in Canada around the 15th century. Living in the predominantly Arctic regions, they depended on various fish and land animals for food, shelter, and tools. Oral traditions of the various Inuit groups tell of violence against outsiders. The harsh Arctic environment created tension between neighboring groups, and raids were common. Oral tradition is filled with tales of supernatural creatures and ancestral spirits; sea creatures especially are central to Inuit mythology. Norse objects also have been found in Inuit settlements. A 14th-century account tells of a Norse settlement taken over by the *skraelingy* and describes a race of small people who battle with the Norse. However, no proof exists of direct interaction or warfare.

The most insightful information on Native American attitudes toward strangers is found in the various oral traditions and early colonial accounts that have been passed down and documented. Most reports of foreigners or strangers focus on warfare and migration. One such account was given to a Moravian missionary named John Heckewelder (1743–1823) by the Lenni Lenape, a tribe that at the time of contact (ca. 1600) occupied the areas around the Delaware River, the

lower Hudson River, and Long Island Sound. The story tells of the Lenape's great migration eastward to the land inhabited by the Allegewi, whom the migrants describe as giants. The Lenape conquer the powerful strangers and settle into their new homeland.

According to the Lenape language, foreigners are those who speak a different language, not necessarily those who are ethnically unrelated. For example, the Iroquois were called the Minqua, a name that means "treacherous" and reflects the bitter animosity between the two peoples. Likewise, the language of the Huron, who originally occupied present-day Quebec, distinguishes between natives and foreigners, calling the tribes that spoke their language or a similar one Attiuan-daronk and those that spoke another tongue Akouanake.

Many Native American myths and legends, especially tales of migration, speak of confrontations with supernatural strangers. For example, the Algonquian, a people who occupied lands from the eastern coast of North America to the Rocky Mountains, have legends filled with assorted supernatural beings like giants, magicians, and witches. Similarly, the Seneca, an Iroquois group from the Northeast, have a myth about a powerful boy who conquers supernatural strangers from various foreign lands. In all these myths strangers have both malevolent and benevolent characteristics and may reflect actual interactions with foreign tribes.

The Kwakiutl of the coastal region of present-day British Columbia created a division between the two major constructs in their society: the civilized crest imagery of the chiefs' genealogy and the uncivilized cannibal imagery with its roots in a warrior society. The imagery of the chiefs' lineage appears on totem poles and house fronts, at the center of the civilized village. The imagery of the cannibal focuses on supernatural creatures. Birdlike composite forms appear on masks and dishes, depicting the inhabitants of the dangerous outside world, the forest where the spirits, the animals, and the enemy lurk.

Teotihuacán (ca. 1–ca. 650) at its apogee was the largest city in the Western Hemisphere. Located in central Mexico, its influence would be felt throughout Mesoamerica in the Early Classic Period (ca. 150–ca. 650). Also dominant at this time was the Maya culture (ca. 1000 B.C.E.–1521 C.E.), which dominated parts of Guatemala, southern Mexico, Belize, and Honduras.

The influence of Teotihuacán is evident at various Maya sites, including Kaminaljuyu (Guatemala City), Altun Ha (Petén, Guatemala), Becan (Yucatán, Mexico), Dzibilchaltun (Yucatán), Chichén Itzá (Yucatán), and Tikal (Petén). Many theories have been proposed for this foreign incursion, including the possibility of Teotihuacán hegemony and occupation of several Maya areas and the appropriation by

individual local elite of Teotihuacán style as a form of legitimization or acquiring prestige. In the site of Tikal—the dominant Maya city of the Early Classic Period, located in the lowland region of present-day Petén, Guatemala—various forms of foreign penetration have been found. Teotihuacán-style ceramics were interred in burial sites and Teotihuacán and central Mexican motifs are present on stelae. Moreover, *talud-tablero*, a prominent Teotihuacán-style architectural element consisting of a sloping wall and a horizontal tablelike section, was used in several building structures.

However, evidence also points to a reverse interaction. In the Tetitla, an apartment compound in Teotihuacán, a Maya-influenced mural and various ceramics were found. Further, the use of central Mexican motifs served a very specific purpose: Rulers depicted themselves in the guise of Teotihuacáños as a form of emulation, appropriating the warrior mystic of the powerful and militaristic foreigners. The interaction between the Tikal and Teotihuacán cultures was many sided, bringing together divergent belief systems and several cities from central Mexico and the Maya lowlands. Later dominant cultures would use the same takeover techniques, including the Aztecs, who appropriated the people of Teotihuacán and Tula as their ancestors to legitimize their own dreams of domination.

The Maya also used propaganda to claim dominance and legitimacy. Maya dynastic histories were inscribed in stone and were featured prominently on monumental sculptures. These works emphasized the role of the lord or king and his political, divine, and cosmic purposes. Carvings on the monuments depicted the dynastic lines of the individual polities, the succession of one king by another, the conquest of one state over another, and ultimately the divine right of the king's rule. The Maya portrayed conquest of various foreign states until the Late Classic Period (ca. 600–ca. 900). Captives were depicted naked, a sign of the utmost humiliation and defeat, and some works even include the names of captives and neighboring rulers.

The Aztec (ca. 1200–1521) were the last of the long line of cultures to flourish in Mesoamerica. The empire, centered in the Mexico Basin (present-day Mexico City), was cut short by the ultimate barbarian invaders, the Spanish. Before that notorious meeting, however, the Aztec had another foe, the Chichimecs, a nomadic Nahuatl-speaking people who lived in the north and west of the basin of Mexico. The word *chichimec* means "son of dogs" and was later adopted by the Spanish to address all the people living north of Mexico, whom they considered barbarians.

In October 1492 Columbus landed in Hispaniola, an island in the Caribbean encompassing present-day Dominican Republic and Haiti. He first encountered the Taíno (ca.

1200–ca. 1500), an Arawak people who had originated in South America. This meeting would mark a decisive change of fortune for the people of the Caribbean. The inhabitants of the island were a sophisticated culture that spread across the whole of the Greater Antilles, including present-day Dominican Republic, Haiti, Puerto Rico, Cuba, Jamaica, and the Bahamas. Within a generation the Taíno would be decimated by disease, slavery, and warfare. The estimated loss of life hovers close to 1 million people. The destruction of the Taíno culture did not end its impact on the future of the Caribbean. A rich cultural legacy remains, including words such as *barbecue*, *hammock*, *canoe*, *tobacco*, and *hurricane*. The bloodlines of the Taíno people freely mixed with the African, Spanish, and other indigenous groups of the region.

According to Spanish sources, the Taíno believed the Spanish to be gods. These foreigners with long beards and strange clothing were so exotic that the indigenous people first believed the Spanish ships to have come from heaven. A later account, however, describes a vision that foretold of a foreign invasion by clothed cannibals who would kill their children and enslave them.

The Taíno had a vast network of related communities under the leadership of a select group of chieftains called *caciques*. The various communities of the culture were united by a common ceremonial and recreational ball game that involved large gatherings of many groups. During the game an assortment of interactions would take place, including the exchange of goods, gift giving, dispute resolution, and community consolidations through marriage alliances. Despite the ceremonial meetings and possibly a common cultural ancestry, warfare did exist among rival groups, especially between the Taíno and the Caribs, who resided in the Lesser Antilles.

The Moche civilization flourished during the first 700 years of the Common Era on the northern coast of Peru. In this arid environment the Moche developed a distinct naturalistic and narrative style quite unusual in the Andean artistic canon. In ceramic slip paintings, metalwork, and textiles the Moche depict prisoners of war in scenes of battle and sacrificial rituals. Captives usually are shown being held by the hair, a symbol of dominance, or ritually bled as a form of offering. Unlike their predecessors from the Chavín culture (ca. 900–ca. 200 B.C.E.), Moche artists relied heavily on narrative realism to represent their world and disseminate their beliefs. Individuals' rank, actions, and moods are conveyed through certain artistic modifiers such as regalia, pose, positioning, and physical appearance. Moche artists used these conventional modes to relay and possibly maintain social and political norms.

The Inca (ca. 1450–1532) were an ethnic minority of approximately 40,000 individuals who ruled a territory ex-

tending over 350,000 square miles and subjected more than 10 million people. The Inca capital at Cuzco, in the heart of the Peruvian Andes, was a sacred site and the center of their empire, which they called Tahuantinsuyu, “Land of the Four Quarters,” because it consisted of four territories: Chinchasuyu to the east, Antisuyu to the north, Collasuyu to the south, and Contisuyu to the west. From the center of Tahuantinsuyu, at the Temple of the Sun, known as the Coricancha, 40 imaginary lines radiated out and connected more than 400 sacred sites, or *huacas*. Central to the Incan system of control, the *huacas* were places of ritual practices that culturally connected the vast territories under Inca control. One ritual performed at the Coricancha was the sacrifice ritual of *capac huacha*, where young children from the four quarters of the Incan territory were offered for sacrifice. The sacrifice ritual procession followed the same path of the sun from east to west where offerings were made at the *huacas*. The offering ensured the health of the king, the land, and the people. The symbiotic relationship required for the *capac huacha* enabled the Inca to unify the provincial territories and made Cuzco the main site for pilgrimages.

Much like the Roman Empire, the Inca conquered the vast lands and various barbarian tribes and societies of the Andean region. From northern Ecuador to the tip of Chile and into the Amazonian basin, the Inca united diverse groups through ritual practice. The landscape was intrinsic to the Inca cosmic worldview. Architecture and landscape were at the very heart of their domination.

## ASIA AND THE PACIFIC

BY KIRK H. BEETZ

By the end of the Han Dynasty in 220, the Chinese had a very strong sense of nationhood that they maintained despite civil wars, invasions, and division among rival kingdoms. Part of that sense of nationhood was the abiding belief that to be Chinese was to be better than anyone else and that Chinese culture was the most advanced and most civilized in the world. During the medieval era the Chinese viewed all other peoples as barbarians. That perception may have been condescending, but it was often benevolent as well. Other nations were forced to send tribute to the Chinese emperor, and foreign leaders were required to acknowledge him as their leader. But whatever the tribute sent to him, the emperor sent gifts of greater value back to show his benevolence and wealth, and foreign leaders were almost always left to run their countries without China's interference.

During the Tang Dynasty (618–907) China welcomed foreigners. Learned foreigners were especially welcome and often earned high places in China's government. For exam-

ple, Indian mathematicians, astronomers, and physicians were sought after, and Indians ran the national government's astronomical observatory. For tax purposes foreigners who took up residence in China were divided into three classes based on their wealth, with the wealthiest paying 10 silver coins per year, the middle-income group paying five silver coins, and the poor paying no taxes.

The city of Guangzhou was China's main trading port, and south of the Zhu River was an area for foreign settlers. Foreign settlements were allowed to manage their own affairs and were usually run by elders within the settlements. When people of the same nationality committed crimes against each other, a Chinese magistrate tried to determine the merits of the legal case and the punishment on the basis of the laws of their nation of origin. When crimes involving more than one nationality occurred, or when lawsuits involving more than one nationality were filed, Chinese law applied.

Until the 840s foreign religions prospered. The most successful was Buddhism, which had great wealth. Other popular foreign religions were Christianity, Zoroastrianism, Manichaenism, and Judaism. These were brought to China by missionaries, traders, and skilled workers. In 842 China's emperor Wuzong (r. 840–46) began persecuting the foreign religions, claiming they were undermining the government, but the actual motive was greed. The emperor wanted the wealth of the religious groups, especially of the Buddhists, and their foreign origins were only a pretext for taking their money and property. In 845 the government closed more than 4,600 Buddhist monasteries and 40,000 Buddhist shrines, leaving only 49 monasteries. The government also ordered that monks under age 50, and those over 50 who did not have documents proving they had been ordained, must be defrocked. As a result, more than 250,000 monks could no longer conduct religious services and only 800 practicing monks remained in China.

By the time the Venetian traveler Marco Polo reached China in the late 1200s, the Mongols had conquered much of the nation and were pressing southward to finish off the Song Dynasty (960–1279). At that time China was a nation of many ethnic groups. The Han Chinese, by far the largest ethnic group, regarded other groups as inferior or even not truly Chinese. This resulted in occasional unrest in parts of the empire when minority groups thought the imperial government was treating them unfairly because of their ethnicity. The Mongols believed they should rule over all foreigners, and they slaughtered entire populations of foreigners in some cities, yet strangers often were met with hospitality by the nomadic peoples north of China. Polo was an honored guest at many meals. In northwestern China some local cultures regarded all foreign visitors as being superior in hardiness or

knowledge, and women would try to entice foreign men into their beds so that the foreigners' bloodlines could be added to theirs. Other regions also welcomed foreigners and called them *se mu*, meaning "colored eyes."

During its early history the Ming Dynasty (1368–1644) had a somewhat similar attitude toward foreigners. Great fleets of huge vessels sailed as far as the city-states of East Africa, seeking trade and knowledge. But there were signs of another attitude that came to dominate dealings with outsiders. The Great Wall was rebuilt, sturdier than ever before, to separate the farmlands south of the wall from the grazing lands north of it. In 1433 the truly amazing voyages of discovery were ended and the great ships destroyed. Foreigners came to be regarded as having no value for China.

Throughout the medieval era Koreans had very mixed reactions to foreigners, partly because for much of the period they were divided into separate nations with separate policies toward outsiders, and partly because foreigners often brought misery and ruin to the land. The Chinese were simultaneously admired and loathed. In the early medieval era Korea imported Chinese scholars and Chinese Buddhist priests, and Korean governments were modeled after Chinese examples. They may have regarded the Chinese as superior to themselves, but they considered the Japanese inferior. After all, when the Japanese wanted teachers they asked Korea to supply them.

Invasions by Chinese groups that the Koreans considered barbaric, the Mongols and Manchurians, led to insularity. Koreans might greet an individual foreigner respectfully and provide hospitality, but groups of foreigners were associated with violence and usually unwelcome. In the 1400s Korea strove to establish secure borders and began the process of withdrawal from the world that peaked in the 1600s, although Koreans retained trade relations with Japan.

For almost all the medieval era the Japanese were eager for foreigners to visit. The Japanese government sent embassies to its allies in Korea and to the emperor of China primarily to have teachers and craftspeople sent to Japan. A Korean scholar headed Japan's first university, and Japan's earliest blacksmiths probably came from Korea. The shores of the islands of Honshu and Kyushu were frequented by Malaysians, Koreans, and Chinese as well as being occasionally visited by traders from Indonesia, India, and Sri Lanka. They were usually welcomed for the experiences they could relate, the merchandise they could sell or trade, and the skills they could teach.

Japan's attitude toward foreigners began to change when the Mongols began invading Kyushu in the 1200s. The Mongol emperors had sent emissaries to Japan's shogun, demanding that the shogun and Japan submit to the authority of China.

The shogun reacted to each successive set of emissaries with contempt. Twice the Mongol army invaded Kyushu to enforce the emperor's will, and each time the stubborn defense of the outnumbered Japanese and stormy weather thwarted them. The last attempt was in 1281, but for decades thereafter the Japanese maintained their defensive walls and remained watchful.

In medieval India foreigners were called *mleccha*, meaning "jabberers." Meant to be contemptuous, the word is of unknown origin, but it may have come from an ancient Sumerian word for the people of the Harappan culture (ca. 2600–ca. 1500 B.C.E.). In medieval Indian art foreigners often were depicted in the garb of people from northwest India, where the Harappans once lived.

The word *mleccha* was also representative of medieval Indians' attitudes toward non-Indians in general. Muslim visitors to India recorded that the Indians believed their land to be the only worthwhile land in the world and that all culture, all knowledge, and all civilization originated in India. Thus foreigners tended to be treated as inferior to Indians. Foreign scholars were welcomed at Indian universities as visitors or lecturers, and merchants were valued for the wealth they brought to India. Still, every foreigner was regarded as having no caste. Indians of high caste might allow foreigners into their homes, but they would not dine with foreigners or allow foreigners to dine in their homes. Foreigners were even banned from attending theatrical performances.

On the other hand, Indian kings enjoyed playing host to foreigners. Foreigners would be invited to entertain the court with stories of their travels. Once a year medieval Indians held a feast day for foreigners. That many foreigners were in India, at least in cities, is suggested by the feast day held once a year for foreigners. On that day foreigners and Indians would come together to eat and dance.

The picture of foreigners' lives in Southeast Asia is unclear. The peaceful spread of Indian culture through most of Southeast Asia suggests that foreigners could safely visit the region. The Chinese established many colonies in Southeast Asia, mostly as trading posts. People in the regions of modern-day Burma and northern Thailand showed hostility toward outsiders and deeply resented the Chinese, probably in response to China's occasional efforts to absorb the region within China's borders.

In the Philippines the Chinese seem to have been feared. Chinese visitors may have been avoided except for trading. In contrast, Polynesians seem to have been welcomed, and Polynesian settlers were absorbed into the Philippine cultures. The treatment foreigners received in Indonesia depended on what culture they visited. Like the Philippine peoples, Polynesians appear to have struck up good relations with Indonesians,

and many Polynesians settled in Indonesia and became part of the everyday fabric of the local cultures. Nonetheless, in parts of Sumatra foreigners found by local people were likely to lose their lives. Constant wars made local people hostile toward any outsider.

The peoples of Oceania were separated by dangerous open water. Many islanders in Micronesia were suspicious of people even from nearby islands, and trade required following strict rules to avoid bloodshed. A person washed ashore after experiencing an accident at sea or losing course often enjoyed a kind reception among the Polynesians of the central and western Pacific. Among the islands associated with Tahiti were cultures that were xenophobic, killing foreigners who strayed within reach. On New Guinea some peoples attacked and took prisoner or killed anyone not of their particular group. Outsiders were forbidden to tread on lands claimed by a group, and when two groups claimed the same land, each would persecute members of the other group.

The peoples of medieval Australia usually kept to themselves, but they had rules about how foreigners were to conduct themselves. These rules applied even when the foreigners and hosts did not speak the same language. Getting permission was important. In general, if outsiders asked in the right way under the right circumstances, they could gain authorization to pass through lands other than their own and even to use local natural resources. For instance, strangers could be given permission to hunt on local territory. It was implicitly understood that the strangers had to do something good for their hosts in return. If there was a drought, people who controlled a watering place might allow strangers to use it.

## EUROPE

BY BAILEY K. YOUNG

The Roman Empire included within its still-intact borders in 400 C.E. a multitude of peoples whose ethnic particularism overlapped with their common, or cosmopolitan, identity as imperial citizens (*Romani*). A merchant living at Lyon in Gaul might be from a Greek family whose main branch was in Syria; he was thus a foreigner of sorts to his customer, a Gallic gentleman whose ancestral language was Celtic but whose career in the emperor's bureaucracy was conducted in Latin. But to a Germanic warrior from the Rhineland both men were Romans while to them he was a *Barbari*, or barbarian, a term the Romans had borrowed from the Greek to designate an outsider. Although this term might, and often did, convey disrespect, it did not necessarily do so; already many high-ranking officers in the Roman army were *Barbari*, including the commander in chief that year, Stilicho (ca. 365–408), whose son married into the imperial family.

Over the next century the Western Roman Empire fragmented into pieces ruled by barbarian kings such as the Ostrogoth king Theodoric (r. 474–526) in Italy and Clovis, king of the Salian Franks (r. 481–511), in Gaul. During this time a paradoxical process of distinction and blurring was taking place. The successful barbarian groups sought to consolidate and enhance their sense of ethnic identity by such stratagems as turning their oral customs into written law codes (still written in Latin) to be applied in place of Roman law. They maintained ethnic styles of dress and adornment, and some, most notably the Franks, invented an ostentatious form of burial with weapons and jewelry that proclaimed their difference from the Romans or the other barbarians they ruled.

There was a profound ambiguity in this ethnic assertion, however, as shown by a detailed analysis of the burial of Childeric I, king of the Salian Franks (r. ca. 457–82), at Tournai. His bejeweled weapons, the sacrifice of his royal stable, and the imposing earthen mound built over his grave stress his “barbarian” identity. At the same time, objects like the gold signet ring inscribed with his name and the golden bow brooch, which had long been a badge of high rank in the Roman administration, seem to express what the written historical record also does: that he was a loyal and highly regarded player on the Roman side. When his son Clovis was baptized a Catholic, he was seen by the leading Gallo-Romans as chosen by God to be the leader of their side.

Recent scholarship has shown that it was under the Merovingian Dynasty (447–751) that the Frankish identity was really constructed and that it was a complex and composite identity, incorporating Roman as well as Germanic features. The foremost writer from the period, Gregory, bishop of Tours (538–94), who proudly describes his impeccably aristocratic Gallo-Roman family history reaching back generations, lays no stress on ethnic difference from the Franks. Instead he writes of the two groups intermarrying, giving their children names from the other tradition, and competing with one another for high positions in the king’s service or in the church.

Archaeological research confirms this picture of cultural synthesis. Around 550 Frankish-style burials appear in the cemetery of Frénoville, near Caen in Normandy, but careful analysis of the skeletons shows they were not newcomers but leaders of the native Gallic community who had adopted the new burial style. By the time the Carolingian Dynasty had seized control from the Merovingians, their realm was most frequently called Francia instead of the old name, Gaul, and the term *Franks* might equally signify merchants in the old Gallic town of Tours speaking the Romance dialect or a village of farmers by the upper Rhine speaking Germanic. It was highly unlikely, of course, that such people would ever meet.

The horizons of most people had shrunk to their local world, and anyone beyond it was a foreigner, to be feared and distrusted. But for the few who did travel about—warriors, landowners, churchmen, and a few merchants—the distinction that now mattered was between “us,” Franks and Christians, and “them,” dangerous outsiders, often pagans.

The great achievement of Charlemagne, king of the Franks (r. 768–814) and emperor of the West (r. 800–14), and of the educated churchmen who shaped the European worldview over the next centuries was to consolidate this new identity. “Pagans are wrong and Christians right!” proclaims the poet of the *Song of Roland*, using a legend set in Charlemagne’s time to convey a message that both expresses the strong conviction of his own time (the First Crusade, 1096–1099) and creates a template for attitudes toward dangerous foreigners. Thus the knights who captured Jerusalem in 1099 remorselessly massacred the population—men, women, children—considering them all pagans, even though many were Jews or Eastern Orthodox Christians. Their attitude toward the Byzantine Greeks, who were, for them, Christians of the wrong sort (not acknowledging the claims of the Roman pope to universal authority), was also marked by suspicion, negative stereotypes (the Greeks were unmanly and treacherous), and outright hostility.

In 1204 crusaders sacked and plundered Istanbul (then called Constantinople) itself. Other crusaders waged relentless war against the Muslims in Spain, the pagan Slavs in the Baltic region, or even dissenting Christians in southern France (the Cathari), unconcerned with differences among them: What mattered was that they were impediments to the ideal of the unified, doctrinally correct Christendom proclaimed by the clerical elite to be God’s will. By 1100 non-Catholics had come to be seen in much the same negative light as barbarians during the Roman Empire.

The dynamic growth from the Crusades to the Black Death, roughly 1100 through the 1300s, meant that increasingly more Europeans were encountering foreigners in a different, not hostile sense, more like that of the present day. Mostly these were other Europeans, different in speech and in customs from one’s own cultural group. The bustling towns and cities offered many opportunities to encounter others as expanded trade led to much more nonmilitary travel. By 1200 London was the great trading hub of northern Europe, and a community of Flemish and German merchants lived there under its own laws and customs. The rue des Lombards, in the heart of Paris, preserves the memory of the merchants and bankers from northern Italy who did brisk business there. Great lords eager to develop profitable new towns deliberately invited skilled foreigners to settle there. In 1257 a Polish duke, Boleslaw, founded Kraków, inviting Germans to

come and live there under a charter based on that of Magdeburg, Germany; he even forbade Slavic peasants from nearby villages to become burgesses.

Many eastern European cities developed German-speaking communities, with their own schools, churches, and sometimes law courts, that lasted right into modern times. Mediterranean port cities, like Venice and Genoa in Italy, Marseille in France, and Barcelona in Spain, were accustomed to foreigners of all sorts passing through, and business ventures frequently took their own citizens to foreign cities, such as Istanbul in Turkey (where the Italians lived in a separate quarter in the later Middle Ages), Alexandria in Egypt, and Damascus in Syria. Despite the official hostility of the church to Islam, these merchants did business with Muslims and others, and this interchange encouraged new, more open attitudes. In the 1270s the Venetian explorer Marco Polo (1254–1324) traveled across Asia and wrote a book on his return describing the wonders of the cultures he encountered, especially praising the China of the Mongol conqueror Kublai Khan (1215–94). Although many thought he was exaggerating, the book was very popular and showed a new European curiosity about the wider world.

Two other factors made later medieval Europe a more cosmopolitan place and encouraged a positive attitude toward foreigners. In the early 1200s Saint Francis of Assisi (1181 or 1182–1226) from Italy and Saint Dominic (ca. 1170–1221) from Spain founded a new kind of religious order whose vocation was not to stay in one place and pray (like the older Benedictine monks) but to travel about preaching and teaching. Both branches of the order, the Franciscans and the Dominicans, grew at phenomenal rates and were international in scope. Francis started with a handful of disciples from his hometown; before he died there were thousands of Franciscans throughout Europe, especially in the towns where huge new churches were built for the crowds who came to hear the preaching. Friars traveled widely and lived in communities of mixed nationalities.

The same was true of the other great institution that was reshaping society, the university. From the time universities first emerged around 1200 in Paris (France), Bologna (Italy), and Oxford (England), students flocked from all over to study theology or law and thus qualify for high positions in the church or state. They formed associations based on their native language to negotiate conditions of work and study with the authorities (for example, English students in Paris), but all shared Latin as a common language of learning. They also played and drank together in this universal language of educated Christendom, for some of their drinking songs have been preserved. The faculty of medieval universities was also international in character; leading philosophy professors at

Paris in the later 1200s were Albertus Magnus (ca. 1200–80) of Germany and Thomas Aquinas (1225–74) of Italy. Small towns and villages, in the later Middle Ages and long after, tended to be closed communities with limited exposure to foreigners (which could mean people from 20 miles away) and often kept a wary attitude toward them, but the larger towns and cities were cosmopolitan places where residents recognized the value of attracting foreigners.

## THE ISLAMIC WORLD

BY JUSTIN CORFIELD

As the Islamic world expanded from Arabia to Egypt, the Holy Land, North Africa, and Asia Minor, large numbers of Christians, Jews, and others came under Islamic rule. Despite numerous wars, pilgrims continued to travel to the Holy Land and other places connected with Christian saints, and some traders and craftspeople from Christian Europe visited the Islamic world.

For roughly four centuries after the Muslim Arabs captured Jerusalem in 638, Christians continued to visit the Holy Land, as they had since the fourth century. The Arabs also allowed Jews to enter the city, lifting the ban imposed during Byzantine rule. There are many accounts of foreigners visiting Jerusalem on pilgrimages during the period of Arab rule, and the large number that did so suggests that they were not put off by the long journey and were received by relatively tolerant or even welcoming Muslims.

Of the various pilgrims described in historical accounts, an Anglo-Saxon, Willibald, descended from the king of Kent, managed a pilgrimage to Jerusalem in the 720s, and about 300 years later Sweyn Godwinson (d. 1052), the eldest son of Earl Godwin of Wessex and brother of Harold II (later king of England), also went to Jerusalem, apparently completing much of the journey in bare feet. Two English clerics, Alured, the bishop of Worcester, and Ingulphus, the abbot of Croyland Abbey, went to Jerusalem in 1058 and 1064, respectively.

A major change in access to Jerusalem occurred in 1071, when the city was captured by Seljuk Turks. Descended from the Turkoman people of central Asia, the Seljuk Turks rejected foreign rule of any lands under their control. They opposed anyone who was not Muslim and immediately began a process of discrimination against Christians. In this atmosphere of heightened tensions Pope Urban II called for the First Crusade in 1095. The crusaders captured Jerusalem in 1099 and began establishing crusader kingdoms in the Holy Land.

The behavior of the crusaders—usually identified by Arab writers as Franks—led many in the Islamic world to despise European Christians and the crusader kingdoms. How-

### THE TRAVELS OF WILLIBALD

Willibald was born in about 700 in Wessex, England, and was probably the grandson of Hlothere, the king of Kent (r. 673–85). When he was about 20, Willibald decided to go on a pilgrimage, initially to Rome; on arriving there, he decided to press on to Jerusalem and then to the lands of the Arabs. To do so, he proceeded to Syria in 722, where he seems to have been treated well initially. But many people were suspicious of his activities, and it was not long before he and his traveling companions were in trouble. At the town of Emesa (modern-day Homs, Syria) they were taken prisoner by the Saracens, who claimed that Willibald was a spy. They were released soon afterward, and Willibald himself spent four years traveling around the Christian religious sites of the Holy Land, visiting Jerusalem many times. It was during one of these visits that Willibald was arrested and accused of smuggling balsam from Jerusalem. It is likely that he had indeed been smuggling, but nonetheless he was released. Returning to Europe, Willibald settled at Monte Cassino and was later sent to Germany, where he worked with Boniface (later Saint Boniface), a missionary to the Frankish Empire. He died in 781 or 787 in Eichstatt, Bavaria, Germany.

The account of Willibald's travels was recorded by Hygeburg (also called Huneberc), an Anglo-Saxon nun who was living at Heidenheim. Written between 767 and 778, probably based on stories told by Willibald himself, it provides an insight into the treatment of Christian pilgrims nearly 300 years before the Crusades and shows a remarkable level of tolerance by the Arabs for genuine Christian pilgrims. Although the account of Willibald's time in the Holy Land has been recorded, it seems probable that he was only one of many who made pilgrimages during the eighth century.

ever, soon after the founding of the kingdom of Jerusalem, pilgrimages from Europe started again. Edgar, the grandson of King Edmund II of England (r. 1016) reached Jerusalem in 1102, and Godericus, another Englishman, is recorded as being a pirate who sailed to the Holy Land in 1103 and attacked Muslims.

Fighting in the Holy Land took place at the same time as fighting between the Normans and the Muslims in Sicily and the battles that the Spanish and Portuguese fought with

the Moors in the Iberian Peninsula. Some rulers of Christian Spain managed to cement ties with some Muslim rulers, and even the Spanish warrior Rodrigo Díaz de Bivar ("El Cid") formed alliances with many Muslims to remain in control of Valencia.

As a result of the many wars between Muslims and Christians fought during most of the medieval period, tens of thousands of European Christians were held as slaves in many Islamic regions but mainly in North Africa, where pirates from the Barbary States (Morocco, Algiers, Tunis, and Tripoli) captured hundreds of European trading vessels and made occasional attacks on some European ports. In addition, the failure of the Children's Crusade in 1212 led to the capture of large numbers of European children, who became slaves of the Seljuk Turks. The enslavement of European Christians—of whom some were treated well but others were forced to work in galleys or mines—overshadowed any possibility of good relations between the kingdoms of Europe and

"Challenging the Iranians," from a *Shahnameh* (*Book of Kings*) by Firdawsi, opaque watercolor, ink, and gold on paper; early 15th century (Freer Gallery of Art, Smithsonian Institution, Purchase, F1930-48)

the rulers of the Barbary States. Ironically, another impediment was that during the later medieval period North African slaves were being exported to the Americas.

However, despite the general view in the Islamic world that the people of Christian Europe were hostile, Muslims made some important contacts with European artisans. Certainly houses around the Kasbah in Algiers show evidence of Venetian architecture and glassmaking. It is also clear that the Genoese were involved in trade with parts of North Africa, with an increase in the European demand for luxury goods from the East. The Islamic world also showed renewed interest in European weaponry, some of which likely originated in China (such as crossbows and gunpowder) and had earlier reached Europe through the Arabs.

Evidence of foreigners being accepted into the courts of Islamic kingdoms came when fighting took place in Austria in 1242 and soldiers serving the duke of Dalmatia (a region of the Balkan Peninsula) captured an Englishman working as an emissary of Batu Khan (d. 1255), grandson of Genghis Khan, who controlled the Mongol armies in southern Russia. The man was put on trial and executed in July 1242. One historian suggests that he could have been Master Robert, a Roman Catholic priest from England who had accompanied two knights on a mission from King John to Morocco in 1213. On completing the mission, Master Robert returned to England but, disenchanted with King John, decided to go back to the Islamic world and ended up in the crusader city of Acre. He subsequently embraced Islam and was appointed to a senior position at the court of Batu Khan. His skills were so highly valued that he was sent twice to talk with the king of Hungary on behalf of the Mongols.

The Genoese traveler Marco Polo (1254–1324) provided more details about the acceptance of foreign traders in Islamic lands. In 1271 Polo accompanied his father and uncle, prosperous merchants and traders from Venice, on their second visit to China, a journey of about 25,000 miles that took them through much of the Islamic world. In his account of the trip, titled *The Travels*, Marco Polo describes his dealings with Christians, Armenians, and other peoples in the region, but most of the information he provides on the Muslim population is general, implying that he found out about them and often had business dealings with them but was not invited into their houses.

Some years after Marco Polo, Ibn Battuta (1304–77), from Tangier, Morocco, started traveling throughout the Islamic world in 1325. Trained as a scholar, he explored regions of the Byzantine Empire and traveled to parts of the Mali Empire and sub-Saharan Africa. During his voyages, which covered about 75,000 miles, he traveled to India and the Far East, including China. His attitude toward people in the re-

gion was fairly relaxed, reflecting the extensive contacts that had already occurred, through trans-Saharan trade routes, between the Arabs of North Africa and the people of the Sahara and sub-Saharan Africa. While Marco Polo found some of the people he met in the Islamic world to be extremely fearful of Westerners, Ibn Battuta, with a greater degree of openness and religious and cultural affinity, seemed to have received a better reception. That the Polos were chiefly traders and Ibn Battuta was a traveler-explorer was probably another important factor in the differing attitudes encountered by each among the local people. This is evident from the intent of Ibn Battuta's book, suggested by its title, often translated as *A Gift to Those Who Contemplate the Wonders of Cities and the Marvels of Traveling*.

As early as 1099, during the siege of Valencia, Spain, a Spanish chronicler noted that the Moorish soldiers included 300 black female warriors led by Nugaymath Turquia, a Tureg woman who had joined the Moorish Almoravid army to fight the Spanish army led by El Cid. This acceptance of black Africans could be viewed as an indication that the attitude of the Islamic world toward people of different races was more open than that of Christian Europe, but during some periods in parts of North Africa, most black Africans were slaves. Indeed, Arabs were prominent slave traders in western Africa as well as along the east coast of Africa.

Some people of the Islamic world were also in contact with Chinese merchants and traders. Many medieval artifacts of Chinese origin have been found in Arabia and other parts of the Middle East, indicating a major trade in the works of Chinese artisans. In 1421 the Chinese admiral Zheng He led a massive naval expedition around the Indian Ocean. Zheng was well received in much of the Islamic world because he was a Muslim.

The Islamic world conducted a flourishing trade in spices as well as sandalwood and tin from Southeast Asia, and the Silk Road was the historic route of east-west trade not only in silk but also in gold and other metals. As a result of the extensive trade between Muslims and Southeast Asians, many of the merchants of modern Malaysia, Indonesia, and Vietnam embraced Islam.

With the emergence of the Ottoman Empire in the 14th century a single entity gradually took over much of Asia Minor and later controlled much of the Middle East. Although the leaders of the Ottoman Empire were Muslim, they did not discriminate against Christians and others as much as the Seljuk Turks had. At the heart of the Ottoman army was the Janissary Corps, recruited from Christian youth from the Balkans who converted to Islam and after training became the troops often fighting battles with armies from Christian Europe.

≈ *Fulcher of Chartres: The Capture of Jerusalem (ca. 1100)* ≈

**CHAPTER 27: THE SIEGE OF THE CITY OF JERUSALEM**

On the seventh of June the Franks besieged Jerusalem. The city is located in a mountainous region, which is lacking in rivers, woods, and springs, except the Fountain of Siloam, where there is plenty of water, but it empties forth only at certain intervals. This fountain empties into the valley, at the foot of Mount Zion, and flows into the course of the brook of Kedron, which, during the winter, flows through the valley of Jehosaphat. There are many cisterns, which furnish abundant water within the city. When filled by the winter rains and well cared for, they offer both men and beasts an unfailling supply at all times. Moreover, the city is laid out most beautifully, and cannot be criticized for too great length or as being disproportionately narrow. On the west is the tower of David, which is flanked on both sides by the broad wall of the city. The lower half of the wall is solid masonry, of square stones and mortar, sealed with molten lead. So strong is this wall that, if fifteen or twenty men should be well supplied with provisions, they would never be taken by any army. . . .

When the Franks saw how difficult it would be to take the city, the leaders ordered scaling ladders to be made, hoping that by a brave assault it might be possible to surmount the walls by means of ladders and thus take the city, God helping. So the ladders were made, and on the day following the seventh, in the early morning, the leaders ordered the attack, and, with the trumpets sounding, a splendid assault was made on the city from all sides. The attack lasted till the sixth hour, but it was discovered that the city could not be entered by the use of ladders, which were few in number, and sadly we ceased the attack.

Then a council was held, and it was ordered that siege machines should be constructed by the artisans, so that by moving them close to the wall we might accomplish our purpose, with the aid of God. This was done. . . .

When the tower had been put together and had been covered with hides, it was moved nearer to the wall. Then knights, few in number, but brave, at the sound of the trumpet, took their places in the tower and began to shoot stones and arrows. The Saracens defended themselves vigorously, and, with slings, very skillfully hurled back burning firebrands, which had been dipped in oil and fresh fat. Many on both sides, fighting in this manner, often found themselves in the presence of death. . . .

On the following day the work again began at the sound of the trumpet, and to such purpose that the rams, by continual pounding, made a hole through one part of the wall. The Saracens suspended two beams before the opening, supporting them by ropes, so that by piling stones behind them they would make an obstacle to the rams. However, what they did for their own protection became, through the providence of God, the cause of their own destruction. For, when the tower was moved nearer to the wall, the ropes that supported the beams were cut; from these same beams the Franks constructed a bridge, which they cleverly extended from the tower to the wall. About this time one of the towers in the stone wall began to burn, for the men who worked our machines had been hurling firebrands upon it until the wooden beams within it caught fire. The flames and smoke soon became so bad that none of the defenders of this part of the wall were able to remain near this place. At the noon hour on Friday, with trumpets sounding, amid great commotion and shouting "God help us," the Franks entered the city. When the pagans saw one

standard planted on the wall, they were completely demoralized, and all their former boldness vanished, and they turned to flee through the narrow streets of the city. Those who were already in rapid flight began to flee more rapidly.

Count Raymond and his men, who were attacking the wall on the other side, did not yet know of all this, until they saw the Saracens leap from the wall in front of them. Forthwith, they joyfully rushed into the city to pursue and kill the nefarious enemies, as their comrades were already doing. Some Saracens, Arabs, and Ethiopians took refuge in the tower of David, others fled to the temples of the Lord and of Solomon. A great fight took place in the court and porch of

the temples, where they were unable to escape from our gladiators. Many fled to the roof of the temple of Solomon, and were shot with arrows, so that they fell to the ground dead. In this temple almost ten thousand were killed. Indeed, if you had been there you would have seen our feet colored to our ankles with the blood of the slain. But what more shall I relate? None of them were left alive; neither women nor children were spared.

### The Islamic World

#### ≈ Abraham Ibn Daud: "On Samuel Ha-Nagid, Vizier of Granada," from *Sefer Seder ha-Kabbalah* (1161) ≈

One of the great disciples of Rabbi Enoch was Rabbi Samuel HaLevi, the Prince, the son of Joseph, who was known as Ibn Nagrela, of the community of Cordova. He was an unusually fine Talmudic scholar and was also well versed in Arabic literature and language. He was of the type that could occupy a high position in the royal palace.

Samuel was a merchant, supporting himself with great difficulty until the devastating days in Spain which followed the fall of the Amirid kingdom when the Berbers secured the power.

It was then that the land of Cordova began to decline and its inhabitants fled. Some of them ran away to Saragossa, where their descendants are even now; some fled to Toledo and their descendants are known there even to this day.

This Rabbi Samuel HaLevi fled to Malaga. There he had a shop and was a petty merchant. His shop happened to be near the palace of Ibn alArif, the vizier of King Habbus, the son of Maksan, the King of the Berbers, in Granada. At the request of a maid servant of the vizier, Samuel used to write letters for her to her master the vizier, Abu alKasim ibn alArif. This latter saw his letters and was amazed at his wisdom.

Some time later this vizier, Ibn alArif, got permission of his king, Habbus, to return to his home in Malaga. There he asked the people of his house: "Who used to write those letters that came to me from you?" "A certain Jew," they answered, "who comes from the community of Cordova and lives near your palace—he used to write them for us." Immediately the secretary issued a command and they rushed Rabbi Samuel HaLevi to him. "It is unbecoming for you to sit in a shop," he said to him. "Stay here with me." He did so and became his secretary and adviser.

The vizier used to advise the King according to the advice given by Rabbi Samuel HaLevi, of blessed memory. All his advice was as though it came from God, and the King Habbus prospered through it very much. After some time the vizier, Ibn alArif, became mortally ill, and King Habbus, who came to visit him, said to him: "What shall I do? Who will advise me in the wars which encompass me?" "I have never advised you," he answered him, "out of my own mind, but at the suggestion of this Jew, my secretary. Take care of him, and he will be as a father and a minister to you. Do whatever he advises you, and God will help you." So

(continued)

(continues)

after the death of the vizier, King Habbus took Rabbi Samuel HaLevi and brought him to his palace and he became his vizier and councilor.

In the year 4780 [1020] he was in the palace of the King Habbus. The king had two sons: the name of the elder was Badis, and the younger, Bulukkin. All the Berber princes favored Bulukkin, the younger son, as the successor, but all the rest of the people favored Badis. The Jews, too, and among them Rabbi Joseph ibn Migas, Rabbi Isaac ben Leon, and Rabbi Nehemiah, who was called Escafa, three Granada notables, favored Bulukkin, but Rabbi Samuel HaLevi favored Badis.

On the day that King Habbus died, the Berber princes and their distinguished men rose in the morning to crown his son Bulukkin. Bulukkin, however, immediately went and kissed the hand of his elder

brother Badis. Thus Badis was crowned in the year 4787 [1027] and the face of his enemies turned black like the bottom of a pot; and against their will they had to crown Badis.

After this Bulukkin regretted that he had made his brother king and kept on getting the upper hand over his brother Badis, with the result that King Badis was unable to do a thing, big or small, without his brother's interference. But after this his brother Bulukkin became sick, and the King gave orders to the physician not to cure him. The physician obeyed, and Bulukkin died. Thus was the kingdom established in the hands of Badis. These three distinguished Jews of the city, whom we have mentioned, fled to the land of Seville.

## ► forests and forestry

### INTRODUCTION

Paleontologists believe that the first human beings appeared on open grassy plains in East Africa. Perhaps from that time to the present forests have been mysterious and somewhat alien to people, who are built to move swiftly over open ground. Much of the story of forests during medieval times is one of people trying to control them, either by destroying them or by managing their growth.

In western Europe people sometimes abandoned unwanted children in forests, in the hope that people there would take in the youngsters. In China and Southeast Asia young orphans starved, were made slaves, or found sanctuary in for-

ests, often becoming bandits who preyed on rural villages and unwary travelers. In India forests were feared because of the ruthless bandits they sometimes sheltered. Forests sheltered other people as well. Even during the medieval era India's forests harbored hunter-gatherer cultures—people who worshiped forest gods and would fight to drive away those who would build roads among the trees. For many years historians and anthropologists believed that such forest dwellers lived in perfect harmony with their environments, finding food and game without altering the pristine natural environments. It is unlikely that medieval peoples harbored any such illusions, and modern research has shown the idea to be nonsense. Wherever people and forests came together, people altered the forest environment for their own purposes.

For instance, on forested Pacific islands, many people lived in clearings among the trees, venturing into what would seem at first glance to be unaltered forests. But they planted taro roots among the trees, and to do so they cleared spaces between trees, moved dirt into heaps, and kept their plots clear even though the forest canopy was unbroken overhead. In the forests of the Amazon people made mounds of dirt and planted trees that produced nuts or fruit, altering the forest environment in favor of trees directly beneficial to them. Further, people changed forest environments through hunting. In Oceania people sometimes wiped out wild animals on an island and then moved to another and did the same.

People also tried to control forest growth. In North America people of the central plains set dry grass on fire to clear the land for new growth of forage for their staple food: bison. Without their actions over thousands of years the great eastern forests of North America would likely have extended much farther westward than they did. In many parts of the world people burned forests to make room for farming. In western Africa this was part of a system of rotation. A plot would be farmed for a few years and then would be left alone for about 10 years, allowing the soil to recover while other plots were farmed. People would again burn away growth on the plot when the time came to replant it. Elsewhere, as in Central America, people burned without thought to renewing the land, resulting in ecological catastrophes such as that which befell the Maya. The Maya were not unique in this—even in faraway southern Africa, the Great Zimbabwe civilization met with a similar fate in the late 1400s.

Among some medieval peoples, managing forests was institutionalized. In Europe laws were created to govern who could use a forest and how the forest was to be used. In India foresters were craftsmen charged with managing forests. They determined which trees would be felled at what time, and they took care that animals were not overhunted. Further, they were required to replant with trees any areas that had been logged, creating forests that appeared primeval but actually were filled with trees chosen by people because the trees were useful.

Thus, there were competing needs for the civilizations that arose in and near forests. People needed forests to remain intact yet also needed to remove forests to use the wood and to make room for people to settle. This conflict sometimes led to outright destruction of forests, but there were examples of the ways in which a culture could manage its forests to preserve them. By late medieval times China had nearly eradicated its northern forests and was losing its southern forests all the way to its southern mountains, where logging was difficult, but in much of India forests remained thick upon the land. In Europe, even while great swaths of forest were cleared for farms, large tracts were protected by law from destruction. In Japan, where wood was used to build almost everything, continuous replanting of forest kept its islands covered by trees. Many of the forests that exist today are the result of the efforts of medieval cultures to conserve them and even to nurture them.

## AFRICA

BY LEAH A. J. COHEN

In modern times the definition of *forest* varies depending upon the criteria used. Definitions can be related to canopy cover, biomass, tree type and size, or land use. Forests can

be classified as old growth or secondary/fallow and also are classified based on ecological characteristics, such as species, rainfall, and elevation. Defining forests has become increasingly complex owing in part to the impact that humans have on forests. People can clear forests, selectively harvest species and thereby alter the composition of a forest, replant forests with different species, and plant specific species of trees for a multitude of uses, such as conservation or agriculture. These varied uses of forests and forest resources increased dramatically just before and during the medieval period as humans' activities affected and altered forests more extensively than ever before.

Reconstructing a picture of forest cover during medieval times is based on archaeological evidence of the human use of forest resources and research on climate and ecological characteristics. In general, forest ecology is supported in areas of Africa that receive more than 55 inches of rainfall annually. Rainfall of between 15 and 55 inches annually supports savanna or grassland ecology with interspersed trees and woodland areas. Furthermore, forests tend to occupy riversides in many areas. During the medieval period there were equatorial rain forests in central Africa, forests in the higher elevations of eastern and southern Africa and the Atlas Mountains of northwestern Africa, and coastal forests in western Africa and eastern and southeastern Africa. Woodland ecology extended in a band from present-day Cameroon toward the southeast into present-day Mozambique.

The exact boundaries and expanse of these forests and woodlands varied during the medieval period based on climate changes. The changes in the boundaries of these ecosystems have been detected in the archaeological record by the movements of pastoralists. Herders avoided forested areas because these were the natural habitat for tsetse flies, which carried the disease trypanosomiasis that infected and killed large livestock. At the start of the medieval period forests and woodlands still extensively occupied the mountainous regions extending from Ethiopia into southern Africa. Land use during this period reduced the forest cover in this area. Furthermore, the climatological and archaeological records from the medieval period show that forests lay farther to the north during the Medieval Warm Period (800–950 C.E. through 1300 C.E.) as the result of the northerly route of the seasonal rains. As the temperatures dropped during the 1300s and the seasonal rains began to move across a more southerly route, the forest boundaries moved with them.

Before and during the medieval period the use of forest resources changed forests and human life dramatically. Rainfall was no longer the most important factor that determined whether forests thrived. The spread of iron-smelting technologies, the Bantu expansion (the third phase of which oc-

curred in the first millennium C.E.), and general population growth led to the clearing of forests and increased use of forest resources. An enormous number of trees were needed for the growing number of iron-smelting furnaces that turned natural iron ore into iron tools. As the population grew, more land was cleared for growing food. With the expansion of iron smelting and agriculture, the forests and woodlands of the highland areas of eastern and southern Africa, in particular, were transformed into grassland.

The areas that remained forested in central Africa tended to be the home of groups of people who continued to live primarily by hunting and gathering. One exception was the forested kingdom of Benin, which was located in present-day Nigeria (no geographical relation to the present-day country of Benin). The kingdom of Benin reached its peak of power during the late medieval period (ca. 1400). It differed from the medieval kingdoms that developed elsewhere in Africa because the forest served as a barrier to Muslim travelers, who did not reach Benin until much later than other medieval kingdoms, sometime after 1600.

People had many other uses of forest resources in addition to iron smelting during medieval times. Wood from trees was used for cooking and building homes. Plants and trees were used for medicine. The seeds and fruits of trees were used as a food source, and some were traded through the trans-Saharan trade routes. People living in forested areas traded forest resources with people outside the forests. For example, the forest dwellers of western Africa during the medieval period used dugout canoes to travel the Niger, Senegal, Volta, Cross, and Gambia river systems toward the coasts to trade with communities that specialized in fishing and salt production. In addition, ivory from the forested regions of Africa became an important item of trade during this period. The great empires of Ghana, Mali, and Songhai, although not located within the forests, benefited from the gold mines of the Guinea forests during the medieval period.

For many cultures the forests held a certain amount of spiritual and cultural significance. The African baobab trees, in particular, have been a focus of colonial and modern explorers and scientists. The Wolof of western Africa had a custom of burying deceased members of the bard caste (of poet-singers) at the base of baobab trees, which they thought would prevent drought. In a well-known African creation myth in which each animal is given a tree, the Great Spirit assigns the baobab to the hyena. The hyena is so disappointed that he throws the tree down, and it lands upside down, giving the baobab its unique appearance.

In the regions of present-day Burkina Faso, Senegal, and Ethiopia certain cultures believed that the forests and specific trees were homes and meeting places of important spirits

and ancestors. The people who lived in Burkina Faso believed that the baobab tree was a resting spot of gods and a refuge for ancestors; when a tree that was particularly important in the community died, the people conducted a funeral service. Since there are limited written records of the mythologies of people before the travel documents of the Arabs from medieval times and Europeans after the 15th century, it is not known how old these myths are, but they were probably present in medieval cultures.

Deforestation as the result of human activities during medieval times became a pattern seen in many regions of Africa, even though the time frame varied slightly. In eastern Africa substantial deforestation from iron smelting and the expansion of agriculture began in the Great Lakes region of eastern Africa just before and during the first millennium of the Common Era and by the start of the medieval period in about 500. The forested landscape in this region had already changed to grassland, secondary forests, and agriculture; by 1000 the area included a notable population of domesticated cattle. Examination of archaeological remains indicates that initially the wood used in iron-smelting furnaces was from old-growth, mixed and mature forests in the area. Over time iron smelters had to use younger trees and those from areas that were less convenient, such as swamps. After stripping the forests and causing serious erosion, people left the area for a better resource base in the late first millennium. People moved back during the 13th and 14th centuries after the forests had partially recovered.

All over Africa iron-smelting activities resulted in the massive clearing of forests and exposed the fragile forest soil to the elements; this may have contributed to the collapse of great civilizations. This pattern of deforestation often led to an adaptation of livelihoods, and in some places it prompted people to turn to pastoralism when the forests were gone. As the forests lands were cleared, the natural habitat for the disease-carrying tsetse fly shrank, but the more open habitat of the malaria-carrying mosquito replaced the forests. The detriments and advantages to the transformation of the forested regions of Africa were widespread.

## THE AMERICAS

BY MICHAEL J. O'NEAL

At the time of Christopher Columbus's arrival in the Americas, roughly 80 percent of North America's forests were located on the eastern half of the continent. Heavily forested areas extended from modern-day eastern Canada down through New England to the upper American South, then across the Great Lakes states to the eastern edge of the midwestern plains. The other 20 percent were located primarily

in the American and Canadian Northwest and parts of the Rocky Mountain regions.

The presence—or absence—of forests in many ways shaped the cultures of the people who inhabited these regions. Forest dwellers were able to feed themselves with game animals that lived in forests and fish from the rivers that watered the forests. The forests were a source not only of lumber and firewood but also of such food items as nuts and fruits. In contrast, people who lived in more barren areas, such as the American Southwest, had to rely more on agriculture aided by extensive irrigation systems to grow most of their food. Those who lived on the plains led a more nomadic existence as they followed herds of game animals, such as buffalo.

Historians disagree about the nature of forestry management practices among pre-Columbian Native Americans. Some argue that the impact of Native American communities on forests was minimal. This view is based in part on low population estimates, perhaps 8 to 15 million for North, Central, and South America. According to this view, much of pre-Columbian North America was covered by vast expanses of forests that were in many places cut down only after the arrival of European settlers.

Other historians, though, believe that this view is romantic, driven more by the politics of modern environmentalism than by hard science. These historians refer to this belief as the “myth of the pristine wilderness,” the idea that forests remained virgin and in their natural state, undisturbed by humans. They note recent evidence that shows that the population of the Americas was probably at least 43 to 63 million and possibly up to double that number, making it inevitable that human populations affected the forests. They point to evidence that this much larger population engaged in practices that resulted in extensive modification of forests, creating some 30 to 40 newly treeless acres per person during the centuries before the arrival of Europeans.

One of these practices was the use of fire to create open areas for two purposes. One purpose was to clear fields, making it easier to hunt game, especially larger animals, such as deer, antelope, and elk. This practice was especially widespread at the margins of the Great Plains. Native Americans set large fires to prevent forests from spreading and even to push them back. Some historians even believe that the open grasslands of the plains were essentially a creation of Native Americans, who deforested parts of the region to form what in effect were “buffalo farms,” or large, open game preserves. In many places fires also were used to open up living spaces. In particular, fire eliminated the low brush that provided habitat for snakes, rodents, and other undesirable species.

Fire was used to clear agricultural land as well. Many Native American communities relied on slash-and-burn farm-

ing techniques. They cut down trees in forested areas to clear fields of 20 to perhaps 200 acres. After they cut the trees, they burned off the rubble and stumps and planted such crops as maize (corn), squash, and beans. Often conditions for a community deteriorated because of deforestation. Demand for firewood was constant, so land was deforested in an ever-widening radius around a village. Further, maize consumes a large amount of essential nitrogen in the soil, so soil conditions in maize fields quickly degraded. When these conditions arose, the people simply picked up and moved, engaging in the same forest-clearing practices elsewhere.

Some Native American communities consumed large tracts of forestland for building purposes. For instance, the Cahokian culture, which occupied land at the confluence of the Mississippi, Missouri, and Illinois rivers, built an extensive defensive stockade around the community’s central hub. This stockade consumed up to 20,000 trees, and it frequently had to be rebuilt as the wood deteriorated. Progressive deforestation in the area led to extensive soil erosion, reducing the amount of tillable land in the fertile river bottoms and driving forest-dwelling game animals farther and farther away. Interestingly, after such cultures as the Cahokia collapsed in the centuries before the arrival of the Europeans, forests began to rejuvenate and creep back into the grasslands in such places as Nebraska, Kansas, Wisconsin, and parts of Texas. This phenomenon has led some historians to assert, controversially, that Native Americans may have had a greater impact on forests than European settlers later had.

These kinds of problems were by no means restricted to North America. Mesoamerica—the region encompassing central and southern Mexico, the Yucatán peninsula, and such modern nations as Belize, Guatemala, parts of Honduras, and El Salvador—faced similar problems, particularly in the more arid regions. Mesoamerica encompassed a number of zones with marked differences in terrain and flora. These areas included dense tropical rain forests, sparser highland forests, savannas (grasslands), and arid regions. Forestry management, of course, was not an issue where there were no forests or in the rain forests, where the sheer immensity of the forests muted the impact of human activities. But forestry management was a particular concern in nontropical forest areas and the regions at their margins, not only in Mesoamerica but in South America as well.

In these regions, too, slash-and-burn farming was often the norm. Many historians believe that the decline of the Mayan civilization beginning in about the ninth century is attributable to deforestation and soil erosion, at least in part. The Maya had the same problem that North Americans had. They cleared more and more land for agricultural purposes, and maize cultivation depleted the soil. There are no domes-

## FORESTRY AND CULTURE

Despite modifications in the forests that medieval Americans might have made, the fact remains that when the first European settlers arrived, they were met by two continents that in many places were densely forested, particularly in the eastern regions where the first Europeans put down roots.

Forestry practices at this point in history came into conflict with one another. In North America, for instance, several factors influenced the way Native Americans managed the forests that surrounded them. One factor was technology. Without the iron tools that were the product of European manufacture, Native Americans were limited in the types of forests they could clear and the extent to which they could clear them. Simply put, they were unable to clear large old-growth trees that in many instances were hundreds of years old, because their stone tools were unequal to the task. In contrast, the first European settlers brought with them iron tools that enabled them to cut such trees.

A second factor was the sheer immensity of the Americas. During the medieval period Europe was beginning to get crowded, and in many places old-growth forests had long been cleared. This was particularly the case in England, where old-growth oak forests were essentially gone by late in the medieval period. The English, occupying a relatively small island, had developed a long tradition of modifying their restricted environment to create farms, pastures, and gardens. Water wheels and windmills were common sights. When these settlers arrived in the Americas, they saw vast forests that appeared to them to be inexhaustible. It is little wonder, then, that they used wood for every conceivable purpose: to build plank roads, homes, and wagons; as firewood; to make tools; and to produce charcoal for iron production. In contrast, while Native Americans modified the forests, it is also the case that they allowed forests to regenerate over periods of hundreds of years. They cleared an area for farming and when the soil became depleted, they moved on to another area, allowing the earlier area to return to its natural state.

A third factor was philosophical and religious. Native Americans tended to regard the forests as sacred. The forests were home to animals and plants that provided them with sustenance. They saw themselves as just one of many species that occupied the forests. In contrast, the first European settlers were frightened of the forests. Forests in the popular imagination were occupied by spirits, witches, and demons as well as by various predatory species—bears, cougars, wolves, and similar animals that turned the forests into what the English called a “howling wilderness.” It was a place where a person could easily become lost—the English word *bewildered* literally means “lost in the woods” or “lost in the wild.” One reason that the first settlers distrusted Native Americans was that the natives seemed comfortable living and moving about in the forests. To medieval Native Americans, forests were home. To the first settlers, forests were something that had to be tamed.

tic herds in the Mayan area. Progressively less productive land was available, leading to population decline and, along with other factors, the eventual fall of the Maya as a major power in the area.

In the Peruvian Andes more than 1.5 million acres of terraced fields can still be seen, and historians believe that many millions more were under slash-and-burn cultivation. Historians, archaeologists, and botanists differ sharply about pre-Columbian forests and forest-management practices, particularly in the Amazon basin, which is home to an immense rain forest. The region has come to the attention of the public as scientists have learned more about the role of rain forests in absorbing carbon dioxide and releasing oxygen into the atmosphere. Many contemporary environmentalists vigorously oppose cutting down rain forests for agriculture. They regard the shrinking of the Amazon rain forests as symbolic of human degradation of the environment.

The traditional view is that pre-Columbian Amazonians lived in harmony with the rain forest and that human activities had only a very limited impact on it—again, the myth of the pristine wilderness. Other scientists, however, dispute this viewpoint, and some even contend that the rain forest as it is known today is in many respects a human creation. These scientists note that the soil in much of the Amazonian rain forest has always been poor, primarily because nutrients leech away in the persistent rain. The conventional belief is that for this reason, populations were limited to small bands who cleared relatively small areas of forest and then left when the soil was no longer able to produce crops. The forest reasserted itself until a new group came in and began the process all over again. However, some historians are revising this conventional view. They note that clearing rain forest without the benefit of modern machinery is an immensely difficult process—so difficult that few people during the pre-Colum-

bian period tried it. Instead, they planted trees, often on top of immense earthen mounds they constructed. These trees, unlike annual crops, such as maize or squash, were perennial crops, providing nuts, fruits, and other resources for a period of many years.

Thus, rather than being a pristine wilderness, parts of the Amazon rain forest are actually what some historians call “built environments.” These historians believe that at least 12 percent of the rain forest, and possibly much more, was actually created by humans. This point of view is the subject of controversy because in the eyes of some environmentalists it suggests that continued cutting of rain forests for agriculture is acceptable; environmentalists who oppose this view want to preserve the “pristine wilderness” view to justify making the forests off limits to any kind of development.

While much South American rain forest soil is poor, scientists have located areas where quite the opposite is true. They refer to these soils as *terra preta*, meaning something like “prepared earth.” Here the soil is thick, dark, and rich with microorganisms and nutrients. Some scientists believe that *terra preta* makes up about 10 percent of the Amazon rain forest, possibly more. What is astonishing about this soil is that it seems to be in effect self-regenerating. Scientists believe that during the pre-Columbian centuries these regions were, in effect, huge compost heaps, where people scraped off soil for use in agriculture and landscaped gardens, leaving a layer of it behind. This layer continued to “brew,” turning debris and the soil under it into new, rich topsoil. Again, this effect was the result of human forestry management.

Other Amazonian cultures took a different tack on forestry management, particularly in areas subject to annual flooding. In these areas people constructed immense earthen mounds to provide elevated areas for habitation. To keep water out of their fields, they built extensive networks of earthen dams, weirs, and canals. They then stocked these bodies of water with fish that could be caught for food. To maintain this system, people regularly burned away immense areas of trees and undergrowth. The result over time was a complex ecosystem of plant species that depended for their survival on human burning.

## ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The range of forests in medieval Asia and the Pacific was immense, as was the number of species that lived in them. But few forested areas were left untouched by humans. Forests stretched from the Himalayas across southern China to the sea, much of eastern Siberia was blanketed in pine forests, and India was covered from north to south by forests that

were interrupted but not dominated by human settlements. Tropical and temperate forests extended from Indonesia to Hawaii, and even Australia, now famous for its wide open lands, had vast areas of both types of forests. The story of the medieval forests is also the story of how people saw themselves in relation to the awesome mysteries of wooded lands and how they exploited those lands.

The trees in medieval Tibetan forests were well adapted to high altitudes and uneven terrain. Junipers, pines, firs, spruces, birches, and cherry trees were common. But perhaps the best-known and most highly valued Himalayan tree was the deodar, a cedar found throughout the central mountains and westward. Its timber was valued for building because of its durability. Above 8,000 feet were tough Bhutan pines. At even higher altitudes, up to 14,000 feet, were found the Himalayan birch, a tree that grew from Tibet into the mountains of southern China. Among forests of pines and other trees, from the Himalayas into central Asia, was the Indian cherry tree, whose wood was valued for furniture and decoration. Its acidic cherries were used in local medicines.

More than 30,000 plants were native to the territories of China. By the medieval era most of the forests of the north had been felled for fires or building. Vast oak forests near the Yellow River were cut during the period and used for building or fuel or cleared to make way for agricultural development. The forests farther south harbored alligators, monkeys, wildcats, and pandas. The pandas lived in vast bamboo forests, where people ventured to harvest bamboo shoots for food and mature bamboo for use in construction. Often found in these southern forests and the forests of Manchuria were tigers, leopards, bears, wild pigs, deer, pheasants, and chickens. Before the medieval era China had a long-standing custom that hunters should not kill every game animal they found but leave at least 50 percent. During the Han Dynasty (202 B.C.E.–220 C.E.) nobles had violated this custom, sometimes killing wantonly. The destruction continued in the medieval era, and forests resources were further depleted by a burgeoning rural population that supplemented its diet with wild game.

China’s forests had many trees that were important to people. The Yulan magnolia, from southeastern China, had white, cupped flowers that symbolized purity; it was grown in the gardens of Buddhist temples during the Tang Dynasty (618–907). The common walnut grew naturally from the Near East to Japan and thrived particularly in Korea. Its nuts were valued everywhere. The camphor tree grew throughout China, except in the far north. Fast growing and tolerant of almost any kind of soil, the camphor persisted despite people’s extracting oil from every part of it—roots, wood, and leaves—to use in medicines and to repel insects. The lychee

*Painting of a stream flowing through a bamboo forest by Wang Fu, China, 1410* (Freer Gallery of Art, Smithsonian Institution, Purchase, F1952-7)

tree produced a very sweet fruit that was considered a delicacy raw or cooked. The timber of the lychee was valued for its decorative beauty.

Korea had bountiful forests, the fruits and nuts of which were abundant. There were oaks, willows, elms, spruces, pines, and poplars as well as forests of bamboo. Within Korea's forests lived tigers, leopards, bears, wild pigs, deer, pheasants, ducks, quails, herons, and cranes. Common fruits were apples, pears, and persimmons. Tangerines and grapes were found in southern Korea. Frequent wars and invasions made management of the forests difficult, and invading armies sometimes lived off the food of the forests. The Korean pine grew not only in Korea but also in Japan and Manchuria. The seeds of its cones were eaten as food, and its timber was widely used for construction.

Eastern Siberia and Manchuria had huge forests. As China depleted its northern forests, Chinese lumbermen turned to harvesting the trees of Manchuria and Korea. The forest regions of eastern Siberia were very cold and remote from population centers. In them lived huge brown bears and Siberian tigers as well as wolves and deer. The forests included larches, osiers, crab apples, and pines. The fruit of the Siberian crab apple tree was fermented into wine.

In medieval Japan reforestation was considered a sacred duty. The practice of replanting where trees had been harvested probably began with a Buddhist priest named Gyogi (668–749). Reforestation became a requirement for students attending Buddhist schools, and shoguns and lords made laws requiring the practice. Most Japanese chose to live on the coastal plains or in mountain valleys rather than the mountains most prevalent in Japan's landscape. On those mountains grew vast forests. Even in the 1600s, when foreign mariners approached the island of Kyoshu, they saw dense forests rising up and out of sight, with the homes of people being low, near the seashore.

In medieval Japan wood was abundant and used for almost any sort of construction as well as for heat. Japanese homes typically had little furniture except for tables and cabinets. Among the multitude of tree species originating in Japan, many were valued for timber, including the red cedar, umbrella pine, magnolia, and keyaki (used extensively for temples). Trees valued for their decorative woods included the Hinoki cypress. The nut of the Japanese walnut was commonly eaten, although the husk was poisonous. Another significant food source was the Japanese chestnut; this tree produced nuts in enough quantity to make it worth growing in orchards. The inner bark of the paper mulberry was used to make paper.

The forests of Southeast Asia, Indonesia, and the Philippines were among the most varied in the medieval world. For instance, the lowland forests of Malaysia had more than 800 species of trees, and Sumatra's lowland forests had more than 100 species. River valleys had swamps filled with peat, which was used for fuel. The forests in these regions were very dark, and the lack of light on the floor limited the amount of undergrowth, enabling people to move through them quickly. Activity among the forests' wildlife was primarily in the branches of the trees. The systematic destruction of these forests probably did not begin until the 1400s, when Chinese lumbermen began harvesting trees on Borneo for export to China.

On mountainsides of Southeast Asia, Indonesia, and the Philippines grew forests of oak, myrtle, and laurel. Along the shores grew nipa palms, casuarina, and mangroves, all cut for timber used in construction. The tree with perhaps the highest cash value was the nutmeg, originally from the Moluccas islands in Indonesia. It was valued for its scent and as a spice, and oil from the seeds was used in local medicines. Also from the Moluccas came the clove tree. Its immature flower buds were dried and used for medicine and perfume and as a spice.

Also of great value was teak, found in Southeast Asia and India. Its hardwood was used for furniture and decorations.

The breadfruit tree grew on many Indonesian islands and in southern Malaysia. Its seeds were eaten, and its starchy fruit was baked for food. Having much the same range as the breadfruit tree, the golden apple tree produced edible but sour fruit year-round. On the Southeast Asian mainland, Borneo, and a few other islands grew the durian, the fruit of which smelled putrid but tasted delicious. The elephant apple found throughout Southeast Asia produced a fruit that was used to make drinks and jellies. The fruit of the rambutan was popular in Southeast Asia and as an export to China for its sweetness and juiciness.

India and Sri Lanka had longstanding traditions of forestry. Foresters were a class of craftspeople charged with managing forests. Everything in the forest technically belonged to the king, although he was expected to grant people permission to harvest timber for building and to hunt for food. The foresters also saw to the replanting of land where trees had been harvested. Usually the foresters felled the trees for carpenters. Cut trees would be rolled or carried by elephants, either to rivers, where they would be floated downstream to areas where carpenters would cut them into planks, or onto carts for transport to villages, towns, and cities.

India was famed for its spices, and among the most in demand was cinnamon from a tree native to southern India. The spice was made from young bark. The black, hard wood of India's ebony tree was used to make furniture. Found in the northern and eastern areas of India, ebony was heavily harvested to satisfy a large export market as well as a local one. Mangoes were found throughout India and provided a popular juicy fruit. The curry leaf tree of India and Sri Lanka had edible, peppery berries, and its bark and roots were used to produce tonics. Its leaves were added as flavoring to curry dishes.

The variety of cultures in medieval Oceania was so vast that it is difficult to generalize about their forestry practices. In much of Polynesia people used forests for gardens. For example, taro root would be grown among the trees of a forest, in the shade provided by the forest canopy. In most areas trees were harvested for their wood for building shelters. Although most people found reasons to keep their forests intact, not all did. For instance, the people of Easter Island denuded their island of trees, leaving themselves stranded for lack of wood for boats.

Perhaps the best known of all Oceanic trees is the coconut. Oceanic peoples used the tree's trunk for timber, its leaves for roofing, its flower for brewing a drink, and its tips for food. The fruit itself was eaten, and its milk was a popular beverage. The husk of the fruit was used as fuel and for mat-

ting. Another valuable tree found in Indonesia, New Guinea, and Australia was the Leichhardt tree, which grew in swamps and along rivers. Medieval Australians used its trunks for canoes and the bark for a yellow dye and for pain relief. Its fruit was edible. One of the world's most popular nuts, macadamia, originated in northeastern Australia but did not become of worldwide interest until the late 1800s.

## EUROPE

BY DOLLY JØRGENSEN

In the Middle Ages the word *forest* (or its Latin equivalent, *foresta*) designated a legal entity consisting of extensive land, including both woodland and pasture, within which the right of hunting was reserved for the king or his designees and subject to a special code of laws administered by local officials. The first known forest was documented in a charter for the monasteries of Stavelot and Malmédy in the Ardennes in Belgium in 648. From that humble beginning, forests were designed throughout the former Merovingian and Carolingian lands. After the conquest of England by William the Conqueror (r. 1066–87) the term *forest* took on the same legal character as on the continent.

The medieval forest did not imply continuous tree cover, although many forests were well wooded. In England, for example, designated forests such as those of Dean and Hants encompassed wooded lands, but others like Dartmoor and Exmoor were moorland; still others, like Sherwood, were heath. Not all wooded areas were designated as forests. For example, few forests were established in the two biggest concentrations of woodlands in England in the Anglo-Norman period, the Weald and Chiltern Hills.

Forests that were wooded operated as multipurpose areas for wood collection, pasturage, and hunting. Woodland played such a central role in medieval agriculture that the economy of the time is often referred to as "silvi-pastoral." Rather than extensive wilderness areas, woodland thus consisted of tamed, tracked areas where animals could graze and wood could be gathered. These areas were consciously managed in the Middle Ages through physical and legal means.

Wood was critical to any medieval settlement for maintaining buildings, mending fences, firing baking ovens, and creating fires for warmth. The construction of bridges, water mills, windmills, and ships compelled the use of large timbers. Early industries relied on wood for fuel; charcoal, made by burning wood slowly with insufficient oxygen for complete combustion, fueled the early iron, salt, and glass industries. Trees also provided edible fruits and household items. As a result of these needs, every community depended on woodlands located close to the settlement.

The Germanic tribal peoples who settled in western Europe established laws about wood resources. The Visigothic Laws of the Judges included penalties for cutting down large and small oaks as well as other trees and allowed for the seizure of the oxen and vehicle of anyone entering another's forest with a cart to carry away wood. The Burgundian Code of the late fifth and early sixth centuries required that anyone felling a fruit, pine, or fir tree had to pay the tree owner 1 solidus. The law, however, also recognized the need for wood even if one did not own wooded land: "If any Burgundian or Roman does not have forested land, let him have the right to cut wood for his own use from fallen trees or trees without fruit in anyone's forest, and let him not be driven away by the owner of the forest." The Laws of the Salian Franks had the following restriction: "He who takes a tree after the year that it was marked for cutting shall bear no blame. If he cuts it down during that year, he shall be liable to pay 3 solidi." This particular law shows that the early Franks managed their woodland by designating trees of sufficient size for their needs each year and did not indiscriminately cut down forested areas.

In the ninth-century code of King Alfred of Wessex (r. 871–99) the act of burning or felling trees carried a fine per tree based on size: 5 shillings for a big tree and 5 pence for a small one. The Danish king Canute, ruler of Denmark and England (r. 1016–35), supposedly issued a law code specific to English forests, *Constitutiones de Foresta*. Although the law code was altered by a Norman scribe to agree with post-conquest practices, it probably contains the general concept of Anglo-Danish forest law. Capitulary 28 stated that anyone who disturbs the wood or undergrowth without the permis-

sion of the minister of the forest is considered to have violated the laws of royal chase.

Wood collection relied on the practices of coppicing and pollarding. Trees could be cut approximately 3 feet above ground level to create a sprouting stump that yielded a significant number of smaller branches (coppiced) or higher on the trunk so that young sprouts were out of the reach of grazing animals (pollarded). Ash and field maple were used for poles, hazel for fences, and others such as oak and birch for firewood and fodder. Coppice stands usually consisted of one species growing from regularly spaced stumps and, scattered among them, larger trees, called standards, grown for construction timber. The practice of coppicing dramatically increases the life span of a tree as well as its wood yield, so less clear-cutting is required.

Woodland in forests also provided fodder for livestock. To integrate wood collection and pasturage, two practices became common. First, the practice of pollarding the trees allowed livestock such as cattle to graze on grasses without reaching the trees' new growth. Second, lords permitted swine in the woods during the time of *pannage*, or, in medieval Latin, *pasnagio*, when the pigs were allowed to gorge on the fallen acorns and beech mast, typically from mid-September through mid-November. This period was followed by the slaughtering season in preparation for the winter months. Despite the variability of the crop, feeding pigs on fallen acorns in the fall was a common practice, to make them plump before the slaughtering season. These fattened pigs were a necessity over the slim winter months; hence their common inclusion in "occupation of the months" illustrations on medieval calendars, called "books of hours." These "occupations of the months" pages became common in later 14th-century manuscripts, such as *Le livre d'heures* of Jeanne d'Évreux (1310–71), the third wife of Charles IV of France, in which a swineherd knocks down acorns to feed his pigs, and *Les petites heures* of Jean of Valois (1340–1416), duke of Berry and Auvergne, in which pigs forage in October and are slaughtered in December.

While royal forests acted as sources of pasture, timber, and wood, their primary legal purpose was as hunting reserves. Medieval chroniclers stress the creation of royal forests as reserves for the privilege of hunting game for the king. These hunting areas were not always densely wooded; many of them were open glades with some tree cover. This tradition in England dated back at least to the Saxon days (early fifth century to the conquest), when the right of the chase was reserved in areas close to royal residences. Examples of Anglo-Saxon hunting grounds (*haia*) afforested by William the Conqueror (r. 1066–87) were the Forest of Galtres in the center of Yorkshire and the Forest of Peak. Southern Europe had hunt-

*The Savernake Horn, ivory, England or Scotland, 1325–50. Various forest scenes are depicted, among them a king seemingly in conversation with a bishop, with a forester alongside; the scene is thought to portray the forming of a forestry agreement.* (© The Trustees of the British Museum)

ing grounds in forests as well. Alfonso XI, king of Spain (r. 1312–50), compiled *El libro de la montería* (Book of Hunting), listing hundreds of *montes* in Spain. *Montes* were not necessarily mountains or forests but rather hunting grounds. Often hunting occurred in a park, which was a man-made, fenced enclosure to keep deer contained within an area. Some forests had parks, but not all parks were connected to forests.

“Beasts of the chase,” including red deer, fallow deer, roe deer, and wild boar, were reserved for the king and nobles within hunting grounds in forests and in parks. The red deer was the largest British deer and primary beast of the chase. The fallow deer, a species introduced from the European continent, was found more typically within parks. The roe deer was the smallest deer species in England, measuring only 26 inches high at the shoulder. The wild boar was common throughout woodland areas. Huntsmen frequently used dogs to drive deer into hedges or nets placed to ensnare them, and the use of dogs in the forest was restricted to these hunters.

The king and other lords employed men to control access to forests. Royal foresters acted as the king’s servants to keep the peace in the forest, enforce forest law, and present violators at the forest courts. Local lords and abbeys also retained the service of foresters. The *Domesday Book*, a countrywide survey completed for William the Conqueror, records that great landholders such as Hugh d’Avranches (d. 1101), the earl of Chester, established their own forests and parks and had foresters to manage them. Forester responsibilities included protection of the game, protection of the trees, regulation of grazing, distribution of the hunting tithe, and financial accounting for forest resources. By the 1300s business account books were being used by large manorial estates to keep track of income and expenses, and the account books for forests were handled by foresters. For example, the Champagne region of France had numerous detailed forestry accounts revealing complex management practices.

Designating land as royal forest was often a contentious affair because it involved the restriction of land use, tax payments, and a separate court system. The magnates who forced King John of England (r. 1199–1216) to approve the Magna Carta made several statements decrying the forestry practices as of 1215 and included the requirements that all lands named as forests by King John be “disafforested” and that an inquiry into bad forest customs take place within 40 days. The nobles demanded the restoration of the forest boundaries to their extent at the end of the Anglo-Norman reign and the beginning of the kingship of Henry II (r. 1154–89). In the issuance of the Second Great Charter of Liberties on November 6, 1217, all mention of the forest was removed because the forest clauses of the Magna Carta were deemed to be so important

that they deserved their own treatment; they were handled in a separate document, the First Forest Charter.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

Most of the medieval Islamic world encompassed dry regions with vast open lands devoid of forests. Muslims had the disadvantage of sweeping out of Arabia and through the Near East and North Africa after other cultures had stripped the land of much of its forests. Thus, for a long time forests were either out of reach or on the edges of the Islamic world. As the Islamic world extended its reach into India, sub-Saharan Africa, and the Iberian Peninsula, forests became more accessible, but in general the conquerors left forestry to local peoples. Even so, forests were important to medieval Islamic culture. Wood from forests was traded throughout the Islamic world for use in mosques and palaces as well as for furniture and window screens. Forest products, such as fruit harvested from wild trees, animal skins, and exotic oils for perfumes, found their way into markets far and wide.

Rainfall in Arabia was usually too little to support a forest. In southern Arabia people made good use of rainfall by creating cultivated terraces on mountainsides, which absorbed and retained rainfall well enough to allow for crops sufficient to support towns. In most of the rest of Arabia there was not enough rain even for terrace farming. Trees appeared at oases and in northwestern Arabia, where there were orchards of date palms; some orchards had thousands of trees.

The first significant forests encountered by the Islamic world probably were composed mostly of cedars, which grew from the Levant to what is now southern Turkey. The once-dense cedar forests had become patchy after centuries of the trees being felled for use in buildings and ships. The cedars of Lebanon were considered important by Muslims because they may have been used in the building of Solomon’s Temple in ancient Jerusalem, and successive Islamic governments seem to have tried to conserve the trees.

The best source of wood in the Near East may have come from the region that is now Turkey but was part of the Byzantine Empire until the 1400s. Pine and oak were harvested in Turkey and for centuries were exported as far away as Egypt. The stone pine grew throughout the northern Mediterranean as well as Turkey, and the Scots pine grew throughout Europe and well into central Asia. The seeds of the stone pine were eaten as nuts. The wood of Turkish pines was used in the making of the *mushrabiya*, a latticework consisting of a multitude of small oval balls connected by straight pieces, all without the benefit of glue. In many parts of the Islamic world the temperature changes during night and day could split

wood, but the dowels of a *mushrabiya* were set loosely in holes in the oval balls so that they could expand and contract freely. The *mushrabiya* was used to filter light through windows and often decorated balconies, from which the latticework gets its name. (*Mushrabiya* means “balcony.”)

The mountain ranges in the far north of Africa had forests because the ground was too steep and rocky for herding cattle, sheep, or goats. Although the ancient Romans had much depleted the wildlife of the Atlas Mountains, those mountains retained enough game to be a favorite hunting spot for Islam’s social elite. The Atlas cedar (also known as the Atlantic cedar) was the fastest growing of cedars, and it seems to have been quick to take advantage of any open spaces in the mountains. The Syrian juniper was found all along the northern mountains of North Africa.

Trade had existed for centuries between the northern reaches of North Africa and the peoples of western Africa and central Africa. Islam found its way into two notable kingdoms south of the Sahara: Ghana, which existed from about 700 to 1200, and Mali, which existed from about 1200 to 1500. Recent research indicates that Ghana was mostly Muslim among its aristocrats and royalty but not among commoners. On the other hand, Mali’s population probably was mostly Muslim. Both kingdoms occupied grasslands and parts of forests. The people who lived in the forests seem to have been fiercely independent, and they guarded the mysteries of their lives even from government officials.

Most secretive of all were the gold miners. The gold miners hid themselves from outsiders as much as they could, and they took such great care in hiding the locations of their mines that it seems no outsiders ever figured out where they were; even today archaeologists are uncertain of their exact locations. Sometimes intrepid Muslim traders or explorers ventured into the forests around Ghana and Mali, with some choosing to remain in forest villages. Many Muslims could read and write, and many societies in the forest regarded being able to write as a source of spiritual power. Muslims could become oracles in forest villages, free to propagate their faith. There seems to have been constant friction between those who made their livings exploiting the bounty of the forest and those who wished to burn it down in order to create grazing or farming land.

There were several hundred species of trees and plants in those forests at the edge of the western African Islamic world. The kola nut tree, the baobab, the Portia tree, the tamarind, the ackee, the Meru oak, the dita bark, the sausage tree, the Senegal date palm, and the African oil palm were some of the useful trees of the forest. Of these, the kola nut, the baobab, the Senegal date palm, and the tamarind were the most important. Growing in the humid lowlands along the shore of

western Africa, the kola nut produced a seed that was chewed for the stimulation its caffeine provided, and chewing it was considered medicinal. The baobab grew all the way from the west coast to the east coast of Africa. Its fruit was edible, and its bark was used to make rope. The Senegal date palm grew in open woodlands and along streams, making it accessible to people coming from the outside into the forest. Its orange fruit was eaten, made into wine, and used in cooking. The tamarind grew throughout the forests south of the Sahara. The wood of the tamarind was used as timber, and its fruit was used for juice as well as in cooking.

Although much of the old forest had been eliminated during classical times, there were mountains where trees thrived but with terrain that was difficult for people to exploit. There were the common yew tree, the wych elm, the cork oak, the English oak, the hawthorn, and the common ash. Yew wood was used for furniture; the wych elm’s dense wood was used for shipbuilding; the English oak grew in lowlands, and its wood was used for building, furniture, and decoration; the hawthorn was dense and hardy and was used to form windbreaks and enclosures for animals; the common ash provided durable white wood that was used for anything that had to endure rough handling. Of particular importance was the cork oak, the bark of which yielded cork. These trees lived for more than 300 years and appeared not only in mountain forests but in orchards as well.

In India, Muslim conquerors found a forest-management system already in existence, and differences in how Muslims and Hindus believed forests should be treated were a steady source of friction between the two groups. As Muslims fought their way through northwest India into the heart of India, they encountered vast forests of many different species of tree. For about 2,000 years a caste of foresters had tended the forests, charged by tradition with managing the harvesting of trees and the hunting of game. The Hindus believed that trees could be inhabited by usually benevolent spirits who could tell people the future. Thus, the spirit of each tree had to be given an apology before harvesting because moving to a new tree was a tremendous inconvenience for the spirit. Moreover, it was an important part of Hindu ritual to replant places where trees had been cut down. By and large such beliefs and activities were nonsense to Muslims, for whom apologizing to tree spirits was paganism. The process of accommodation between the two faiths on the matter of caring for forests took well beyond the medieval era to reach a state where both Muslims and Hindus believed they were in agreement.

In Muslim-governed lands of India the forests provided numerous products. As had been the case under Hindu governments, most of the products were controlled by the government. Timber was harvested for use in local building and

for export. The cutting of trees usually was done by Hindus, who used elephants to pick up and carry felled trees, which were set in a place nearby for carpenters to cut into boards; on carts for taking to villages, towns, or cities; or in rivers to float downstream for export. Some of the wood was made into charcoal. Other forest products included coconuts, resin, honey, and ivory from elephants.

Huge banyan trees grew through much of India. A single tree could cover several acres, with aerial roots growing down from branches. These roots could be fatal for other trees because the other trees were deprived of the sunshine they needed. Thus, the banyan tree was thought to be the enemy of the spirits that inhabited trees. The cinnamon tree grew in the southern half of India. Its bark that made the famous spice had to be young when harvested, so foresters took care that young trees were always available, leading to the creation of cinnamon plantations. The bo tree grew throughout India, and it was considered sacred by Buddhists because the Buddha had attained enlightenment while sitting in the shade of a bo tree.

In the far north of India were forests dominated by the sal tree. It produced a wide variety of products, such as resin used in inks and varnishes, resin for incense, and resin for burning in torches. Its seeds were made into butter. Also in the north was henna, the leaves of which were crushed and then mixed into a paste that temporarily dyed hair, nails, and skin orange. Among the most valuable of India's trees was the ebony, with its heavy, jet-black wood valued for furniture and decorative carving. Found in forests of the southern and eastern reaches of medieval Muslim India, teak was extensively harvested for its wood, which was used to make furniture. Growing in semiarid parts of India, the neem tree provided timber, medicinal oil from its fruit, and insecticide from grinding its leaves and bark. The mango tree grew throughout India, where its fruit was eaten. Its fruit was a valuable export to other parts of the medieval Islamic world.

## ► gender structures and roles

---

### INTRODUCTION

Gender roles informed almost every aspect of medieval life. People dressed, worked, socialized, married, and held property on the basis of sex. Indoctrination in gender roles began early. Adults taught children how the genders should behave, whether it was through Aztec rituals, Islamic schools that taught only boys, or simply example. In many societies people expressed their gender and marital status by means of clothing or hairstyles. In parts of Europe, for example, married women covered their hair, while girls left their hair uncovered. In North America unmarried men and women wore their hair long and loose, and married people of both sexes wore theirs pinned up or bound in some way. Many Islamic women veiled themselves from the time they reached puberty.

In most of the medieval world men had higher social status than women. This did not mean that there were not powerful women and that women could not make decisions for themselves, but as a rule women were subordinate to men. Islamic law, for instance, stated that women had no power and that men controlled the actions of women. Women could inherit only half what men could, and in court it took the testimony of two women to equal that of one man. In Europe, men had far more rights to own property than women did.

Throughout the medieval world people divided jobs on the basis of sex. The fact that women were often pregnant

or tending small children made it difficult for them to leave home for extended periods. Consequently, in most places women were responsible for the domestic sphere, cooking, tending children, making clothing, keeping house, and cultivating kitchen gardens. Men typically did heavier labor, such as heavy plowing, planting, and herding livestock. Men also did any tasks that required extensive travel, such as hunting, long-distance commerce, and waging war. In parts of Africa, for example, cultivated lands were considered the province of women and wilderness the province of men. Women tended gardens and men hunted in the forests. In eastern North America men traded with distant communities while women traded locally. Both sexes worked together in some endeavors, particularly agricultural tasks such as planting and harvesting, which required large numbers of laborers for a short time. Gender associations with jobs varied by society; weaving and pottery, for example, were considered female jobs in some places and male jobs in others.

In much of the world, marriage was considered an alliance between two families, not a romantic tie between two individuals. Families chose spouses for their young people. Women typically married at a young age to men much older than themselves. A bride would often move in with her husband's family, where she was expected to care for his mother and produce children. In much of the world, families considered sons more valuable than daughters. It was not unusual for wives to be punished for their failure to produce sons or for infractions such as adultery; this was especially common

in societies such as that of China, where Confucianism set rules for family behavior. Chinese wives had to obey their husbands and mothers-in-law, though a wife who survived until her eldest son married could then take on the powerful role of mother-in-law herself. Men were typically expected to provide for their families and to defend their women and children from external threats. In Islamic society, men had to defend their family honor, a practice that could lead to extended feuds with other families. Men were considered the guardians of the women in their families. Widows were a problem in many societies. In India, for example, widows were discouraged from remarrying but also excluded from their dead husbands' families; they were instead encouraged to burn themselves to death at their husbands' funerals.

Many medieval societies regulated sexuality quite strictly. Throughout the world, people valued female virginity, though in most cases they did not place nearly so much importance on male virginity. In Europe, the Islamic world, and much of Asia a woman was expected to be a virgin when she married for the first time; a bride who was believed not to be a virgin could be punished severely. Polygyny, the marriage of one man to more than one woman, was allowed in much of the world. Muslims, Chinese people, and many African cultures allowed men to take more than one wife. Christians, however, did not allow multiple simultaneous marriages. In most places pre-marital sex was forbidden or at least discouraged, though this was not always the case; in many African societies, for example, pre-marital sex was common. Islam made some provision for sexuality outside permanent marriage by allowing short term temporary marriages. Homosexuality was considered either sinful or odd in most of the world, though it did exist.

## AFRICA

BY KIRK H. BEETZ

Entire books could be devoted to the gender structures and roles of medieval Africa and still not cover all the complexities of the issues, because each African culture had its own way of organizing genders. However, a few generalizations can be made. Many historians agree that medieval African women were the subjects of widespread discrimination by men and that generally men dominated economic and social life, even in matrilineal societies. Other valid generalizations are that sexual intercourse was rarely the objective of gender structures and that medieval Africans were well familiar with the concept of being in love.

Most medieval African societies clearly distinguished the roles of the genders. For instance, in farming communities in western and central Africa and much of East Africa,

men were the heads of families, and they often held exclusive rights to important crafts such as blacksmithing, which was believed to confer supernatural powers on its practitioners. In farming communities men organized the fields and decided who was allowed to work them. Hunting was usually a male province because wild lands were considered male. The earth was considered female, which often meant that women were the ones who quarried clay and used it to make pottery and build houses. In general, women tended the gardens that produced green vegetables, did most of the trading in goods, and cared for children. Yet the "woman" tending the garden could be a man, and the "man" ruling a family could be a woman. This seeming incongruity stemmed from a distinction Africans made between gender roles and actual genders.

In general, the gender role of a woman was considered inferior to the gender role of the man, but a man could be in the gender role of a woman, and a woman could be in the gender role of a man. For example, a wealthy man with a large household and a few wives might have no male heirs. The man would want his family's accumulated wealth and power to continue after his death, maintaining his family's heritage, rather than allowing it to be divided. This could be an urgent matter for him, because to have a good afterlife, he needed many descendants who collectively remembered and honored him. If his goods were divided, so would be his family, and he and his revered ancestors would be forgotten. The solution to his problem would be to declare a wife or daughter the heir to all his wealth; any wife or daughter could be designated, because none of the women in the family had a legal priority in the matter. Thus, the man would pick whomever he loved best.

The catch was that a woman could not be the head of a household and could not inherit his wealth and power. He solved this problem by declaring that the wife or the daughter was a son. A ritual was usually required, such as inviting all his male relatives together, serving them palm wine, and formally declaring the woman to be his son. At that moment the woman became male by gender. In some societies she would even have to wear men's garments. Her former responsibilities as a woman would fall to another wife or a daughter. She would take up men's tasks, and after the man's death she would be recognized as the head of her family. This would not be without controversy, because other males in the family may have greedily anticipated looting the family coffers after the man's death. Yet women could and did hold together their family holdings, which would likely be inherited on their deaths by a grandson born of a daughter. Further, as the head of the household, a woman could take a man as a wife, who would assume the role of a woman within the family.

In most medieval African societies women could accumulate wealth. Although a woman was expected to contrib-

ute much of what she produced to her family, she could own cattle or employ other women to work her gardens. Owning cattle, sheep, or goats would enhance her prestige within her family and within her village, but men often had an advantage over her, because a man could have more than one wife at one time, with each wife working for him and contributing to his family and his personal wealth and status. In some cultures an ambitious woman could purchase a woman slave and declare that woman to be no longer a slave but her wife, making herself a female husband. A woman with adequate means could have several wives. Further, it was possible for a woman to have grandchildren by inviting a man into her home to live as a surrogate son and obtain the status of that role in the family.

This shifting of gender roles, often giving women a degree of power not immediately evident to outside observation, is only one aspect of the complexity of medieval African gender structures. In addition, men could become priestesses and garb themselves as women. Sometimes kings were considered wives of the elder statesmen of their lands and would be required to dress as women and wear women's jewelry and cosmetics, symbolizing that they could take no important actions without their husbands' consent. With men being sisters and women being brothers, relationships between families that intermarried could be extremely complicated.

The practice of polygyny allows one man to have several wives. Although this custom occurred in many medieval African societies, it did not necessarily dominate. Whether the society was agricultural or pastoral, most husbands had just one wife. The ability to have more than one wife was limited by the wealth of the husband and by his concern about the peace of his household. In many cultures social wealth was more important than material goods. In a system that anthropologists call social banking, people accumulated social wealth by having other people obligated to them by favors. The more favors owed to a person, the more social wealth that person had, which brought prestige and power within a community. The more wives a husband had, the more connections he had with other families, which created mutual obligations between him and the birth families of his wives, increasing his social wealth.

Often a wife was expected to return frequently to her birth family's home to care for a tree that had been given to her by her father or brother or to participate in meetings of the daughters of the family, which meant that she maintained strong ties between her old and new families that further increased her father's prestige. Having more than one wife and several children from each wife not only enhanced a husband's prestige but also brought him material wealth, because he and his sons could clear and work more land and his wives

and daughters could produce more food in their gardens and do more trading that would bring in more luxuries. A luxury item usually was not so much for using as for showing off, a visible sign of success; for example, a finely ornamented pot might sit unused where visitors could see it.

A possible downside of polygyny was that the family could become a political unit, with its members jostling each other for preeminence. Apparently jealousy over the sexual attentions of the husband was uncommon. Instead, wives bickered, fought, or even killed over perceived slights to their children or when a particular family member received more affection from the rest of the family. Moreover, having many sons meant having many heirs, each vying for his father's esteem. Rivalries among heirs could result in murder, as the sons and their mothers and wives schemed for control of the estate. Add to this the complication of wives having wives of their own, and the polygynous family could be more than a husband, or his first wife, could bear.

On the other hand, a polygynous relationship had certain advantages for women. Often a husband would marry sisters. The sisters could confide in and share activities with each other. Just as the husband could increase his leisure time by having several sons to work his land, each wife could take life a bit easier if several other wives were on hand to share the tasks of gardening, cooking, and raising children.

The terms *patriarchal* and *matriarchal* do not apply well to medieval African cultures. Each implies a rigid dominance by one gender or the other that did not apply to everyday medieval African life. Labeling a society patriarchal cannot properly explain why many women held dominant, powerful roles, and calling a society matriarchal creates a similar problem. One apparent trend was that in all African societies men contrived to have the dominant social position.

The terms *patrilineal* and *matrilineal* better explain the patterns of gender structures in medieval African cultures. In a patrilineal culture people trace their lines of descent through males, sometimes including women who were social males. People in a matrilineal culture trace their lines of descent through women. In either case the men or the women were not necessarily supposed to dominate society, although some matrilineal societies incorporated social freedoms for women that some men resented. For instance, in various matrilineal cultures the heir to a man's property was not his son but the son of one of the man's sisters. This applied even to kings and even after some kingdoms adopted Islam. When a king died, the line of descent had to be traced through the women of his family, making the son of his eldest sister the new king. If he had named the nephew as his heir, a peaceful transition of power could take place; otherwise, if the eldest sister had more than one son, murder or even civil war could occur.

## THE AMERICAS

BY ARDEN DECKER

Gender and sexuality are areas that must be addressed when studying the society of any culture. Gender plays a fundamental role in shaping and defining religious practice, labor, rulership, and social status in society. Archaeologists, anthropologists, and art historians seek to understand gender in the medieval period through analysis of burial caches, household excavations, and depictions of gender in the arts. Such analysis provides a more complete understanding of the daily lives of members of these cultures as well as the sociopolitical systems as a whole. While gender was consciously constructed throughout the Americas, it is important to note that most, if not all, medieval period societies in this area viewed male and female genders as complementary opposites. This suggests that men and women were both considered to be necessary for the growth and survival of any given community.

Division of labor is one social function that is heavily affected by gender roles. For medieval American cultures, labor tasks often fell along gender lines and assumed the model that most Western cultures have exhibited. This model suggests that women took on labor tasks associated with the domestic sphere, such as sweeping the house, maintaining crops, preparing food, or producing textiles, whereas men were primarily responsible for hunting large game.

Although labor assigned to women was often tied to the home, among the Mississippian cultures of North America (ca. 750–1500) it was acceptable for women to roam outside the confines of the home, suggesting that women had some degree of independence. Moreover, there are examples of both genders working together to perform labor tasks. In fact, it is perhaps more accurate to describe labor division as malleable, in that gender lines shifted depending upon the specific outside forces that might affect a community. For instance, in many of the Pueblo cultures (ca. 900–ca. 1300) both men and women were responsible for trading goods such as food, pottery, or ceremonial tools. Men typically took on the task of trading with distant communities, while both men and women would trade locally. This seems to have been the case also for Mesoamerican and Andean cultures. Similarly, among the pre-Inca cultures of South America, men and women had equal access to land and labor, and it appears that socioeconomic factors, rather than gender, affected this distribution. For all intents and purposes, labor was viewed as something that required the equal participation of both sexes working together for the greater good. One example of this equal participation can be found in Andean cultures, where men and women worked together in agricultural production. Frequently the men prepared the

*Clay figurine of woman seated at a loom, Maya culture, Mexico, ca. 500–900* (Courtesy, National Museum of the American Indian, Smithsonian Institution (catalog number 232865))

soil, and the women planted the seeds; both would harvest the crops.

However, certain types of labor were clearly divided along gender lines. Weaving and textile production was an essential economic and political endeavor that was primarily controlled by women in the Andes as well as in the Mayan (ca. 200–ca. 1200) and Aztec (ca. 1300–1521) regions of Mesoamerica. Textiles were essential for establishing and continuing trade lines and political alliances because cloth was often given as a gift or worn as a symbol of power. This suggests that women were considered to be an essential component in maintaining the political, economic, and ritual power of the community. Cloth production was so important to the Inca that the state set up training centers called *acllas* where selected women were sent to learn weaving techniques and to produce textiles in the service of the ruler. It has been suggested by some scholars that the women of the *aclla* served as models of womanhood for the rest of the empire. Weaving, spinning, and embroidery were tasks to be performed by all Aztec women, regardless of their social status. Andean women were also responsible for producing *chichi*, a beer made from corn that was an essential component of Incan ritual practices. Aztec and Mayan women were trained to use

plants for healing and medicinal uses. Some of the tasks that were associated only with men were armed combat, large-game hunting, and the holding of government or high-status positions. This appears to have been common to the Incan, Mayan, and Aztec cultures as well as many cultures of North America.

While it is doubtful that medieval American communities were completely egalitarian in nature, there is substantial evidence to support the notion that women's roles were becoming increasingly visible and important during this period. Unlike those of the ancient period, life expectancy and health rates for males and females were similar, suggesting that quality of life was more dependent on economic status than gender.

In North, Central, and South America gender and social status were most often distinguished through clothing, hairstyle, and ornamentation. This is supported by the existence of artworks (including figurines, effigies, ritual objects, and monumental art) in which gender is explicitly apparent. Among the Aztec of central Mexico gender was not assumed to be an innate characteristic. Rather, children were taught gender roles through various rituals designed to allow for the formation of a gender identity. Through alterations in appearance and behavior, gender differentiation would become more and more specific as the child matured. One such ritual involved the burial of a baby boy's umbilical cord on a battlefield, while that of a baby girl would be buried by the hearth. Clearly, the Aztec associated the male gender with battle and the female with the domestic sphere. The association of specific objects with each gender further emphasized this difference. The Aztec associated shields and weapons with males and weaving tools with females.

In the case of North American cultures, depictions of women and men include specific hairstyles that indicate not only gender but also marital status. For example, married men would wear their hair in a ponytail or bun, as would married women, because this bound hairstyle signified marriage. Younger, unmarried men and women wore their hair long and loose. Hairstyle also served as an important gender marker for the Aztec. Men would begin wearing a bound hairstyle (such as a bun or ponytail) after they had taken their first captive of war, while women would adopt the bound hairstyle once they were married. It also seems that in Aztec society a bound hairstyle connoted controlled, adult sexual activity. Piercing and intentional scarring were also used to communicate the sexual status of a person.

In Andean society the state's official policy on female premarital sex was that it was strictly forbidden, but this was not the case among local communities, where premarital sex was accepted, as were trial marriages. The Aztec strictly for-

bade any sexual misconduct, including premarital sex and same-sex behaviors. Women who engaged in such behaviors were particularly frowned upon. Those who engaged in homosexual acts often were ridiculed or even physically punished. All members of Aztec society were expected to follow these moral codes, but they were more rigorously applied to members of the elite or noble class.

Males were the primary holders of power throughout the medieval Americas. This is not to suggest that women did not play a significant role in sociopolitical matters. Since many societies of the medieval Americas followed a matrilineal social organization, it is not surprising that women were highly valued for their roles as child bearers and wives. Among the Mississippian cultures of the present-day United States it has been suggested that women exercised a great deal of control over when and how often they reproduced, depending on their desires and personal beliefs. Marriage was one of the most significant aspects of social organization across medieval American cultures. It was the primary method for establishing alliances among high-ranking, powerful families that would then affect the economic, political, and ritual success of the community at large. It appears, at least among North American cultures, that it was acceptable for men to take several wives, but there is no evidence that women could take more than one husband.

While elite women undoubtedly enjoyed many privileges not extended to those in the greater community, they were never given the opportunity to hold positions of power exactly equal to those of men. However, there were some exceptions to this rule. Images of female warriors and chiefs in North American art suggest that some women did indeed hold positions of great power in society. Similarly, at several Mayan sites, images of female rulers and important female ancestors have appeared in monumental works of art. There is also significant evidence to support the participation of women in ritual ceremonies across the Americas when they often acted as shamans, witches, or sorcerers.

## ASIA AND THE PACIFIC

BY BRET HINSCH

The millennium between 500 and 1500 saw enormous changes in the fundamental character of Asian societies that inevitably affected relations between the sexes. Although each society underwent different transformations, in general each became more complex. In simple societies, labor and social roles tend to be allocated primarily by gender. As interactions become more complicated, society becomes increasingly stratified, and identities other than gender gain importance. In a complex society people assume varied professions and

ways of life. One example can show how social change altered gender relations. In sixth-century China, most weaving was done by women at home. But by the 15th century, textile production was becoming a specialized profession undertaken by men in commercial settings. This instance of changing work roles shows how gender relations were realigned because of increasing social and economic complexity.

Many historians and anthropologists have observed that as a social organization becomes more complex, the women within it often become less prominent. During China's ancient Shang Dynasty (ca. 1500–ca. 1045 B.C.E.), for example, royal consorts played key roles at court, even leading armies. But as China developed a centralized bureaucracy, women were officially excluded from affairs of state. When Wu Chao (625–705) dared to reign over China as “emperor” rather than empress, the sight of a woman wielding overt political authority was widely criticized as a freakish and destabilizing aberration. The same phenomenon played out in many places and across a wide range of institutions. Originally the Buddha (after repeated requests) allowed women to become nuns. But in many areas where Theravada Buddhism was practiced, the custom of female monasticism disappeared around the 11th century.

Some medieval Chinese thinkers argued that widows should not remarry. Although widow chastity might seem like a serious restriction of female autonomy, some widows came to see chastity as a positive condition, because it allowed them to act as head of their own household. A resourceful widow could control the family property, manage her children's affairs, and perform many stereotypically male tasks. In this way, an oppressive custom was manipulated to become a source of self-liberation.

Scholars have become less interested in ascertaining the “position” of women in a given era, as this term simplistically implies that all women in a particular society had a similar social status. Of course, the lives of an empress and a female slave would have been extremely different, and scholars have come to admit that any search for a single, easily defined position of women is doomed to frustration. Instead, it is more fruitful to think of gender as a series of intertwined roles that evolve over the course of each person's life. Thus the roles expected of a young girl, new wife, mother, and elderly matriarch are extremely different. As a result, the relations between men and women change throughout the life cycle. A medieval Indian girl might start out life with little autonomy, but if she lived to be a mother and a grandmother, she could expect a degree of respect and deference from her progeny in the name of filial piety. Likewise, Hinduism also envisioned a man's life journey as a series of roles, each with unique duties and privileges. He begins life as a filial son, marries and

becomes a householder, and in old age might renounce the world to devote himself to spiritual practice.

In each part of Asia the rise and decline of major ideologies also had an enormous impact on gender interaction. Ideas taken from religions, elite philosophies, and popular beliefs were often used to justify changing traditional patterns of life. The introduction of Confucianism to Japan, Korea, and Vietnam from China allowed men to justify female subservience by asserting that unequal gender relations mirror the hierarchy of ideal heaven over earth. Most important, the export of Hinduism and Buddhism from India saw an enormous impact on societies across Asia and spurred the reconsideration of ideal relations between women and men. For instance, the introduction of Buddhism into the Thai kingdom of Ayutthaya was used to justify polygyny (the custom of having more than one wife) and other practices favoring male interests.

The content of religious beliefs provided templates for ideal male and female behavior. Indian religion had an unusually large number of prominent female deities, although the worship of female deities did not necessarily translate into greater gender equality. In fact, many depictions of women in the Hindu epics tend to relegate them to passive roles. Most famously, the Ramayana describes the kidnap of Rama's wife, Sita, by the evil demon Ravana. This epic reinforces stereotypical ideas about the importance of female chastity and depicts men as strong and decisive, while women are shown as weak victims. In contrast, native traditions such as shamanism often allowed more active participation of women. Khmer women in medieval Cambodia were believed to have special powers that allowed them to communicate with the spirit world. This power imbued them with potent magic that they could use in healing and in controlling weather.

The native customs of some places were far more amenable to gender equality than others. Where land was more plentiful and the population sparser, patrimonial customs were usually less intense. These conditions predominated in Southeast Asia and tended to provide more opportunities to women. Khmer women were the primary domestic merchants of the Angkor kingdom. Chinese visitors expressed surprise at the predominance of women in the thriving local markets of this prosperous empire. Medieval temple sculpture depicts women as active participants in the full array of Khmer life, including warfare, politics, and literature. In this society, kinship descended equally through male and female lines. Women also could readily initiate divorce. The equality of Southeast Asian gender customs contrasts starkly with the more restrictive elite ideals of India and China. Both of these high civilizations had schools of thought emphasizing female fidelity and chastity, which attempted to confine women to household roles.

Because marriages in most places were virilocal (meaning that the bride moved in with the groom's family), husband and in-laws had an enormous impact on a woman's life. Marriages were traditionally arranged by parents in most cultures, as these unions were usually seen as bonds between families rather than individuals. Prevailing customs and ideologies often exhorted women to be humble and make themselves amenable to their new circumstances. In response, many women constructed what anthropologists have termed a "natal family" inside the usual patrilineal family. Surrounded by potentially hostile strangers, a mother would encourage her children to feel sole loyalty toward her and often would teach them to regard their father as an outsider or even a prospective enemy. The popularity of natal families helps explain the intense bond between mothers and sons seen in cultures as diverse as India, China, and Japan.

Women excluded from marriage found themselves on the margins of society. Widows were sometimes considered a social problem. In China they were sometimes called on to remain chaste. Indian ideas were even more radical. After the sixth century suttee (widow suicide) became more widespread. Some widows would immolate themselves on their dead husband's funeral pyre as an extravagant show of fidelity. Religion could provide some women with an excuse to remain unmarried, as was the case with Buddhist nuns. However, early medieval biographies of Chinese nuns show that devout thinkers found it difficult to reconcile female chastity with traditional ideas about the importance of marriage and procreation. Prostitutes and courtesans represented a very different kind of unmarried woman. Prostitution varied widely. At its lowest level, it was degrading and barely allowed women to survive. But some women trained as courtesans, distinguished by non-sexual skills. In China many elite men turned to educated courtesans for companionship and entertainment not provided by marriage, and these relationships were sometimes extremely passionate.

Rising female literacy had a notable influence on gender relations in several regions, particularly in China and Japan. Because of the Confucian emphasis on self-cultivation, some Chinese families of the educated gentry began to educate their daughters. Women usually followed a curriculum similar to that of male students, although they rarely received schooling that was nearly as intense, since they were barred from taking the official examinations. Some authors even began writing textbooks targeted specifically at female students, such as the Tang Dynasty (618–907) work *Nü lunyu* (Women's Analects), which taught ideal female behavior based on Confucian principles. In China women's literacy had contradictory results. Although it allowed women access to written knowledge, it

also exposed them to highly conservative works that taught female humility and submission.

In Japan the results of female literacy were equally contradictory. Women during the Heian Period (737–1185) were discouraged from writing in the prestigious foreign idiom of classical Chinese, which was considered inappropriately intellectual and manly, and were usually restricted to writing in their native language using Japanese script (*kana*). Ironically, this linguistic segregation doomed Japanese men to writing sterile prose in a difficult foreign language that they poorly understood, while women were free to employ their own vernacular to create some of the most important classics of Japanese literature, such as the 11th-century *Genji monogatari* (*Tale of Genji*) by Lady Murasaki Shikibu.

Generally speaking, many cultures viewed both masculinity and femininity as a life cycle consisting of progressive phases. Social conditioning nudged an individual's life trajectory toward conformity with this model. However, some social roles challenged these ideals and were often hotly contested. The ideal elite Chinese man would seek out a role in government and scholarship, but the chaos of the early medieval period made statecraft dangerous, and many talented men deliberately withdrew from the world to a life of quiet contemplation, decadent bohemianism, or hedonism. The morality of this sort of self-proclaimed eremitism, or reclusiveness, became a subject of debate. Similarly, the Buddhist renunciation of the world, often before marriage and procreation, was initially deplored by many Chinese scholars as a violation of basic family roles. Shaving the head, seen as ritual self-mutilation, was denounced as ungrateful because it harmed the body given to a man by his parents.

Gender relations in the Pacific are difficult to study because no written documents from the era remain. Nevertheless, given basic similarities in the customs of distant island peoples with common ancestors, it is possible to deduce the general outlines of earlier gender relations. Classic studies in Melanesian ethnography, for example, stress the importance of male bonding and a deep sense of male psychological insecurity. The most famous example of male bonding is the ritualized homosexuality of the Gebusi of Papua New Guinea, which deliberately created intense bonds between men of different generations while excluding women from a central social practice. However, the most important factors in gender relations remained marriage and residence patterns, which varied considerably. Couples in some societies lived with the husband's relatives, while in others they resided with the wife's kin. There were even cases of multilocal residence, in which a couple would shift from one set of kin to another. Of course, each of these basic social patterns produced extremely different forms of interaction between the sexes.

Likewise, the aborigines of Australia lived in hundreds of extremely diverse societies, making generalizations difficult. Overall, the indigenous societies of Australia are noted for their material simplicity and egalitarianism. In the absence of complex political organizations and social classes, gender became the main social distinction. Women usually worked as gatherers, and the vegetation and small animals that they found provided about two-thirds of the traditional diet. Men were hunters who specialized in obtaining large animals, valued for their protein. Taboos often enforced different spaces for men and women, and sometimes each sex participated in different religious cults. Customs ensured that these two differentiated groups, male and female, each carried out vital roles and cooperated for mutual survival.

## EUROPE

BY BRADLEY A. SKEEN

In the Middle Ages of Europe the primary context for gender roles was the family. Marriage was the means of propagating the family and passing on its wealth and traditions to legitimate heirs. The most important roles that men and women could play were as husbands and wives and as fathers and mothers. This ancient Mediterranean social structure survived intact in Christian Europe.

The self-understanding of the medieval aristocracy of Europe was dominated by chivalry. The word derives from a Latin word for “horse” (*caballus*) and is closely related to the term *cavalier*, another word for “knight.” Aristocratic men saw their purpose in society as waging war. The code of chivalry regulated the life of a knight devoted to warfare. In the first place the knight had a duty to God to defend the church, to uphold religious orthodoxy, and to fight heretics and infidels (non-Christians). The knight also had duties to his lord and to the king, to answer the call to war when it was issued and to fight expertly and bravely. Last, the knight had the duty to defend the weak, particularly women and the poor. Chivalry also dictated that the knight ought to have refined manners so that he could be presented at court without embarrassment and that his time not fighting be spent in pastimes that made him ready for war: hunting and tournaments in which knights would engage each other in group or single combat under controlled conditions. At the same time, knights were discouraged from engaging in behavior that was considered unmanly, above all acts of cowardice. Reading and study did not seem like knightly virtues but appeared rather too much like courtly women’s reading of the extensive romance literature of the period or the work of monks and friars at the university. Strategy was distrusted as being too calculating and exposing a lack of faith in the justice of one’s cause.

Although they were subject to many legal and social restrictions, knights’ wives usually had considerable power and authority, since the women were forced to take over the administration of the household (even a castle with a staff of dozens or hundreds) while their husbands devoted themselves to military pursuits. The position of the church was that women were physically and spiritually inferior to men and that they led men to sin by inducing desire (based on the biblical example of Eve). Marriages were intended to be celibate except as necessary to have children. The universal practice of marriages arranged in childhood discouraged romance between husband and wife.

The ideals of chivalry, however, saw women in quite a different light from the teaching of the church. Medieval aristocratic culture created the idea of courtly love, widely propagated throughout Europe by the troubadours, a group of poets that originated in southern France in the 12th century, of whom the most widely regarded was Andreas Capellanus. His treatise *De amore* (On Love) describes the ideals of courtly love. It begins when the knight becomes physically attracted to a woman, usually of superior class and often the wife of his lord but never his own wife. The first indication is flirtatious eye contact. The knight then declares his love to the lady, who rejects him as unworthy. Crushed, the knight then dedicates himself to carrying out acts of superior courage on the battlefield or at a tournament. In this way, the knight is saved, having become spiritually improved through his love for the ethereal beauty and superior nature of his lady. In the end he is rewarded by winning the lady’s love in

Spindle whorl, England, ca. 500; Saxon housewives spun woollen thread and wove cloth to make clothes for the family. (© Museum of London)

a spiritual union that leads to perfection, though not, in general, to physical consummation. While courtly love was an ideal of the aristocratic class, it is unclear how it functioned in actual society.

According to Christian theology, the full implications of gender identity were a result of the fall from grace described in the biblical story of Adam and Eve and their expulsion from the Garden of Eden. The original purpose in founding the monastic way of life was, if not to counteract the Fall (something that could be achieved only by divine grace and not by human effort), to live in a manner more closely resembling God's original plan for humankind. To this end, monks and nuns lived in monasteries or convents, single-sex communities devoted to worship. Besides the sexual segregation of their establishments, the monks and nuns carried out what was commonly called "spiritual warfare" against the fallen condition of their own bodies. The things that the body most needs to flourish are food, sleep, and freedom from physical suffering. These are the very things that monks and nuns denied the body by keeping vigil (praying all night instead of sleeping), fasting, and mortification (for example, by beating themselves with whips or by wearing garments whose inside surfaces were studded with nails). In this way, they brought the body into a state of exhaustion, hunger, and pain such that it could not feel sexual desire.

At the same time, nuns and monks, secluded from the things of the world, focused their attention and imagination on holy matters, such as contemplating Christ's suffering on the Cross, so that the mind would not wander toward thoughts that would produce lust. Even within the monastery or convent, monks and nuns were admonished not to treat their fellow monastics with undue familiarity in terms of touching, making eye contact, and having familiar speech on trivial topics. Although it is never mentioned as such, these kinds of rules were probably meant as a guard against homoerotic desire. Not all monastics carried out all of these practices all the time, but this struggle against the flesh was an ideal of the monastic way of life and one that was highly appreciated and respected by everyone in the Christian world. One purpose of monastic life was to turn the monastic into a person for whom sex had no meaning, effectively erasing gender identity.

Precisely because the monastic way of life was so honored in the medieval world, the monasteries soon found themselves in receipt of large gifts, usually in the form of land from which peasants' rents were collected. This forced abbots and abbesses to take on new responsibilities as administrators and merchants and other monks to engage in various agricultural professions. It also freed monks to follow intellectual pursuits. Throughout the Middle Ages the preserva-

tion, copying, and translation of ancient texts were in the hands of monks, and the universities were entirely overseen by monastics. (Even secular students of law and medicine had to take minor clerical orders.)

While this part of monastic life was generally the province of monks, at least one nun, Hildegard (1098–1179), became a leading intellectual. Hildegard founded two women's communities (Rupertsberg in 1150 and Eibingen in 1165), over which she presided as an unofficial "abbess." While formal study at a university was impossible for her, she nevertheless published in the field of natural history (largely in herbal medicine) and was widely recognized in her own time as an important artist, composer, and poet. Although she does not deviate from Catholic orthodoxy, much of Hildegard's thought was highly original, in part, no doubt, because the limits of her education relative to many of her male contemporaries denied her access to the tradition of learning but also because, as she claimed, much of her information was directly inspired in visions and auditions (hearing voices) that she experienced throughout her life, beginning even before she was dedicated to a convent by her parents at age eight.

The greater part of the population of medieval Europe constituted peasants living and working in the countryside. Their lives were prescribed by the agricultural labor they performed. Field work, because of its physically demanding nature, mostly fell to men and domestic labor, by convention, to women. Specialized work was also stereotyped by gender: Men, for example, largely ran mills, and women spun and wove cloth.

In the towns people of the peasant class generally owned various shops for trading goods or manufacturing wares. It was by no means unusual for women to work in shops. As the economy grew in the later Middle Ages, many men and women became for the first time employees of larger shopkeepers and paid servants in wealthy households of both merchants and aristocrats. Wealthy members of the peasant class came into increasing contact with aristocrats at court and so began to imitate their refined manners. This led to the writing of courtesy books, handbooks on manners and comportment based on those of chivalry. In this way aristocratic life became a model for all orders of society.

The social structure of the Byzantine Empire had more continuity with the Roman world than did western Europe. In the east the monastic communities were, if anything, more militant in their war on the body than were those in the west. Secular society was organized around multigenerational families whose head was the most senior male. Such a network would stretch out over family servants and employees as well as blood relations. While they were not bound to the land in the same manner as in the west, small farmers would look

to the heads of such great families as their protectors, in turn offering their support and service. The greatest such patron was the emperor.

A somewhat idealized conception of the life of a Byzantine emperor is given in the *Alexiad*, the biography of the emperor Alexius I Comnenus (r. 1081–1118). The author of this biography is more interesting than its subject, however. It was written by Alexius' own daughter, Anna Comnena (1083–1153), who violated the expectations of every role of Byzantine women. As an imperial princess, she was able to receive the education of an intellectual and scholar, and she showed a great natural ability for such studies. Dissatisfied with the rather limited part she was intended to play at the imperial court, when her father died, she attempted to stage a palace coup and seize power for herself and away from the legitimate heir, her younger brother. She had to do this in the name of her husband, since the public would have been reluctant to accept a woman as sole ruler of the empire. Her husband, however, betrayed her. After the coup failed, her brother, John II, forced her to retire to a convent to live as a nun. There Anna had a second career, so to speak, as the head of a private philosophical school (the normal setting for higher learning in Byzantium, because there were no institutionalized universities). There, toward the end of her life, she wrote the *Alexiad* which is in no way inferior to other Byzantine historical texts in its style or learning and is one of the most important sources for the period (which saw the loss of most of Asia Minor to the Turks and the beginning of the Crusades).

## THE ISLAMIC WORLD

BY MASSOUD ABDEL ALIM

Gender roles and structures can be understood from several perspectives: the world in which Islam originated, existing norms in the lands conquered by Muslim armies, the status of women within Islamic law, and the status of women among the *dhimmi* (Christians and Jews), or subjugated groups living under Islamic rule. Pre-Islamic seventh-century Arabia was a harsh desert, with a few scattered oases on the peninsula's borders. Society was tribal and ruled by elders, who were held in esteem; both mothers and fathers were included among revered ancestors. The nuclear family unit in Arabia's pastoral-nomadic communities consisted of three generations. Men tended the flocks and women the household and children. Women were neither veiled nor secluded but were subordinate to men. Men owned land and landed property and passed them exclusively to male children.

Males were collectively responsible for the safety and protection of family members. The blood feuds that they

waged to avenge crimes against their kinship group could have devastating effects. A man's concept of honor required him to provide for and defend members of his family, especially women and children. This precept incorporated the man's sense of honor, which could be affected by behaviors in women that were deemed either lacking in modesty or disruptive to the social order. Acts that avenged male honor were permitted against any member of the adversary's group, a situation that protracted blood feuds and left clan members vulnerable to the misdeeds of a single member.

The Mediterranean world of the seventh century had inherited Hellenistic culture, to which it added the Christian biblical tradition. The gods and heroes of antiquity included princesses and queens, such as Semiramis of Assyria, Nefertiti of Egypt, and Zenobia of Arabia. Within the Hebrew scriptures are stories of women who had an impact on their societies, including Deborah, Ruth, Esther, and Jezebel. With the advent of Christianity, the status of women in the Holy Roman Empire improved through several reforms. The emperor Constantine (r. 306–337) forbade pagan sacrifices and outlawed temple prostitution and religious orgies. He replaced the existing rule permitting divorce by either spouse with more limited grants based on commission of serious crime, adultery on the wife's part, or for the keeping of a brothel. He also discouraged infanticide by providing poor families with public grants. Neither polygamy nor child marriage was sanctioned. Still, as in Arabia, the overall status of women was subordinate to that of men, and women were confined to the domestic sphere.

The role of women from the seventh-century Arab conquest onward into the modern era is grounded theologically in the Koran and legally in Islamic law, the sharia. Islamic law recognizes three official groups: free Muslim men, women, and slaves. *Dhimmi*s were not full citizens but were guaranteed their lives and permitted to practice their faith, provided they paid the poll tax and endured the restrictions and discrimination against them. Sharia enforcement, however, was uneven. Cases relating to personal status—marriage, divorce, and inheritance—were the most rigorously enforced and those concerning commerce less so; questions relating to penal and constitutional questions were given least emphasis. Nevertheless, from the Abbasid Caliphate (749–1258) onward, the sharia was accepted by both the population and rulers.

The historian Ibn Khaldun (d. 1406) expressed the status of women most starkly when he wrote that “women have no power whatever” and that men by and large control all their actions. The Koran itself posits the inferior status of women relative to men: “Men have authority over women because God has made the one superior to the other.” Other passages

of the Koran express the relative value of women's testimony in legal cases, calling for the testimony of two women and a man when there are not two male witnesses. Likewise, the inheritance of females is stipulated to be half that of males.

The Koran is specific in matters pertaining to marriage. The practices of polygamy (having more than one wife) and concubinage (sexual relations with slaves) are both sanctioned. According to the sharia, a woman is required to have a male guardian, and her marriage is essentially a civil contract between the groom and her guardian. If a girl has not reached puberty, her guardian may give her in marriage without her consent. Otherwise, her consent is necessary. Consent may be given by sheer silence if the woman has not had a previous marriage. The groom provides a dowry (*mahr*) to the bride, which she may retain in addition to other property she owns or inherits. Wifely obedience is expected in return for a home, clothing, protection, sexual intercourse, and general maintenance. The Koran sanctions even child marriage, and such marriages were common in seventh-century Arabia.

The sharia permits the marriage of a Muslim man to a non-Muslim woman, who may keep her faith. A non-Muslim man, however, may not marry a Muslim woman; doing so is considered a capital offense punishable by death. Islamic clerics created this rule because they held that Islam must dominate. Divorce was easily accessible to the Muslim male—he merely had to repeat the phrase “I divorce you” three times, a provision that left women vulnerable to their husbands' fits of anger.

Most medieval Muslim philosophers overwhelmingly declared the domestic sphere as women's natural place. Women's purpose, according to the writer and vizier to a minor Seljuk sultan, Nizam al-Mulk (d. 1092), “is the continuation of the lineage of the race,” meaning that women's role was to ensure the royal succession. Umar ibn al-Khattab, the second caliph (r. 634–44), wrote against female literacy and advised men to take the opposite course of action after seeking women's counsel. The philosopher al-Amiri (d. 992) attested to the natural subordination of women to men. And the philosopher Ibn Sina (Avicenna, d. 1037) recommended that lawgivers prescribe that women be veiled and secluded. He also advised that they not have their own incomes and that they be forbidden to divorce.

Within the context of seventh-century Arabia, Muhammad's teachings, as laid down in the Koran, provided some reforms relative to existing practices. He sought to limit the scope and duration of blood feuds by permitting vengeance only against the transgressor rather than the latter's whole clan. Women were permitted to keep their property upon returning to their father's tents after divorce. Despite the fact that Muhammad himself did not limit his own access to

## THE VEIL

The veiling of Muslim women is one of the most controversial issues today in the clash between Islamic and Western cultures. The veil typically consists of a head scarf, called a *hijab*. A more extensive form of veiling involves covering the face. The most extreme form of the veil is the burqa, which hides the entire face including the eyes, but this was a local medieval development in the remote mountainous territories of central Asia (modern-day Afghanistan and Pakistan).

Muhammad established the separation of the public and private spheres of life, symbolized by the veil. In the Koran women are admonished to act one way when they are with their husbands or among only their family members and another when they are in the larger world, among strangers. Women in public are expected to conduct themselves so that they will not become an occasion for sin by others, in whom they might arouse sexual desire or envy. Accordingly, they are not to meet the eyes of strangers or engage in unnecessary conversations with them. (This is an injunction against what we might call flirting and is also standard advice offered by medieval Christian authorities to monks and nuns.) Women are also not to dress so as to reveal physical attractiveness.

At the same time, Muslim women are neither to wear clothes that will draw attention to themselves nor to display jewelry. The significance of this last point is often missed. It was and still is a common custom in the Middle East for much of a family's wealth to be invested in gold jewelry worn by its female members, so the injunction here is against an ostentatious display of wealth. On the other hand, the more extreme forms of veiling that developed during the Middle Ages were possible only for women from wealthy families who did not have to work; thus it became a social display of wealth on its own.

If the Koran says nothing specifically about the wearing of scarves or other veils, this practice nevertheless became enshrined in later Islamic law. It represents the common practice of the Mediterranean world. In the Middle Ages, Christian and Jewish women would not have appeared in public without a scarf or hat, and even today many older women in places like Spain, Italy, or Greece follow the same custom.

women, he enjoined men to have no more than four wives. Within the context of Muslim society he encouraged men to treat their wives with a modicum of respect.

*Dhimmi* groups were left largely to govern themselves. They maintained their own court system to resolve issues in family law, inheritance, and commerce. They provided for education, for the poor, widows, orphans, foreigners, and the ransom of captives. Christian and Jewish women, like their Muslim counterparts, lived in patriarchal societies that subordinated their status relative to men. Women's sphere of influence was the domestic sphere. Property rights and inheritance laws favored males. Women's educational opportunities were likewise limited, though basic literacy was more prevalent.

Some important differences remained. Both Christian and Jewish communities prohibited slavery, polygamy, concubinage, and child marriage. Both limited divorce. Indeed, under Roman Catholic rule, divorce was prohibited. An annulment could be sought but only for extreme reasons. Neither community practiced infanticide or female circumcision. Although female modesty was encouraged, neither set of religious edicts required the extensive covering required of Muslim women.

Most *dhimmi* men were town-dwelling craftsmen or businessmen and belonged to the middle classes of urban craftsmen, master artisans, and professionals. A few found their way into the elite upper class of officials, doctors, and judges. Women worked in textile-related occupations—embroidery, spinning, weaving, and dyeing. They were also health care providers (primarily of folk medicine and midwifery), astrologers, fortune-tellers, and brokers.

## ► government organization

### INTRODUCTION

People have created a dazzling number of ways for organizing themselves into communities. Their reasons for forming governments are many. Often, people organized under leaders in order to defend themselves against attackers bent on seizing slaves or a year's new harvest. On the other hand, people sometimes organized under leaders in order to attack and steal from others. Pastoralists sometimes needed to create government structures as a way to prevent conflict over rights to grazing lands. People with copper, tin, silver, and gold mines would form governments to distribute the wealth among community members and to protect the mines from outsiders. In areas where farmers competed for scarce water, people would organize come together to cooperatively build irrigation canals and dams as well as to allot water fairly to farmers.

There seems to have been a universal desire to justify the rule of government, and for this reason many cultures had myths saying that their governments were founded by God

or by great leaders of the past who had wisdom far greater than most people. These justifications of rule almost always resulted in the creation of rituals through which rulers symbolically fulfilled the role of the founding deity or founding ancestor. Indeed, the rituals often persisted long after people stopped believing the myths on which they were based. Thus, in China, long after Confucianism's secular governmental structure had become the empire's governing ideology, emperors continued to visit shrines, make pilgrimages to sacred sites, and seek ritual communication with the gods of the earth and weather even after most people had forgotten why the rituals existed in the first place.

It is human nature for someone reading about history to focus on the complexities of mighty empires. The Holy Roman Empire, the Mongol Empire, and the Islamic Empire amaze us because of their scope, covering thousands of miles of territory, spanning cultures, and organizing millions of people into a government run by a ruling elite. The ritual complexity of the medieval Japanese, Maya, and Indians capture the imaginations of readers. Still, some caution should be exercised in drawing conclusions about the relative cultural richness of a society with a huge government and numerous rules of decorum and that of societies with small or no governments. Even in a stateless society, government can be a complicated matter.

During the medieval era there were notable stateless societies in Africa, Siberia, Australia, Arctic North America, and South America. Sometimes there were not even chiefs. Nonetheless, people in these societies often behaved in an organized manner. They did so in part as a result of centuries of social adaptation to the demands of their environment. In western Africa people's survival depended on a rotation of farmlands, growing crops for a few years on a plot and then letting it lie fallow for 10 years or so. When Europeans colonized the region and forced people into European ways of managing land, environmental disaster followed, with poor soils ruined and land overworked. The stateless people had developed a system of rules of social conduct that enabled people to manage land cooperatively, with no one being able to control the lion's share of land. How did they manage to control crime and other antisocial behavior? They did so by ostracizing miscreants, a fate worse than death in their cultures, and through forming social groups based on family relationships that meted out punishment.

A leader in such a society was often someone whose behavior had earned him or her respect. Doing favors for others, caring for people in need, solving a problem such as where to find food after a crop failure could cause a person to become the acknowledged leader of a community. Occasionally, this person would have a title such as chief, but sometimes he or

she was just known in a community as the person to talk to when there was a problem. Another common way for leaders to come to power was through religious status. In many medieval societies a priest or priestess would have governmental power. Such people could be asked to intercede with supernatural beings on behalf of the living. In Africa these beings could be the spirits of dead ancestors, and among the Maya they could be gods of the underworld.

Such leaders usually had to perform rituals to establish their status, and often the rituals had to be repeated regularly to maintain status, such as the bloodletting rituals of Mayan rulers. Whether considering a government of no more than a village or an entire empire spanning a continent, the notion of governments having divine sanction was often invoked. The Mongol conquests were justified by the doctrine that God had designated them to become rulers of the world, but the also doctrine helped unify about a million Mongols such that they could organize and rule hundreds of millions of people of other cultures. Monarchs in Europe claimed the divine right to rule, and Muslim political theorists developed the same notion for caliphs and sultans. The reasoning was that God chose someone to care for his people and that there could be only one such person at a time; that person was likely to be the son or daughter of a monarch or of a sacred line of descent. Muslims fought civil wars over this matter, with some insisting that a caliph had to be the direct descendant of Muhammad and others believing that any descendant of Muhammad's extended family was acceptable or even that any good, just, and moral person could claim God's preference.

By uniting religion with secular power, governments could make powerful claims on the obedience of their people, but this authority was two-edged, because a government that failed to defend the kingdom against invasions, suffered repeated crop failures, or endured plagues could be judged a false government that lacked the necessary favor of God or the gods. In China, for example, weakness in an emperor or the government justified overthrowing the government and replacing the emperor with someone who had divine favor. Confucians regarded this notion as superstition, but emperors ignored the doctrine at peril of their lives.

## AFRICA

BY KIRK H. BEETZ

Information for the governments of medieval Africa is often vague, and the validity of evidence is much disputed by historians and archaeologists. Written records tend to be scant, partly because many cultures were nonliterate and partly because documents have been lost or destroyed through warfare and neglect. The reliability of oral histories varies ac-

According to culture and time. In some cultures reciting oral history with exactness was a requirement for storytellers, but in many African cultures storytellers modified their accounts

of history to make them more exciting or to make a moral point, turning pastoralists into giants, transforming chiefs into gods, and imputing magical powers to great kings. Ar-

Among the African societies organized as monarchies in the late medieval period were Kanem, Zimbabwe, Kongo, and Songhai.

chaeological evidence has limitations: Evidence is found in physical remains, and physical remains do not tell complete stories; they often just offer possibilities. Thus, there has been a great deal of speculation about government organization in medieval Africa, based on oral histories, rare written accounts, and the physical remains. For instance, a community of large buildings and a fortress might be thought to be a capital of some sort, perhaps of a kingdom or of a province. Written and archaeological resources often have been combined to create pictures of how a government organized itself. For Ethiopia there are some written records of the doings of monarchs and church leaders; for Axum, Nubia, and East African city-states, archaeological findings are the primary source of knowledge, whereas oral traditions have been extensively studied for stateless societies and many of the empires of western, central, and southern Africa.

### AXUM, ETHIOPIA, AND NUBIA

Axum was an old kingdom, having begun as a trading city in about the 11th century B.C.E., soon expanding to encompass its port city of Adulis, much of the Ethiopian highlands, and even for a time part of southern Arabia, ruled by a viceroy appointed by the king. The wealth and power of Axum depended on trade with Europe, the Near East, and southern Asia. Thus, the government was much concerned with controlling and protecting trade. The government ships that kept the sea-lanes open were characterized by medieval geographers as large, powerful, and capable of great speed but were not described in greater detail in surviving documents. To facilitate trade, the government created a mint and issued coins featuring depictions of the sun and the crescent moon, adding a cross in the fourth century when the royal family converted to Christianity.

A trader who arrived in Adulis would probably have first encountered representatives of Axum's government at the port. Axum charged tariffs on goods brought into its port, and officials assessed imported goods and enforced the law regarding tariffs. Adulis had a governor, appointed by the king, who oversaw the city's day-to-day operations. The capital city, Axum, was an eight-day trek from Adulis. Protecting the route from Adulis to Axum fell to an army directed by generals, who probably came from Axum's nobility. The fortresses of Axum dominated the heights above Adulis and were said to be intimidating to people who saw them when approaching Axum from the sea. The fortresses, army, and port officials were all tightly governed by a king whose responsibility was to keep Axum's borders secure, to collect enough taxes to maintain the military, and to keep open the sea-lanes and the overland trade routes from the interior of Africa.

In the seventh and eighth centuries Axum was powerful enough to shelter Muslims who had fled persecution in Arabia. The first group of such refugees included followers of Muhammad, and Muslim historians gave credit to the Axumite government for saving the Islamic movement from its enemies. Later, Muslims had a fierce dispute over who was the proper heir to Muhammad, with many fleeing to Axum for protection. What exactly happened to these refugees is not known for certain, but they may have settled in Axum. Such outsiders often were given honored status by the king, and they may have become vassals with their own territory. This situation may have contributed to the near collapse of the Axumite government, because Muslims eventually seized control of much of the coastal lowlands of Axum. With trade from the sea cut off and Muslim regimes to the north and the south, the king and his court retreated ever deeper into the Ethiopian highlands; for this reason most historians refer to the government as Ethiopia for the period from the 10th century onward.

Even though Ethiopia eventually regained control of Axum, its seat of government moved southward, following trade routes, onto the Shewan plateau. The royal family tried to meld religious faith with secular power and solicited the help of clerics with generous gifts to monasteries, which were the most influential Christian institutions in Ethiopia. In 975 there was a rebellion of the Jews in Ethiopia, nearly causing the collapse of the government. The rebels met with much success. The king survived by moving from camp to camp, setting up tents for himself, his bureaucrats, and his military aides. It was likely his vassals who turned the tide of battle. At present evidence suggests that in the medieval era Ethiopia formed a feudal society somewhat similar to that which developed in medieval Europe. Various nobles, some of whom were powerful lords of their own fortresses, could have mustered troops from the minor nobility and farmers in their territories. The rebellion was defeated, and the monarchy was more beholden to the goodwill of its vassals than ever.

Sometime in the early 12th century the royal family was deposed by Christian lords of the Agau people in the southern province of Lasta. At least one medieval Ethiopian king list suggests that the Agau ruling family was founded in 916 in Lasta, with the 10th in their line seizing the throne of Ethiopia. This lord founded the Zagwe Dynasty (ca. 1100–1270). The Zagwe monarchs depended on the support of the church for their dominance of Ethiopia because they apparently were otherwise unpopular. Thus, pleasing clerics by building churches, monasteries, and shrines was considered an essential part of the duties of government. The Zagwe established their capital at the town of Roha. They seem to have claimed that they were descended from Moses, an assertion

that formed part of the ideology that justified their rule. Both the nobility and the peasants appear to have been restless under the rule of the Zagwe, who were regarded as weak and corrupt, except for King Lalibela (r. 1189–1229). He alone of the Zagwe was remembered as a great man. He managed his empire partly by keeping his people occupied in public works, including carving churches out of solid stone near a village renamed Lalibela. These churches were an expression of royal power as well as a great source of income for the builders. Lalibela was believed to have been a sincere and pious Christian. Even so, most Ethiopians never accepted the Zagwe Dynasty as legitimate.

In 1270 Yekuno Amlak (r. 1270–85), an aristocrat claiming descent from the Axumite royal family, seized power and was declared *negus negasti*, the “king of kings.” He founded the Solomonid Dynasty, which claimed direct descent from King Solomon and the Queen of Sheba and ruled Ethiopia until the 1970s. The Solomonid kings oversaw a government composed of clerics and bureaucrats who managed the affairs of a feudal society. Ethiopia was divided into provinces, which were divided into chiefdoms. Each tribal chief and each noble ruler of each province had vassals who served him.

The royal government placed a heavy burden on its subjects. Instead of residing in a capital city, the royal government lived in 5,000 to 6,000 tents, which housed the emperor, the chief nobility, the courtiers, and their staffs. In addition, there were the tents of those who served the tent city—blacksmiths, potters, grooms for the horses, and so on. The tent city would remain in one place for three or four months and then would move to another place, usually in another province. Moving the tents and other gear required more than 50,000 donkeys, with the commoners often carrying their tents themselves. The tent city would not revisit the same site for at least 10 years.

One reason for the mobile capital of tents was that no one area could support the government administration indefinitely. Another reason for the mobile city was the way in which Ethiopia was governed. The emperor was not an absolute monarch; his authority was checked by the authority of the church and the collective authority of the nobility. This fragmentation of power frequently resulted in chiefs or lords refusing to pay their taxes or even declaring their independence. Further, in northeast Africa there were many small chiefdoms and kingdoms that paid tribute to the emperor and sometimes withheld payments. Thus, the emperor moved his entire capital to areas that were rebellious, placing the empire’s army and its supplies as well as government bureaucrats on top of the problem area. Should war break out, the tent city could be moved to get out of the way of invading armies or to be close to the fighting, allowing the emperor to

wage a military campaign and still tend to public business. This form of government had its ups and downs, but eventually Ethiopian emperors were able to regain access to the sea and its trade, and at the end of the medieval era they were aggressively expanding their realm.

Much less is known about the Nubian kingdoms along the Nile to the west of Ethiopia. They were Christianized by missionaries beginning in the sixth century. Many small kingdoms arose and disappeared during the medieval era in the general region of Nubia, but three kingdoms stand out in history: Nobatia, Makuria, and Alodia. Of these, the southern two, Makuria and Alodia, are best known to modern researchers, partly because Lake Nasser, formed by the Aswān Dam, has inundated the former Nobatia as well as much of what was Makuria. In the 1960s archaeologists uncovered extraordinary paintings and exceptional examples of architecture, indicating that the Nubian kingdoms were artistically and scientifically advanced cultures. Each had a literate class of government officials, and it is possible that the general populace was literate as well, giving archaeologists hope of someday finding documents that describe their governments.

Church government and state government were separate in the Nubian kingdoms, although the church and the state cooperated with each other. The royal government’s public works programs in each kingdom were heavily involved in building and improving churches and shrines. Visitors to the kingdoms reported that the churches were impressively beautiful and well maintained. The governments may have been confederations of small chiefdoms that were pledged to the king; the king could draw on small military units that were maintained in each chiefdom, but diplomacy seems to have been the basis of foreign policy. When Egypt fell to Muslim invaders, Nobatia, Makuria, and Alodia made treaties with the new Muslim government that were honored by successive Egyptian regimes until 1276, when Nobatia was invaded and its people put to the sword, with some fleeing south to Makuria and Alodia, east to Ethiopia, and west to the region of Kanem.

The capitals of Makuria and Alodia were Old Dongola and Soba. Pressures from Muslim attacks and raids by nomads from the south and the west may have caused the abandonment of Soba during the 13th century. In 1287 a visitor reported that Alodia had broken apart and was ruled by nine Christian warlords, each of whom commanded a small region from an impressive fortress. On the other hand, Makuria held out against attacks from Egypt for about a century, with its kings apparently doing an impressive job organizing a long-term defense before the prolonged war consumed its resources and the kingdom fell apart in about 1376, with some of its people being put to the sword and some becoming refu-

gees. These refugees may have contributed to the literacy of Kanem, near Lake Chad. Alodia's nobility held out against Egypt into the 15th century, when Alodia was overwhelmed.

### STATELESS SOCIETIES OF THE GRASSLANDS AND FORESTS OF WESTERN, CENTRAL, AND EAST AFRICA

To understand the development of kingdoms of medieval western, central, and much of eastern Africa and the organization of their governments, it is helpful to examine the social organization out of which they arose. Large cultural groups arose in the region even in ancient times, but very little is known about them—not even whether they were kingdoms, confederacies, or some other form of government. Most people were either pastoralists or farmers. During the medieval era the pastoralists were gradually absorbed into empires but often retained their independent ways.

When anthropologists speak of the stateless societies of medieval Africa, they usually mean farming communities. These stateless societies were extremely complicated, in spite of their seeming to have no government. Many historians and anthropologists refer to the stateless cultures as democratic, though they were not societies in which people typically voted in open elections; the term *egalitarian* is more often preferred.

In these stateless societies leaders were not always easy to recognize, because a leader might have a home not much different from anyone else's and might work at the same tasks as anyone else. Status was achieved not through material wealth but through mutual obligation—the giving and owing of favors. The more favors a person was owed, the higher his or her status. This giving and owing additionally worked on the village level, with people of different villages owing each other favors that could be fulfilled during times of drought. In such times villages with food and water could gain favors or fulfill favors by helping villages without food or water. This system helped keep military conflicts rare and small, usually involving only a handful of warriors. Such conflicts could be bloody, however; in some areas near the Congo bringing home a slain enemy's head brought prestige.

Stateless societies often had governing bodies at the village level. These took the form of secret societies. They were not secret in the sense that nobody knew about them, because they were well known. Instead, they were secret because they held meetings and conducted rituals that only members could attend. These societies had their basis in family, in cult, or in craft. The family-based secret societies could be very complex. For example, in many cultures women formed social groups that limited membership to daughters of a certain family, and women who had married into that family. Thus it was that a

woman could be a member of more than one women's group, by being a daughter-in-law in one and a daughter in another. No one was allowed to prevent a woman from attending a meeting of her group. During the meetings women shared food and dealt with problems such as a husband beating his wife; as a group, they could impose sanctions on the husband, such as denying him food at family gatherings or denouncing him as an outlaw.

Cult secret societies were based on the veneration of a particular deity or of certain ancestors. Members of these groups often had special masks that they wore only at meetings. The masks were thought to empower wearers with the wisdom of the deity or ancestors. Like family secret societies, these groups could enforce social customs. Members of the groups could face denial of religious services for transgressing against customs. A cult society often had a specific responsibility in society, such as making or changing village laws, presiding as judges in criminal proceedings, or organizing armed forces in times of war. Crafts often had their own secret societies, with distinct rituals for their particular work. They would police the quality of their members' work. The kingdoms that arose out of stateless societies often depended on these secret societies in villages to organize warriors, supplies, and tribute on which their imperial governments depended.

Archaeologists and other anthropologists are uncertain as to why kingdoms and empires arose out of stateless societies. One possibility was the increase in raiding for slaves from across the Sahara after North Africa fell to Islam. Perhaps to protect themselves from slavers, people united under a chief who organized defenses; when the raiding parties became larger and better armed, the chiefdoms selected a leader to lead an army from all the chiefdoms. These leaders sought to make their rule permanent by declaring themselves close friends of the gods or even godlike. It is worth noting that while this theory is plausible for western African cultures of the grasslands south of the Sahara, kingdoms were arising farther to the south among the Kongo peoples without similar pressure from outside forces. Control and defense of important resources, such as copper mines or superior farmland or pastureland, may have contributed to the development of these kingdoms.

The process of development of governments seems to have begun with the establishment of chiefs of villages, perhaps village elders empowered to organize defense of a village or another important project. The manner in which such chiefs were chosen varied, with some chiefs being chosen by a council of elders, themselves holding their status because of their having built up respect by favors that made many people obligated to them. Sometimes chiefs were elected, perhaps at

feasts held for the purpose of choosing a leader. At other times they were selected by a secret society charged with providing political leaders. Often, the person who was village leader had no formal title or position but was the person most respected for his services to his community; he was accepted by general consensus as the person to be appealed to for guidance in public affairs.

None of these kingdoms seems to have ever been able to impose uniform rule throughout their territories. Their governments were based on support either from peasants or from cities. Those that depended on cities often declined or collapsed when their cities suffered economic recessions. In general, federal law did not supersede local laws. Villages tended to rule themselves according to their traditions; those villages that had mutual obligations might unite under a single chief, who would be their spokesperson when dealing with the imperial government. Sometimes these chiefs became threats to the imperial government, which was a reason why some monarchs traveled with their armies to various parts of their empires as a way to impose their authority on their provinces. Provinces themselves often represented sets of villages and towns that were united by a common set of beliefs, especially belief in an account of their founding by a common ancestor, often a deity.

When a kingdom or empire collapsed, it was sometimes a catastrophe for city dwellers, because the order imposed by their government had ensured that food and other necessities were supplied from outside the cities, yet such a collapse was not necessarily a catastrophe for rural peoples. It sometimes was, with rural peoples being swept into slavery by their conquerors, but the stateless social customs that were the foundation of their governments often preserved everyday life in villages.

## KANEM

The kingdom of Kanem was shaped somewhat like a triangle, with its flat southern end including most of Lake Chad and its northern point being marked by the town of Bilma. Its people were the Kanuri. The northern Kanuri were pastoralists who kept sheep, goats, camels, and horses. The southern Kanuri were farmers who supplied the kingdom with grain. The people of Kanem were animists, and from about 800 to 1085 the monarchs were believed to be divine. The Kanuri were a literate people, and there is hope of finding documents about their government, although at present what little documentation there is comes from Bornu, a later kingdom formed by the Kanuri when the territory of Kanem was made unlivable by war.

The monarch was called the *mai*. Apparently the *mai* was not supposed to eat or drink because of his divinity and was therefore secretly fed by food and drink delivered to his pal-

ace in the capital, Njimi. The pastoral villages as well as the farming villages had a high degree of independence, with the *mai* running a confederation of villages rather than a strong central government. The *mai* was a military leader who commanded the combined forces of Kanem. Exactly how well these forces were organized is unclear, but the Kanem cavalry was a fearsome fighting force, and Kanem traded slaves for armor from the cities of North Africa. In 1076 the Sefuwa royal family converted to Islam, but the nobility and commoners remained mostly animists. Not until 1221 did Kanem become fully a part of the Islamic world.

## EMPIRES OF WESTERN AND CENTRAL AFRICA

During the medieval era there were numerous kingdoms of various sizes in western Africa and central Africa, about which very little is known, although some archaeologists suggest that evidence may exist in the forests for kingdoms the size of Kanem. The two best-known and probably most important empires were ancient Ghana, which is unrelated to the present-day state of Ghana, and ancient Mali, which existed in roughly the same territory as modern-day Mali.

Ghana existed mostly on the grassy plains and in the temperate forests of the Sahel, a band of highlands stretching west to east across Africa south of the Sahara as well in some of the denser forests to the south, along the Niger. Although Ghana was famous for the gold it exported, it did not actually control the gold mines, which remained in the hands of very secretive people who defied every effort to follow them to their sources of gold. Ghana became a powerful and rich empire. Its emperors were in general smart, worldly leaders whose government monopolized the gold trade between the forest peoples and traders from the north who brought European and North African goods south across the desert. The emperors were aided by the secretiveness of the gold miners because the government ensured that only Ghanaian traders could meet the miners at special trading spots, and the miners did not strike out on their own to meet directly with North African traders.

Ghana arose long before it had contact with Muslims, and its government took care to keep Islam separate from government operations. Its main ethnic group was the Soninke. The capital was El-Ghaba, "the Forest," and the monarch lived in a fortress within the city. Archaeologists have yet to discover this city. The monarch was a very visible ruler, meeting with officials during most of the day. When he came out of his chambers to conduct business, his subjects knelt and poured dirt over their heads; visiting dignitaries clapped. He ruled through governors, who reported directly to him. They would sit on the floor in front of a pavilion in which the emperor sat. To his right sat the sons of the subject kings of his empire. These were usually

trusted confidants who had regular access to the royal family. Seated on the floor around the emperor were his aides and bureaucrats, who gave advice on law and policy. Chief among the concerns of the emperor and his government was holding together the empire, because it consisted of people whose local customs tended to be those of stateless societies, and the niceties of taxes and tribute were alien to them.

When trade with Islam became vital to Ghana's prosperity, the government established Kumbi Saleh near El Ghaba. Kumbi Saleh is known to archaeologists and is in modern-day Mauretania. Kumbi Saleh had 12 mosques and freshwater wells and was apparently run by Muslim scholars. Even after Ghanaian emperors professed the Islamic faith, the government continued to keep foreign Muslim traders isolated in town, separating government business from religious business.

Ghana was western Africa's dominant power from about 700 to about 1200. In 1076–77 Kumbi Saleh was sacked by the Almoravides of Morocco, who believed that even other Muslims worshipped God incorrectly; the people they conquered either converted to their religious views or were killed. Ghana regained independence in 1087 but collapsed in 1203, with its territory being absorbed in 1235 into the vast empire of Mali, which flourished for about 300 years.

Although Mali was officially Muslim for most of its existence, it arose out of local African societies and reflected the customs of those societies in its government. Visitors from Islamic countries often mentioned the power and position of the women of Mali. Indeed, one of the problems most monarchs of Mali, called *mansas* (conquerors), had to deal with was the influence in government affairs of powerful women. Mali's government had arisen out of a matrilineal society—a society in which ancestry was traced through women rather than through men. Consequently, the heir to the throne was not a child of the *mansa* but a son of one of his sisters. Therefore, the Malian government was influenced by the *mansa's* mother and the mother of his heir. The *mansa* tried to keep these women out of government affairs by forcing them to live in residences separate from his, but he was often away at war, leaving government officials to consult with the next-most important people in the royal family, the *mansa's* mother and sisters.

Another concern of the Mali government was the tendency of subject peoples to revert to stateless customs whenever the army was not around. The government tried to cope by dividing the population into *kafus*, units of 1,000 to 15,000 people, which were governed by *famas*, hereditary rulers beholden to the *mansa*. However, even the *famas* could become lax in their duties to the central government. Thus, at great expense to the government, the army had to be huge because Mali was the size of western Europe and was well maintained. Like Ghana before it, Mali managed the trade in western and

central African gold, and it charged tariffs for goods entering the country and even higher tariffs for goods leaving the country. As a result, Mali's government was very rich and could afford to pay the troops and maintain a well-organized bureaucracy. The government not only kept track of income but also maintained a well-enforced legal system; foreign travelers noted that they could move freely through even isolated areas without being robbed or otherwise victimized.

## CITY-STATES OF EAST AFRICA

The city-states of East Africa were once thought by historians to have been created by foreign traders from Indonesia and the Near East, but archaeological studies have proved that these states were established by local, animistic peoples who were primarily responsible for the city-states' growth as ports of call as well as for their governments. When these peoples began to convert to Islam is not known, but in the 10th century they were recorded as being animists, and even in the 13th century many (possibly most) people in and around the cities were still animists, despite the presence of mosques and Muslim populations.

Most of the city-states remained small, perhaps no more than 10,000 people within their city limits; the cities of Mogadishu, Pate, Malindi, Mombasa, and Kilwa, however, grew larger and eventually controlled sizable territories beyond the immediate areas of their cities. For instance, in the 14th century Kilwa stretched its authority more than 900 miles south along the coast to the city of Sofala, a center of southern Africa's trade in gold from the interior. Sofala was ruled by a governor from Kilwa, perhaps making Kilwa the richest of East Africa's cities, although Mogadishu may have become more powerful. When the Portuguese invaded, looted, and murdered and enslaved the populations of all the other cities in the late 15th century and the early 16th century, Mogadishu was the only city to defeat a Portuguese invasion.

The rulers of the city-states called themselves sultans, but it is not known how absolute their power may have been. It is possible that some of them served only at the pleasure of a powerful merchant class that may have controlled most civic affairs. At Kilwa, Husuni Kubwa, the royal palace, had more than 100 rooms, with a freshwater pool for bathing, patios, and galleries, suggesting great wealth and the possibility that the sultan was a rich merchant. Kilwa took on some of the traits of a nation-state, including establishing a mint that produced coins in six denominations.

## KINGDOMS AND EMPIRES OF ZIMBABWE AND THE SOUTHERN INTERIOR

The kingdoms of the interior of southern Africa are known primarily through folklore and archaeological research,

even though the empire of Great Zimbabwe survived until the arrival of Europeans in that part of the world in the 15th century. In the modern-day nation of Zimbabwe, on the Zimbabwe plateau, are the ruins of the city of Great Zimbabwe. Its huge stone walls and other structures may have been built as visible signs of an emperor's power. The Zimbabwean culture was extensive; so far, archaeologists have found more than 150 other sites with similar structures, exceeding 300 structures in all. Taken as a whole, these sites may represent a society that was slowly becoming a modern urban state.

The empire of Great Zimbabwe was the largest of the Zimbabwean kingdoms. Archaeologists are reconstructing its organization and extent on the basis of excavations at settlements. These settlements show relationships to Great Zimbabwe through building styles, such goods as pottery in similar styles, and goods that were first imported into the city of Great Zimbabwe and then distributed outward, such as glass beads. There is a discernable pattern of remote villages tied to towns probably populated by an elite group that governed the nearby villages. The towns acted as regional centers of government that were controlled by an imperial government in the city of Great Zimbabwe. In this arrangement of villages, towns, and the capital city may be evidence of a well-organized government that was able not only to exercise efficient control over its population but also to distribute aid and material goods efficiently from its center of commerce to its provinces. In their turn, the villages supplied crops from their farms or cattle and sheep from their pastures.

There were probably other smaller kingdoms in southern Africa that may have shared the Shona culture in common with Great Zimbabwe. These kingdoms seem to have been subservient to Great Zimbabwe, paying tribute in the form of milk and cattle. Great Zimbabwe appears to have had an army, and it may have been able to add to its army by calling on its tributary kings to supply troops. According to accounts recorded by Europeans at the city-states, the emperor seems to have been regarded as divine, and people approached him only by crawling on their bellies. During audiences the emperor's actions were imitated by his courtiers. For instance, if he coughed, they coughed. If he became infirm from illness or advancing age, he was expected to commit suicide by taking poison, to make way for a healthy, strong heir. The size of his household was greatly exaggerated, with claims of 3,000 serving women living in it; in actuality the place could have held no more than 300 people and most likely had about 100 to 200 inhabitants. The emperor's courtiers apparently held hereditary positions in the management of the government, and they may have managed the state religion as well. At present it seems that the people of the urban areas of Great Zimbabwe overexploited the land, creating an ecological disaster

in which soil eroded and crops failed, causing the empire to be abandoned in the 16th century.

## PASTORAL AND HUNTER-GATHERER CULTURES OF SOUTHERN AFRICA

Little is known about the effects of kingdoms on the Khoi and the San of the southern African plains and southwestern Africa. There are archaeological indications that some of the Khoi, who were primarily herders of cattle, were required to pay tribute to Zimbabwean kingdoms, perhaps in exchange for being able to pasture their cattle in certain lands within the kingdoms. The Khoi may have waged occasional armed resistance that was put down by royal armies. The San were primarily hunter-gatherers. They regarded their territory as belonging to themselves and would defend it from outsiders, usually only in small tribal groups. The San were an adaptable people, and many may have served in the armies or on the farms of outside governments, but not enough evidence exists to suggest how this practice might have worked.

## THE AMERICAS

BY KEITH JORDAN

### NORTH AMERICA

Knowledge of medieval government in what is now the eastern United States comes from a mixture of sources. For most of the period before the Renaissance in the Old World, evidence for Native North American government east of the Mississippi is limited to archaeological finds. Elaborate burials, chiefly regalia of exotic materials, elite houses and mausoleums built atop high earth platforms, and large, often fortified towns tell of social inequalities and centralized governments. During the 16th century the Spanish expeditions of Hernando de Soto and others penetrated the U.S. Southeast. The diseases they brought led to the destruction of indigenous traditions and social organizations, but some of these European intruders, like the so-called Gentleman of Elvas, left written accounts of the governance of the Native American societies they found. Although native societies underwent rapid change following the European invasions, some pre-European forms of governance may have survived as late as the 18th century in some parts of the Southeast. The Natchez people of modern-day Louisiana, for example, had a very hierarchical social system led by a divine chief into the 1730s, at which point they were nearly exterminated by the French. Some anthropologists use this Natchez society as a model for understanding earlier government in the same region, but caution is needed. It is possible that much changed between the 1500s and 1700s, especially when indigenous

populations were so drastically reduced in number by the new European diseases.

Between about 900 and the Spanish incursions of the 16th century the peoples of the Mississippian cultural tradition were organized into chiefdoms. The term *chiefdom* is employed in anthropological theory to refer to relatively small (up to thousands of subjects per polity) hierarchical class societies ruled by chiefs whose office is inherited. Unlike kingdoms and other states, chiefdoms lack extensive bureaucracies, and formal political offices are limited to the chief and perhaps a few other positions like chief priests or war leaders. Chiefs and their families constitute the wealthiest and most powerful social class. Most chiefdoms, and certainly the Mississippian examples, had their economic base in agriculture, and the chiefs controlled the surplus food supply and its redistribution among their subjects. The majority of the Mississippian chiefs' subjects were maize farmers, though other social strata included slaves, privileged craftsmen attached to the service of the chief, and priests.

The Natchez social structure was broadly divided into nobles and commoners, or "Stinkards," with the nobles further separated into Suns (families of the chiefs) and lesser-ranked "Honored People." Chiefs, in general, often controlled trade with outsiders and had preferential access to exotic imported goods and raw materials, which they displayed and conspicuously consumed as marks of their power and which they used to reward their followers. Mississippian chiefs were also religious leaders who legitimized their claims to power by public performance of sacred rituals. Natchez chiefs, or Great Suns, were seen as living gods, descendants of an emissary of the sun god, and carried the power of life or death over their subjects. But in most chiefdoms the power of chiefs was not absolute. The chiefs' decision making and use of force often was limited by a council of nobles or elders serving as advisers, and their influence often rested on their personal charisma and ability to reward followers from their excess wealth. A decline in status or wealth could lead followers to desert their leaders.

Chiefs usually exercised their rule from a central town or capital with a population that could number into the thousands, and they controlled surrounding smaller towns by outright conquest or by recruiting local leaders into their orbit with rewards and the promise of status. The territories controlled by chiefdoms often fluctuated greatly, depending on an individual chief's success in holding on to subordinates by might or influence. In complex chiefdoms the ruling capital and its chief could dominate two to three levels of subordinate chiefs and governing centers. Paramount chiefdoms, of which several were encountered by De Soto in the Southeast, dominated whole networks of less powerful chiefs by

defeating or co-opting them. The subordinate chiefs had to pay tribute in foodstuffs and other supplies to the paramount chief, but without well-organized armies or bureaucracies, paramount chiefdoms were difficult to maintain and their domination over other chiefdoms often short-lived.

Mississippian chiefs could command their subjects to labor on large-scale building projects for the chiefs' benefit and glory. The largest, most influential, and probably the original Mississippian chiefdom had its capital at Cahokia, Illinois, between about 1000 and 1350. The first true North American city, with a population of 10,000 to 15,000 at its height, Cahokia's area of influence extended north into present-day Wisconsin and south into Georgia and Oklahoma. Its rulers lived atop massive earthen mounds, including the 105-foot high Monks Mound, the largest structure in North America before the 19th century. Young men and women, some of them from distant areas, were sacrificed to accompany Cahokia chiefs into their tombs. Community and religious leaders in smaller outlying towns and villages maintained their influence through their connections to the great city's rulers. Chiefdoms far to the south collected and displayed Cahokian ruling regalia—hammered copper images, carved stone effigy pipes of mythic ancestors, and shell ear ornaments showing a long-nosed character—as part of their claims to rule. These symbols of rule equated Mississippian elites with the mythic hero Red Horn or Morning Star and portrayed chiefs engaged in activities exclusive to their rank: impersonating Morning Star by wearing falcon costumes or playing the game of *chunkee*, in which a stone disk was rolled across the ground and the object of the game was to stop or hit the disk with a throwing stick.

Mississippian chiefs were treated with elaborate displays of respect by their subjects. They were carried in litters—at the time of De Soto's expedition, some were too well fed to move in any other fashion. Although most Mississippian chiefs were male, De Soto did encounter several female rulers during his travels. The symbolic center of a Mississippian chiefdom was the ancestral temple, where the bones of the chief's ancestors reposed alongside the chiefdom's sacred objects, the wealth used by the chief to reward followers, and the weapons employed in the capital's defense. Enemy warriors sacked and desecrated these ancestral shrines when they captured chiefly capitals, symbolizing their total defeat of the conquered chiefdom.

Our understanding of government in what is now the southwestern United States during this period relies on archaeological evidence, often interpreted in light of the behavior of the modern descendants of the medieval inhabitants, the Pueblo Indians. During the period from the first European contacts in the 16th century up to the early 20th century, Pueblo societies were seen to be very egalitarian on the

surface, with an ethic based on cooperation; with no class divisions; and, where chiefs were present, with chiefly offices that had only ritual or ceremonial functions. In fact, in each town much decision-making power and control of access to farmland rested with certain privileged families who maintained control over the masks, equipment, and rituals conducted at annual religious ceremonies. Still, one cannot speak of ruling classes or strong centralized governments, and for years the social organization of the Anasazi peoples (ca. 900–ca. 1300), the Pueblos' ancestors, was interpreted as being similar in principle.

Recent reevaluation of the evidence, however, suggests that a distinct ruling group presided over the enormous site of Chaco Canyon, New Mexico, between about 900 and 1100. The site has evidence of construction in stone and wood on a vast scale, and its planning shows an ability to control and organize labor on a massive level. Large Chaco buildings called "Great Houses" were once interpreted as collective apartment houses for people of equal rank, like the dwellings of recent Pueblo peoples. But new population estimates based on archaeological data indicate that at least one Chacoan great House, Pueblo Bonito, had few residents and that those who did live there did not make their own pottery, probably did not cook for themselves, and were buried with a vast array of turquoise jewelry and perhaps even accompanied by human sacrificial victims. Their bones show that they were better nourished and had fewer diseases than their neighbors.

Pueblo Bonito probably served as an elite residence, but what kind of rulers lived there is a mystery. Were they religious leaders who ran Chaco Canyon as a pilgrimage center to rival Rome and Mecca in the Old World? Did they manipulate their knowledge of astronomy (shown in the art and architecture of Chaco) to impress followers? Did their power depend on their ability to redistribute Chaco's surplus agricultural wealth to surrounding peoples in times of famine, or did they control the regional trade in exotic luxuries like local turquoise jewelry and copper bells and bright macaw feathers from Mexico? The period of Chaco's influence over the Southwest seems to have been relatively peaceful with the exception of cases of extreme violence involving the dismembering and even cooking of individuals. Did the Chaco rulers keep the peace by maintaining a monopoly on extreme force to punish challengers to their power? In any case, after Chaco's power collapsed in the early 12th century, subsequent Anasazi communities do seem to have been organized on a more egalitarian basis, similar to historic Pueblo Indian governments.

## MESOAMERICA

The Late Classic (ca. 600–ca. 850) Maya were organized into about 40 independent and rival city-states ruled from capi-

tal cities some 12 to 19 miles apart from one another. Each capital city held the residences of the royal family and also functioned as the main religious center of the kingdom. Some of these ruling cities were quite large—Tikal in present-day Guatemala and Caracol in present-day Belize, for example, may have had as many as 100,000 inhabitants each in the seventh century. Increased insight into the offices and workings of these polities has come from the recent decipherment of Mayan hieroglyphs as well as the evidence of palaces and royal tombs. A hereditary king called an *ahau*, or "holy lord," of that city ruled each Mayan kingdom. A less frequently found title in inscriptions, *kalomte*, may be translated as "overking" and refers to rulers who conquered or persuaded other city-states to submit to their rule. A lower office, *sahal*, referred to the subordinate rulers or governors who administered smaller towns for the *ahau*.

Mayan kings adopted the role of religious specialists to justify their right to govern, performing public rituals to ensure the well-being of their subjects' harvests and mark the passage of time in the Mayan calendar. The *ahauob* conjured up ancestors through trance states induced by bloodletting in order to receive their forefathers' legitimizing blessings on their rule. Besides functioning as state shamans, *ahauob* were also war leaders and were expected to validate their claims to power by capturing enemy prisoners before their coronations. Mayan monuments frequently show *ahauob* triumphant over royal prisoners from rival city-states. Such defeated rivals were either tortured and sacrificed or returned to their cities to rule as vassals of their conquerors. Conquered states paid tribute to their conquerors in the form of goods and labor, but the conquerors did not occupy vassal kingdoms or expand their physical borders. Alliances were created through strategic marriages between ruling families and the exchange of rich gifts among elites. Although several Mayan city-states like Tikal and Calakmul in Mexico at times dominated a number of their neighbor polities, these arrangements were not stable. No permanent "empire" arose in the Mayan region, nor did Mayan kings apparently have much control over the economies of their states.

Succession usually passed from father to firstborn son, but female rulers are also documented in the inscriptions. One, Lady-Six Sky, ruled the city of Naranjo as regent for her young son but had herself portrayed on sculptured monuments carrying kingly regalia and taking captives in battle. Since the king was seen as the earthly representative of the maize god, princes were called "sprouts" (*ch'ok*) and the heir apparent "the head sprout" (*baak ch'ok*). At their accession rites kings were seated atop a scaffold or platform. After the sacrifice of captives, they received their royal regalia and a new "divine name," often incorporating the name of a god.

Members of the royal family who were not in the line of succession took on the role of royal scribes and artists. An *ahau*'s entourage not only consisted of these relatives and officials but also included dwarfs, apparently viewed as having supernatural abilities and consulted for advice by the monarch.

At the time of the Spanish conquest in 1521 the Zapotec of Oaxaca were scattered into separate, small kingdoms, each ruled by a lord called a *coqui*. These independent polities occasionally joined together to create unstable and short-lived alliances, as in the 15th century when they banded together against invasion by the Aztec. Disputes over succession could be resolved by consulting a powerful oracle priest, whose judgments supposedly reflected the will of deified royal ancestors. Zapotec social classes were rigidly defined, and marriage between members of distinct classes was forbidden. At the top were the nobles, including the family of the *coqui*. In the middle stratum were commoners—mostly maize farmers. Serfs—landless peasants—and slaves occupied the bottom rung of the hierarchy.

A variety of historical sources are available to shed light on Aztec government: the writings and letters of the Spanish conquerors who vanquished the Aztec in 1521, the writings of missionaries sent from Spain to Christianize the newly conquered territory of Mexico, and oral accounts recorded by colonial Spanish chroniclers as well as the archaeological record. However, the biases of European chroniclers have led to some misunderstandings of the Aztec system. What is commonly and erroneously referred to as the Aztec “empire” of the 15th to early 16th centuries was, in fact, an extended tribute network. Three cities in the basin of Mexico—Tenochtitlán, Texcoco, and Tlacopán, known as the Triple Alliance—conquered large parts of Mesoamerica, from Veracruz in the east and Oaxaca in the south all the way to Soconusco in modern Chiapas on the southeastern border of their influence.

Unlike the rulers of an empire like the Roman Empire, the Aztec did not set up their own administrators over the territories they dominated and for the most part did not garrison troops there. Rather, the conquered peoples were allowed to keep their own rulers and retain their own lifeways, provided they paid tribute in agricultural produce, textiles, clothing, and luxury items to the Aztec. Refusal to pay or violence toward Aztec emissaries or merchants led to punitive expeditions intended to get tribute flowing into the basin of Mexico again. Captured warriors were brought en masse to Tenochtitlán to be sacrificed, rebellious rulers were executed, and humiliating punishments were visited on recalcitrant peoples. One defiant people was forced to pay tribute in dangerous (and hard to catch) snakes. Subject rulers and sometimes even the enemy leaders of rival states were invited to Tenochtitlán on ceremonial occasions to witness the mass

sacrifice of captives—a potent means of intimidation for would-be rebels.

Aztec “kingship” actually was a dual rather than a single office. The ruler, called the *tlatoani*, or “one who speaks,” was the officer equated by the Spanish conquerors with their notion of an emperor. The *tlatoani*, ruling from Tenochtitlán, functioned both as supreme military commander and chief high priest for the Triple Alliance. He presided over massive public rituals aimed at the maintenance of rainfall and agricultural fertility. Like the Mayan rulers, he had to demonstrate his ability as a warrior as part of the rituals of coronation and underwent fasting and bloodletting before taking office. He was also the highest and final authority that could be appealed to in matters of judgment. The *tlatoani* was both a hereditary and elected position, selected from among the sons, grandsons, brothers, and nephews of the previous ruler by a council of nobles.

Paired with the *tlatoani* was a second ruler, the *cihuacoatl*. Although the title literally means “snake woman,” this official, like the *tlatoani*, was always male. The *cihuacoatl* presided over the state bureaucracy as chief administrator and “treasurer.” He also took the place of the *tlatoani* in the latter’s absence from the capital and served as his adviser in military matters. The office of *tlatoani* gained in power in the decades before the Spanish conquest of 1521, but the council balanced the influence of both offices. Life at the *tlatoani*’s court was characterized by feasting and the cultivation of poetic, formal manners of speech. His subjects treated the *tlatoani* with extreme deference as a semidivine being.

While Aztec nobles, or *pipiltin*, occupied the top of the Aztec class system, there was some room for upward mobility, as warriors who distinguished themselves in combat could be awarded land and wealth by the *tlatoani* and could pass their status to their descendants. Another wealthy and politically powerful class was the merchants, or *pochteca*. Although they were technically commoners, they accumulated considerable riches and played an important role for the state as spies. The base unit of Aztec social organization in the basin was the *calpulli*, a family-based landowning and farming collective. In the early days of the Aztec state, representatives of the *calpulli* advised the *tlatoani*, but their power decreased as that of the *tlatoani* expanded.

## THE CARIBBEAN

At the time of Columbus’s “discovery” of the islands of the Caribbean, the Taino peoples of the Greater Antilles had been organized into chiefdoms for some three centuries. The office of chief, or *cacique*, was inherited via the maternal line. A *cacique* succeeded his maternal uncle rather than his father. The size of Taino chiefdoms varied. Some appear to have

been complex chiefdoms, called *cacicazos* by the Spanish. The whole island of Puerto Rico was ruled by a single paramount chief at the time of European contact, with subordinate chiefs beneath him. Chiefs could expand their influence and territories via marriages of convenience with other chiefly families as well as through warfare.

Taino chiefs functioned as religious as well as political leaders and controlled the most powerful sacred objects possessed by the polity, though priests and shamans were part of Taino society as well. In particular, *caciques* presided over massive public ceremonies aimed at promoting unity at times of transition for a chiefdom, like the death of a ruler's predecessor or a natural disaster. They appeared on elaborately decorated sacred seats, or *duhos*. But their power was not limited to religious pageantry. *Caciques* conspicuously displayed their wealth and were permitted to enter polygamous marriages as another prerogative of their status. Unlike Mayan *ahauob*, *caciques* exercised control over trade and the production of trade goods like textiles in their domains.

## THE ANDES

On the north coast of Peru the Moche culture (ca. 100–ca. 700) was politically organized into at least two states, one ruling from the capital city of Cerro Blanco, and at least one separate state on the northern edges of Moche territory. Moche rulers seem to have had prominent religious roles. They are portrayed in paintings and sculpture impersonating deities and presiding over the sacrifice of prisoners of war. Their ruling ideology seems to have revolved around the person of the individual ruler to a greater degree than any other Andean government, and portraits of individual rulers, rare elsewhere in Peru, are common. Moche kings lived atop massive adobe platforms and were buried in them along with their riches in gold and silver jewelry.

Traditionally, archaeologists interpreted Wari (or Huari) in Peru as the seat of an empire (ca. 550–ca. 1000), like that of the Incas, in order to explain the wide distribution of its art and architectural styles. Its contemporary metropolis, Tiwanaku in Bolivia, was supposedly a theocracy whose extensive influence was spread by religion. Current evidence seems to confirm that the Wari conquered surrounding peoples and demanded tribute from them in the form of work, like the Incas. They built provincial outposts with Wari-style architecture and, also like the Incas, used *quipus*—knotted cords ordered around horizontal ropes—to keep records. Whatever the precise nature of Tiwanaku's government, it was sufficiently well organized to create massive agricultural projects and colossal architecture. It is possible that an individual monarch ruled Tiwanaku. Ruler images are rare, however, and the site may have been governed by a collective leader-

ship drawn from different family groups. The city seems to have influenced peoples to the south, in present-day Chile and Argentina, by maintaining trade relationships with local leaders who became clients of Tiwanaku, receiving ceremonial objects and luxury goods in return. It is possible that Tiwanaku also established colonies in agriculture-rich areas to the east of the city. Whatever the nature of their respective governments, the influences of these states overlapped and came into conflict in southern Peru, where both apparently sought to control a mineral-rich region.

The Inca Empire was called Tawantinsuyu in the Quechua language, translated as “the four quarters of the world”; at its height at the time of the Spanish conquest of 1532 it encompassed 80 separate provinces spanning the modern-day countries of Peru, Ecuador, Bolivia, and northern Chile and Argentina. The capital, Cuzco, was viewed as the center of the empire and indeed of the universe itself. Only Incan nobles resided in the sacred core of the capital. Skilled artists from conquered areas often were relocated to Cuzco to beautify the city with their work. These craftsmen and Incan administrators inhabited the surrounding “suburbs” of the capital. The nature of the top level of Incan government has been the subject of many debates among anthropologists. The Spanish conquistadores interpreted it as ruled by a single emperor, and they recorded lists of what they took to be a succession of kings. However, more recent theories suggest that Incan kingship was dual or multiple, with two or more royal offices held simultaneously by kings representing different elite family groups.

The basic social unit of the Inca Empire, and indeed even of some Andean peoples of today, is the *ayllu*, family-based landholding and farming collectives, divided into moieties, often with specific, separate, and complementary social roles and duties within the larger whole. In Incan times two nobles or *kurakas* presided over each *ayllu*, one for each moiety. *Kurakas* were ostentatious in their displays of wealth and had the privilege of polygamy, which enabled them to increase their riches through the textiles and other luxury goods manufactured by their many wives. Besides organizing community labor, the *kurakas* also functioned as religious specialists.

The *ayllu* was the basic unit of taxation in the Incan realm. These in turn were broken down into subgroups in units of 10. A group of 10 taxpayers constituted a unit directed by an overseer. Ten of these units were under the supervision of a higher official and so on up to the post of the “Lord of Ten Thousand,” who was subject to the Incan provincial governor. The state collected taxes from its subjects in the form of labor (the *mita* system). *Mita* service to the state could consist of construction work on buildings and infrastructure like the

extensive system of highways uniting conquered territories, or producing food or textiles for the state's storehouses. In return, the Incan state provided food to those engaged in construction projects and redistributed surplus food from its storehouses in time of famine, though the latter task was left mostly to local rulers. Incan administrators kept up a census of people and llamas using *kipus*.

Outlying provinces were administered from centers built in Incan style and connected by state roads. Local subjects—able-bodied young men—periodically gathered at these provincial outposts to perform *mita* labor and participate in ritual feasting and alcohol consumption under the direction of the resident Incan officials. To keep order in their conquered provinces, the Inca sometimes forcibly removed rebellious ethnic groups en masse and resettled them in distant regions, while subject peoples of proven loyalty were sent in to colonize newly acquired and potentially unstable territories. Local rulers often were left in power, their loyalty to the Incan state assured by rewards (luxury goods) and preventive measures (their families, and even their local gods, being taken back to Cuzco as hostages). Newly conquered local leaders might be bought off with gifts of fancy textiles, while Incan garrisons were installed in some provinces to keep order. The Incan language, Quechua, served as the official language of the empire.

## ASIA AND THE PACIFIC

BY KENNETH HALL

Indian religion and Chinese Confucianism were critical to the founding and development of most Asian states, which emerged out of earlier tribal societies. The Indian governmental ideal was the mandala state, a conceptual “heaven on earth” in which regional political authority centered on a sacred royal court, a court's sacred temple complex, or a network of strategic temples sponsored by a monarch and his court elite. As the focal center of the realm or as the chief patron of the realm's temples, the monarch held power through his divine association as the gods' delegated authority on earth, if not a divine being himself who had temporarily taken human form, to return to divinity after death.

The debate in Indian kingship was whether the ruler should lead by moral example, with his subjects modeling their lives after his as a means of achieving their own salvation, or by direct intervention. The alternative was to rule by threat or to use force when necessary to maintain societal order. The greatest threat in the Indian system of statecraft was the potential autonomy of the state's temples and temple networks and the popular empowerment of priests as the moral alternative to a ruler's secular authority.

Chinese Confucian tradition resolved this dilemma by clearly distinguishing the state as a secular institution. The Confucian state was centered in its urban capital, which was primarily an administrative rather than a ritual center. Professional bureaucrats who had passed civil service examinations filled the state's administrative posts, and priests could not hold bureaucratic appointments. The Chinese emperor was the highest administrator of his secular realm but was subject to the conceptual Mandate of Heaven. In theory, an emperor received the mandate of the divinity, an assurance of their favor, as acknowledgement of his capacity to lead humanity successfully. If, however, the emperor became corrupt or ineffective, the mandate could be withdrawn and granted to another. The civil ruler was thus empowered by the divine but was a human ruling over a civil society in which the actions and decisions of humans determined the course of their existence on earth. A failed ruler who no longer held the mandate could be overthrown by public rebellion, in contrast to the Indian notion of kingship in which the monarch could be replaced only by direct divine intervention. As in Indian kingship, Confucians disagreed as to whether the emperor should lead by moral example or by aggressively involved civil leadership.

## INDIAN POLITICAL CULTURE

In India's Dharmasastra (“dutiful law”) ideal there was no hierarchy among the caste tribunals and village and marketplace councils that had overlapping governmental jurisdictions. Every social group was allowed to formulate and apply its own customs and conventions. Governmental law and political institutions were not rigid but could be changed to meet fluctuating local needs and to achieve the best interests of the local community. Ultimately, Indian institutions were expected to make decisions consistent with the interests of the most powerful among the community's members, whose prominence was a combination of their political, economic, religious, or hereditary stature. Most local legal decisions resulted in expulsions and boycotts rather than the fines or the severe physical penalties that were typical of the Chinese political system. In theory, only a royal court could impose a death sentence.

A royal court of justice consisted of a king or an emperor or his designated agent assisted by learned Hindu and Buddhist clerics. Local justice could be appealed to royal courts, where kings made practical legal decisions based on their sense of common usage rather than on a written code of law. Few cases went all the way to the royal court, and such cases put the community at risk since the king's justice would not necessarily benefit the community's interests. While kings were supposed to pass judgments after weighing both the

Dharmasastra and local traditions, ultimately kings took actions based on their own best interests. Thus, it was in a community's best interests to reach a local resolution rather than to have the outcome dictated by a king.

Gupta imperial patronage of Hinduism (ca. 220–ca. 650) made the Hindu temple and its priesthood the centers of everyday life. In the absence of a strong central government that followed the collapse of Gupta rule, the temples, the temple networks, and their priesthood were the alternative source of societal leadership and set the cultural standards, based on the regulations of the Hindu caste system, for Indian society. This system empowered the Brahmin priest as the caretaker of Indian social order and human well-being, in partnership with kings (Kshatriya), who might exercise secular authority but were ultimately subject to the moral authority of the Brahmin priest. The Vaishya middle class (artisans and merchants) and Shudra laborers subjected themselves to Brahmin and Kshatriya leadership.

Perhaps in response to the organizational needs of settlements on the edges of settled agricultural zones, surrounded by hostile tribesmen—a response to the hostile physical and human environments in the development of India in the post-Gupta age—sophisticated village-based governmental institutions developed in the absence of centralized authority. In this age dynastic governments were impermanent. As one dynasty replaced another, group solidarity at the local level compensated for instability at the imperial level. Collective negotiation offered advantages in a village's relationship with other parallel commercial and religious institutions as well as with imperial regimes. Local institutions might evolve into regional governance (*nadu* in southern India and *visaya* in northern India), notably when there was a common geography, such as a river valley, or when there was need for cooperation to ensure regional access to water—as in the construction, maintenance, and management of irrigation systems. These local institutions collected taxes (normally a share of the local harvest and required labor dues), exercised varying degrees of land control, and assumed judicial powers, all of which contributed to the appearance of local autonomy.

Against this perceived autonomy, in the distribution of village resources local institutions were in a continuing process of negotiation between the village and the upper levels of governance. To ensure their right to regulate their own affairs and to minimize the opportunity for external interventions and to limit external knowledge of and control over local affairs and thereby to retain local resources, village governments went out of their way to convey an image of local solidarity. Imperial regimes and kingships seized every opportunity to extend their authority through intervention when a local crisis occurred, for example, a factional split

or the local inability to deal with certain types of problems, such as recurrent external threat of raids by armed warriors, whether neighboring tribesmen or competing armies. Royal governance in this age was itself subject to sudden expansion and contraction and lacked the institutional or bureaucratic capacity to integrate the local institutions into a continuous system of governance. Royal administrations were concentrated in the king's court; the royal army and a core of royal secretaries and petty officials, who were designated by impressive Sanskrit titles, made regular rounds to remind locals of royal authority and to maintain local submission.

To negate their governmental weakness, Indian kings patronized clerics and religious institutions. Over time these temples and their networks provided a ritual and institutional centrality that the monarchy lacked. Temples were independently empowered by their hold over delegated rights to shares of a land's produce. In some cases these were linked transfers that affected undeveloped land, which might be paired with lease rights or reassignments of war captives or bondsmen, but in many cases the land was already occupied and involved a transfer of all or partial income rights to land, paired with specified administrative rights over that land. Thereby, temples became more than agents of political centralization and religious well-being owing to their contributions to local economic vitality. Directly or indirectly they had an impact on local governance that superceded the rise and demise of dynastic authority.

The alternative potentials of the temple as partner, opponent, or center of governance were repeated throughout Asia. In the case of China, the Tang and subsequent Chinese dynastic regimes consciously monitored the activities and limited the resources of Buddhist and Dao temples to negate their potential for political rivalry.

### CHINA'S CONFUCIAN GOVERNANCE

The Tang China state (618–907) was based in a network of administrative cities, centered in the Tang capitals of Luoyang and Ch'angan (now Xi'an), where Tang rulers negated the potential for split loyalties between ritualized courts and Buddhist temple centers. Tang Confucian bureaucrats thought of Buddhism as foreign, immoral, and a threat to the Chinese way of life. In their minds, Buddhism, which had developed strong roots during the interregal chaos from the fall of the Han Dynasty in 220 to the rise of the Tang, encouraged individual dedication to the Buddhist Church rather than to the Chinese state. To Confucian elite, Buddhism did not honor the traditional Chinese societal hierarchy: gentry, peasants, artisans, and merchants. Consequently, twice in the Tang era emperors ordered the closure of monasteries and the confiscation of Buddhist property by the state.

The confiscated property was assigned to private citizens in order to make this property (primarily land) subject to taxes. (Religious property was tax free.) This practice forced monks and nuns to return to civilian life to fulfill their family obligations. In doing so, they were forced to submit to the elaborate traditional family order that was based in a rigid Confucian code of filial piety. Confucian ethics stressed the subordination of the individual to the collective secular interests of the family; this included honoring parents and others in the family who held seniority over others. In 845 as many as 4,600 monasteries and 40,000 temples and shrines were destroyed, and 260,000 Buddhist monks and nuns were returned to their homes. Although this ban was lifted a few years later, the practice of the Buddhist faith never returned to its previous level of popularity.

Confucian statecraft was based on the teachings of the sage Confucius (551–479 B.C.E.). Unlike other teachers of the time, Confucius believed that it was possible for all people, regardless of their station in life, to do right. He taught “right relations,” which included “human heartedness,” benevolence, respect for superiors, and filial piety. More a set of ethical rules or a moral philosophy than a formal religion, Confucianism avoids questions of a divine being and is vague in its discussion of the afterlife and otherworldly matters. The Confucian ideal is a ranked or hierarchical social and political order composed of status groups and graded roles, from the ruler at the top through officials and gentry (landed and educated elite) to the family head. According to Confucian philosophy, the key to effective authority is setting a good example through “right relationships” in order to ensure “virtuous behavior.”

Confucius believed that the threat of punishment and a formal legal code were no guarantee of individual virtue or social harmony. He also believed that in a properly run society rules and punishments were ineffective and unnecessary. In the ideal Confucian order, people *want* to do right, a situation that is achieved only by making the Confucian ethical code of correct social relationships a part of one’s own thinking. Violence is only a last resort, when the social system has broken down.

As popularized in the writings of the scholar Mencius (ca. 371–ca. 289 B.C.E.), early Confucianism presents a highly optimistic view of humanity and society. Later Confucian scholars, known collectively as legalists, had a very different perspective. They argued that humans drifted naturally toward chaos and thus required an intervening force, or at least the threat of force. Legalists believed that people need a formalized code of law to achieve and maintain universal social harmony.

Both traditions, however, affirmed people’s right to rebel against immoral or unjust rulers, leaders who had forfeited

the Mandate of Heaven by their own lapse from virtue. While loyalty to superiors was the basic commandment of Confucianism, commitment to moral principles could prevail, especially in times of corrupt leadership. This situation, however, presented individuals with a severe psychological dilemma—loyalty to leader versus commitment to moral principle. Consequently, civil disobedience was extremely rare; however unjust, authorities (from the emperor at the top to one’s parents on the bottom) were seldom challenged.

The Tang governmental system that evolved through the medieval era tended more toward a “rule by law” rather than a “rule of law.” This system required severe penalties that would discourage disobedience: public humiliation, hard labor, physical mutilation, banishment, slavery, or death. The Confucian moral code advocated continuous self-cultivation and the performance of one’s proper social role in a hierarchically structured society. Aggressive selfish behavior was unacceptable. Since criminal activity was considered the by-product of improper management of a family’s individual members, the relatives of a convicted criminal could also be punished.

Most labor penalties lasted from one to six years; mutilation could include shaving the offender’s beard or head, branding, cutting off a nose or a foot, or castration. The sentence of death could take several forms, including being torn apart by horse-drawn chariots, although decapitation and hanging were the norm. Penal labor was the usual penalty for theft or other civil crimes. Even those who were required to pay fines might work off the sentence through a stipulated term of servitude. Those with servants or wealth could receive credit for work performed by others in their place. Males might redeem their relatives by performing services on their behalf.

Laws were intended not only to regulate common people but also to constrain officials. There were rules for keeping accounts, supervising subordinates, managing penal labor, conducting investigations, and dealing with the public. Those officeholders who violated this code of conduct might be fined, lose their official positions, be reassigned to a bureaucratic post on a distant frontier, or in extreme cases, be executed.

The Chinese legal system depended on magistrates who were state bureaucrats rather than appointees with local roots. Private lawyers were prohibited because they were considered to be social parasites whose involvement was more likely to result in further disputes rather than in a peaceful resolution. The government magistrate was both the judge and the prosecutor. (Chinese law held the accused guilty until proved innocent.) Nevertheless, the magistrate was expected to investigate a case thoroughly and to impose a fair sentence. A case could be reopened if one party claimed to be the victim of injustice. To prevent corruption and wrongful verdicts, the

Chinese state held the magistrate absolutely responsible for mistakes of law or fact, regardless of good intentions or absence of malice. To protect themselves from reprisals, magistrates tried to avoid accepting formal complaints and instead devoted most of their efforts to the mediation of settlements rather than to litigations inside their courtrooms.

The Chinese legal system was willing to make allowances for or penalize according to the extenuating reasons for a crime. Among these crimes was the failure to avoid inauspicious days in performing a ritual action, such as sacrificing to and burying the dead or marrying, thus allowing the demons and malignant spirits to work their will. An individual's crime also might be blamed on another family member who was negligent in ritual actions and thus made the guilty relative unknowingly vulnerable to a malign spirit's reprisal.

By the Tang Dynasty era, under the Tang Code (624), there were three mandatory automatic reviews of a sentence of death before an execution could take place. Family members could appeal any conviction all the way to the emperor, but they were subject to the risk of punishment if their appeal was ruled to lack merit.

From the Tang era onward civil service appointments filled vacant government positions on the six imperial bureaucratic government boards: personnel, rites, public works, war (provisioning the military rather than commanding it), revenue, and justice. Appointees served at one of three levels of government: local, provincial, and the imperial court. Applicants underwent written examinations; passing each of three exams qualified the candidate for successively higher government appointments. The Chinese civil service was one among three "branches" of the Chinese imperial government; the other branches included the imperial court (consisting of the imperial secretariat, the eunuch corps of imperial guardians, ritual specialists, and the imperial household—the imperial family inclusive of the emperor's relatives, his wives, his concubines, and his children and their servants) and the imperial army (consisting of a corps of troops resident in the capital city as well as military regiments in each province). As a check on dishonesty, the Imperial Censorate held the power to investigate any seeming impropriety throughout the imperial system and to impose penalties that would discourage similar misconduct.

In theory, the Chinese civil service was open to any adult male, regardless of wealth or social status. In practice, however, preparing for the exams was costly and time-consuming. Because China lacked public schools, candidates had to study under the direction of a private tutor. As a result, most successful candidates came from a hereditary class of wealthy landholding gentry, who had the resources to afford private education. Aristocrats had an additional incentive to fill the posts: At least

one family member from each generation was required to pass the exams in order for a family to maintain its aristocratic status. However, passing the exams was no guarantee of personal success. Because there were not enough positions to employ all qualified applicants, only about 5 percent of those who took exams passed and received government posts.

The civil service and examination systems were also the critical means by which the Chinese government maintained the loyalty of the elite classes, or *shih*. Passing the exams without holding public office had other benefits. Only those who had passed the exams, whether or not they received government positions, were allowed to communicate directly with the Chinese government. Thus, non-*shih* had to secure the services of non-officeholding *shih* in order to deal with the government. *Shih* businessmen frequently received profitable government contracts and commissions not available to non-*shih*.

The system, however, often produced too many expectant *shih*, who believed they were entitled to receive benefits as the government's local agents. In fact, many *shih* depended on commissions as a valuable supplement to the family's land-derived income. Dynastic decline normally coincided with the court having too few rewards to distribute to retain the loyalty of the *shih*. As the opportunities for appointments or rewards diminished, the elite began to think in terms of their own self-interest rather than remain loyal to the imperial court, hastening a dynasty's fall from power.

## JAPAN, KOREA, AND SOUTHEAST ASIA

Tang China's political culture spread to its neighbors, at first as an elite-level overlay. Over time, however, China-derived Confucian statecraft, with mixtures of traditional local practices considered to be critical, became the basis of new urban-centered court cultures. Imperial Japan, centered in Nara and Kyoto, and Korea's imperial Koryo civilization, centered in Kaesŏng, each built court cities that were faithfully modeled on Tang Ch'angan. East Asian cultures generally respected the Chinese written language as the universal language of eastern Asian scholarship (like Latin was in the contemporary Western world) and read Buddhist and Chinese books, written or printed in classical Chinese, which supplied the philosophical base for new urban-focused states. Common to the Tang model, these new states patronized the centers of worship of Buddhism and other major religions, but the new political regimes were careful to establish their own royal court complexes, rather than temples, as the focal points of their societies. The court complexes in Korea, Japan, and Vietnam might include significant temples, but these temples and their priesthood were, with rare exceptions, administered by secular elite.

## FROM IMPERIAL RULE TO WARRIOR STATE IN JAPAN

The foundation for Japanese imperial order was the Seventeen Article Constitution issued by Prince Shōtoku (573–621) in 604. The constitution promoted a mixture of Buddhism, Confucianism, and the Chinese model as the basis of replacing traditional hereditary ranks with new Chinese-style designations of senior, junior, upper, and lower grades, totaling 26 divisions. Buddhist priests and the elite accepted their proper place in the new Yamato political and religious order.

The Taihō Code (701), written under the guidance of the Fujiwara noble family, who remained in control of day-to-day governance throughout the imperial era (604–1185), codified a new Japanese political order, formalizing the Yamato state structure that had emerged gradually over the previous century. The imperial system (inclusively known as the *ritsuryō* system) was modeled on that of Tang China, but with local adaptations. The Japanese imperial state was based in the imperial court centered at the imperial capital. In contrast to the Tang model, which had three divisions and six boards, the Japanese imperial bureaucracy was divided into two divisions, which in theory reported directly to the emperor. The Department of Worship (Jingikan) was thought to be the most powerful administrative unit owing to its administration of Shinto shrines and leadership in the worship and ritual affairs of the state. Civil administration fell to the Department of State (Daijokan), which had eight ministries: secretariat, ceremonies and personnel, aristocratic affairs, popular affairs (land, census, and taxation), war, justice, treasury, and the imperial household. Beyond the imperial court, 66 traditional provinces were centered in a provincial capital administered by a governor appointed by the court. Further administrative subdivisions included the county and the village, whose households were accountable for the payment of grain and silk taxes and mandatory labor and military services.

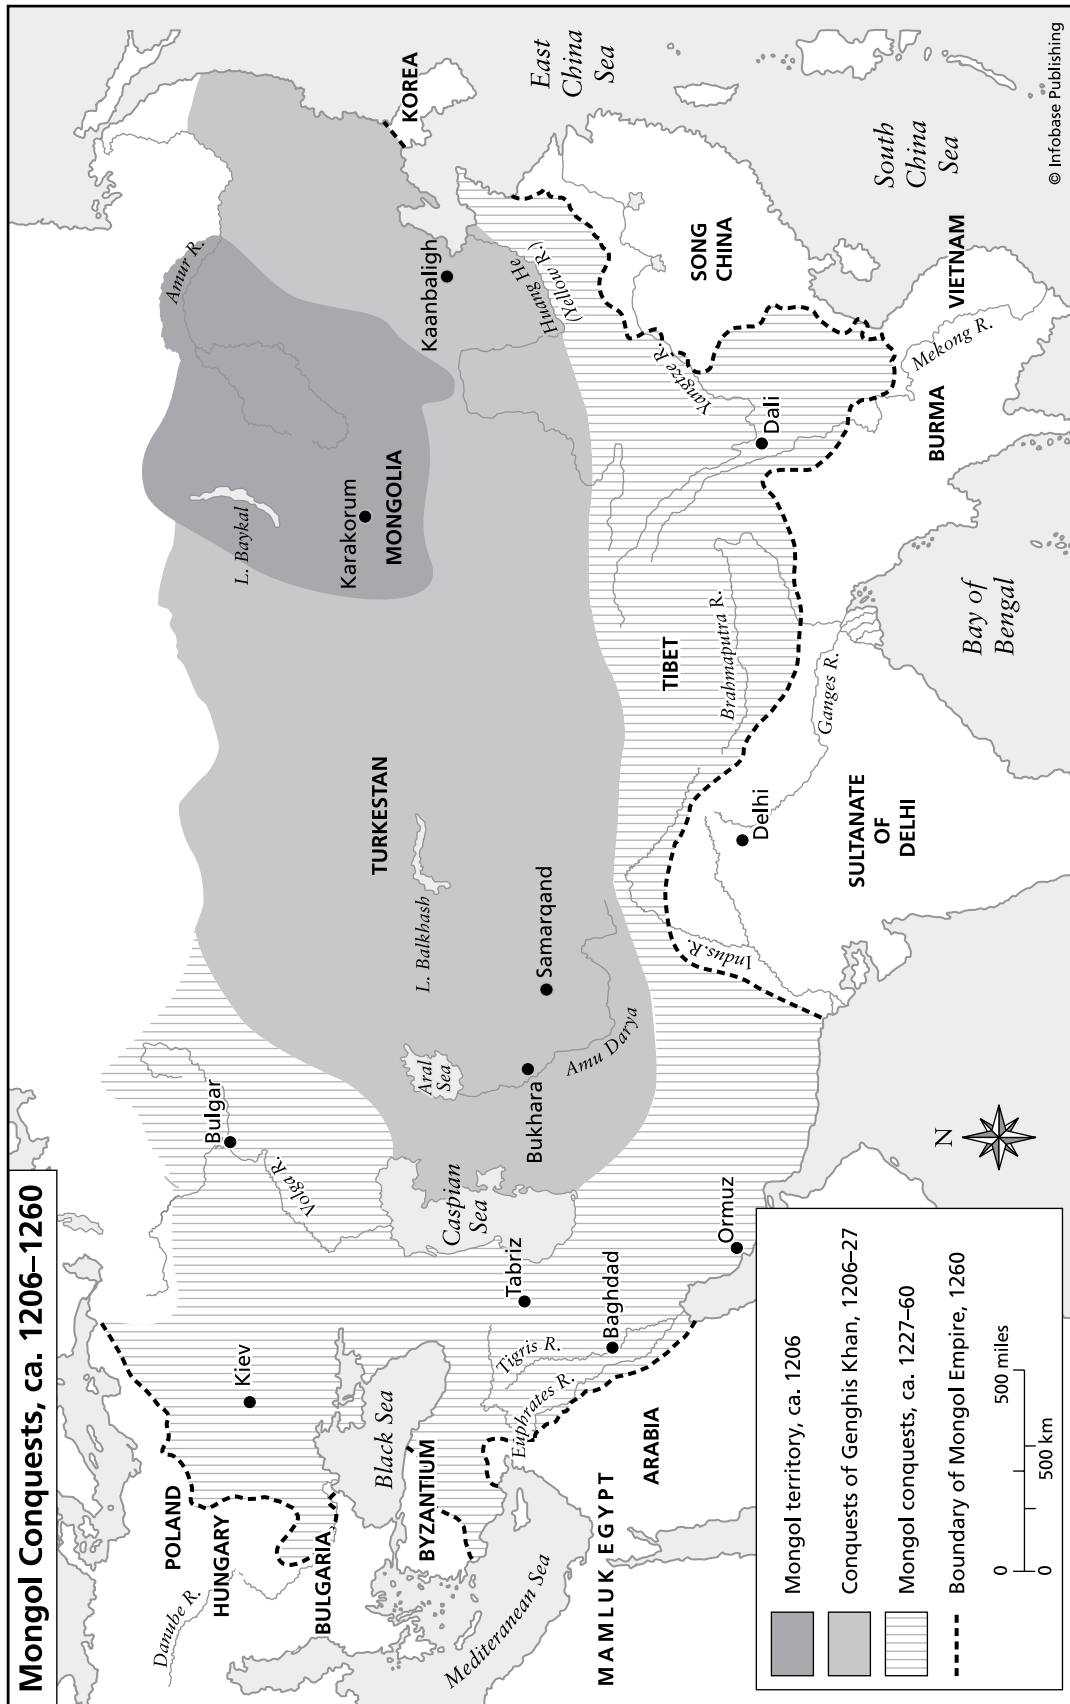

By the 12th century political authority had decentralized into the regional estates assigned to support absentee court elite. Lay officials managed the estates, keeping peace and administering taxation and labor services in the absence of the court elite. Military authority decentralized to professional warriors—samurai—who formed military regiments led by a shogun (“military guardian against barbarian peoples”), who protected Japan’s core agricultural regions from the periodic attacks of bandits living on the core’s frontiers. When the court finally collapsed in 1185, the local civic officials, religious orders, large landowners, and Buddhist temples became the new centers of Japanese authority, in partnership with new warrior elite, simply confirming the reality that had emerged over the past century.

A series of military strongmen, shoguns, wielded ultimate political authority in Japan for the remainder of the medieval era. The shogun received his authority from the emperor after winning battles against armed opponents. In theory, the emperor delegated to the shogun responsibility for running the Japanese imperial state, similar to prior authorization of the Fujiwara court “regents” in the previous age. In practice, local “stewards” and “constables,” who had managed the aristocratic estates during the imperial period, assumed the day-to-day affairs of what remained of the Japanese state. The now hereditary samurai military elite, who were ultimately bound by service contracts to the shogun, imposed local order.

The shogunate system, called the *bakufu* (“tent government”), depended on the shogun’s willingness to acknowledge the local territorial rights (*shiki*) of the samurai lords. Under the initial Kamakura Shogunate (1185–1333), although regional samurai lords were submissive to the Kamakura shoguns, they also were allowed to maintain their own samurai armies and had to enlist the cooperation of local administrators. The Kamakura Shogunate had two political centers. The shogunate was based in Kamakura, southeast of modern-day Tokyo, and was notable for its successful institution of the decentralized shogunate system, in which educated samurai became hereditary administrators who managed the affairs of the Kamakura court and were a key source of contact between the shogun and his regional subordinates. The Kyoto court, supported by court-based elite and the major Buddhist temple networks, continued to appoint civil governors, receive tax revenues, and directly administer the Kyoto region. The Ashikaga (1336–1573) shoguns who followed, based in Kyoto, took control over the remaining imperial government, but there was further decentralization of power. Samurai allied in regional warrior bands led by daimyo (feudal) lords. These alliances culminated in the Ōnin War (1467–77), in which regional samurai largely ignored the Ashikaga court and rival samurai armies openly competed for the right to govern the Japanese countryside.

## THE MONGOL ALTERNATIVE

In contrast to eastern and southern Asia, the Mongolian state evolved from and remained consistent with its seminomadic roots in the central Asian steppes. The Mongol conquests, which at one time gave the Mongols authority from China’s shores in the east to the Mediterranean Sea in the west, was impressive since the Mongols numbered only about 1 million in an era in which China’s population alone numbered roughly 100 million. Mongol success was based on the Mongols’ skills as warriors; they literally spent their lives in the saddle. The Mongols’ great military advantage was their mobility and their superior cavalry tactics. The Mongols were the

Genghis Khan and his sons and grandsons conquered a wide swath of central Asia during their reign, building the largest land empire in history.

first to use signal flags to coordinate their battlefield actions and short compound reflex bows that they could load and fire at full gallop. They could cover 100 miles in a day, carrying whatever small food rations and supplies they needed in their saddlebags and therefore never having to wait for their supplies. In the absence of food, a Mongol warrior could cut open a vein in the neck of a spare mount, drink some blood, and close it again so the rider and his horses could continue.

The Mongols rarely lost a battle. Local populations found it better to submit to them than to fight, since a battle loss normally resulted in the butchering of men and the raping, slaughtering, and enslaving of women and children. This terror worked to the Mongols' advantage; they were widely described as inhumane monsters, often by their own spies and agents, who spread horrific tales about their exploits. The Mongols actively recruited local allies. Ultimately, the Mongol victory over China depended on the Chinese technicians, siege engineers, gun founders, artillery experts, and naval specialists, who helped the Mongols conquer China's heavily fortified cities that were defended by gunpowder weapons and explosives. The Mongol conquest of China involved the first use of cannon warfare, which quickly spread to Europe in the early 14th century.

The Mongol realm came into existence under Temüjin, who was proclaimed Genghis Khan (r. 1206–27), “universal sovereign,” by an assembly of all the Mongol chieftains. This assembly acknowledged Genghis Khan's conquests of central Asia, the Near East, and eastern Europe as well as his initial victories in northern China. Genghis Khan's success was based in his ability to unite under his personal leadership the traditionally divisive Mongol tribes living in what is now Mongolia and reorganize them into 1,000-man fighting and administrative forces (*minggan*). To maintain order among his ranks, Genghis Khan introduced a code of law that provided examples of appropriate military and social behavior. The code emphasized loyalty to the Mongol military over family clans, promised reward for meritorious service rather than for hereditary social standing, and promoted ethnic and gender equality. Genghis Khan's realm had four regional divisions (khanates): the Golden Horde in western Eurasia and Russia, the Ilkhans in modern-day Iran and the Middle East, the Chagatai in central Asia and Siberia, and what would eventually become the Yuan in China and eastern Eurasia.

Unfortunately, the unity of Genghis Khan's reign did not last, as the traditional Mongol tribal assembly system never had a clear succession policy and was unable to ensure successful transition following the great Khan's death. After Genghis Khan's death, the Mongol chieftains divided the realm among his four sons, each of whom was based in one of the four Mongol regions, but proclaimed Genghis Khan's

third son, Ögödei (r. 1229–41), as his father's successor, now titled Mongol “emperor.”

## POLITICAL SYSTEMS OF THE PACIFIC ISLAND

The traditional political systems of the Pacific islands varied greatly. Yap island society in modern Melanesia, for example, never had a strong, centralized authority system. Order was based on a local chief who shared power with a council composed of the heads of the family clans. Village societies were arranged in an island-wide ranking based on the debts owed by one village to others.

In contrast, the islands of Kosrae and Pohnpei were once ruled by supreme chiefs. Kosrae traditionally had a single chief who ruled the entire island, with the assistance of sectional chiefs who passed on the head chief's share of local production (food or handicrafts), to which he was believed to be entitled in payment for his successful community leadership. Pohnpei initially had several roughly equal confederated chiefs who held control over villagers in their region. They were assisted by “talking chiefs,” chosen from the second-ranking family clan in each region, who acted as designated mediators if disputes arose between two regions. As in Kosrae, the two elite clan lines received an entitled share of local production from the local nonaristocratic clans.

The Kosrae and Pohnpei supreme chief system reached its height, perhaps as early as the eighth century, under a mysterious line of kings known as the Saudeleurs. These kings built a spectacular capital city at Nan Madol, on the southeastern shore of Temwen Island, off the coast of Pohnpei. The remains of this city consist of a coral reef of 92 man-made islets intersected by a network of artificially constructed canals and waterways, protected by seawalls of loglike basalt stone that are up to 50 feet high and 20 feet wide. The focal centers of this ancient city were the 58 islet sites of elaborate funeral rituals, the residences of priests, and royal tombs, which were surrounded by the islet residencies of state elite and marketplaces.

In New Zealand's Maori society the *marae*, an open grassy area in front of a large, carved wooden meeting-house, symbolized group communal unity. Community elders managed the *marae*, where they passed along group traditions and cultural practices to the young by teaching oral folktales, songs, and the traditional arts of weaving and woodcarving. Among the most important lessons taught at the *marae* was distinction between *tapu*, that which is sacred, and *noa*, that which is held in common. A person, an object, or a place that is *tapu* could not be touched or even approached except according to specific rules and prohibitions. By tradition, those of lower rank could not touch the *tapu* objects of those of higher rank, as those of higher birth

could not touch the *tapu* belongings of the lower ranks. If a person of low status touched the glass of a higher-ranking person, the drinking vessel would be destroyed. Such an elaborate code of ethics reinforced societal hierarchy as well as respect for individual rights and possessions within the local communal order.

## EUROPE

BY JUSTIN CORFIELD

The system of government in medieval Europe relied on the interplay between important political forces. The church, contending rulers, dynastic rivals, powerful political and military figures, parliaments, city councils, and mass movements involving the peasantry all shaped the organization of government throughout medieval Europe.

### THE PAPACY

The peak of the organized government system at this time was the Papacy of the Roman Catholic Church. Selected by the College of Cardinals, the pope, the leader of the church, was able to bring considerable symbolic and actual power to bear on political disputes. Rome was not a significant urban center—after its sacking by the Visigoths in 410 it had long since declined. However, with the popes living in Rome, the city was a center of pilgrimages for rulers as well as their subjects, who traveled to Rome to satisfy their curiosity, to demonstrate their power or their piety, or to show remorse for bad decisions. In spite of England's geographical distance from Rome, a number of English rulers did visit the holy city, with Alfred the Great (r. 871–99) establishing an English college there and King Henry II (r. 1154–89) going there in penance after the murder of the archbishop of Canterbury Thomas à Becket (ca. 1118–70) in 1170.

The Papacy's power was clearly shown by what it influenced. Pope Leo III (d. 816) crowned Charlemagne (r. 800–14) in 800, Pope Alexander II (d. 1075) supported Duke William of Normandy's invasion of England in 1066, and in 1095 Pope Urban II (ca. 1035–99) used his power at the Council of Clermont to call on the people of Europe to join the First Crusade. Other examples of papal influence on the running of countries in medieval Europe include Pope Adrian IV's (ca. 1100–59) promulgation of the Bull *Laudabiliter*, which King Henry II of England used to justify his conquest of Ireland 16 years later; Pope Innocent III's (1160 or 61–1216) launch of the Albigensian Crusade against the Cathars in southern France; Pope Clement V's (ca. 1260–1314) refusal to help after the French monarchy started persecuting the Knights Templars in 1307; and, at the very end of the Middle Ages, Pope Alexander VI's (1431–1503) assistance in setting up the

Treaty of Tordesillas in 1494, dividing the world between the Portuguese and the Spanish.

In an extreme situation the pope could declare an interdict on a country, a state, or a city. An interdict was official censure by the Roman Catholic Church, excluding people from receiving church sacraments. Adrian IV even declared an interdict on Rome itself following the murder of a cardinal. Pope Innocent III placed England under an interdict from 1208 until 1215 because King John (r. 1199–1216) refused to accept the papal choice for the archbishop of Canterbury.

However, papal power was not unlimited, and the authority of some popes was challenged by France and by the Holy Roman Emperors. Indeed, during the 11th century there were antipopes who claimed to be lawful popes, and from 1378 until 1417 there was the Western Schism, or the Great Schism, following the election of Pope Gregory XII (ca. 1325–1417) in Rome and then the election of Pope Benedict XIII (ca. 1328–1423) in Avignon, France. The matter was resolved at the Council of Constance in 1414–18; by the end of the medieval period the Borgia family of Pope Alexander VI (1431–1503), particularly his son Cesare, had established an effective temporal state of Romagna, which was later turned into the Papal States.

### HOLY ROMAN EMPIRE

In addition to the Papacy bringing its power to bear on the running of countries and states, the establishment of the Holy Roman Empire in 800 dramatically changed the political landscape of central Europe for centuries. While the emperor

*Chest made of iron plates (Britain, early 15th century), used as a safe for the storage of important civic documents, valuables, and the City of London seals; six keys, kept by six different people, were required to unlock it* (© Museum of London)

was officially determined by a vote of electors, there were also constant disputes on the investiture and the exact role, if any, the Papacy should play in the ceremonies connected with the office. After 1452 the Hapsburg family of Austria dominated the Holy Roman Empire, allowing much of central Europe to be controlled from Vienna.

The major political system in Europe throughout the entire medieval period was that of a hereditary monarchy, with kings ruling in England, Scotland, Ireland, France, Léon, Navarre, Aragon, Portugal, Hungary, Poland, Russia, Denmark, Norway, and Sweden. In 1282, after the Vespers rebellion, the Kingdom of Sicily split to form the Kingdom of Naples and the new Kingdom of Sicily based only on the island of Sicily. Other parts of Europe were controlled as principalities, and there were also a small number of republics, mainly in the Italian peninsula.

## MONARCHIES

Many of the monarchies operated through advisory bodies, such as parliaments, but the success of the political system relied largely on the effectiveness of the monarch. Several medieval rulers earned the title “the Great,” some for good deeds and some for their military victories over their enemies. The first medieval ruler acknowledged as “the Great” was Theodoric (r. 474–526), king of the Ostrogoths. Of those who became known as “the Great” because of their role as nation builders, the first was Charlemagne. Others included Rhodri the Great of Wales (r. 872–78); Alfred the Great, king of Wessex; Otto I, “the Great,” of the Holy Roman Empire (r. 936–73), who overcame internal revolts and established the Ottonian system; Canute the Great, king of England (r. 1016–35) and of Denmark (r. 1018–35); William V, “the Great,” of Aquitaine (r. 994–1030); Vytautas the Great of Lithuania (r. 1392–1430); Ivan III, “the Great,” of Russia (r. 1462–1505); and Stephen III, “the Great,” of Moldavia (r. 1457–1504), who was also later declared a saint, as was Edward, king of England (r. 1042–66), who gained the title “the Confessor.”

Those who are known solely for their military prowess rather than for their administrative skills include Alfonso III of León (r. 866–910) and Sancho III of Navarre (r. 1000–35), who both defeated the Moors; Valdemar I of Denmark (r. 1157–82), who became Valdemar the Great for defeating a foreign invasion; Peter III of Aragon (r. 1276–85), who gained the title “the Great” through his campaigning in the Mediterranean; Llewellyn the Great (r. 1194–1240) of Wales; and Louis I, “the Great,” of Hungary (r. 1342–82), who extended the lands of Hungary to incorporate Dalmatia, Bosnia, and parts of modern-day Bulgaria. Mention should also be made of King John I of Portugal (r. 1385–1433), who gained the title “the Good” or occasionally “the Great” and was the king whose capture of

Ceuta in 1415 led to the start of overseas European colonies. King Edward I of England (r. 1272–1307), for his military victories, gained the title “Hammer of the Scots.”

Although the monarchs known as “the Great” successfully ruled their respective lands, there were also many kings and princes whose rule was disastrous. There were also many rulers, including four English kings—Henry III (r. 1216–72), Richard II (r. 1377–79), Henry VI (r. 1422–61 and 1470–71), and Edward V (r. 1483)—who inherited the throne while young, with the first only narrowly surviving a civil war and the other three all being deposed. Henry VI also spent much of his reign ill. King Henry III of Castile (r. 1390–1406) was 11 when he became king; he became known as King Henry, “the Infirm.” Erik V (r. 1259–86) became king of Denmark in 1259 around the age of 10. An exception was Louis IX (r. 1226–70), who was 12 when he became king of France in 1226 but went on to reign for 44 years and later to be canonized. Because of the potential instability, many states tried to avoid having a young king and broke from traditional hereditary succession to allow an older man to become king.

In addition, there were problems with young kings who had mothers with lovers who tried to rule their kingdoms. Alfonso I (r. 1139–85), the first king of Portugal, was only two when he became the head of the ruling family. In 1128, when he became 17, he raised an army and defeated his mother and her lover at the Battle of São Mamede; and in 1330 King Edward III of England (r. 1327–77) managed to have executed Roger Mortimer, the lover of his mother. In Aragon, in northern Spain, James I (r. 1214–76) was five when he became king, and when he was 11, he staged a palace coup to end the regency of his granduncle.

On many occasions the illegitimacy of succession led to revolts, and the three English kings who took over to prevent nephews from being crowned all spent most of their reigns fighting challenges to their rule. Two of them, Harold II (r. 1066) and Richard III (r. 1483–85), died in battle, and King John became known as “Lackland” because of his rule at the time of the end of the Angevin Empire. The advent of a female ruler was also seen as inherently dangerous, with the reign of Matilda, also known as Maud (r. 1141), daughter of King Henry I of England (r. 1100–35), initiating a disastrous civil war. The death of Charles IV (r. 1364–80) in France created debates over the Salic law (preventing women from ascending the throne), and when King Edward III of England claimed the crown through his mother, the act led to the Hundred Years’ War (1337–1453) between England and France. For Margaret, Maid of Norway (1283–90), many accounts do not recognize her as a ruler.

With so much aura invested in the monarchy, the issue of illegitimate birth occasionally raised some problems.

There are debates over the legitimacy of the English Saxon king Edward the Martyr (r. 975–78) as well as King Edward IV of England (r. 1461–70 and 1471–83). William I, “the Conqueror” (r. 1066–87), described by English Saxons as “the Bastard,” managed to rule successfully, but queries over the birth of King Edward V of England led to his deposition and possibly his murder. Certainly, murder was a traditional way to resolve dynastic disputes, and the number of kings who were murdered is large. In medieval England six kings were murdered, including William II (r. 1087–1100), whose death was ascribed at the time to an accident, and Edward V. The record in Scotland is not much better, with six Scottish kings being murdered, along with John III Comyn (d. 1306), the guardian, who was killed by Robert Bruce. Spain also saw a large number of murders in the late 14th century, starting with the killing of Pedro the Cruel (r. 1350–69) in 1369.

The sanctity of the institution of the monarchy meant that abdication was rarely accepted. Both of the English kings who abdicated, Edward II (r. 1307–27) and Richard II, were subsequently murdered, although Constantine II of Scotland (r. 900–42 or 43) did manage to live another nine years after abdicating and becoming a monk. Several murders were associated with hunting “accidents,” the best known being that of William II of England. The murder of King Erik V of Denmark in 1286 while he was sleeping after hunting was certainly no accident. The death of King Louis V of France (r. 986–87) in May 987 does, however, appear to have been a genuine hunting accident.

Most of the threats to the monarchy came from rivals who tried to use dynastic disputes to overthrow rulers. Probably the worst dynastic disputes plagued the Byzantines and also the Merovingian Dynasty in France, which saw many warring brothers and rival queens. The Wars of the Roses from 1455 until 1485 marked the longest period of fighting in medieval England, largely deciding a number of dynastic claims.

In addition to dynastic disputes, rulers in medieval Europe also had problems dealing with important nobles and others who were able to establish large power bases, often in regions of countries. This situation occasionally led to pretenders, often with no real royal connection, trying to rule through rulers and then trying to depose them. In Anglo-Saxon England some Vikings managed to establish virtual fiefdoms in parts of England. Earl Godwin of Wessex (d. 1053) exerted great influence during the reign of Edward the Confessor, leading to his son Harold’s succeeding Edward in 1066. Simon de Montfort (ca. 1165–1218) was able to lead a successful rebellion against King Henry III, forcing the king to call a parliament. Subsequently, Harry Hotspur

## DOMESDAY BOOK

The maintenance of the governments of medieval Europe relied on the raising of taxes, and this in turn depended on the maintenance of accurate records by central authorities. The greatest of the early medieval surveys, produced for taxation purposes, was the *Domesday Book*, commissioned by the English king William the Conqueror in 1086. Besides the ambitious scope of the *Domesday Book*, also important were the speed of its compilation and the accuracy of its records, making it one of the best examples of government organization in medieval Europe.

The *Domesday Book* was put together by seven or eight groups of commissioners who worked through various counties collecting information on every village and also noting the estates owned by the Crown and by major tenants-in-chief. Once the information was collected, it was summarized, and this summary forms the basis of the *Great Domesday Book*. It covers most of England but excludes some parts of the north and also the counties of Essex, Norfolk, and Suffolk. For some administrative reason, the three latter counties were not summarized, and the complete returns from them were sent to Winchester, where they form the *Little Domesday Book*. The *Inquisitio comitatus Cantabrigiensis* (The Inquisition of the County of Cambridge), an early surviving draft for Cambridgeshire, helps show how the information was initially collected, as do other extant records for some other counties.

Overall, the *Domesday Book* provides a list of each feudal lord in the country and also the names of all the landholders in 1066 as well as in 1086, which has been used by historians to show how property changed with the Norman Conquest. Similar records, called the *Rotuli hundredorum* (Hundred Rolls), were collected by later English kings, but none was ever as comprehensive as the *Domesday Book*.

(1364–1403) and Richard Neville (1428–71), “Warwick the Kingmaker,” both died on the battlefield trying to control the kingdom. William Wallace (ca. 1270–1305) and Owen Glendower (ca. 1359–ca. 1416), respectively, in Scotland and Wales led initially successful and ultimately disastrous campaigns against the English. In Spain, Rodrigo Díaz de Vivar, “El Cid” (ca. 1043–99), tried to move from being a leading general to establishing his own dynasty in Valencia.

## REPUBLICS

There were a few states in Europe that maintained republican political systems. Most were in Italy, with the oldest being San Marino, where the republican tradition dates back to 301. The parliament in San Marino also is said to date back to 301, the year in which the city-state became a republic. As such it has the oldest continuous legislature in the world. Other Italian republics include Venice from the ninth century until 1797, Amalfi from 839 until 1131, Pisa from the 11th century until 1406 (and again from 1494 until 1509), Genoa from about 1100 until 1797, Florence from 1115 (although Emperor Otto I conceded many privileges in 962), and Siena from 1167 until 1557. Nearby Ragusa (Dubrovnik) was a republic from the 14th century until 1808, and Iceland was a republic from 930 until 1262, with the Novgorod Republic in Russia lasting from 1136 until 1478.

## PARLIAMENTS AND OTHER ELECTED BODIES

A number of the countries that had kings also had parliaments or other forms of elected bodies. The Viking lands of northern Europe also had a tradition of parliaments that served to restrain the rule of their kings. The *Løgting*, in the Faeroe Islands, dates from at least the ninth century, but its exact origins are unknown. The Icelandic parliament, the *Althing*, was founded in 930 at Thingvellir. On the Isle of Man, the *Tynwald* was established in 979, although many historians believe it can trace its origins to the 800s, when a similar body existed. However, from the 11th century until the 15th century it fulfilled the role of a judicial court rather than creating legislation. From the 10th century there were regional assemblies in Norway, with the system amalgamated in the mid-13th century under King Magnus VI (r. 1263–80).

Poland, which for much of the Middle Ages had a monarchy elected by the parliament, was one of the first places in Europe to hold elections. According to folklore, the first Polish election was held in the ninth century for the legendary Siemowit, who founded the Piast Dynasty. The Polish parliament, the *Sejm*, dates back to 1182, when it held a meeting at *Lęczyca*. The original *Sejm* consisted of nobles, elected from within their number.

The Anglo-Saxons had a system of advising the king through the *witenagemot*, which is usually described in history books as the “witan.” Its origins were in the Germanic assemblies that were gathered to provide witness to royal grants of land. These operated in parts of England in various forms beginning the seventh century, and initially there were different *witans* for each of the Saxon kingdoms. However, with the creation of England under Aethelstan (r. 929–39), the *Witan* of Wessex came to dominate English politics, al-

though some of the local *witans* met until 1065. The most important role of the *witan* was in the choice of a king. In 1066, rather than choosing the young Edgar Atheling, the *Witan* of Wessex supported Harold Godwinson’s claim to the English throne, leading to the Norman invasion later that year. The *witan* also had the right to depose kings, with the Wessex *Witan* deposing Sigeberht in 755 and the Northumbria *Witan* deposing Ethelwald (r. 759–65) in 765.

When William the Conqueror took control of England, he exercised his rule through the feudal system using a council of tenants-in-chief and church authorities to advise him before he made laws. The system was effective when presided over by somebody with the strength of personality of William the Conqueror, who ruled a land in which insurgencies were organized by the Anglo-Saxons. Although the civil war between Matilda and Stephen (r. 1135–54) did shake it, the system was used to administer England in the absence of Richard I, “the Lionheart” (r. 1189–99), when he embarked on the Third Crusade. However, the absence was to lead to other problems involving the formation of powerful factions, as happened when other rulers left for the Crusades: Robert of Normandy (ca. 1054–1134) on the First Crusade (whose lands were taken from him by Henry I) and Henry of Burgundy, who left for the Second Crusade. Philip II of France (r. 1179–1223) on the Third Crusade and Louis IX on the Seventh Crusade both managed to leave competent administrators behind, and the former was also assisted by the fact that the English king was away for even longer than he was.

In the early 13th century there were important administrative changes in Europe. In 1215 the feudal tenants-in-chief in England managed to force King John to agree to sign the *Magna Carta*, which states, among other things, that the king cannot collect taxes, with the exception of feudal dues, without the consent of the Royal Council. This change gradually led to the formation of a parliament, with King John’s son, Henry III, having to accept the first elected parliament, which was called in 1265 by Simon de Montfort, sixth earl of Leicester. Members of the parliament were elected from county constituencies, which had a franchise allowing citizens to vote provided they held freehold land producing an annual rent of 40 shillings or more. In addition, boroughs could also send members to the parliament, elected under various laws and charters. The unicameral structure of the Model Parliament of 1295 was adopted by Henry III’s son, King Edward I, and his son, Edward II, separated the parliament into two houses, one consisting of the nobles and the higher clergy and the other consisting of people elected to represent the counties and boroughs.

In Spain the system of *cortes* also had its origins as advisory councils that consisted of feudal lords who advised the

kings of Castile and León—the two entities being combined from 1188. In all the kingdoms except Aragon, within the *cortes* there were three *brazos* (estates): prelates and representatives of cathedral clergy (not clergy from parishes), the *ricosombres* (magnates) and knights, and the representatives of particular towns. In Aragon the kingdom's *corte* divided the magnates into the major nobles and the lesser ones, giving them four estates. With the enlarging of the cities in Spain in the 12th century the kings in Spain started to allow more urban representatives to be members of their respective *cortes*, the members occasionally vetoing decisions made by kings. When King Henry III of Castile came to the throne in 1390 at the age of 11, the *corte* appointed 12 governors to form a regency council. In addition, there were regional assemblies, the most famous being the one that helped with the rule of the province of Biscay, the members traditionally meeting under the famous oak tree in the town of Guernica—the Gernikako Arbola. The extra power of the nobility in Aragon resulted in the kings of Aragon having to grant more privileges to the nobility.

The États généraux (States-general, or Estates-general) in France also originated in an assembly that served to advise the kings of France. As with the English Parliament, traditionally the States-general existed at the behest of the kings, who could technically call it or not as they chose. The manner in which it was called also varied considerably. In 1302 Philip IV (r. 1285–1314) called a large assembly that was representative of the people in order to show the strong support for him in his dispute with Pope Boniface VIII (ca. 1235 or 40–1303). The concept of the assembly as a legislative body came much later, with the term States-general being used for the first time in 1461 and coming into common use from 1484, when the body met at Tours. However, unlike the bicameral English houses of Parliament, the States-general had three assemblies for the three estates of the kingdom: the nobility, the church, and the commoners. It should be noted that some of the nobles attended only through proxy. While the English Parliament gradually made itself indispensable to the governing of England, the role of the States-general from 1302 was solely to counsel the king, only needed to grant subsidies when the Crown wanted funds to fight a war or at other times when large amounts of money were required. However, when Charles VII (r. 1422–61) went to war, he ensured that the States-general gave retrospective support for the taxes he raised. In France the members of the house of the nobility in the States-general were all nominated by the Crown; those of the church were chosen by ecclesiastical bodies. Only the Third Estate (the commoners) was elected, from a narrow franchise.

Elsewhere in Europe several other countries also had advisory bodies that existed on a similar basis. The Estates of

Parliament met in Scotland from 1235; in Switzerland power was in the hands of the Tagsatzung, which consisted of the executive council and the legislative council of the Swiss Confederation. Regional diets existed within the Holy Roman Empire—some, such as that in Brunswick-Lüneburg, having more power than others, such as in Bavaria, where the regional assemblies remained weak until the 14th century. The States-general of the Netherlands emerged from the 15th century, with the first meeting consisting of delegates from the constituent states being held on January 9, 1464, at Brugge (in what was then Flanders and is now Belgium), with regular meetings subsequently held at Brussels. Even in Russia, where the royal rule was absolute, there was occasional reference to “advice” being given by the boyars (nobles), which was important in administrative matters but far less so in policy decisions.

## JUDICIARY

The judiciary within the various countries of Europe during the Middle Ages varied considerably. In most places justice was delivered in towns, with punishments involving fines, branding, floggings, and, for major offenses, executions, usually by hanging. In the early Middle Ages there were also trial by ordeal, trial by fire, trial by water, and trial by combat, with little mercy shown to heretics, especially relapsed heretics, who could be executed, usually by burning. Such was the fate of many suspected witches throughout Europe and also the Cathar “heretics” of southern France. Even formerly powerful men like Jacques de Molay (1243–1314), the last grand master of the Knights Templars, could face charges of heresy, Molay's case resulting in his execution by burning in 1314.

## LOCAL GOVERNMENTS

Although parliaments were important in medieval Europe, the councils and lord mayors of various cities and towns exerted considerable political influence and power, especially in Italy and Germany, which had many city-states. Some cities held elections for their councils, with elections for the Signoria in Florence being held every two months. Even those councils that maintained a level of democracy were heavily influenced by the city and town guilds. Some of these guilds gained considerable power, the Mercers Company in London quickly emerging as one of the wealthiest and most influential of all. The Mercers Company had more of their members elected as lord mayor of London than any other company, one being Sir Richard Whittington (ca. 1350–1423). At a lower level, throughout medieval Europe, parish councils existed, run through parish churches.

One situation that made some states inherently unstable during the Middle Ages was the fluid nature of boundaries,

which changed with wars and treaties. The collapse of the Western Roman Empire, Viking invasions, the collapse of the Angevin Empire, the Hundred Years' War, the constant fighting in Germany and Italy, and the battles between the Christian kingdoms of northern Spain and also against the Moors led many cities and towns to move from the jurisdiction of one kingdom to another. Combined with these changes there were a few changes in capital: The Western Roman Empire, for example, moved its capital from Rome to Ravenna in 402. The change from Winchester, the capital of Wessex, to London, as the capital of England (though Winchester was still used for administering Wessex until the late 1060s) symbolized the move from an inland capital to one that was a port. In the Kingdom of Asturias in Spain, Pelayo (r. 718–37) established his capital at Cangas de Onís, but his successors moved it to Pravia, and Alfonso II (r. 791–842) moved it to Oviedo. In 1910 León became the new capital, with the kingdom being renamed.

### UPRISINGS

In spite of the kings and assemblies, the efficient running of the government relied on the acquiescence of the population. In times of exceptional troubles there were peasant, or popular, uprisings. In England there were three “peasant” revolts: those of William FitzOsbern in 1196, the Peasants' Revolt of 1381, and Jack Cade's Rebellion in 1450—the first coinciding with the emergence of “popular” bandits, encapsulated in the story of Robin Hood. The relative success of the latter two (although the Peasants' Revolt of 1381 was quickly crushed) relied on being able to get large numbers of supporters into London as quickly as possible. In Europe there were similar revolts, such as that in Flanders in 1323–28 and the Jacquerie in France in 1358. Of more importance were the uprisings that took place in city-states, such as the popular insurrection in Florence in 1250 that ended the Ghibelline predominance. These uprisings showed that even though a government run by an unelected ruler did not need to get the support of the people, it still had to placate them.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

In a broad sense, the story of government organization in the medieval Islamic world was about a struggle to determine the proper balance between political power, military power, ethics, and morality. In the earliest years of the Islamic world government leaders had little experience in running an empire, and they often used or improvised government institutions left over from the people they had conquered. They looked to the Koran and the Hadith, a compilation of the sayings and actions of Muhammad, for guidance, as well as to

the community of Islamic jurists and religious scholars. More important, there was the well-known Medina constitution, written in 622, which served as a model for the Islamic state during the succeeding centuries. This was a social compact to enable the peaceful coexistence of diverse groups—Muslims, Jews, Christians, and others.

### TRADITIONAL GOVERNMENT ORGANIZATION IN ARABIA

A large chunk of northeastern Arabia was under the control of the Sassanian Empire (sometimes called the Persian Empire) in the 600s. The Red Sea coast and southern Arabia sometimes were united under a single government but more often were composed of independent towns near the west coast, farmers in the south, and nomadic herders elsewhere. The southern end of Arabia was often under the control of the African kingdom of Axum, which had a viceroy governing its Arabian holdings. Axum frequently sent its army into southern Arabia to influence local governments.

During the pre-Islamic period government organization among the Arabs was loose, without clear hierarchies or chains of command, and the farther one was from the towns of western Arabia, the looser the organization became. Among the nomads, honor was highly valued, and people, tribes, and clans were judged on the basis of their honor. A clan that failed to help one of its own, failed to show hospitality to strangers, or failed to make common cause with other clans against an outside enemy lost honor. The loss of honor resulted in very real problems, because members of a dishonored clan would have little claim on other clans for help, and members would be scorned even in trade.

There were no written laws for the nomads, who relied on the family as the basic unit of government. Families helped and protected members. Clans were composed of groups of families who had a common ancestor, either male or female, and preferably someone of such honor that he or she had become the subject of songs and poems of praise. Within a clan, a man sometimes rose to prominence and was called a *shaykh*. A *shaykh* had moral authority but no legal authority, so his ability to organize and rule his people depended on how much they respected him. A *shaykh* of proven honor could become respected enough to earn the loyalty of other clans, especially those related by intermarriage. Most of the time a *shaykh* could arbitrate disputes among family members and between clans and could suggest punishment for thieves and other criminals. On occasion, a *shaykh* could acquire such moral authority that he could organize clans into united governments able to wage war.

In the villages and towns of pre-Islamic Arabia families and their clans ran the government. Usually, one family be-

came preeminent in wealth or in moral authority and therefore ran the essential aspects of village or town life, such as the marketplaces and the defense of the village or town. Authority would change when the dominant family dishonored itself or another family became more powerful. Perhaps the key difference between the organization of the nomads and the organization of settled communities was that a *shaykh* in a settled community could use coercive power—that is, he could control a police force, the army, or courts of law, and through any of them force other people in the community to do as he wished. This meant that he could try to make his family’s dominant position permanent.

Soon after Islam emerged, the prophet Muhammad became the key figure who tried to provide the people of Arabia with a strong unifying government based on religious principles and practical needs, and during the early decades of Islam his followers fought and defeated the followers of rival groups. Under Muhammad’s leadership, until his death in 632, the Medina constitution, or compact, served as the pluralistic model of relatively peaceful coexistence among diverse groups. The first caliphate began with the death of Muhammad.

The loose government organization of Muhammad’s time did not mean that his followers were bands of undisciplined cavalry. There was enough warfare before his time for towns to organize their own infantries, and a leader as capable as Muhammad could organize the cavalry of the nomadic clans into units that worked closely with the infantry. Thus, when the Muslims exploded out of Arabia in the seventh century, they met opposing armies with tough infantry units of their own, and their army proved a match in discipline and skill for those of the Sassanian and Byzantine empires.

The early Islamic world was organized under caliphs, who were the successors of Muhammad. Disputes over who was rightfully a caliph led to civil war even during the first few decades after his death. From 632 to 661, during the reign of the immediate successors of the prophet, *Khulafa-ur-Raashidun*—the four “Rightly Guided Caliphs”—and then from 661 to 750, during the Umayyad Caliphate, the office of caliph combined secular and religious authority. The caliph was expected to set the standards for moral behavior and to make final rulings on matters of faith. Ideally, a caliph ruled all of the Islamic world, but only during the first two centuries was this nearly the case.

There were three divergent views of the authority of a caliph. The Sunni view became the dominant one. The name Sunni derived from the phrase *ahl al-sunna wa l-jamaa*, which refers to Muslims who in addition to the Koran are guided by the Hadiths. The Sunnis believed that a caliph should be a member of Muhammad’s extended family but,

more important, should be chosen by consensus of prominent followers. The Shia Muslims believed that a caliph had to be a direct descendant of Muhammad. The fourth caliph, Ali ibn-abi-Talib, was such a descendent, the son of the Prophet’s daughter, Fatima, and her husband, Abu Talib, the only one recognized as legitimate by Shiites. In the Shiite view, a caliph was both a political leader and an infallible religious leader whose religious pronouncements were to be accepted without question.

## EMPIRES OF CITIES

Within a generation or two the Islamic world was an empire that encompassed almost all of the Near East, some of central Asia, and much of North Africa. The new caliphate initially established its headquarters in Damascus (in modern-day Syria), which had been part of the Byzantine Empire for many centuries. The official government language of that part of the empire was Greek. Another center of government administration was the former Sassanian capital Ctesiphon (in present-day Iraq), where the official language was a dialect of Persian. In Egypt the official language of government was Coptic. Since the Islamic scriptures fundamentally accommodated the followers of other faiths, in particular, Jews and Christians (“People of the Book,” as they were known to Muslims), often there were non-Muslims in prominent government positions.

Many of the peoples of the Near East had flexible attitudes toward religion. For centuries the Roman Empire and the Parthian Empire had fought each other over the lands of the Near East; then the Byzantine Empire and the Sassanian Empire had continued the fight, weakening each other enough to allow the Arabs to defeat each. The people in the territories that changed hands during these wars often shifted their religion accordingly. They worshipped Rome’s gods when Rome was in charge, changing to Christianity when Rome became Christian and worshipping Iranian gods when Parthians or Sassanians were in charge. Perhaps because of similarities with Christianity, shifting to Islam was easy for them, but they could not be counted on to conform to Islamic laws.

Thus it was that in the regions formerly part of the Byzantine Empire, the government was organized as if still under Byzantine rule. The Byzantine government kept a very firm hold on the government organization in its provinces, with governors (called prefects) of cities under the careful watch of officials of the central government. All crafts were carefully organized to serve the state by producing what the state wanted in the quantities it dictated and selling products at prices set by the government. Farming communities paid heavy taxes that provided the principal revenue of the empire. In the eastern part of the Islamic empire, Sassanian

Objects from the Nihavand find, Iran, 11th–12th centuries; the group includes an amulet case, silver plaques, and a belt buckle ring (belts being an emblem of rank) inscribed with the name of a Turkish Seljuk courtier. (© The Trustees of the British Museum)

practices prevailed, including the exaltation of the emperor as more than human, a practice adopted by the caliphs.

It was during the Umayyad Caliphate that Muslim scholarship became of great importance to the Islamic government. While the rulers had little or no experience in governing an empire, there was the model of the Medina constitution for guidance, along with direction from the Holy Scriptures and jurists. Specifically, guidance was also available from the relatively secular, socially oriented Koranic verses that appeared in Medina. By 700 Islamic scholars were transforming the language of government into Arabic, and the central government used Arabic to help unify and organize its imperial government. Some aspects of pre-Islamic practices of Arabia seemed inescapable. There was a tendency in government to treat the caliph like a *shaykh*, the powerful head of a family, and members of his family expected and tended to receive a share of the power and wealth of the government. Nepotism became a common complaint against the government.

Playing on the discontent of the public, the Abbasid family fomented a rebellion against the Umayyad government and overthrew it in 750. The Abbasid Caliphate, centered in Baghdad, was to last until 1258, when the Mongols overran the empire. This era included the most important period of Islamic civilization, the golden age of Islam, during which

the Greek legacy was rediscovered, synthesized, and further developed in all its manifestations, for the benefit of future generations.

The Abbasids organized their empire by cities, with each city having its own governor. The pattern was one of a confederation, with each city being semiautonomous from the central administration. This seems to have been an adaptation intended to solve the problem of ruling an empire with large populations in very different climates—wet to dry and hot to cold, with rich soil and barren soil. Each governor had the power to adjust civil laws to the needs of the land he ruled. A weakness in the confederation was that independent-minded governors tended to manipulate the system of appointments so that they were succeeded by family members, and thus most governorships became hereditary.

The cities had zones of control, forming a pattern that would be imitated even after the Islamic world had fragmented into many independent states. The city itself was the center of Islamic life. Each city had mosques next to markets, and the prestige of a city often was judged on the basis of how many mosques and markets it had and on how large and beautiful they were. The cities were centers for the arts and for learning. In them the *ulema* (an educated class of Islamic legal scholars) formed an important body that could

be consulted by governors and later sultans. A pervasive rule of conduct was the separation of the *ulema* from public officials, the purpose being to maintain the independence of the former so that they could give dispassionate advice to government officials based on their scriptural and philosophical knowledge, without prejudice to any group. One scholar wrote that there was a special valley in hell awaiting members of the *ulema* who accepted social invitations from governors. Such was the influence of the *ulema* that it could stir up revolt against governments and declare leaders unfit to rule because of transgressions against Islam, and their declarations could be used as excuses for overthrowing a leader.

The governor was expected to use the military forces at his command to keep trade routes open and safe. Muhammad had been a merchant, and therefore merchants and trade were highly regarded. Islamic leaders believed their governments depended on the vigor of trade. Just outside of a city was the next zone of control. In a ring around the city were the gardens from which the city reaped fresh produce and where many of its residents worked. Caravans camped in that region, and people seeking employment went into it to find work. It also harbored malcontents and criminals and was a source of vexation for governors. Each city had a police force charged with keeping streets, homes, and businesses safe, but outside the city they had trouble controlling criminals. The farmers of the gardens paid most of the taxes collected by the government. Beyond that ring were desert, steppes, oases, and low mountain areas. This zone was administrated by local chiefs who were subordinate to the city's governor, and it produced surpluses in agriculture and in herds of domesticated animals that the government could collect through the chiefs. The final zone extended into mountainous terrain and remote deserts, far from cities. The people in these areas tended to follow chiefs who ruled as they pleased, with more authority than chiefs in regions closer to a city. Often, the city government accepted the pledges of the chiefs to follow Islam and to provide troops in case of war without asking for more. This zone often was out of the control of a governor, and its trade routes were kept open by the imperial government.

The early Abbasid caliphs reformed the Islamic government. They put imperial administrative power in the hands of a small elite group drawn from their family and clan as well as from others of unquestionable loyalty. Sometimes these officials were Christians or Jews whose knowledge of the intricacies of government bureaucracy made them invaluable. Many people outside the government's inner elite were suspicious of non-Muslims in government, suspecting them of disloyalty, but throughout the medieval era Islamic governments found people of other faiths to be useful for cutting through the numerous intrigues that seemed to incessantly develop among

pretenders to the throne. Further, their professional dedication to running a government made them almost indispensable during transitions between governments.

The office of the vizier, or minister, became perhaps the most visible part of Islamic government. The vizier was the chief executive assistant of a caliph or sultan. He was in charge of running the civil government, except under the Mamluks of Egypt and Syria (1250–1517), when the vizier ran only the treasury. Another important office was that of the *hajib*, who controlled access to the ruler. The government was divided into three parts: the department in charge of writing official documents (and preserving them), the treasury (managing revenues and expenditures), and a military department. A ruler was expected to maintain a strong, well-disciplined army. In addition, the state was obligated to build socioeconomic infrastructure—schools, hospitals, bridges, irrigation canals, and the like—as well as to fund monuments that would attest to the power and cultural glory of Islam. As long as he maintained flourishing trade within his domain and managed tax collection effectively, a ruler could generate funds to fulfill the infrastructural needs of the economy and the social welfare needs of the general public. In much of the Islamic world well-developed infrastructure supported, for example, the irrigation canals that enabled bountiful production of food and generated taxes that kept cities thriving.

The city of Baghdad was an example of what was expected. It was founded in 762 by the caliph Abu Jafar al-Mansur (r. 754–75) as Medina al-Salam (“City of Peace”) and later named Baghdad (“Gift of God”). The city was set in the midst of rich farmlands and designed in the shape of a circle. Over many years great mosques were built in it, and schools and colleges proliferated; the city welcomed trade from all over the world. People speaking hundreds of languages from many cultures walked its streets and attended its colleges. There was a problem inherent in having chiefs and governors responsible for collecting taxes: The chiefs and governors took cuts of the revenues and sometimes just kept all the revenues for themselves. Caliph Hisham ibn Abd al-Malik (r. 724–43) tried to change this by shifting the task of collecting taxes from governors to officials—about like tax auditors—whose sole duty was to enforce the tax laws.

## LOCAL VARIATIONS

After 945 the concept of a united nation of Islam became an ideal rather than a reality. The Fatimids (909–1171) had established their own Shiite caliph in North Africa, first in Tunisia but eventually ruling from Egypt. In Spain the last surviving member of the Umayyad family established himself as emir; a descendant eventually proclaimed himself to be caliph, es-

establishing a new caliphate in Spain. This meant that the Islamic world had three caliphs, where supposedly there could be only one caliph. The *ulema* found themselves becoming irrelevant, being pushed aside by military rulers more intent on ruling by force than by consent. By finding ways to support the institution of the caliphate, scholars found ways to justify their position in society as experts on jurisprudence.

The caliph most scholars chose to support was the one without much actual power outside his palace, the Abbasid caliph. Most scholars believed that a caliph should administer the government, should be the final arbiter on matters of faith, and should be a military leader. During the 1000s and afterward many scholars settled on an alternative: that three men could form one caliph. This was unacceptable to the Fatimids, who believed that a caliph was God's voice on earth. It proved to be a practical compromise, however, for most Islamic governments, and it helped preserve Abbasid rule. An Abbasid caliph was characterized as the leader of religion, which gave him moral authority. Other government monarchs found this acceptable because they and sultans like them were given the military role of the caliphate. The third part—government administration—was left to viziers or other chief administrators, usually answerable to the military leaders.

Perhaps the most influential writer on government practices was an administrator for the Seljuks (the first important Turkish Muslim dynasty, ruling from 1038 to 1194), Abu Ali Hasan ibn Ali (1018 or 1019–92), who was better known as Nizam al-Mulk, roughly meaning “Order of the Empire.” The son of a tax collector, he won admiration as an expert in the law. He became the vizier of the Seljuk Empire in 1063, and he placed his family in control of much of the empire's civil administration. The book for which he is known is *Seyasak-nameh* (Book of Statecraft).

To Nizam fell the task of transforming Turkish tribes into a centralized state. To do this, he used religion and education to unify the empire. He established madrassas—religious schools—in all the cities of the empire. His hope was to move the Shiites of the eastern part of the empire toward a view more compatible with Sunni beliefs. To help him, he summoned Muhammad al-Ghazali (1058–1111), a political theorist who believed in a system of cooperation between caliph and sultan. These men argued that a caliph had to be a legitimate successor to the Prophet and had the duties of managing worldly concerns and caring for the Islamic faith. Their effort was to provide a philosophical rather than a theological basis for government, one in which a caliph was not the final arbiter of all matters in the Islamic world but was instead part of a government in which his authority was balanced by that of sultans and the *ulema*.

Although the Byzantine government's organization was very influential on the governments of Islam, the Sassanian manner of government became ever-more influential, and it tended to shape Islamic governments in the Near East and India. It gave the central role in government to the king. Kingship was a hereditary office, because a king must stand apart from those he rules in order to make dispassionate judgments about right and wrong. In the Sassanian view, a king was selected by God to rule; that is, he ruled by divine right. To challenge a king was to challenge God. Thus, even a tyrant was to be tolerated. A king could be deposed only if he plainly defied God's will. Many a sultan would build mosques and so on, thus proving that he was doing God's will. Like a caliph, a king was to be wise and just. This notion was central to medieval Islamic concepts of government. When a Muslim geographer visited the kingdom of Mali in Africa near the end of the medieval era, he took pains to praise the people of Mali as the most just in the world, with a ruler who forgave no crimes.

In Muslim India the influence of Sassanian kingship was particularly strong. By the end of the 1200s a sultan in India was considered “the shadow of God”—God's representative on earth, to be obeyed and honored as such. When the sultan gave audiences, those approaching him had to kiss the ground and then kiss the sultan's feet. Failure to follow such rules of decorum resulted in the instant death of the offender at the hands of armed retainers.

In the 1300s Egypt and Syria were ruled by a sultan of the Mamluk Dynasty. The Mamluks organized their lands in a military fashion, perhaps partly because they were military men and partly because they were threatened by significant military enemies—the Ottoman Turks and the Mongols. They divided their land into provinces called *mamlakas*, each with its own capital, a town or city, and each divided into smaller territories. These territories, too, had capitals. A viceroy ran the government of a *mamlaka*, with a council of Mamluk soldiers and scholars that helped make decisions on local policy. A civilian scholar usually led the council. The *mamlaka* government organization had four parts: the Mamluks, the religious scholars, the religious leaders, and the army.

Set apart from Sassanian notions of kingship was al-Andalus, the name for Muslim Spain. In 756 Abd al-Rahman I declared himself the first Umayyad emir of al-Andalus, reigning until about 788. He established his center of power in the city of Córdoba. North of Córdoba, he divided al-Andalus into three marches, or border regions, each centered on a city. The Northern March centered on Saragossa; the Central March centered on Toledo; and the Lower March centered on Mérida. Each city was an administrative center for the collection of taxes, the organizing of military defense, and the

building of public works. Al-Rahman I was particularly desirous of creating a rich agricultural basis for al-Andalus, probably remembering the rings of gardens surrounding Islamic cities to the east, and he had the land of al-Andalus accurately surveyed so that he could organize the land's agriculture efficiently and build irrigation canals where they could bring water to parched, but otherwise fertile territory. His purpose seems to have been to give his cities a sound grounding in the countryside around them, enabling them to survive independently in times of war as well as providing a deep tax base. He and his successors tended to depend on foreigners to man their armies, rather than drafting farmers. This may have been a sign of the importance he placed on the work of farmers, or it may have indicated a distrust of farmers, many of whom were only recent converts to Islam and could switch back to Christianity or Judaism when convenient. If there was suspicion, it eased a little under Abd al-Rahman III, who gave Jewish merchants trading privileges and protections.

On January 16, 929, Abd al-Rahman III (r. 912–61) declared himself caliph, basing his claim on his descent from the Umayyad caliphs and effectively breaking off from the Fatimids and Abbasids. In al-Andalus and much of western North Africa he was regarded as the only true caliph, the others in Baghdad and Cairo being regarded as usurpers. Cities in al-Andalus were run by governors who were responsible for collecting taxes and maintaining public order. The Hafsun clan had taken over much of eastern al-Andalus, and members of the caliph's family had taken control of the cities of Seville, Ronda, and Jaén and taken their territories away from the imperial government, leaving only the province of Cordoba for al-Rahman III to inherit. In only two years, he retook the cities and expelled the Hafsun from al-Andalus. He later established governors for much of North Africa.

Al-Rahman III reformed the imperial government, centering control of public order, tax collection, and public works in his capital of Córdoba. His government administration was focused on an elite group of administrators, with himself serving as the chief administrator. He was a hands-on ruler, personally visiting parts of his empire and organizing a new irrigation program for farms. He treated foreign policy with vigor, developing a good diplomatic corps and establishing diplomatic relations with the Holy Roman Empire and the Byzantine Empire. Further, he reorganized the military administration, taking authority from regional governors and placing it in Córdoba, where he favored the military leadership of Slavs and Berbers, who served directly under him. An important part of his administration was fostering the arts, literature, and sciences, bringing scholars and poets to his court. His reforms seem to have eased rivalries among dif-

ferent regions of al-Andalus, which some historians credit with fostering the widespread conversions to Islam during his rule. The overall effect was to give his subjects a strong sense of unity.

## ► health and disease

---

### INTRODUCTION

Medieval people were not, on the whole, very healthy. Throughout the world infant and child mortality rates were high, and only about half of all children born survived to adulthood. Of those, perhaps another half survived their reproductive years. Women died in childbirth, men died in wars, and both sexes were equally vulnerable to diseases that had no cures and for which treatments were generally rudimentary.

That being said, medical treatment and overall health were not the same around the world. In China, India, and the Islamic world doctors studied for years and actually knew a good deal about anatomy, diseases, surgery, and pharmaceuticals. People in many parts of the world understood the need for sanitation. Western Europeans, on the other hand, lived in extremely unsanitary conditions and were treated by doctors with little or no scientific background.

The causes of most diseases were a mystery to medieval people. Even the best-educated people living in the Middle Ages could not know about microorganisms and the germ theory of disease. Lacking scientific evidence, people did their best to concoct explanations for illnesses and epidemics. For many, sin was believed to be a cause of illness. The Inca, for example, saw disease as a manifestation of a person's sins and thought that disease could best be cured by washing away those sins through rituals and treatments such as bleeding or

enemas. A belief in curses and witchcraft was very common throughout the world, and treatment for illness often took the form of counterspells and charms.

Regardless of what people of the time believed, many medieval diseases such as typhoid and cholera were the result of poor sanitation. Europe was particularly unsanitary. Although Byzantine towns and cities such as Constantinople maintained the old Roman sewer systems, western European threw their food and toilet wastes into gutters running alongside streets. This waste traveled directly to rivers and streams that also served as sources for drinking water.

Other diseases were carried by insects. In Africa and Asia large numbers of people died from malaria, yellow fever, and other diseases borne by mosquitoes and other insects. Travel contributed to the spread of all types of disease. The bubonic plague, for example, traveled from Asia to Europe in the 14th century in the entrails of fleas that infested black rats.

Medical theory generally was based on the balancing various bodily aspects, though the details varied from place to place. Chinese, Islamic, and Ayurvedic medical theory all taught that illness was caused by imbalances of elements such as yin and yang or the four humors of the ancient Greek physician Galen. Doctors used diet, massage, herbs, enemas, acupuncture, and a variety of other practices to correct imbalances and maintain health. Asian doctors, in particular, used such a holistic approach to health. Herbal medicines, many of them developed in ancient times, were common throughout the medieval world. European monks still consulted the

works of ancient doctors such as Dioscorides. Muslim doctors and doctors in China and India used a wide variety of drugs to treat numerous ailments.

Medieval peoples could successfully perform basic types of surgery, though some did not produce the desired effects. Many practitioners knew how to set broken bones. Inca doctors would cut holes in their patients' skulls to treat headaches, and most patients survived this operation. In Europe barbers had the joint duties of cutting hair and conducting such surgical procedures as excising tumors or amputating limbs. In India, Ayurvedic practitioners could remove bladder stones and cataracts. The best Islamic doctors could perform a number of complicated operations, including removal of breast tumors and thyroid cysts.

In many cases basic nursing care was the best that medical workers could offer. European monks and nuns cared for the poor and the sick by providing their patients a comfortable place to rest and a good diet. The Maya used massage therapy to treat infertility and to ease pregnancy. Ethiopian doctors gave their patients steam baths. Islamic doctors built hospitals to provide a comfortable place for patients to receive treatment and convalesce.

Many medieval health practices seem downright dangerous. The Maya would bind the heads of their infants to elongate them, causing the skull to become misshapen. They sometimes gave patients enemas of alcohol, which can be poisonous. Childbirth in the medieval period was extremely dangerous. Midwives or female family members assisted at most births. Most of these assistants had little or no training in obstetrics or hygiene and consequently could offer little real help to mothers who were in trouble. Ill-trained midwives could harm mothers and spread infection from their unwashed hands. Many women bled to death or died from infection after birth. It is no wonder that life expectancies were relatively short.

## AFRICA

BY KAREN FLINT

Africa is a huge continent with numerous ecological zones where a number of tropical diseases flourished in the medieval period but also were contained by geographical features as well as by public health initiatives undertaken by local population groups. These diseases included malaria, blackwater fever, yellow fever, sleeping sickness, bilharzia, typhoid, and river blindness. In addition, Africans encountered a number of parasites that not only created their own discomforts but also led to ailments resulting from nutritional deficiency. Malnourishment weakened the immune system, causing greater susceptibility to disease and infection. Persons who

lived in areas with high incidence rates of malaria and yellow fever acquired genetic defenses against these particular ailments but also were more inclined to have sickle-cell anemia, a painful genetic blood disorder. The harsh disease climate led Africans to give their children temporary names and put tattoos and scarifications on their bodies to dissuade the spirits believed to cause disease and death from taking them. Europeans were led by the proliferation of tropical diseases to dub western Africa the “white man’s grave,” and, until the development of antimalarial drugs like quinine, that proliferation largely prevented European settlement in Africa except along the coastline and in the cape of southern Africa, which enjoyed relatively milder disease climates.

The trade routes of Africa, Europe, and Asia effectively exposed the populations of these continents to numerous contagious diseases. The trans-Saharan and Indian Ocean trade routes predate the medieval period, but both saw significant increases in traffic between the 1250s and 1500s, thereby speeding the transfer of trade, culture, religion, and microbes. Population groups along these two trade routes—which included much of western Africa and the coastline of East Africa—had the greatest exposure to worldwide diseases and consequently developed a certain degree of immunity against epidemics. Contagious diseases were passed inland as well, via internal trade routes, though many of these communities suffered less-virulent epidemics. The degree of immunity conferred by previous outbreaks can be seen by the fact that Africa largely avoided the “virgin soil” epidemics that so drastically affected peoples in the Americas and Oceania,

*Kilga, a support for a water jar, 12th century; marble kilga were designed to hold a large jar of unglazed earthenware that allowed water to filter through into the stone receptacle beneath, thus filtering the polluted water of the Nile and making it fit to drink. (© The Trustees of the British Museum)*

with the primary exception of the relatively isolated Khoisan people, who died in great numbers from diseases like smallpox that accompanied European settlement at Africa's most southern tip. Virgin soil epidemics refer to epidemics that cut a swathe through a population not previously exposed to a disease.

After Europeans traveled to the Americas and accelerated world trade during the Age of Exploration, new diseases were introduced not only from Europe but also from Asia and the Americas. The slave trade, which itself had a devastating impact, served only to heighten this interaction. Given the similar climatic environments in parts of Asia, Africa, and the Americas, global trade facilitated the spread of tropical disease among these three continents. Such transfers of disease intensified with colonialism. European settlement and trade not only resulted in more virulent forms of smallpox and the plague but also introduced whooping cough, cholera, polio, syphilis, tuberculosis, pneumonia, and leprosy. The so-called Columbian exchange between the Americas and Europe introduced new food crops such as cassava and maize, which were readily adopted by Africans, given their larger crop yields, but they provided significantly less nutrition. These factors, in combination with the slave trade, produced a significant reduction in the African population. While the slave trade extended well beyond the medieval period, it is nevertheless important to note the beginning of its impact during this early period. Not only the numbers of persons killed in warfare fueled by European weapons traded for slaves must be considered but also the impact on farming and population growth that resulted from taking the healthiest and most fertile members out of Africa.

How did Africans comprehend the origins of ill health? In many ways Africans understood the body and disease as did other medieval world populations—though such views differed regionally throughout the continent. Although Africans did not believe in the humoral theory that attributed disease to an imbalance of bodily fluids, they nevertheless viewed blood and bile as being particularly important to health and vitality; this can be seen in the bloodletting and medicinal purgatives that were used throughout many areas of Africa. Other Africans told stories of the influence of snakes and bugs that either lived metaphorically within the body or penetrated it and thus caused numerous ailments. Such causes of disease were seen as natural and treated with a variety of natural substances, massage, poultices, enemas, steaming, bloodletting, and minor surgeries. In Ethiopia, vapor baths were used to heal a number of ailments among the royal and upper classes. Such medicinal baths were created by building houses around natural springs as well as by heating water using a fireplace and underground flue that distributed

the hot water and steam into a bathhouse. Other treatments and minor surgeries included those associated with the extraction of teeth, ritual surgeries such as scarification and circumcision, and treatment of injuries.

Not all illnesses, however, were seen as the result of natural forces. Depending on the specific circumstances in which they emerged, certain illnesses could be deemed retaliation by ancestral or territorial spirits or the result of witchcraft. Whether an illness was natural or supernatural was determined by judging the symptoms, the duration of illness, and the social relations of the patient at the time of sickness. Medical treatments to cure the symptoms would be administered, but healers needed to diagnose the root of the illness to adequately eliminate it. Once it was determined, measures were taken to appease or to make reparations to ancestral or local spirits or to find the witch or wizard. In the case of witchcraft, the person accused of practicing witchcraft had either to be killed or to be stripped of his or her powers and sent into exile.

African public health practices can be seen in African architecture, in community planning, and in a strict adherence to rituals and avoidance taboos. Responsibility for public health fell primarily on the kings, chiefs, and healers, though the effectiveness of their measures was dependent upon the compliance of the community. While spiritual elements were often incorporated, African health initiatives resembled many modern public health practices. These included measures to control both epidemics and environmental hazards. Throughout West Africa vaccinating against smallpox was practiced by pricking the arm of a healthy person and rubbing in pus from a smallpox pustule. This practice often could be deadly, but those who survived did gain immunity from the disease. Slave traders in western Africa were said to look for evidence of such immunity on their captives.

To avoid disease and pestilence, Africans often moved entire communities to healthier sites. In Ethiopia people fled to the mountains to avoid pestilence, and the cooler region of Danqaz was chosen as the monarch's headquarters to avoid the plague. In central and southern Africa local populations minimized the threat of the tsetse fly that caused sleeping sickness by creating buffer zones between residential and farming areas and uncultivated areas that contained game which attracted the flies. Likewise local taboos and edicts generally prevented the contamination of drinking water with human and animal refuse.

Given that African ideas of health and well-being were intricately connected and that good social relations played an important role in the maintenance of community health, African public health initiatives also included ensuring rainfall, preventing lightning strikes, and protecting the community

from sorcerers. In East Africa persons suspected of witchcraft, either by causing the illness or death of an individual or by withholding rain from the whole community, would be subjected to a poison ordeal. While this poison ordeal varied from area to area, basically a poison drink prepared by a chief or king determined who had bewitched a community or individual. Surviving the poison was proof of one's innocence.

While much detailed information regarding African health, medicine, and medical practices comes from the period of European contact, particularly the 19th century, there is considerably less evidence for medical practices and the impact of disease in medieval Africa. Ethiopians, Nubians, and Egyptians left written documents that describe health and medicine during the medieval period. A lot of information regarding African health and healing, however, comes from sources written by outsiders, predominantly Muslim traders and, in the later period, the Portuguese who interacted with Africans along the coast from the 1450s onward. Smaller communities and those that were geographically isolated from major trading routes received less attention from outside visitors and remain outside the written record.

Fortunately, historians can assemble information for this early period through oral histories, historical linguistics, and the archaeological record. Oral histories from the ancient kingdom of Mali tell of the important role that kings and blacksmiths played in the maintenance of public health for the community, while historical linguistics tells of common medical traditions and practices shared throughout southern and central Africa. Likewise, archaeology can help date medical paraphernalia such as medicine containers, cupping horns, surgical tools, enemas, and snuff spoons. Medieval African art sometimes depicts not only the use of medical paraphernalia and medicinal plants but also the existence of various medical conditions and diseases suffered by Africans. Finally, by studying the skeletal remains of Africans who lived during this period one can gain a sense of nutrition levels as well as various surgeries that may have occurred or the ways in which broken bones were set. Unfortunately, it is not known with certainty whether specific medical procedures observed in the 19th century were practiced during the medieval period, since many procedures left no tangible evidence.

## THE AMERICAS

BY BRADLEY SKEEN

Medical treatment throughout the Americas in the Middle Ages may be termed *shamanic*. It consisted of religious and magical rituals or the administration of herbal medicine (the formulation of which was often obtained through visionary

experience), performed by a healing specialist believed by the community to have special access to the supernatural world. Because of the lack of writing, there is little direct evidence of the characteristic practice of shamanic medicine in most native cultures. However, we have a far better understanding of the specific forms that healing took in the three great American civilizations of the Aztec, the Maya, and the Inca because of either their own written records or the records made by both the Spanish and the natives themselves immediately after the European discovery of the Americas.

In Mesoamerica and Peru, the home of the Aztec (ca. 1200–1521), the Maya (fl. 150–1521), and the Inca (ca. 1400–1532), the average age of adults at death during the medieval period has been calculated as 37. This information comes from examining archaeologically recovered skeletal remains. The average life expectancy must have been much less, since there is no reason to think that many more than half of all children born lived to adulthood. Many factors contributed to this short life span. Perhaps the most important was the absence of the germ theory of disease, leading to the inability to treat illness effectively. The ordinary diet consisted largely of potatoes or of maize and beans and so lacked many elements vital for health. The lack of knowledge about the transmission of disease through insect vectors, such as mosquitoes, also encouraged settlements near lakes and swamps, contributing to the spread of epidemic diseases, among them, yellow fever.

The diet of the Aztec may have been somewhat better than that of contemporary European peasants, for instance, owing to a higher protein level derived from the Aztec habit of eating insects. While ritual cannibalism was widely practiced as part of the Aztec religion, it could not, as has been argued, have been an important part of the people's diet. The sanitation procedures in the Aztec capital city (with at least 200,000 inhabitants) of Tenochtitlán (modern-day Mexico City) seem to have been better than in many other large medieval cities. Tenochtitlán was built on a group of islands on Lake Texcoco, but its water supply was brought in by aqueduct from nearby mountains. Many houses had their own latrines, and there were even public restrooms. Owing to the ease of transport provided by the lake and the canal system, the city's night soil was transported to the mainland each night for use as fertilizer. The government maintained a special labor force to clean the city streets.

The Aztec were aware of simple medical procedures, such as setting broken bones. Such procedures usually were done by an herbalist, who could also perform simple surgeries. (Without steel to make scalpels, the herbalist relied on obsidian knives.) However, there were essentially three levels of medical treatment available, depending on the patient's

*Stone pipe in the form of a squatting figure, Paint Creek, Ross County, Ohio, North America; Mississippian Period, 1200–1500; such pipes were used in ceremonies to ensure both the health of the community and the maintenance of the power of the principal clan. (© The Trustees of the British Museum)*

understanding of his own condition or on the advice given from divination or other sources. Disease or accident might be caused by divine disfavor. In that case, a priest would perform divination (sometimes via interpreting an experience of the divine world he would induce using hallucinogenic drugs) to determine which deity the patient had offended and whose displeasure he had incurred. The herbalist would then prescribe the appropriate rituals the patient had to perform in order to be relieved. If, on the other hand, the patient believed that he had been cursed by a witch, he could consult a witch doctor, or *tlictil*. This specialist would then determine which spells the witch had used and enact appropriate counterspells.

If the patient believed that his condition had a natural cause, he would turn to the herbalist. The plant materials could be administered variously: by applying the plant as a poultice over a wound or a broken bone or by boiling it into either a drink or a compound for general anointing of the whole body. Moreover, each drug used by the herbalist was said to have properties against numerous different conditions, and the particular condition of any patient had to be treated by a unique combination of drugs determined by the herbalist. Therefore, it seems very unlikely that any pharmaceutically active qualities of the herbs involved actually

benefited the patient. Tobacco could be used for almost any medical condition.

The differences among the three kinds of treatment are not entirely straightforward. If a warrior suffered a wound in battle, for example, and had a dressing applied by an herbalist, he still might easily believe that the ultimate cause of the wound had been the will of a god or the curse of a witch and seek further treatment elsewhere. The Aztec idea of “natural cause” was far different from ours: For instance, the Aztec believed that an infant would naturally fall sick if an adulterer or a homosexual entered the room in which it was sleeping.

Mayan cities were essentially royal courts with attached temples and ceremonial complexes. The peasant population was spread out over the countryside, so the Maya did not have to deal with the health and sanitation problems of large concentrations of people, such as in the Aztec capital of Tenochtitlán.

Mayan medicine shared many features with that of the Aztec culture. The setting of broken bones was possible, and simple sutures closed wounds. Women were actively involved in many Mayan professions relating to health. Herbal medicine was used, as were priestly shamanic practices in an attempt to determine the supernatural cause of disease. Chocolate, in particular, was considered an effective treatment for almost any disease or medical condition. The Maya possessed a wide range of effective drugs that could be used to ease sleep, induce hallucinogenic experiences that were often given a religious interpretation, or numb pain. These drugs allowed an extensive practice of dentistry. Fillings were made from iron pyrite (fool’s gold) or out of semiprecious stones, such as jade or turquoise, but they seem to have been used mostly for cosmetic purposes (for example, to introduce a small jade medallion into each tooth that would be visible in a smile) rather than to treat tooth decay. The usual treatment for toothache (short of pulling the tooth) was to exorcise the “worm” causing the pain.

Mayan aristocrats had an extensive culture of health whose practices cannot be described as either purely religious or purely medical in character. These practices began in infancy, during which time children’s heads were bound in order to produce a somewhat flattened face and an elongated skull, because this head shape was considered by Mayan physiognomy (the pseudoscience of predicting character from the shape of the head) to be indicative of a superior individual. It can be seen in a highly exaggerated form in the characteristic idealizations of Mayan art.

It was also thought that saunas, massage, and enemas generally promoted health, though their purpose was as much for ritual purification as for inducing physical effects. The idea was that these practices helped restore physical and

spiritual balance. Such was not necessarily the case. Frequent enemas, for instance, can actually interfere with the absorption of nutrition from food and result in starvation even in a person eating a healthy diet. If, as seems probable, the Maya introduced such drugs as tobacco (nicotine) and alcohol into the body through enemas, this practice was extraordinarily dangerous because lethal doses could quickly be absorbed through the bowel. An outgrowth of massage therapy was the practice of treating women for infertility and other characteristic problems, such as menstrual cramps or menopausal discomfort, by actually breaking and resetting bones in the patient's abdomen.

The Inca believed that disease was caused by sin. The sin a person committed manifested itself as a harmful presence in the patient's body. In order to cure the patient, the sin and its physical effects had to be washed away. Healers could attempt to wash away sin in several ways. One way was to give the patient a drink or an enema with specific herbs that were believed to be effective for the apparent illness. The sin and illness could be sucked out if the patient had sores or lesions containing a liquid, such as pus. The patient could be bled in the hope that the illness would drain away with the blood. The patient's clothes could be thrown out in the hope that whoever took and wore them would take the illness with him. In any case, the patient had to confess all of his sins to the physician. All of these activities would be accompanied by rituals of divination and propitiation of deities. The public health of the Inca Empire was promoted by the Citua ceremony, the ritual purification of the capital city of Cuzco held every spring. Sin and illness were driven out of the city by priests and warriors and sent away down rivers to the ocean, just as they were driven out of a sick patient's body by the physician.

Despite this highly mythological conception of disease and its cure, the Inca did have practical medical knowledge. Coca leaves (a plant native to the Andes and the source of the modern drug cocaine) were chewed as a stimulant and a cure-all. Trepanation is a surgical operation in which the physician cuts a small hole into the skull of a patient, either for some medical purpose, such as to relieve pressure after a head injury, or for various ritual purposes. The hole could be made with a drill or with abrasives (particularly in the Mayan culture). Its practice in the past can be detected archaeologically by finding skulls with the characteristic healed-over holes (the bone will fuse back over the hole but not with the original thickness) and from surgical implements designed for the operation.

The procedure was invented in prehistory and was practiced worldwide. It was certainly practiced throughout the Americas, but it had a special prevalence in the culture of the Inca. While the Maya used trepanning mostly as part of their

interest in reshaping the human skull, the Inca seem generally to have used it for medical purposes. Trepanning is effective in reducing swelling after a serious head injury, but it was used just as often to relieve headache, for which it could have had only a placebo effect. Studies of trepanned skulls suggest an amazing 70 percent survival rate among trepanned patients.

Understanding the medical practices of Americans outside the Maya, Aztec, and Inca civilizations is problematic. We have no written sources for other parts of North America north of Mexico, and archaeological research offers little help. Mended bones and trepanned skulls have been found, but it would be difficult to identify a stone tool as being specifically surgical. Plant material would not survive to be found by archaeologists. The usual procedure therefore, when dealing with medieval American civilizations of North America, is to infer their medical practices from the Mesoamerican world or to derive information from the traditions of modern successor peoples whose cultures seem to be descend from the medieval civilization.

The Anasazi (ca. 900–ca. 1300) civilization seems continuous with those of modern-day Pueblo tribes. While they did not disappear, their large settlements and structures in the four corners area of the Southwest were relatively quickly abandoned, so that public health issues were probably never fully addressed. Settlements such as those at Chaco Canyon or Mesa Verde had large saunas, suggesting that they were used in common by the aristocratic class, if not the entire population. Pueblo people still use the sauna, but in connection with the rites of the Kachina religion, which postdates the Anasazi culture. It is therefore possible that the more ancient saunas were used for health-related reasons, as in Mayan culture.

In the case of the Mississippians (mound builders centered at Cahokia in southern Illinois and diffused up the Ohio valley, dating to ca. 750–ca. 1500), archaeologists turn to the Choctaw and Chickasaw people to help understand the earlier culture. The primary traditions about medicine that survive concern herbal medicine. Shamans among these peoples believed that their knowledge of herbal medicine came from visionary experience of the teaching of a forest spirit manifest in the form of a tiny human being. Storytellers relate that those destined to be shamans were kidnapped by this spirit and taught herbal lore before being returned to their parents. In other respects, the city of Cahokia grew rapidly from a population of as few as 1000 in about 1050 to as many as 40,000 by 1400, when the site was abandoned. It must have had adequate public health measures, though the site has not been excavated thoroughly enough to tell exactly what these were.

The same kind of shamanic herbalism was common throughout North America. The Sioux shaman Black Elk

described in the 1920s how he had had a dream in 1890 in which supernatural beings pointed out to him a new medicinal plant as well as its purpose and the means of applying it. The next day he found a plant previously unknown to him and identified it with the one from the dream. This pattern of identifying and prescribing herbal medicine based on visionary experience seems to have been commonplace among many native peoples in the 19th century and can reasonably be inferred back to the Middle Ages. Exact patterns vary between tribes and probably changed over time. For instance, among the Ojibwa female shamans identified the plants to be used, while male shamans devised the rituals and ceremonies to be used in conjunction with them.

We have some historical information about the Arawak, Carib, and other peoples living on the Caribbean Islands and coasts at the time of the Spanish conquest. Although colored by Christian antagonism to traditional religion, Spanish writings suggest that the practice of medicine among these peoples was largely shamanic. The primary emphasis was on the belief that illness was caused by evil spirits entering and attacking the body and that these spirits had to be expelled through ritual actions (exorcisms). The use of herbal drugs played a part but was not the most important element. The same is generally true of medical practice among peoples from the interior of South America in later times and was probably not much different in the Middle Ages. There is some evidence of large settlements in South America whose inhabitants must have understood something of public health measures.

## ASIA AND THE PACIFIC

BY TOM STREISSGUTH

Two of the world's earliest medical sciences originated in Asia, where the civilizations of India and China had fully developed systems of diagnosis and treatment of disease by the first millennium of the Common Era. Chinese medical tradition harkens back to a classic text, of uncertain date, attributed to Huang Ti, the Yellow Emperor. The basic precept of this work and all Chinese medicine is the opposition and balance of two basic principles: yin and yang. According to this tradition, the attainment of balance between these two principles allows the patient to achieve good health and a long life. Loss of yin-yang balance and harmony results in disease.

The Chinese physician also employed the principle of five basic elements: wood, fire, earth, metal, and water. Interactions of the five elements had an effect on the physiology and functioning of the body and the occurrence of disease. Diseases were endogenous (in which the causes lay within the body and the emotional state of the patient), exogenous (caused by exterior environmental factors, including climate,

temperature, humidity, and precipitation), or caused by miscellaneous factors such as accidents, poor diet, sexual habits, or disease brought on by overstimulation of the body and the senses. Observation of the body was carried out by visual inspection, the posing of questions, olfaction (smelling), and feeling the pulse.

The Chinese physician put great store in the condition of the pulse. The pulse gave many indications of the state of the body, and some doctors spent long hours in interpreting its speed, intensity, and rhythm. The pulse indicated the heart rate and rhythm, the condition of the blood and arteries, the blood pressure, and the severity of disease. *Mai ching* (The Pulse Classic), written in the third century, was a respected text on this subject used in China throughout the medieval period. The book spread via trade routes to the rest of Asia, India, and the Middle East, where it was considered a standard text on the art and science of reading the pulse.

Many therapies were available to the Chinese physician to restore the body's needed harmony. *Qigong* were breathing exercises. Acupuncture was a method of puncturing the skin at certain points to relieve pain and release unhealthy energy. The practices of acupuncture and moxibustion (the application of the ground-up mugwort herb) spread to Japan and Korea and eventually throughout eastern Asia as Chinese traders and physicians migrated beyond the borders of the empire. The Chinese also had an extensive catalogue of herbal remedies, dietary prescriptions, massage, and physical exercises designed to release harmful energy.

Drug therapy, using mineral and plant material, was used as a last resort to treat disease. The *Shennong bencao jing* (Shennong Emperor's Classic of Materia Medica), the standard text in this field, recorded 365 kinds of drugs, including many that are still used and considered effective. Around the same time as this book was written in the second century B.C.E. a method of anesthesia was first developed by the physician Hua Tuo.

The treatment of disease considered the state of the body as a whole rather than as an assembly of independently functioning parts. This feature of Chinese medicine distinguishes it from the science of medicine as it was developing in Europe during the Renaissance of the 15th and 16th centuries. Rather than the disease, the entire patient was treated to bring the five basic elements and the yin and yang principles back into their proper balance. Much of the prescribed treatments came from a work of Zhang Zhongjing, *Shanghan zabing lun* (*Treatise on Febrile and Miscellaneous Diseases*), dating to the second century C.E. Another respected work was the *Zhou hou bei ji fang* (Handbook of Prescriptions for Emergency Treatment), written in the fourth century by Ge Hong, who was the first to describe smallpox. Describing the treatment

of rabies in his work, Ge Hong suggested applying a small amount of infected tissue to healthy patients as an inoculation against rabies. This was the first instance of vaccination and the predecessor to the smallpox vaccines that were introduced in China in the 1500s and in the West in the 1700s.

The Tai Yi Shu, or Imperial Academy of Medicine, was established during the Sui Dynasty (598–618) and was one of

*Standing Bhaishajyaguru, the medicine Buddha, cast bronze with gilding, Korea, ca. 668–800* (Los Angeles County Museum of Art, Purchased with Museum Funds, Photograph © 2006 Museum Associates/LACMA [M.2000.15.123])

the world's first colleges of medicine. It trained physicians in internal medicine, pediatrics, massage, and incantation. Students apprenticed to a master who prepared them for their roles as doctors, assistants, nurses, and pharmacologists. Students were subject to frequent examination and rigorous qualifications. During the Sung Dynasty (960–1279) China also pioneered the field of medical criminology and the examination of the dead to determine cause and time of death. The principles were applied to cases in which suicide or homicide was in question, and evidence gathered by physicians was considered valid in criminal cases against suspected murderers.

Medical ethics was an important field of study in medieval China as well. A book entitled *Beiji qian jin yao fa* (Prescriptions for Emergencies Worth a Thousand Pieces of Gold), written by Sun Simiao in the seventh century, treated the conduct of the doctor, instructing that the physician should practice diligence in study; treat all patients regardless of their rank, age, or gender; and take the greatest care when making diagnoses and prescribing treatment. In addition, doctors should refrain from criticizing others of their own profession and avoid jealousy or an arrogant posture.

As contact increased in the early medieval period between China and neighboring states in Korea and Japan, disease epidemics became more common in these outlying areas. In 735 a devastating smallpox outbreak occurred in Japan, brought first to the northern port of Kyushu from Korea. Several more outbreaks over the next two centuries had a devastating effect on Japan's society and economy. Mystified by the workings of the malevolent spirits whom they believed had brought the epidemic, the rulers of Japan turned to a caste of Buddhist monks, who employed effigies, astrology, and ritual to combat the disease.

In Southeast Asia the medieval civilizations of Thailand, Burma, Laos, and Vietnam all had traditional medical texts, which listed diseases and their descriptions and remedies. Influenced by medical theories of China and India, these works were preserved in court libraries and frequently copied out for the use of royal physicians. Parasitic diseases of the digestive system, including cholera and dysentery, were common subjects of medical treatises in the region.

The people of the Pacific Islands and Australia were largely isolated from these outbreaks but still had to deal with endemic diseases, particularly malaria. Migrants from Southeast Asia and the East Indies who spread through the western Pacific brought with them respiratory infections, enteritis, arthritis, yaws, and a skin inflammation known as filariasis. Ciguatera, brought on by eating poisonous reef fish, was combated with purges, while other digestive diseases were often treated with healing massage and herbal remedies. Witch

## THE HEALING TEMPLES OF HAWAII

The Hawaiian *heiau ho'ola*, or healing temple, was a unique institution in Polynesia. Those taken ill and unable to combat disease on their own or with the help of a family elder paid a visit to the *heiau ho'ola*, which was consecrated to one of the Hawaiian gods. Home to the *kahuna la'au lapa'au*, or herbalists, and *kahuna lapa'au*, or healers, the *heiau ho'ola* served many different functions. It was a training center for medical students and also served as a research center for the gathering and testing of medicines. It offered pregnant women a birthing place and a child-care center. Physicians at the temple performed simple surgeries and healing massage, set broken bones, and called on spiritual forces for the purpose of healing disease and bodily disharmony.

The system of healing—both practical and spiritual—worked well throughout the medieval period, when Hawaiians were largely isolated from the epidemic and endemic diseases that were more common in the rest of Polynesia. Most medical problems were related to injury or poor functioning of the digestive or nervous system, which the Hawaiians put down to disharmony of the body's spirit or the displeasure of the gods. This era came to a sudden end with the arrival in 1778 of Captain James Cook and his crew, who brought a range of deadly infectious diseases previously unknown in the Hawaiian Islands.

doctors, always male, were trained in the folk medicine and ritual necessary to combat disease and heal injuries.

Precepts of Chinese medicine spread through Asia as the powerful imperial dynasties, particularly the Ming Dynasty (1368–1644), gained in social and political influence. On the Indian Subcontinent, however, a long-established system of medicine known as Ayurveda had been in use for millennia. This medicine arose from the ancient religious texts known as the Vedas and from ancient practices that combined systematic observation with magical prescriptions for the treatment of disease.

Ayurveda dealt with the spiritual and physical condition of the patient. This system of medical practice and training was passed on orally from masters to apprentices. The Ayurvedic tradition held physicians to a life of chastity, modesty, study, and the avoidance of meat and alcohol. Doctors were trained for seven years and continually tested on their knowledge and skills. They learned through observation, as

dissection was prohibited by religious doctrine. Ayurveda conceived of three basic *doshas*, or aspects: *vata* (air, corresponding to the working of the nervous system), *pitta* (fire, the digestive system), and *kapha* (water, the system of blood and nutrients). These aspects in turn were composed of five elements: space, air, earth, fire, and water. In observing patients, Ayurvedic physicians examined the breathing and pulse, which was checked on both wrists. They listened carefully to the heartbeat, which was considered the indicator of life force within the body by its speed, rhythm, and strength.

Treatment of disease was carried out by the use of emetics to induce vomiting; purgatives, or enemas mixed with oil, water, and herbs; and the administration of herbs designed to cause sneezing and the expulsion of unhealthy humors. Indian physicians used leeches to bleed the body and employed cupping, in which a vacuum is created by the application of a hot glass or cup to the skin and then allowing the air to cool and form a vacuum that creates intense pressure on a localized area. Physicians prescribed a strict diet and a ritual cleansing of the body as means of prevention. They performed various forms of surgery, including the setting of broken bones, removal of bladder stones, removal of cataracts, and suturing of wounds.

Ayurveda considered the effects of certain foods on the body and classified food as *madhura* (sweet), *amla* (sour), *lavan* (salty), *katu* (pungent), *tikta* (bitter), and *kasaya* (astringent). All foods and herbs, according to the practice, had these properties in various proportions and could be used as medicine and to maintain health. Physicians combined herbs with minerals, animal parts, oils, cooked food, and water for treatment. Purification techniques were applied to cleanse the body of disease-causing humors and included diet, massage, purgatives, enemas, and sweating. Massage was another central feature of Ayurvedic treatment, designed to relieve pain and nervous anxiety, ease sleep, calm the emotions, and improve the digestion and the circulation of the blood. Massage was believed to release poisons and allow the body to eliminate them naturally.

Ayurveda formed the philosophical foundations for later medical treatises. The original Vedic texts were revised by the physician Charaka in his work known as the *Charaka samhita* (Compendium of Wandering Physicians). Another important medical text was the *Sushruta samhita* (Shushruta's Compendium), written by the renowned surgeon Sushruta. In the medieval period Ayurvedic medicine was divided into eight branches of study: surgery, pediatrics, internal medicine, toxicology, purification, longevity, spirit, and the study of the eyes, ears, nose, and throat. The distinct schools were founded by different masters at various times, and they have basic texts that were emended in the medieval period.

## EUROPE

BY BRADLEY A. SKEEN

During the Middle Ages no one had any idea that microorganisms could cause disease. Medieval Europeans relied on the authority of the Bible, and disease, whether personal or epidemic, was usually seen as either a divine punishment or the work of demons or witches. Consequently, systems of public hygiene were rudimentary at best. Constantinople, the capital of the Byzantine Empire, maintained its original Roman sewer system, built in the third century, which routed waste through underground conduits with water flowing constantly to the ocean. In most other European cities, however, sewage was thrown into gutters or (especially as city population expanded after about 1300) into underground dry sewers, to be washed into the local watershed (usually a nearby large river) only when it rained. In the countryside night soil was generally kept for use as fertilizer in agricultural fields. In his writings the Arab explorer Ahmed ibn-Fadlan mentions that the people of Kievan Rus (in modern-day Russia) in the 10th century practiced the quarantine of any ill person. However, such measures probably were motivated by the desire to isolate spiritual pollution. Leprosy was an exception and was routinely dealt with in Europe by lifelong quarantine of lepers.

The lack of public hygiene in medieval culture combined with the absence of any effective treatment of infectious disease contributed to an infant mortality rate so high that no more than half of everyone born could expect to live to age 18. Women of childbearing age died at almost the same rate because of the inability of midwives to stop bleeding or to otherwise aid difficult births. (A cesarean section, for instance, was routinely used only on mothers who had already died from complications of labor, since its use on a living mother scarified her for the life of the child.) Given the high mortality rate from simple infections, probably only about half of those who survived childhood lived past their reproductive years, attaining ages 40 to 50. The biblical life span of “three-score and ten”—70 years, less than the average age attained in western Europe today—was considered a divine blessing. For these same reasons royal and noble lineages did not usually last more than a few generations.

The main inheritance of medieval medicine from antiquity was a sense that medicine was a rational practice based on a sophisticated understanding of the physical world rather than the magical healing practices of the folk tradition or the hope of curing disease through prayers and appeals to the shrines of saints (although this was probably as common a way to treat disease in the Middle Ages as was turning to medical practitioners). Medical practice existed primarily in three places in the culture of medieval Europe: the monas-

tery, the village, and the university. In the early Middle Ages only monks had any access to the few ancient medical texts that survived. Moreover, the medical care of the poor was an important aspect of Christian charity that occupied many monks and nuns. Care provided by monastic institutions usually consisted of bed rest, a healthy diet, and the use of herbal medicine.

One of the most important medical books circulating in the West was the herbal text of the ancient Greek author Dioscorides (ca. 40–ca. 90). This work is an exhaustive treatise on the preparation of medicines from plants. However, it is unlikely that many of the medicines (except for a few, such as sleeping potions made from the opium poppy) were actually effective. The book is divided into entries by individual species of plants, and it is now usually impossible to identify precisely the plant to which an entry refers. Each plant might be said to be effective for 50 to 100 different symptoms. With the lack of any scientific method of testing their results, even the herbalists (or apothecaries) who practiced such medicine could not have determined whether the treatments were effective. In such traditions, any recovery from illness or alleviation of symptoms is usually attributed to the medicine given, while failure of the same medicine in a different instance is explained away. There was no shortage of medieval writers, from Saint Augustine (354–430) to Saint Bernard of Clairvaux (1090–1153), who argued that medieval medicine was a sort of high-sounding fraud unable to cope with disease.

A common medical practitioner in the villages in which most medieval people lived, and especially in the cities, was the barber-surgeon. He (the profession was exclusively male) was called upon to perform such simple surgeries as were possible, including extracting teeth, setting broken limbs, rearticulating dislocated joints, and excising tumors and other skin lesions. Barber-surgeons worked with Hippocratic physicians and often bled patients under their direction. Barbers were especially useful in military camps, where they would routinely perform amputations; usually the only way to stop a serious arm or leg wound from bleeding was to saw off the limb and cauterize the stump using a red-hot piece of metal. (There was, of course, no form of anesthesia available.) Midwives (exclusively female) would use similar hands-on methods to help deliver babies. Without knowledge of the germ theory of disease, barber-surgeons and midwives did not clean surgical instruments, and these inevitably became a means of spreading infection from one patient to the next.

The other common medical practitioner in the village was the cunning man or woman. This tradition probably went back to pre-Roman Celtic, Germanic, and Slavic cultures. Cunning men and women essentially believed that disease was caused by witchcraft. They would often try to discover

*Late Saxon/Norman woman's skeletal feet, showing signs of arthrosis and fused toes, Britain, 11th–12th centuries* (© Museum of London)

the identity of the person who was bewitching the patient and neutralize the original spell. Alternatively, they would cast their own spells to promote healing and also give out herbal remedies, using different (if no more reliable) principles than did the monastic herbalists.

The medical science of the ancient world was essentially Greek and was written about in that language. Only a small portion of the available medical texts had been translated into Latin before the collapse of the Western Roman Empire. However, most of the ancient medical writings in the Hippocratic corpus (fifth century B.C.E.) and of the influential physician Galen (129–ca. 199) had been translated into Arabic in the Islamic world, and extensive commentaries and expansions of them had been written as well. These became available in western Europe during the Little Renaissance of the 12th century. In the 15th century more Greek texts became directly available from Constantinople (where the practice of Hippocratic medicine had continued uninterrupted throughout the Middle Ages). Hence, medieval universities became new centers for educating Hippocratic physicians. Usually a student would complete a basic university doctorate in the liberal arts and then spend an additional year in medical studies. The universities at Salerno and Bologna in Italy and at Montpellier and Paris in France became the leaders in medical studies. In the 14th century medical students at these schools, for the first time in history, routinely learned anatomy through observing the dissection of human cadavers.

Jews were somewhat ahead of other Europeans in academic medicine. A Hebrew language medical literature existed in the Islamic world, based on the more sophisticated

Arabic rendering of ancient medicine. These writings also freely circulated among Jewish physicians living in western Europe. Thus, in the early Middle Ages, Jewish physicians were highly regarded, though this predominance was eclipsed as university-educated Christian physicians absorbed translations of Arabic medical texts.

Hippocratic medicine, named for the Greek physician Hippocrates (460 B.C.E.–370 C.E.), held that the body was made up of four liquids, called humors: blood, phlegm, bile, and black bile. These humors corresponded to the four elements that ancient Greeks believed made up the universe: fire, air, water, and earth. Each humor also had two of the four qualities: hot or cold and wet or dry. Blood, for instance, was hot and wet. These substances should not be confused with elements of the body that modern medicine calls by the same name. What a medieval physician understood as “blood” was far different from what a modern physician understands by the same term. The blood that could be seen flowing in the veins was thought to be a combination of the humor blood with traces of the other three humors mixed in. The humors were manufactured by individual organs: The gallbladder, for instance, produced black bile, while the liver made blood. (This was transported throughout the body by the heart and “eaten” by the other organs, so blood was constantly created anew rather than recirculated.)

In the Hippocratic view a healthy body held the four humors in balance. Balance was to be maintained through diet and exercise and restored by the same means if an imbalance resulted in disease. The balance or imbalance of the humors was called the patient’s complexion. A person might, for example, have a sanguine (bloody) complexion and be hot tempered and fiery. Individual organs, too, were said to have complexions: For instance, the brain was cold and wet and the heart hot and wet. Women were thought to be weaker and less capable than men because they were colder and wetter. Races were stereotyped in this way as well, with Ethiopians considered to be hot and dry, while Scythians (Russians) were cold and wet. The ultimate cause of variations in complexion was the astrological influence of the stars, so the pseudoscience of astrology became an important tool of medical diagnosis.

The Hippocratic physician checked the balance of the humors by examining human waste products to determine the balance in them between wet and dry and hot and cold. If an imbalance resulting in disease symptoms became too great, physicians would allow herbalists to prescribe medications that they believed would increase or decrease the production of the unbalanced humor. Many diseases are accompanied by fever, the heat of which the Hippocratic physician attributed to an excess of blood. Thus, patients exhibiting fever were frequently sent to a barber-surgeon, who would open

a vein purposely to bleed a patient and reduce the excess of blood. Alternatively, the blood could be extracted by applying a leech (a small, blood-sucking eel). For this reason *leech* was formerly a standard title in English for any kind of healer. Increasingly in the later Middle Ages physicians themselves took over the actual procedure of bloodletting. Imbalance of the humors could be corrected by other procedures also. Smallpox pustules, for instance, seem wet and cold, so they were treated by wrapping them in red bandages, since the color red was hot and dry.

In time university-trained Hippocratic physicians came to dominate over the social position of other kinds of practitioners because their education appealed to the aristocratic classes. They took over the institutions of public medicine as these institutions were established in the growing cities of the later Middle Ages. Thus, they carved out the social status associated with the modern physician as a university-trained intellectual in charge of public health as well as private medical practice, without using any techniques or therapies still practiced or considered legitimate today.

## THE ISLAMIC WORLD

BY DAVID W. TSCHANZ

In the prologue to the *Canterbury Tales*, the 14th-century English poet Geoffrey Chaucer identifies the authorities used by his “Doctour of Physic.” Not all were Western Europeans. Among the ones he cites are “Avycen” (Ibn Sina, known to the Western world as Avicenna), “Averrois” (Ibn Rushd, or Averroës), “Razi” (ar-Razi, or Rhazes), and “Haly” (Ali ibn Isa, or Jesu Haly). The Arab physicians Ali ibn Isa, ar-Razi, Ibn Sina, and Ibn Rushd were cited by Chaucer for the same reason that European medical schools used their textbooks and Western scholars regarded them as medical authorities for centuries. First discovering, then translating, and finally adding to the Greco-Roman heritage that Europe had lost, medieval Arab physicians laid the foundations for modern medicine and created some of its institutions.

By the middle of the fifth century C.E. a series of barbarian invasions had caused the collapse of the Roman Empire in the West. While Europe stagnated in the wake of this onslaught, Islamic civilization rose in the east. Islam’s birth and the period of political expansion that followed led to a period of sustained progress and development in all branches of learning. The Arab conquerors not only achieved political supremacy but also assimilated the cultures of their subjects. Muhammad’s insistence that the Koran be studied only in Arabic meant that a single language brought together peoples from the Rann of Kutch, a salt marsh in northwestern India, to the Pyrenees, the mountain range that divides Spain from France. Arabic rapidly became the language of

literature, art, and science as well as the common tongue of learned men.

Medicine was the first of the Greek sciences studied by Islamic scholars. Following the conquest of Persia in 636, Arab rulers gave active encouragement and support to the great medical school at Gundishapur, the old Sassanid capital in what is now southwestern Iran. For 200 years Gundishapur was the greatest center of medical teaching in the Islamic world. There Islamic physicians familiarized themselves with the works of Hippocrates, Galen, and other Greek, Roman, and Byzantine physicians. At the same time they were exposed to the medical knowledge of Persia, India, and China.

Recognizing the importance of translating Greek works into Arabic to make them more widely available, the Abbasid caliphs Harun al-Rashid (r. 786–809) and his younger son, al-Mamun (r. 813–33), established a bureau of translation in Baghdad. The most important of the translators was Hunayn ibn Ishaq al-Ibadi, who was reputed to have been paid for his manuscripts by their weight in gold. He and his team of translators rendered the entire body of Greek medical texts, including all the works of Galen, Oribasius, Paul of Aegina, Hippocrates and the *Materia medica* of Dioscorides into Arabic by the end of the ninth century.

Muslim medical practice was primarily based on the Greek physician Galen’s concept of humors and their role in health. This theory held that the human body is made up of the same four elements, which constitute the entire world—earth, air, fire, and water. These elements could be combined in various ways, and the mixtures in turn gave rise to different human temperaments and humors, or body fluids. Galen identified the four humors that govern the human body as blood, phlegm, yellow bile, and black bile. When the body’s humors are in their correct proportions, a person is healthy. Sickness, the absence of health, was not thought to be due to supernatural forces but instead caused by an imbalance among the humors. This imbalance could be corrected by a skillful doctor.

While the development of uniquely Islamic clinical medicine was delayed by the monumental task of translation that went on in the ninth century, major advances were being made in other health-related fields. Harun al-Rashid established the first Muslim hospital at Baghdad in about 805. Within a generation, 34 more hospitals had been founded throughout the Islamic world.

Islamic hospitals (*maristans*) bore little resemblance to their present-day European counterparts, but their basic purpose served as the prototype on which the modern hospital is based. The sick entered expecting to be tended and cured by physicians who were masters of the art of healing. Doctors saw the *maristan* as an institution devoted to the promotion of health, the cure of disease, and the expansion and dissemination of medical knowledge. Medical schools and libraries

were attached to the larger hospitals. Students heard lectures and saw demonstrations given by chief physicians and surgeons, who expected them to apply that knowledge at the bedside. The hospital authorities then examined the medical students and issued diplomas.

Special wards were set up for men and women, each furnished with its own dispensary. By the 11th century traveling clinics staffed by hospital physicians brought medical care to those too distant or too sick to come to the hospitals themselves. Like hospitals, the practice of pharmacology also flourished in Arab countries in the medieval period. Islam teaches that Allah has provided people with natural remedies to cure their ills. People in turn are obligated to discover and use these remedies with skill and compassion. Several pharmacological treatises were composed in the medieval period, beginning with those of Jabir ibn Hayyan (fl. 776), the father of Arab alchemy.

The Arab pharmacopoeia was extensive and gave detailed descriptions of the geographical origins, physical properties, and methods of application of all substances found useful in the cure of disease. Arab pharmacists (*sandloni*) introduced a large number of new drugs to clinical practice, among them senna, camphor, sandalwood, musk, myrrh, cassia, tamarind, nutmeg, cloves, aconite, ambergris, and mercury. The *sandloni* also compounded syrups, juleps, aldehydes (all originally

Arabic words), and such pleasant-tasting vehicles for drugs as rose water and orange water. They were also familiar with the anesthetic effects of *Cannabis indica* (marijuana) and hyoscyamine, both when taken in liquids and inhaled.

By al-Mamun's caliphate, pharmacy was a profession practiced by highly skilled and trained specialists. Pharmacists were required to pass examinations in order to be licensed; they were then monitored by the state. At the start of the ninth century the first privately owned and operated apothecary shops were opened in Baghdad. Pharmaceutical preparations were manufactured and distributed commercially in the marketplace and then dispensed by physicians and pharmacists in a variety of forms, including ointments, pills, elixirs, tinctures, suppositories, and inhalants.

Translations of at least 400 Islamic authors writing on such varied topics as ophthalmology, surgery, internal medicine, child care, and public health have survived. Medieval Arab physicians made accurate diagnoses of a large number of diseases, including bubonic plague, diphtheria, leprosy, rabies, diabetes, gout, cancer, and epilepsy. They advanced a theory of infection and introduced the practice of quarantine. Arab doctors laid down the principles of clinical investigation and drug trials. They pioneered surgical procedures for hernia and cataract, filled decayed teeth with gold leaf, and prescribed spectacles for defective eyesight.

There were many important medical practitioners in the medieval period. Abu Bakr Mohammed ibn Zakariya ar-Razi (ca. 865–between 923 and 935) was known to the West as Rhazes. He is regarded as the greatest clinician and most original thinker in the field of Islamic medicine. A prolific writer, he wrote some 237 books, about half of them on the topic of medicine. His treatise on the diseases of childhood led some historians to regard him as the father of pediatrics. He was the first-known medical authority to identify hay fever and its cause. He also wrote important works on kidney stones, smallpox, measles, and the introduction of mercury-based ointments as the basis of experimental medicine. He also called for “continuing medical education” for licensed physicians.

Abu Ali al-Husayn bin Abdullah ibn Sina was known in the medieval Western world as Avicenna (980–1037). His contemporaries called him the “Prince of Physicians.” He compiled the monumental *Al kanun*, or the *Canon of Medicine*. More than a million words in length, it represented a codification of all existing medical knowledge. The *Canon* stressed the importance of adequate nutrition and the influence of climate and environment on health. It included discussions of rabies, hydrocele (a collection of fluid in a saclike body cavity), breast cancer, tumors, childbirth, and poisons and their treatment. Ibn Sina differentiated the symptoms of meningitis (inflammation of the membranes covering the brain) from the symptoms of other acute diseases and de-

Outdoor scene of a mad dog biting a man from an Arabic translation of the *De materia medica* by Dioscorides (Freer Gallery of Art, Smithsonian Institution, Purchase, F1953-91)

scribed chronic nephritis (inflammation of the kidneys), facial paralysis, gastric ulcers, and the various types and causes of hepatitis (inflammation of the liver). He also described the dilation and contraction of the pupils and iris of the eye and their diagnostic value, identified the six motor muscles of the eye, and discussed the functions of the tear ducts. He noted the contagious nature of some diseases, which he attributed to “traces” left in the air by a sick person. The *Canon* also included a description of some 760 medicinal plants and the drugs that could be derived from them. At the same time, Ibn Sina laid out the basic rules for conducting clinical drug trials. The *Canon* served as a medical textbook for a longer period than any other medical work.

Abu al-Qasim Khalaf bin Abbas al-Zahrawi was known to the West by his Latinized name Albucasis (ca. 936–ca. 1013). He was the greatest Muslim surgeon. Contemporary and later medieval European surgeons came to regard him as a greater authority than Galen. Al-Zahrawi produced a medical encyclopedia in 30 volumes, *at-Tasrif* (The Method of Medicine), covering numerous aspects of medicine, with particular emphasis on obstetrics, maternal and child health, and the anatomy and physiology of the human body. The largest section of *at-Tasrif* was devoted to surgery, the first independent treatise on surgery ever written. The work covers a wide range of surgical issues, including cautery, the treatment of wounds, the extraction of arrows, and the setting of bones in simple and compound fractures. Al-Zahrawi also promoted the use of antiseptics in treating wounds and skin injuries; he made sutures from animal intestines, silk, wool, and other substances; and he developed techniques to widen urinary passages and to explore body cavities surgically. He was also the first to describe the classic operation for cancer of the breast, the use of lithotomy for the removal of bladder stones, and techniques for removing thyroid cysts. *At-Tasrif* is also the first work containing diagrams of more than 200 surgical instruments. Many of these instruments, with modifications, are still in use today.

Hunayn ibn Ishaq, known in the Western world as Johannitius (809–73) wrote *Ten Treatises on the Eye*, composed in the ninth century, which demonstrated considerable advancement in knowledge of the eye and its workings over Greco-Roman treatises on the same subject. It also accurately described the way in which the retina of the eye inverts images.

Ammar ibn Ali al-Mawsili (fl. ca. 900) specialized in eye care. His only surviving writing discusses 48 eye diseases. The book also describes surgical instruments for use in eyes, including a hollow needle that could remove a cataract from the eye by suction. This hollow tube is mentioned by later ophthalmologists. The removal of a cataract by suction with a hollow needle was observed by the oculist and historian Ibn Abi Usaybi in about 1230 in the famed Nuri hospital in Damascus. A high degree of surgical and diagnostic skill was displayed in al-Mawsili’s treatment of trachoma, the major cause of blindness in the medieval period, and the disorders that sometimes followed it. Treatment consisted of scraping the interior of the eyelid with a selection of scrapers. Intricate surgical procedures were used for dealing with trichiasis (superfluous or ingrown eyelashes) and entropion (rolled-in eyelids).

Ala-al-din abu al-Hassan Ali ibn Abi-Hazm al-Qarshi al-Dimashqi, known as Ibn al-Nafis (1213–88), was a Syrian-born physician practicing in Egypt, where he was chief of physicians at the Mansuriya Hospital. Some diagrams and a treatise that he had written were rediscovered in Berlin in 1924. These documents demonstrated that Ibn al-Nafis had described the pulmonary circulation of the blood some 300 years before William Harvey.

**ON FRACTURE AND CONTUSION OF THE THIGH AND THE NOSE**

The case of a broken thigh is analogous to that of the arm, but in particular, a fractured thigh is mostly deranged forwards and outwards, for the bone is

naturally flattened on those sides. It is to be set by the hands, with ligatures, and even cords applied, the one above and the other below the fracture. When the fracture takes place at one end, if at the head of the thigh, the middle part of a thong wrapped round with wool, so that it may not cut the parts there, is to be

applied to the perinaeum, and the ends of it brought up to the head and given to an assistant to hold, and applying a ligature below the fracture, we give the ends of it to another assistant to make extension. If it is fractured near the knee, we apply the ligature immediately above the fracture, and give the ends to an assistant, with which to make extension upwards; and while we put a ligature round the knee to secure it, and while the patient lies thus, with his leg extended, we arrange the fracture. Pieces of bone which irritate the parts, as has been often said, are to be taken out from above; and the rest of the treatment we have already described in the section on the arm. The thigh gets consolidated within fifty days. The manner of arranging it afterwards will be described after delivering the treatment of the whole leg.

The under part of the nose being cartilaginous does not admit of fracture, but it is liable to be crushed, flattened, and distorted; but the upper part being of a bony substance is sometimes fractured. . . .

When, therefore, the nose is fractured in its under parts, having introduced the index or little finger into the nostril, push the parts outwards to their proper position. When the fracture is of the inner parts this is to be done with the head of a probe immediately, during the course of the first day, or not long afterwards, because the bones of the nose get consolidated about the tenth day. But they are to be put into the proper position with the index-finger and thumb externally. In order to prevent the bones from

changing their position, two wedge-like tents, formed of a twisted rag, are to be applied, one to each nostril, even if but one part of the nose be deranged, and these are to be allowed to remain until the bone or cartilage gets consolidated.

If the nose become inflamed we may use some anti-inflammatory application to it, such as that from juices [diachylon], the one from vinegar and oil, and such like; or a cataplasm of fine wheaten flour boiled with manna or gum may be applied, both for the sake of the inflammation and in order to keep the nose in position. When the nose is distorted to either side, Hippocrates directs us, after it has been restored to its proper position, to take a piece of leather of a finger's breadth, and having spread one of its ends with taurocolla or gum, to fasten one extremity of it on that side of the nose to which it inclines, and after it dries to bring the thong by the opposite ear to the occiput and forehead, and to fix the other end of the thong firmly there, so that the nose being drawn sideways may take the proper position in the middle. This practice, however, is not much approved of by the moderns. If the bones of the nose are broken into small pieces we must make an incision or enlarge the wound, and having removed the small bones with a hair forceps, unite the divided parts with sutures, and use the applications for recent wounds and those of an agglutinative nature.

### *The Islamic World*

#### ≈ *Ibn Sina (Avicenna): Excerpt from "On Medicine" (ca. 1020)* ≈

Medicine considers the human body as to the means by which it is cured and by which it is driven away from health. The knowledge of anything, since all things have causes, is not acquired or complete unless it is known by its causes. Therefore in medicine we ought to know the causes of sickness and health. And because health and sickness and their causes are sometimes manifest, and sometimes hidden and not to be comprehended except

by the study of symptoms, we must also study the symptoms of health and disease. Now it is established in the sciences that no knowledge is acquired save through the study of its causes and beginnings, if it has had causes and beginnings; nor completed except by knowledge of its accidents and accompanying essentials. Of these causes there are four kinds: material, efficient, formal, and final.

*(continued)*

(continues)

Material causes, on which health and sickness depend, are the affected member, which is the immediate subject, and the humors; and in these are the elements. And these two are subjects that, according to their mixing together, alter. In the composition and alteration of the substance which is thus composed, a certain unity is attained.

Efficient causes are the causes changing and preserving the conditions of the human body; as airs, and what are united with them; and evacuation and retention; and districts and cities, and habitable places, and what are united with them; and changes in age and diversities in it, and in races and arts and manners, and bodily and animate movings and restings, and sleepings and wakings on account of them; and in things which befall the human body when they touch it, and are either in accordance or at variance with nature.

Formal causes are physical constitutions, and combinations and virtues which result from them. Final causes are operations. And in the science of operations lies the science of virtues, as we have set forth. These are the subjects of the doctrine of medicine; whence one inquires concerning the disease and curing of the human body. One ought to attain perfection in this research; namely, how health may be preserved and sickness cured. And the causes of this kind are rules in eating and drinking, and the choice of air, and the measure of exercise and rest; and doctoring with medicines and doctoring with the hands. All this with physicians is according to three species: the well, the sick, and the medium of whom we have spoken.

## ► household goods

### INTRODUCTION

When archaeologists study a site, they often are especially interested in the household goods used by people in their daily lives. Although great fortifications, tall city walls, and elaborate palaces have their appeal, learning about what people

used just to get from one day to the next has its own powerful fascination. Furthermore, household goods can tell archaeologists much about a culture. For instance, finding nearly identical furniture at different sites could suggest that they had a culture in common. Household goods can indicate how prosperous people were and how well people benefited from their governments and natural resources.

This is not a simple matter. One might look at the paucity of household goods in some medieval central African cultures and infer that the people were poor, even miserable, yet this was not the case. The paucity of household goods in those cultures stems more from a lack of interest in material wealth. A fancy pot might be displayed by some people to show off their status, but in general people were more interested in building good relationships in families and villages than in acquiring furniture; they saw wealth as an accumulation of social debt, a matter of befriending others so that they owed favors in return. Children and respect mattered much more than goods. To those people, they had a high standard of living in which material goods mattered little.

Household goods would vary according not only to social attitudes toward what constituted wealth but also to environment. In medieval Europe chairs in the north were made primarily of oak, but in the south Alpine pine prevailed. This meant that northern chairs tended to be heavily carved, because oak was a hard wood, but southern chairs were more likely to be painted, because pine was a soft wood that did not hold carved edges as well as oak did. In each case, the chair could be sturdy, serviceable, and attractive, with the difference in decoration a matter of which wood was available rather than a cultural preference.

Social conditions could have a strong effect on the particular household goods people used. In much of Australia and North America people were hunter-gatherers moving from place to place. They knew where to go at different seasons to find certain ripe fruits or fresh birds' eggs, and they also knew where to go to obtain water during a drought or to escape a wildfire. The key aspect was that they moved often, sometimes daily. Their goods had to be what they could carry. Thus baskets were of special importance, because they were lightweight and could be used for fetching food. Bags of animal skins or tree bark could be sewn into bags for carrying weapons, body ornaments, totems, or objects that indicated status within a social group.

Furniture tends to be more common among settled groups than unsettled ones. Medieval Australians were unlikely to carry wooden benches with them. On the other hand, portable tables and chairs were common in medieval Europe, especially in the early centuries of the medieval era. Some archaeologists interpret the portable furniture as signs

that Europe was unsettled at the time, with people moving often because of war or other social upheavals, but portable furniture could have been just a convenience. In a medieval European home a table that could be assembled at mealtime and disassembled and set aside later meant that the center of the main room could be open for use most of the time. Folding chairs in medieval homes also could be put out of the way when not in use. Monarchs who traveled their lands to meet with people frequently used folding chairs as mobile thrones. Thus, the furniture could be a sign of unsettled daily lives, or it could be a sign that the material wealth of people was improving enough that they could afford something that they wanted just because it was convenient to use.

Cooking and eating utensils offer similar complexities of interpretation. Were the peoples of eastern Asia living primitive lives because they often used two sticks to eat their food? Even emperors used chopsticks. More interesting is to examine the interplay between what was eaten and the utensils used to prepare and eat it. In the case of chopsticks, it is possible that their use inspired a culinary tradition in which meats and vegetables were cut into bite-sized bits, easy for the chopsticks to grab. In its turn, that may have created a need for cleavers and sturdy knives for cutting food when preparing it. Thus, the pleasure in studying cooking and eating utensils may lie not in what they may say about the wealth of those who used them but instead in the complex interplay of the utensils in eating habits, food sources, and techniques of preparation of food.

## AFRICA

BY BRADLEY SKEEN

Because of the relative remoteness of the areas involved and the wide dispersal of the remains to be studied, archaeological excavations concentrating on the Middle Ages have been comparatively rare in Africa away from the homelands of the ancient civilizations of the north coast and Nile Valley. For this reason archaeologists have spent little time on the remains of ordinary households compared with important monuments and significant works of art. Nevertheless, some idea of the range of household goods employed in medieval Africa can be made out from the archaeological record as well as the oral historical traditions of modern-day African peoples.

In Egypt before the Islamic conquest (mid-seventh century), ordinary household items would have differed little from other parts of the Roman Empire. Household implements would have been made of iron or bronze. The main kind of ceramic jar in use for storage of olive oil, wine, and many kinds of materials (including, for instance, carpenter's

*Pottery jug in human form, Wadi Sarga, Egypt, fifth to seventh centuries* (© The Trustees of the British Museum)

nails) were amphorae, elongated jugs with pointed bottoms that could not stand on their own but would fit into special racks that every house possessed. Various kinds of woven baskets and wooden trunks also would have been used for storage. In wealthier homes blown glassware would have been common.

All but the poorest households would have possessed written materials. Books were handwritten and usually took the form of a scroll. Notebooks, on the other hand, would have been bound like ordinary modern books. Loose sheets were also commonly used for writing letters and other brief documents. Scrolls usually were stored in round leather cases. Papyrus, made from reeds native to Egypt rather than linen or wood-pulp paper, was the standard writing material. Pens were also made from papyrus reeds by trimming them with a penknife. Small ceramic oil lamps, which were mass-produced in molds and usually highly decorated, provided light. In Greek- and Latin-speaking households the inhabitants ate dinner lying down on couches arranged in a square with the servers in the middle. In the countryside farmers would have kept their agricultural tools in their homes, but in the cit-

ies where apartments and houses would have been detached from workshops and shops, tools needed for work would not have been household objects.

Ironworking was well advanced in medieval Ethiopia, and many ordinary items (bowls, knives, and so on) were made of this metal. Bronze items continued to be in common use. In particular, precious metals as well as copper and bronze were used for decorative items like jewelry. Coins were minted in Ethiopia and were sometimes of a highly unusual type—bronze flans (the disk of metal used for coins) inlaid with gold or silver details. Ivory and bone were also carved into decorative objects.

Many people in Ethiopia lived by herding cattle, and whether the custom ultimately derived from the goads used to drive cattle or from a history of contact with ancient Mediterranean cultures, men of elite status in northwestern Africa typically carried walking sticks to denote their place in the social hierarchy. Ordinary domestic pottery used for cooking and storage was made of coils of clay that had been crafted without the use of a potter's wheel. However, wheel-made pottery from Egypt that had originally been used to ship wine or olive oil as trade goods was sometimes reused for storage.

To judge by the ideas of modern-day Igbo people (in Nigeria and Cameroon) about their own traditions, family compounds (where family members lived, segregated by gender) within medieval Igbo towns and cities would have contained iron knives, hoes, and other agricultural implements, and, in the case of aristocratic households, metal bells and staves as signs of the household head's elite status. By the year 1000 ironworking had become widespread in western Africa. Wooden shrines, statues, and masks and costumes (worn by men during religious festivals) of local divinities would have been kept throughout the compound. Wooden furniture would have included three-legged stools carved with elaborate decoration. Many houses would have had musical instruments. Other signs of status could have included elephant tusks, usually plain or with only the simplest carving, as well as ivory jewelry, such as bracelets and anklets. Besides a large array of pots, bed frames would also have been ceramic. Animal skins would have been displayed for decorations or sometimes made into seat cushions. Fans and fly whisks seem to have been limited to the male compound.

A royal burial from the 10th century in Igbo-Ukwu (in present-day Nigeria) contained, besides copper royal regalia, a copper fan holder and a wooden stool decorated with copper, which may have served as the royal throne. Elite status was demonstrated by using metal for purposes that cheaper materials served in ordinary households. This burial also contained sophisticated cast-bronze miniatures of human and animal figures that are actually typical of medieval west-

ern Africa, but these were probably limited to the possession of elite classes. While copper was worked locally, there was a special demand among the elite classes of western Africa for imported copper goods of all kinds as well as for imported iron knives. Copper bowls and washbasins seem to have been especially sought after. Their foreign character was a status symbol. Cowrie shells were also traded from the coast and used extensively both as a decorative material on household items and as a form of currency.

After about 1000 copper working and ironworking became more common throughout the vast region of the African interior, the watershed of the Congo and Zambezi rivers, and the lake regions in the Great Rift Valley, conditioning the introduction of new types of household goods in the Middle Ages. The area best studied by archaeologists has been the Upemba depression (modern-day southeastern Republic of the Congo). The common practice of burying people with grave goods—items representative of the kinds of objects they used in life—is helpful in determining the material culture of this region. Based on the disparity in grave goods found between individual burials, after the year 1000 society seems to have become stratified. The most common buried objects are ceramic pots, and graves that have many more pots also have imported cowrie shells and carved ivory jewelry. Water and alcoholic beverages were stored in long-necked flasks or large storage vessels with a capacity of more than 4 gallons. Food was cooked in ceramic vessels of various sizes that were shaped either like a cauldron or like a wok as well as others that included lids. The so-called *yanko* was similar to the woklike vessel but with holes for drawing in smoke for curing meat or fish. The same types of vessels were used for temporary storage. Clay pots were made from coils rather than thrown on the potter's wheel.

The mountains in Shaba Province in the modern-day Congo and its vicinity are one of the richest copper-producing areas on earth, and copper was extensively used in this region. Small cross-shaped copper ingots are commonly found among grave goods; ingots were sometimes bundled together in bunches of five and probably were used as a form of currency. Elite graves contained copper bowls, jewelry, knives, belts, and other paraphernalia that would have been made of clay, iron, or nonmetallic perishable materials (such as plant fibers) in ordinary households. Tools used in agriculture and hunting, such as spearheads, knives, arrows, hoes, and axes, were typically made of iron. Iron objects such as anvils and bells are extremely rare and seem to have been buried only with the most powerful individuals. Other common goods include woven baskets of considerable sophistication.

The typical medieval household goods of the Bambala people, also from the upper Congo region, have been recon-

structed—partly on the basis of archaeology, partly on the basis of the present-day lives of Bambala living in isolated areas and preserving archaic ways of life, and partly on the communal memory of the people as a whole. The Bambala, like most Africans, lived by a combination of farming and hunting and so would ordinarily have possessed the tools necessary for both activities, including knives of various sizes, a hatchet, an adze, a hoe, mortars and pestles, grinding stones, needles, a wood chisel, a throwing spear, a bow and arrows (including poisoned arrows), snares, and a *mvúndji*, a sharp blade used for scraping animals skins but also for use in minor surgical operations such as circumcision.

Each house would have had many baskets; some were made from woven fibers or bamboo, and others were made from wood. Baskets would have included specialized types for storage, for winnowing grain, and as strainers, fishnets, rattraps, and lunch boxes (usually an hourglass shape). Ceramic jugs of various sizes were used for storing, transporting, and drinking water. Cookware was also ceramic. The size and shape of pot depended more on the age and gender of the person who would have consumed the food prepared in it rather than the type of food cooked. Ceramic plates were used only for children. Dry gourds were used to collect sap from palm trees and for storing dried food. Woven mats covered the earthen floors of dwellings. Chairs were often simply sections of logs, while bed frames were made of wood or bamboo.

Great Zimbabwe was a ceremonial site of the Shona people of southern Africa (in modern-day northeastern Zimbabwe) whose rulers concentrated considerable power in their hands from control of a gold trade with the Muslim cities of the Indian Ocean coast. In the late Middle Ages (ca. 1450) the population soared to as much as 18,000, and the most elaborate architecture in the interior of Africa was developed, but the site quickly collapsed owing to lack of infrastructure and other factors. Because of defects in the excavation of the Great Zimbabwe site, not much can be directly demonstrated about the lives of the ordinary inhabitants who lived in huts outside the massive stone walls, but there is no reason to suppose that their lives and possessions were very different from those of Africans in other areas. The life and possessions of the elite class that lived within the stone walls are a different matter. The range of ceramics and utensils ordinarily used in preparing food is absent within the Zimbabwe walled enclosures, indicating that those within were served by people living outside. On the other hand, fine glassware and ceramics imported from the Arab world and as far away as China have been found along with numerous gold objects within the walls, suggesting a life of luxury of the elite class.

## THE AMERICAS

BY ELIZABETH MORÁN

Throughout the Americas household goods were made to suit the specific needs of the culture from materials readily available in the environment. Cooking implements were made from wood, stone, fired clay, woven baskets, and even dried gourds. Furniture typically was fashioned from wood but could very easily have been made from stone and other materials, such as animal hides and cotton.

In the Caribbean home furnishings were spare, and cooking implements were basic and made from clay, stone, and wood. Such cultures as the Taíno (ca. 1200–ca. 1500) created stools called *duhos*, which were initially used by shamans and eventually appropriated by caciques, or chiefs. These stools were ritual in use and were seen as thrones of power. In the common dwellings people sat on the bare floor of the home or on simple woven mats made from palm leaves. Cotton hammocks were used as beds.

In the North American Southwest early cultures, such as the Hohokam (ca. 500.–ca. 1400), created adobe or caliche (dried clay) architecture, yet these dwellings would have had very little or no furniture. Floors of homes often were left bare or were partially covered with animal hides or furs. Sometimes a raised wooden bench would stand in for a bed, although most often people slept on the clean floors, wrapped in hides and furs for warmth. The heart of the home was the hearth, where family groups gathered for everyday activities,

such as cooking, eating, and socializing. Cooking tools were left near the hearth, since they were in constant use and were associated with the fire. Like the furnishings, cooking and serving utensils were made from readily available materials, such as stone and wood. The Iroquois and other eastern Woodlands peoples used the bark of elm trees to make vessels for cooking and storage. Basket weaving was an important skill throughout the Americas, and baskets were used to hold, serve, and store foods. Using a technique called twining, women on the northwest coast made baskets so tight that they could hold water. Baskets were also used to trap live animals, such as eels.

In Mesoamerica the hearth was also a central location for cooking and other activities. Painted manuscripts created by indigenous Aztec artists during the 16th century shed light on the many ways in which cooking implements were created and used. One manuscript, the *Codex Mendoza*, illustrates a mother instructing her 13-year-old daughter in the art of cooking; Spanish glosses, or brief explanations, have been added to assist the European reader with interpretation. Some of the items depicted with the mother and daughter are a metate (stone grinder), an olla (double-handled jar), a *comal* (griddle), and a small tripod bowl containing a grinder. This bowl, called a *molcajete* in contemporary Spanish (or *molcaxitl*, as the Aztec referred to it), had deep incisions on the inside for grinding substances. The *molcajete*, among many other Aztec cooking utensils, is still used in Mexico today. Other painted manuscripts illustrate large tripod vessels, baskets, and a small grinder referred to as a *mano*, used in grinding herbs. These cooking and serving utensils were homemade, locally made, or available at the markets, or they came into the Aztec capital of Tenochtitlán as part of an organized tribute system.

For both Mesoamerica and South America, where groups developed from village cultures to organized states, cooking implements varied according to class associations. Elite classes required more than basic cooking implements made from the natural environment; ceramics became highly decorative and elaborate and were in high demand by the ruling class. Classic Period Mayan (ca. 250–ca. 900) ceramics were created for both ritual and everyday use. Painted pottery gives a glimpse into the kinds of household furniture that existed in the homes of the Mayan elite. Many vessels depict ruling class members sitting on elevated seats with large cushions supporting the sitter's back. Some ceramics show individuals sitting on benches. While it can be surmised that these types of furnishings existed for the upper classes, the homes of commoners would have had much simpler furnishings, such as woven mats for seating. It is also possible that these types of furnishings were linked with ritual rather than household

Stone cup, Mixteca/Pueblo style, Mexico, ca. 900–1521 (Courtesy, National Museum of the American Indian, Smithsonian Institution [catalog number 204073])

use. In addition, Mayan ceramics illustrate many household goods and the ways in which they were used. Some ceramics show certain vessel types used for specific foods.

In pre-Columbian Panama red-and-black polychrome ceramics became important in such sites as Sitio Conte, Chiriquí, and other areas (ca. 500–ca. 1000). Like Mayan painted ceramics, these were often used as status symbols and were part of the elite trade system. Everyday drinking and eating ware was much simpler—unpainted clay and dried gourds. It should be noted, however, that recent archaeological work in the middens (refuse heaps) of commoners in Calixtlahuaca, in the Toluca valley in Mexico, has shown that what was once thought of as elite ware used by Aztec lords actually was considered “good china” by commoners and used only for special occasions. Commoners used their basic clay wares every day, while special pottery probably was reserved for special occasions, such as marriage celebrations and other events.

Some cultures, such as those in pre-Hispanic Costa Rica, used stone as a basic medium. Grinding stones, seats, and tables were made from stone found at nearby areas. In the site of Linea Vieja (ca. 850–ca. 1500), for example, many elaborately carved seats, tables, and grinding stones have been found. While these are associated with tombs and therefore ritual purposes, it is quite possible that simpler models were used in elite and common residences.

## ASIA AND THE PACIFIC

BY JUSTIN CORFIELD

Throughout Asia and the Pacific a wide variety of household goods were used during the Middle Ages. These goods varied, with extremely elaborate items being made in China, Japan, and many other parts of the region, often for sale to other less-advanced areas. By contrast, people living in Australia and on some Pacific islands had few goods beyond hunting or fishing materials.

In much of Asia houses were generally considerably larger than in the ancient world, with most of the furniture continuing to be made entirely from wood. In China hardwoods, such as rosewood, were commonly used. *Pterocarpus* woods (such as sandalwood) were used in southwestern and south-central China, with further stocks imported from Southeast Asia. These woods were used to make tables, chairs, beds, and other items of household furniture, such as cupboards, chests, and altars for family gods. The later medieval period saw increased use of lacquerware. Some of it was inlaid with mother-of-pearl; indeed, workmanship in China, Japan, and Korea became extremely elaborate. In 1029 a Chinese imperial decree ordered that red lacquer beds

be reserved for use by the emperor; most wealthy people had black lacquer beds.

In poorer parts of China and also in much of Southeast Asia, there was heavy use of bamboo for many items in the house. Wealthier homes also used bamboo for outdoor furniture and shades. Japanese and Korean furniture shared many similarities with Chinese furniture, but Japanese and Korean homes tended to be more austere in style, with far fewer items in them; the Japanese also had a variety of other items, such as armrests, neck rests, sword racks, and, in wealthier homes, writing tables. The homes of wealthy Koreans were also well known for their elaborate chests. In wealthier homes in China “medicine chests,” with many small drawers, were used for storing medicines as well as spices; poorer people kept such items in storage vessels of differing sizes.

While most Chinese, Japanese, and Korean household items tended to be made entirely from wood, some medieval Chinese chairs started being made with a cushioned seat, and bedding became softer, with the use of cushions increasing. By contrast, most chairs in wealthy Indian homes tended to be heavily lined, with the seat of the chair itself being cushioned and the back sometimes covered in cloth.

Little is known about furniture from this period in Southeast Asia because the climate has ensured that little has survived. Much of the furniture there was probably made from bamboo or softer woods, though the writings of Zhou Daguan (1266–1346), a member of the Chinese embassy in Angkor (Cambodia) in 1296–97, mention the widespread use of matting but make no mention of furniture. Many people in the Malay world, such as in the kingdom of Majapahit, slept on mats rather than on beds, and bamboo and cane were regularly used for chairs and tables.

Pottery was used in all parts of medieval Asia for domestic tasks, such as cooking food; in most places pottery also served as household crockery for soup and rice dishes. Although there is evidence of coil pots, many potter’s wheels also have been found in excavations in China and India. Much of the pottery was sun-dried, although large settlements often had kilns. There was certainly an export trade from China. Zhou Daguan mentions the existence of much Chinese pottery in medieval Cambodia. Furthermore, significant numbers of Chinese pottery remains have been found in Southeast Asia, in such places as the kingdom of Champa in central Vietnam and also on many islands, including remote ones, such as the Spratly Islands—the shards there being used by late-20th-century archaeologists to prove Chinese ownership of the islands since medieval times. A significant amount of the pottery found on Pacific islands came from Asia; the Aborigines of Australia did not use pots.

*Pillow, stoneware with white slip under transparent colorless glaze, Northern Song Dynasty, China, ca. 1056* (Freer Gallery of Art, Smithsonian Institution, Gift of Eugene and Agnes E. Meyer, F1974-2)

Besides pottery, bone china was made in some parts of Asia. Chinese-made china was used widely throughout Asia. The Japanese also ran an export industry, with kilns operating at Seto, Tamba, and Bizen. Larger pottery items, such as soy sauce pots, were also made on wheels and were often far too large to be dried in a kiln. The Chinese used china crockery for eating, and the Japanese imported Chinese ideas of pottery for use in the tea ceremony and at other festivals. Glassware was used in many parts of Asia, and glass from the Middle East was imported into parts of Asia.

Many vessels for cooking and eating were made from metal, such as the “steamboat,” around which a family would gather for a meal. Metal plates were used on ships, and iron cooking pots were used in China and other parts of Asia. Woks became increasingly common in China, and similar cooking vessels were used elsewhere, known as *penggorengan* in Indonesia, *kuali* in the Malay world, and *kawali* in the Philippines. Grills were used throughout Asia and in much of the Pacific, usually operating with charcoal fires.

Significant numbers of cooking utensils have been found throughout Asia and the Pacific. Initially, many of them were made from wood, but gradually they came to be made from metal, often with a wooden or bone handle. Wealthier Chinese and Japanese homes had chopsticks made from lacquered woodwork. In Fiji and other parts of the Pacific there were wooden forks, which became known as “cannibal forks,” and throughout Asia and the Pacific many homes used skewers to cook meat and other food. In parts of the Malay world used sticks as skewers for cooking small chunks of chicken, beef, and pork.

The Japanese often used silk-screen pictures as decorations in houses; the Chinese hung paintings on the walls. In China during the mid-13th century black and red became

the most popular colors for interior decoration, with large scrolls in either color, or occasionally both colors, dominating an entire wall. Many wealthier houses in Japan, China, and Korea had equipment for painting, which was a favored pastime; many people tried to perfect the painting of bamboo and country scenes. This practice led to the manufacturing of elaborate racks for paintbrushes, with numbers of painters preferring to make their own brushes.

Most well-to-do people in China, Japan, and Korea also had seals, or “chops,” which were used for signing official documents. Some were made from jade, with those of wealthier people having elaborate handles, often in the shape of dragons. Because these seals were important, they would often be kept in locked chests with access to them strictly controlled by the head of the household. Some wealthier houses also kept books, often in the form of scrolls, as well important legal documents.

Heavy carpets were used in parts of Mongolia and Manchuria, to try to reduce drafts as well as to decorate lodgings, often yurts, or circular, domed tents. In India carpets were also used to keep out the hot air. Around the houses in Asia there were other accoutrements needed for everyday life. There was usually a large china bowl for washing, along with soap, which was typically a liquid made from peas and herbs. Some people also had bathtubs, which in China, Korea, and Japan could be made from wood, metal, or earthenware. To warm the water, pieces of metal or stones were heated in a fire and lowered into the water. There is also an Arab reference to the Chinese in the ninth century using specially made lavatory paper and handkerchiefs to wipe their gums after a meal. Men had shaving materials, and there were also bone or wooden combs. Liquids, such as water, were stored in buckets, with fruit and other items kept in baskets made from bamboo and cloth.

Most houses in Asia also had candles or torches made from sticks dipped in tar; these were necessary to illuminate a house after dark. Wealthier people used lanterns. Opium smoking was regarded as important by many wealthier Chinese (and some Indians) and also some poorer ones, and for this purpose elaborate opium-smoking equipment was made. Because of the cost of opium and the smoking equipment, these items frequently were kept safe in a large chest, along with coins and valuable documents—the chest often weighed down by bricks before being locked, to make it impossible for a single person to carry it away. When not being worn, jewelry would also be stored in these chests.

Other household objects include trays, boxes for storing cloth or clothes, and also the equipment needed for sewing and embroidery, such as needles, thread, silk, and brocade. Fans and parasols grew increasingly popular among

wealthier Chinese and Japanese women. The vast majority of households also owned or had access to handcarts and wheelbarrows.

## EUROPE

BY KIRK H. BEETZ

At the fall of the Western Roman Empire in 476, poor Roman Europeans rarely could afford furniture. Often all they had were small metal stoves in their apartments. Those who could afford furniture lay on wooden couches while eating their meals. Their dining utensils were a knife and a spoon. Chairs were rare and usually backless. Most sitting was done on stools. It was considered an honor for a guest to be invited to sit in a chair. Furniture made from wood imported from Africa brought high prices, but most furniture was made from local wood.

To the knife and spoon people in the Byzantine Empire (330–1453) added a two-pronged fork. Byzantine utensils were usually made of copper or silver, and the spoons and forks tended to have long handles. Despite the existence of eating utensils, eating with one's hands was common. Cloths covered tables for meals. On the tablecloth were set trays and bowls of food. Jugs and glasses for serving drinks were part of everyday meals.

It seems that no everyday furniture survives from the Byzantine Empire, which means that information about it comes mostly from paintings, sculptures, and written accounts. Even the humblest of homes had some furniture, at least a heavy rectangular table of wood. Tables were sometimes round, and in large dining halls they could be U-shaped, with the host and hostess seated at the peak of the U. Most households additionally had benches and stools on which people sat for meals and for many domestic tasks, such as sewing. Sewing needles have been found at many archaeological sites. Most homes had cushions that were set on benches and chairs, and quilts sometimes covered seats of chairs. Chairs with backs often had cushioned lining on the back of the seat. Wealthy households had couches and chairs. The couches were covered by heavy cloth and cushions. Most chairs were backless; chairs with backs usually had no arms, and chairs with both backs and arms were rare. In contrast to practices in the late Roman times, chairs during the Byzantine Empire were used for everyday purposes, and sitting on a chair was considered nothing special.

The Byzantines do not seem to have had chests of drawers. Chests with lids that opened on hinges were common and were used to store household goods such as pillows and sheets. Beds were inexpensive and consisted of wooden rectangular frames with thick, square legs at their four corners. Wooden

planks were laid lengthwise on the frames. Poor people sometimes slept on floors, using rags to cover themselves. Even the poor who had beds sometimes covered the planks with only sacking. Most people had sheets, blankets, quilts, and coverlets for their beds. The quality of these depended on the wealth of the household and perhaps on the skill of the seamstresses in the household. Those who could afford them used pillows and cushions on their beds. Carpets often covered floors, and draperies with colorful designs decorated walls. Cloth hangings might have separated one part of a room from another or might have covered windows.

In most of the rest of Europe in early medieval times furniture was less common than in the Byzantine Empire. Whereas in a Byzantine household furniture might be placed throughout a room, in the rest of Europe the furniture typically was set against walls, leaving the middles of rooms open. Some historians believe furniture was made portable because during the first few centuries of the medieval era societies were unsettled by political turmoil. Additionally, having furniture that could be folded and put away would be convenient if people wanted to keep their rooms open for use most of the day. In Byzantium and much of the rest of Europe some metal chairs were designed to fold; they may have been used by officials or monarchs during their travels, perhaps to sit in while holding court. The chairs' iron mountings were

*Late Saxon Shelly ware pitcher, ca. 900–1000* (© Museum of London)

sometimes decorated with enamel and gold. Wooden chairs occasionally were made to fold, and early dining tables were apparently commonly made to be dismantled quickly to be set aside. These were usually made of heavy oak, so people would have needed strength to put them together, but legs and planks were made to slip into notches in frames. A dismantled table could be set against a wall but reassembled by a couple of people in several minutes. In most households diners sat on benches. Ancient northern tales recount how a king's thanes (feudal lords) would gather each evening at a large rectangular table, seated on what were called mead benches. They ate with their hands and with knives. Throughout the medieval era diners were expected to bring their own dining knives with them. Drinks were served in flagons, and food was served on wooden plates.

In the forms of medieval European furniture can be found evidence for the development of a culture that can reasonably be called European. For instance, the chair's basic form was the same in Sweden as in northern Italy, Ukraine, and England. Its seat was usually square; it had four legs, one at each corner of the seat; its back was upright and usually straight. Historians have traced the development of the European chair from crude, blocky seats of oak made in northern Europe through centuries of refinement, probably reflecting the increasing specialization of furniture makers. The early medieval chairs were probably made by the people who sat in them; perhaps when chairs could be made by specialists, the chairs became more artful, with their builders developing ever more sophisticated joints for fitting the parts together.

This is not to say that chairs looked exactly alike; there were many variations on the basic form. One variation had appeared between chairs of the north and chairs of the south by the age of Charlemagne in the late eighth century. The variation was caused by the wood that was available. Oak was readily obtainable in the north, but pine trees were more common in the south. Oak is a hard wood that holds its shape well when it is carved, so chairs in the north were carved with sharp images of plants, animals, columns, or intricate interlacing lines. Pine is a softer wood that does not hold carved designs as well, so chairs in the south were more likely to be painted with designs.

In a kitchen during the era of the emperor Charlemagne (r. 800–14) were a hearth, salt basins, and bread bins. Iron pots and cauldrons were placed over the fire. Wooden utensils were used in the kitchen to mix food, stir pots, and serve food. Although most plates were wooden, plates of lead were common. Bowls for serving food were made not only of wood and lead but also of iron and tin. Ceramic jugs, pitchers, and bottles were used to serve drinks. Some ceramic pots were probably set in fires to cook their contents. A thick, rounded pot was used not for food but to store money. Among well-to-

do people were vases made of silver, gold, horn, maple wood, and even marble.

Perhaps more common than tables by the middle of the medieval era was the chest. Europeans had been experimenting with chests for a long time, finding ways to fit them into the routines of households. Early medieval chests were often logs with a hole dug into them. The development of the plank chest made for lighter chests with more interior space; these consisted of frames of planks covered by a hinged lid of planks bound together by strips of iron. By the 1300s a chest with a rounded lid had developed, as had the clamp-fronted chest, in which its well-carved parts were fixed in place by wooden pegs.

Another development was the box chair. Originally a low chest, this was given a back and sometimes arms. It gets its name from the boxy chest among its legs. Originally rough contraptions, box chairs became elegant parts of households. The seat might have hinges at its back, allowing it to be raised to give access to the interior, or the front of the box might be hinged, allowing it to drop open to give access to its insides. Inside could be cloth, blankets, pillows, or other goods. Chests also were used like benches, perhaps set under a window so that someone could sit in the sunlight. They might be covered with cushions or soft fabrics. Very much in demand were dowry chests. By the 1300s these were available in various sizes, often large and heavy; a premium was placed on chests that were light, made either of light wood or of thinly cut wood. They were painted in rich colors.

An English home in the 1000s had tablecloths, cushions for seats, and mostly wooden plates and platters. The variety of drinking vessels suggests a strong interest in drinks. Most cups were made of ash, but others were made of horn or metal fashioned to look like horns. These were often decorated with carvings or moldings, as were goblets and tankards. Although there were spoons and knives for preparing food, the typical table was not placed with eating utensils; people ate with their hands or with the knives they brought with them. Meals frequently were served on a piece of bread, which made them easier to eat with limited utensils. By this time candlesticks were common, as were tapestries to cover walls. Although modern people might admire the beautifully finished wooden walls of many medieval homes, through the 1500s people generally preferred to cover the walls with tapestries that gave warmth to a room.

By the late medieval era a well-equipped kitchen had pots and pans with long handles, mortar and pestle, tongs, and utensils for stirring, including whisks made of bunches of twigs. The kitchen in a town or city probably did not have an oven, just a hearth. When a cook had something to bake, the cook took it to a baker or to a specialist, such as a pie maker for

baking pies. Boiling and roasting were the preferred methods of cooking. Pewter plates were common by the 1400s.

By the 1200s beds had mattresses and were covered with sheets, blankets, coverlets, and pillows. Curtains were hung from the ceiling to surround the bed, and the bed usually was provided with a lamp, allowing a person on the bed to read in privacy. A wooden cradle was placed within arm's reach of the bed so that those in the bed could rock it without getting up. The main room of a house was typically the dining room, where much of a day's activities took place. It would have an oaken table, one or more chests probably topped with cushions, a chair, and small, low stools. There was often a livery cupboard to store drink and food.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

The medieval Islamic world encompassed not only a vast territory but also a broad variety of cultures, each of which had its own variations on the basic furnishings of a household. The taste of the Arabs of the early Islamic world tended toward such furnishings as those found in the pavilions of nomadic camel herders. A typical house had few wooden or metal furnishings, except for bookshelves and cupboards. Muslims generally regarded literacy with reverence because it was through the written word that Muhammad communicated with them after his death, and a bookshelf would have had a prominent place in a home. Its contents might include a copy of the Koran and copies of the Hadith (accounts of Muhammad's life and sayings), scholarly guides to the Koran and the Hadith, books of poetry, and books of geography.

Most household life took place low, near to or on the floor. A house in a city usually had two stories and an enclosed courtyard, often with rooms for receiving guests that were separate from the quarters where the home's women and children lived. Often people who had low incomes, especially in small towns and villages, would have large curtains or drapes that they could pull across the courtyard to divide it or to divide a large room; on one side would be the women and the children, and on the other would be the male guests and their host. Even in houses where the women and children could be sent upstairs or the guests could be entertained in a separate room, curtains and drapes were common as wall coverings.

Floors were covered by carpets. Rooms typically had an abundance of cushions and mattresses placed near walls or arranged around an eating space. When a person sat, he or she usually sat on a cushion or a mattress. Some homes had sofas, which were low to the floor and covered with cushions.

Occasionally a home had chairs. These could be low to the floor but sometimes were higher. The purpose of chairs was to establish social dominance. The person who sat in a chair sat higher than those who sat directly on a rug or on cushions, symbolizing his superior status. He might be the head of a large extended family or of a clan, or he might be a high-ranking religious or government official. Often when a person wished to show his superior status, he did not use a chair but instead sat on a pile of pillows that elevated him above others who were seated in the room.

Dining tables were made of wood and were very low to the floor because diners sat on or near the floor. Very often no table was used, and dinner was served on a rug. Meals were served on large, circular trays of copper or silver, placed on the floor or on small wooden stools. Poor families might use wooden trays instead. Although city dwellers of the Near East would have been familiar with eating utensils, most eating was done with the bare right hand. Using the left hand was insulting to the others who were present because the right hand was traditionally the clean hand. This custom was common not only among Arabs but also among Indians and people of northeastern Africa. Knives were used for cutting meat, and spoons were used for eating soup. Usually people did not have their own plates but ate directly from the serving trays; however, they would have had their own soup bowls and drinking glasses. Most city households had bowls and glasses of porcelain, glass, or crystal, which might be imported from as far away as China. Eating was expected to follow a friendly decorum, and gluttony was frowned upon.

Of importance to most Muslim households was a cooking cauldron. Much of a family's food was boiled, and soups prepared in a cauldron were especially important because they represented the family's unity. Sharing soup from the cauldron was almost a ritual, binding each family member to the others. This practice was taken to extreme in the Ottoman Empire (1281–1924), where each barracks of janissaries, or elite soldiers, had its own symbolic cauldron and regiments of janissaries carried cauldrons into battle; the loss of a regiment's cauldron was considered to be very dishonorable. The cauldron seems to have been intended to represent to the janissaries their status as a family of soldiers.

Beds were a sign of wealth and social status. The poor often slept on bare floors. Most people had mats or rugs on which to sleep, and a woven carpet could be used as a blanket. A bed with legs and a frame was very desirable and was a sign of a well-to-do family. In general, the more comfortable the mattress and coverings, the higher the status they indicated. Bedrooms often included grooming supplies, such as scent bottles and wooden combs.

*Table, molded, pierced, and glazed ceramic; Syria, late 12th to early 13th centuries* (Los Angeles County Museum of Art, The Madina Collection of Islamic Art, gift of Camilla Chandler Frost, Photograph © 2006 Museum Associates/LACMA [M.2002.1.18])

Households outside urban areas tended to have fewer goods than households in cities had. Nomadic herders lived much as their ancestors had lived, with their tents furnished in rugs and cushions. In farmhouses furniture was unlikely to be found. Curtains and draperies were common, and seating was usually directly on a rug or the bare floor. Cooking utensils consisted of knives and spoons. City homes often had no oven, so food that required baking would be taken to a bakery to be cooked, but in the countryside homes were more likely to have ovens. Both city and rural homes tended to have braziers in which coals were burned to heat the homes in cold weather. Rugs could be replaced with mats of rushes in hot weather.

Rural areas were more likely than cities to retain the customs of their region from before it was conquered by Muslims, but the customs could long linger in cities, too. For example, after seizing control of the Byzantine Empire's lands in North Africa and the Near East, many Arabs had difficulty shifting from the life they had known in Arabia to a life as part of a huge Islamic empire, and to adjust, they often imitated

the lives of the people they conquered. Further, those people who converted to Islam often preferred to continue to use the furniture and household wares that they had grown up using. The many people who lived in the Islamic world but kept their old religious faiths also frequently continued with the traditions of their ancestors, behind the high, blank walls typical of houses in cities of the Islamic world. The customs of the Byzantine Empire and of the peoples of India were particularly influential.

Wooden furnishings were much more likely to be found in households of the former Byzantine Empire and in India than in other parts of the Islamic world; however, as time passed, households in Egypt and the rest of North Africa lost much of the Greco-Roman influence on furnishings, except for special items, such as thrones. During the first several centuries after the Muslim conquest of the Near East, furniture often included couches, chairs, storage chests, beds, and cooking and eating utensils similar to those used by Byzantines. Chairs were often backless and piled high with cushions. Chairs with backs were upholstered with textiles, such as quilts, drapes, and woolen cloth. These were found in wealthy households. In the residences of aristocrats and monarchs, chairs sometimes had symbolic value because the head of the household could sit on a chair and use it like a throne while receiving guests or emissaries. Wood was abundantly available to people in the northwest of the Near East, with much wood for furniture coming from eastern Europe and the Byzantine Empire. Having to import wood from Anatolia may be one reason why Egypt more fully adopted Arabian customs in furnishings than did people in the northern Near East.

In northern India, Islamic and Indian cultures had formed their own unique blend by the end of the medieval era. Much of the early rule of Muslim invaders was oppressive, featuring the desecration of holy sites, the destruction of temples, and the burning of entire cities. However, one of the duties of a Muslim ruler was to build monuments to his faith, and most of the workers available were local Indians long versed in Greek and Indian styles. One result of this situation seems to have been the infiltration of Indian furnishings into Muslim homes—part of the process that gave Islam in India its unique flavor.

As elsewhere in the Islamic world, there were differences between rural and urban households. In rural Islamic India households had few furnishings, and people usually sat on the floor. What furniture there was tended to be wooden, bamboo, or rattan, with wood usually reserved for the frames of beds. Beds could be fairly comfortable, standing on four legs of wood or bamboo, with a wooden or bamboo framework. Across the frame were crisscrossed cords that stretched diagonally. A person might sleep directly on the cords, but matting or cloth could cover the cords. Homes often had small

tables of rattan on which trays were placed. Those households that remained Hindu took care to use pots of metal or earthenware for cooking but not for serving food because once something had been used to serve food, it was impure and had to be broken and disposed of. Thus, meals were typically served on banana leaves. Sometimes cheap pottery was used and then broken—a practice that kept potters busy. On the other hand, Muslims followed more general Islamic customs, eating off trays. It was already traditional among Indians to eat only with the right hand.

In cities many imported goods were available. Wise sultans took advantage of India's geographical location between the Far East and the Near East by keeping trade routes open and respecting merchants. A typical room in a city home might have a wooden bench and an ample supply of cushions on the bench and on the floor. A room in a well-to-do household would have had rugs on its floors. Most rooms had walls decorated with hanging textiles featuring beautiful designs of plants and animals, made in Iran, central Asia, or India. A bedroom would have contained a bed with a wooden or bamboo frame with its stretched cords holding a soft mattress, along with pillows for both head and feet. The room also would have contained a small table to hold toiletries for men or women. A well-appointed bedroom would have had a sofa as well.

## ► hunting, fishing, and gathering

### INTRODUCTION

During the medieval era people pushed ever deeper into what had been wild lands. In heavily populated regions such as China, wild lands were converted to agriculture and settlements to such an extent that wild lands survived primarily in areas that were inaccessible to loggers and unsuited to agriculture. By and large people improved their hunting skills and their hunting weapons, allowing them to kill game more frequently and with more certainty. In the realm of fishing, methods tried and true for thousands of years prevailed among many cultures, but the great fishing fleets of Japan and al-Andalus already presaged a future of massive harvests of fish often from far beyond sight of land.

To look at the hunting, fishing, and gathering practices of the medieval world is to be impressed by its profound importance to almost every community, from tiny bands of nomads in central Australia to cities of sophistication with all the modern conveniences, such as Baghdad. People depended on wildlife for food, for clothing, for medicines, and for religious ceremonies. There was a remarkable similarity in the gear of hunters from place to place and time to time. The bow and arrow and the spear were used in the Americas, in Oceania, throughout Asia, in Africa, and in Europe. There were variations. The bows of the Mongols were small and light but were composite bows made of different woods that when combined gave them unusually great power. In Japan, bowmen used small bows that fired arrows rapidly.

Other sorts of skills and techniques appeared even in remote lands. The Australians had a spear-thrower, a device in which the end of a spear is placed and from which the spear may be flung with an overhand motion with great power and accuracy—enough to fell prey hundreds of yards away. There is evidence that ancient North Americans had a similar device, and perhaps medieval North Americans used it to help kill large prey. In Africa, South America, Australia, and parts of southern Asia wilderness cultures developed blowpipes. These could send darts quickly to kill small prey such as mon-

keys and squirrels. Many disparate peoples independently hit upon this idea, and some also thought of poisoning the darts to help in the hunting down of large animals.

It seems that everywhere people went, they altered the landscape. In some cases they ravaged the land with no sense of conservation. In areas such as Easter Island the results were catastrophic—the turning of wild land into wasteland. Still, during the medieval era many cultures prospered within wild environments. They did so through centuries of social adaptation. In North America this manifested in the custom of allowing forest lands to go without being hunted for a period of years, allowing them to repopulate with wildlife. In South America, India, and Japan people carefully nurtured reforestation. In South America's Amazon forests people replaced fallen trees with fruit or nut trees useful to them or beneficial to game animals. In India an entire class of worker arose, whose job was to manage game and plant new trees where others were taken down. In Japan replanting the forest became a sacred duty for many people, resulting in a populous land with thick forests, which still covered much of its territory even when Europeans began to visit.

Fishing practices had a similar division of disaster and success. In medieval cultures there seems to have been a lack of concern that the ocean's fishes would ever run out. Moreover, there was the belief among some that God had provided the earth's bounty for people to consume and that therefore it would never run out, even though on land it plainly could run out, as it did in many of the lowlands of North Africa and central Asia. Often social elites, as in China and Europe, tried to maintain remaining wild lands for their exclusive use.

Techniques for fishing included ones that were perhaps as ancient as humanity, such as the hook dangled at the end of a line. Harpoons seem to predate the last great ice age and were used to hunt turtles, large fish such as tuna, and ocean mammals such as dolphins and whales. For people living near the sea, fisheries were essential for survival. The peoples of the Pacific islands and the coast of Australia were very dependent on fish for their diet.

The exploitation of wildlife by medieval people was intense and for many of them essential. How they treated wildlife and how they used it often depended on their customs. It seems that in every case experiences in the wild figured in their storytelling, their literature, and their views of themselves as part of or apart from the natural world.

## AFRICA

BY ANTHONIA C. KALU

Hunting and gathering require a great deal of work and have persisted in Africa for millennia. Hunter-gatherer groups

primarily engage in a subsistence lifestyle in which all their needs are met by hunting and foraging from their surroundings. During the medieval period many groups hunted and foraged for food in some parts of Africa. In these hunting-gathering communities men generally did the hunting, while women and children foraged. Digging sticks were used for foraging in the ground, and grinding stones were used to process foraged food items like fruits and grains. Hunters used poison-tipped arrows and spears. The poisons usually were made from natural resources like the larvae of local insects. The arrow and spear tips were made from animal bones, stone, or wood. Groups that lived near large bodies of water also fished using bone-tipped harpoons or fishhooks made from bones or other natural fibers.

The remains of wild grasses, small and large animals, land and water mollusks, and plant fibers preserved in dry or wet sites all serve as evidence that can be examined to help understand the life, survival, and persistence patterns of hunting-gathering traditions in Africa. Although the Bushmen and the peoples who lived in the central rain forest are the most studied hunter-gatherer groups in contemporary Africa, research indicates that, as in many other parts of the world, many African societies developed from hunter-gatherer groups.

There is currently no substantive evidence about hunter-gatherer groups in much of northern Africa during the medieval period. Archaeological evidence suggests that although there is no hard and fast rule to enable researchers to classify groups into cultivators, hunters-gatherers, or pastoralists, the domestication of animals took place early in the Sahel-Saharan regions of the continent. During this period groups like the Bushmen in southern Africa, the Ogiek in southeastern Kenya, and the rain-forest groups in central Africa were already struggling to retain a substantial part of their hunting and gathering traditions as external groups were beginning to enter their territories.

Archaeological and linguistic evidence show that the Khoisan (of southern Africa), the Basarwa (of present-day Botswana), and the central rain-forest peoples maintained their hunter-gatherer traditions during the medieval period. The Basarwa, the Khoisan, and the Ju/'hoansi lived mostly in the arid Kalahari, while the central rain-forest groups lived in what is today the Democratic Republic of Congo. In the Kalahari the absence of surface water for two to four months in the year made it necessary for the Basarwa to find alternative water as well as food sources. They collected moisture-containing plants, like wild melons, and dug waterholes in dry riverbeds. They also hunted wildlife, which became scarce when the animals they used as food sources moved to areas where there was water. In the rain forest the canopy also sup-

## THE BUSHMEN

The Bushmen, or San people, of southern Africa are perhaps the best-known group of hunter-gatherers in world history. The general term *Bushmen* applies to a sizable number of indigenous African groups, all desert-based hunter-gatherers. They have inhabited the southern part of Africa for approximately 20,000 years. By doing so, they have flourished in conditions that later European adventurers would compare with the harsh lands of the Arctic. The southern part of Africa, although considerably warmer than the Arctic, is an equally unforgiving land. The Bushmen have survived and thrived in a region known for its wind-swept desert landscapes and its stifling heat.

The Bushmen moved frequently in the medieval period because of the limited resources, including water, necessary for survival. The same conditions ensured that the population remained small and that social groups rarely grew beyond an extended family. The Bushmen lived primarily by foraging, an activity that required an intense familiarity with the landscape, the flora, and the seasons. They hunted as well, counting on the occasional kill of small game to supplement their diet. They generally lived in caves and in shelters assembled from wood, grass, and animal skin.

While most humans lived in foraging cultures up to about 10,000 years ago, the Bushmen are distinctive because they held to this hunter-gatherer pattern until the 1950s. As other African foraging people came into contact with or under the rule of nation-states, many disappeared, were absorbed into the dominant culture, or were reduced to a marginal existence on the fringes of society. The Bushmen retained their way of life and, as a result, have been seen as surviving representatives of the foraging era or as examples of living medieval history. The days of the forager, however, appear to be numbered. The government of Botswana has attempted to push the Bushmen off their ancestral lands to open the territory to tourism and diamond mining.

ports only certain types of fauna and edible plants during the year. In addition, water levels fluctuate throughout the year. These conditions prolonged the hunting-gathering lifestyle for many groups.

Although there is not much archaeological evidence about the economic life of many African communities dur-

ing the medieval period, the different tools they used strongly suggest that hunting-gathering groups were still highly mobile. In addition to the implements they made from bones, sticks, and plant fibers, medieval African hunter-gatherer groups continued to use stone technology. Evidence suggests that although these groups moved frequently from one campsite to the next, they maintained a more or less stable diet throughout the year. They constructed hunting blinds or set traps for animals, usually preparing the animals they killed on site. For example, in their arid Kalahari homeland the Khoisan collected wild grass seeds, edible plants, fruits, and *mongongo* nuts and hunted wildlife from the surrounding environment. Some of the animals they favored most for food included the kudu, hippopotamus, and elephant.

Depending on the region, Africa's medieval hunter-gatherer groups continued to live in the open, sometimes in small movable huts, under rock shelters, or in caves. Although some of the campsites did not overlap, many groups did maintain camps in the same vicinity of the camps their ancestors had set up in past generations. This meant that each group maintained, but did not cultivate or domesticate, plants and fauna at a given site. The net result is that medieval hunter-gatherer groups continued to sustain the integrity of their environment as their ancestors had over millennia; that is, they did not exploit any given locations or resources beyond certain limits.

Many of the groups in the Kalahari used ostrich eggshells to store and carry water. Ostrich eggshell beads were also used for adornment. However, many groups—including those who lived in areas where there were no ostriches—show evidence of the use of ostrich eggshell beads during this period. This indicates that some forms of exchange existed between the different hunter-gatherer groups and their neighbors, who may or may not have been hunter-gatherers.

Farther north, rain-forest groups like the Ituri, Twa, Aka, and Baka may have begun to form symbiotic and other types of relationships with neighboring farming communities sometime during the medieval period. It is possible that their lifestyle might not have survived without the presence of nearby farming communities with whom they began to interact extensively. Husbanding of bees for the purposes of collecting honey appears to have become more intensive among these groups during this period. They foraged for wild yams and other root and stem tubers, collected palm nuts, and hunted elephants, buffaloes, crocodiles, hogs, monkeys, and duikers for subsistence. They dug game pits for hunting the larger of these animals. Most of their tools in this period were made from wood, the bones of the forest and water animals they hunted, and natural fibers.

Similarly, the Ogiek of Kenya began to interact with the pastoralist Masai and Nandi during this period. However, the

Ogiek as well as the rain-forest groups continued to maintain their distinct hunter-gatherer traditions. In both instances, the rain-forest groups and the Ogiek continued to collect honey, wild plants, and grasses and to hunt wild game in the grasslands or forests in ways similar to those of their ancestors during the later Stone Age. Most of the wild animals used as food sources remained the same as those hunted during the later Stone Age. For example, some of the bones found at the Kisio Rock Shelter in southeastern Kenya include those of animals that do not migrate. This means that hunter-gatherer groups were purposeful in their choices of sites. The animal remains found at Kisio include birds, small animals like the dik-dik, giant rats, hares, and frogs.

All hunter-gatherer groups adorned themselves with materials from their surroundings. For this they used feathers, natural fibers, and other available materials. Not much was wasted because all hunting-gathering groups saw every part of their environment as providing for and protecting them. The persistence of the hunting-gathering tradition in Africa during this period is probably the strongest indication that humans have always tended to hold on to what works for them. The frequent returns of medieval African hunters-gatherers to the same sites meant that, despite the unreliability of the seasons and the apparently hostile environment, they had figured out successful ways to use what each environment offered without destroying it. They adapted, exploited, survived, and succeeded.

## THE AMERICAS

BY MICHAEL J. O'NEAL

By 500 C.E. and through the centuries beyond, most cultures in the Americas had come to rely on agriculture for a large percentage of their food needs. With some exceptions, most communities had become sedentary, so they did not move about searching for game animals or foraging for such food-stuffs as nuts, berries, and fruits, as their distant ancestors had. That said, most cultures continued to supplement their diets—some more than others—through hunting, fishing, and gathering, and fishing remained an important economic activity for people along the seacoasts and rivers. In some instances, overhunting and deforestation contributed to declines in animal populations, in turn leading to declines in human populations as well.

Modern people are likely to assume that hunting, fishing, and gathering were unreliable means of getting food and that people who lived this way led lives that were short and required unceasing labor. The reality may have been quite different. Archaeological evidence shows that life spans for many people who lived this way were relatively long. For most

pre-Columbian societies that relied on these activities for much or all of their food, food sources were relatively reliable, particularly for fishing communities. Also, pre-Columbian peoples were able periodically to regenerate their food supplies by allowing hunting areas to “rest” while game returned (along with the vegetation that game ate), adding to the reliability of the food source. Further, people who relied on smaller game as well as fish and seafood led more stable lives than those who hunted large game. While one large animal could provide a great deal of food, large game animals were harder to catch and kill, sometimes creating a “feast or famine” cycle, but a greater number of smaller animals supplied a steadier diet. Certainly people who ate insects and snakes for protein, such as jungle dwellers in South America, had what must have seemed an inexhaustible supply of food.

The people who relied most on hunting and fishing were those who inhabited the Arctic and sub-Arctic regions of Alaska and Canada, in a swath that extended from the Pacific on the west to the North Atlantic and Greenland on the east. Because of the region’s extremely long winters and cold temperatures, agriculture is impossible. Accordingly, these people, primarily the Inuit, have always relied on hunting and fishing to meet most of their material needs. On land they hunted elk, caribou, and similar large game, while trapping smaller game. A common technique was to drive the elk and caribou into corrals or ambush them at river fords or in narrow passes. At sea they caught fish and sea mammals, such as seals and whales.

To the south, the peoples of the Northwest, including the Tlingit, the Salish, and numerous others, were also unable to pursue much agriculture production. The region was wedged between the sea and mountain ranges, such as the Cascades, and summers were relatively short. However, the inhabitants of this region enjoyed abundant natural resources. Like their Arctic neighbors, they fished and hunted sea mammals in the ocean. Those along the coast fished for salmon and halibut at sea; those farther inland relied on salmon runs in the rivers. The rivers were often so dense with salmon that the fish could be caught with spears as they leapt out of the water. The forests of the Northwest also provided berries, nuts, and tubers (roots), along with mountain sheep, mountain goats, and elk. To the south, in the intermountain regions of present-day Utah, California, and Nevada, people continued to live as they had in ancient times, gathering nuts, berries, wild grains, and fruits; hunting deer; and using nets to capture migratory birds. The resources in both the Northwest and the intermountain region were able to support much larger populations than the more northerly Arctic regions.

The Great Plains of North America, extending from the middle of Canada southward to modern-day Texas, supported

## BUFFALO HUNTING

The Plains Indians used a number of techniques to hunt buffalo before the arrival of Europeans and their horses. One of the most common methods was the “corral” method. A hunter dressed in buffalo robes lured buffalo into a narrow ravine. At the end of the ravine was a long corral, or pen. Other hunters were ranged along the ravine and herded the buffalo into the corral, where they were slaughtered. Another technique was the “jump” method. Again, hunters lured buffalo to the edge of a cliff. Then other hunters appeared and waved blankets and shouted to force the buffalo to jump over the cliff. At the bottom another band of hunters stood ready to kill animals that were injured but not dead. Other techniques included driving the herd into deep snow, where they could not easily move, making kills easier. Sometimes hunters waited at watering holes and killed the buffalo when they came to drink. Another method was to set grass fires, which either drove buffalo into streams or forced them into restricted areas, where they were easier to kill. For the Plains people, buffalo hunting was not just a matter of material survival. Hunting and the rituals associated with slaughtering, cooking, and consuming the buffalo were matters of great religious significance.

Plains Indians used virtually every part of the buffalo. The meat, typically around 225 to 400 pounds from an average mature buffalo, was either roasted or made into pemmican (a mixture of meat, fat, and berries) or sausage, which could be preserved over the winter. Hides were used for clothing, blankets, ceremonial robes, gloves, and the like. Additionally, hides with most of the hair removed were used for clothing, tepees, boat skins, containers, blankets, and rope. Sinews (muscle tendons) were used for thread, webbing for snowshoes, laces, and bowstrings. Bones (especially the ribs) were turned into sled runners, arrow points, hoes, shovels, pipes (for smoking), awls for sewing, and scraping tools; the skull was used for ceremonial purposes.

The list of useful buffalo parts goes on. Horns were turned into containers, spoons, cups, bowls, and even toys. Hair was used to make yarn, pillow stuffing, brushes, and rope; even the buffalo’s beard was used as clothing decoration, and the tail could be used as either a flyswatter or a whip. The buffalo’s brain was employed as a tanning substance to soften hides. Hooves were turned into rattles and boiled to make glue. Fat was used as paint or to make candles and soap. The teeth were used for decorative objects and necklaces. The stomach and bladder served as containers for water and other liquids, and the stomach could be used as a cooking vessel. Even the buffalo’s manure was used as fuel for fires (after it dried, of course).

A controversy among scientists and historians concerns the way buffalo were hunted and used. The conventional view is that the Plains Indians hunted just what they needed and used every part of the animal—acting in this way as North America’s earliest conservationists. In contrast, early European settlers, according to this view, hunted the buffalo into near extinction for their hides, often wasting most of the resources the buffalo provided. Another view notes, however, that Native Americans may not always have been the conservationists of popular myth. In many cases male animals were left to rot in preference for the more tender meat of females. Moreover, the tongue and hump were the preferred meats, so sometimes large portions of the animal remained unused, and occasionally entire herds were killed just for the tongues. In some hunts it was not unusual for as many as a thousand animals to be killed—far more than necessary to meet the group’s needs.

the last hunter-gatherer societies in the Americas, primarily the Sioux, the Cheyenne, and the Arapaho, among others. The Plains Indians survived primarily as nomadic hunting bands, moving to temporary encampments to follow herds of buffalo, their primary source of food. The Plains Indians also hunted other large game, including elk. Frequently, they traded buffalo meat and hides for agricultural produce from more sedentary neighbors.

The Plains people may have “managed” their landscape to increase their hunting success. Some historians and biologists believe that large areas of the Great Plains were created

by hunting groups who used fire to beat back the forests creating what were, in effect, game preserves. In other parts of the Americas human populations altered their environment to create habitat areas for beaver, deer, elk, porcupine, hare, turkey, grouse, quail, and other game birds, all with a view to boosting food supplies.

To the east, stretching from the eastern coast of Canada and down to the Carolinas, then westward to roughly the Mississippi River, numerous Eastern Woodland peoples relied on a mixture of agriculture and hunting, gathering, and fishing. The forests of these regions provided large game, such

as deer, smaller game, such as rabbits, and other foodstuffs, such as nuts, berries, and fruits. Along the seacoast and rivers, groups focused more on fishing and gathered shellfish. Fishing tools included hooks, nets, and spears. In the semitropical areas to the south, people relied more on fishing and gathering shellfish, and they hunted deer with bows and arrows and blowguns. They also fished by actually poisoning the rivers, killing the fish, which they then gathered at will. To the west, the people of the American Southwest and northern Mexico, most notably the Anasazi, had to rely primarily on agriculture. However, this region also offered some game meat, including the occasional buffalo, as well as native edible plants, including species of cactus.

In Mesoamerica—the region that encompassed southern Mexico, the Yucatán Peninsula, El Salvador, Guatemala, Honduras, and Belize—the primary source of food in the pre-Columbian period was agriculture. The sparsely vegetated, desertlike regions of Mesoamerica supported very little game and few wild edible foodstuffs, so crops of maize (corn) and beans were the primary foods. However, from time to time people conducted controlled burns of grasslands and sparse woodlands. The new, tender shoots attracted game, which then was hunted for food. People along the coasts, and especially those who lived on Caribbean islands, depended more on fishing and shellfish, often trading salted fish for other foods from the mainland. In the tropical forests of Mesoamerica people hunted monkeys, among other small animals, for meat.

South America presents a rich variety of terrains and climate zones, from savanna grasslands to tropical forests to deserts to high mountain ranges. In the centuries before the Common Era, agriculture, including crops and herding, became the primary mode of subsistence and remained so in the medieval period. Hunting was simply too onerous in the dense jungles of the Amazon Basin or the mountain highlands of Peru, although some cultures hunted the guanaco, a camel-like animal, as well as some species of monkeys. People who lived along the coastlines met most of their nutritional needs by fishing (usually with traps), gathering mollusks, and hunting sea mammals, including dolphins, seals, and sea lions. This mode of existence was especially commonplace among people at the southernmost end of South America, where short summers made agriculture impossible. These people relied almost entirely on marine life for their subsistence.

## ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The hunting, fishing, and gathering practices of medieval Asia and the Pacific regions were vast and varied, and they were af-

ected by geography, climate, and customs. In China exploitation of wild animals and plants had changed the landscape. When the earliest-known Chinese kingdom formed, which was ruled by the Shang Dynasty (ca. 1500–1045 B.C.E.), the land south of Beijing down into Indochina was composed mostly of deciduous forests, with southern and western mountains blanketed in forests. By the 500s these forests had been mostly cleared away, and during the medieval era the forests were cut back to the southern mountains, where rough terrain made logging too difficult for clearing the land. Thus, medieval Chinese hunters faced ever-changing conditions. They had to hunt in the cold forests of Manchuria, Siberia, and Korea, or in the mountains of the south, or on the eastern slopes of the Himalayas.

An alternative was to hunt in man-made parks built for the use of aristocrats and emperors. The most famous of these was Forbidden Park of Xi'an (earlier, Ch'ang-an) during the Tang Dynasty (618–907). This park had a cultivated forest, and herds of white deer ran wild in it. It was stocked with wild pigs, and its waters attracted wild birds. The emperor and his guests would set themselves in a clearing, and then beaters would drive game toward them, which they shot with arrows. Sometimes hunting dogs were used to chase down animals for the hunters to kill. The dead animals could be eaten in feasts. Many aristocrats liked to hunt in the countryside outside of parks, chasing birds as well as pigs. Most of the countryside was cultivated, which meant that farm fields were sometimes trampled.

Many Chinese who lived near surviving wildlands hunted and foraged in those areas to supplement their diets. In the south they gathered bamboo shoots, oranges, and tea leaves. There were tigers, bears, deer, pigs, and many game birds. The skins of tigers and bears could be used for clothing and their body parts for folk medicines. If captured alive, they would be sold to the government for use in parks. The imperial government sometimes sent out expeditions to gather rare plants and animals for use in gardens as well as parks. The government representatives on these expeditions were loathed by local people for mistreating them and for looting the wildlife many needed for food. On at least two occasions local governors complained—one threw the government agents in prison, and both wrote letters of protest to the emperor. In both instances the emperors involved responded favorably to the protests. In the forests of Manchuria and Siberia, Chinese hunters found huge brown bears, Siberian tigers, deer, hares, and many species of game birds.

Peasants were allowed to own bows and arrows and hunting spears, but professional hunters and aristocrats were usually superior marksmen, and the aristocrats would hunt from the backs of horses. The aristocrats often enjoyed falconry, or

the sport of hunting with predatory birds. Goshawks, which were used to hunt rabbits, pheasants, and other birds, were favored by peasants and aristocrats alike. Eagles sometimes were used to hunt large animals such as deer and wolves. Sparrow hawks were used to hunt small birds, whereas falcons were used to knock larger birds out of the sky.

Fishing was common anywhere there was water in China, and people caught fish to supplement their diets. Along the coasts villagers often made their living from fishing near the coast and shipping their catches to market, usually up waterways inland. In Korea and Japan fishing was a vital industry. There were diverse fishing societies on Korea's long coastline and on its numerous islands, but in general men fished out at sea in boats, while women fished in shallow waters. The women harvested seaweed, with girls learning to cut the plant while leaving enough of it for regrowth. Seaweed was harvested in winter, when the water was cold. In addition, women brought in abalone, crab, crayfish, and shrimp.

The forests of Korea harbored deer, wild pigs, cranes, ducks, pheasants, and swans as well as tigers, bears, and leopards. These animals were widely hunted, but the forests brought other bounties in vast quantities that could stave off starvation in hard times: apples, pears, persimmons, tangerines, grapes, walnuts, chestnuts, pine nuts, and ginkgo. The forests of Japan were also dense and rich. Early in the medieval era the Japanese developed a custom of renewing its forests. It was taken as a matter of religious devotion or as cooperative projects for college students to go where trees had been logged and plant new trees. This did much to preserve Japan's wildlife. So, too, did the Japanese aversion to living in the mountains. Most of the islands of Japan are covered in mountains, which had forests that were sometimes logged but were not cleared for settlement.

Game animals included deer, antelope, rabbits, and wild pigs. The Ainu of northern Honshū and Hokkaidō hunted bear and used bearskins in religious rituals. Game animals were driven toward hunters by beaters; the hunters used bows and arrows. People living in or near forests could add protein from animals of the forests to their diets, but most Japanese relied on fish. The Japanese had tended to live on the coastal lowlands, and they had long fished in the surrounding seas. During medieval times large fleets of boats patrolled the coasts, catching fish that would be rapidly transported inland to be served that very day at dinner in homes or restaurants. The Japanese ventured out of sight of shore, hunting for schools of fish.

Fishing was also important in Southeast Asia. In Cambodia, South Vietnam, the Philippines, and many islands of Indonesia people built houses on stilts over rivers and marshes to give themselves daily access to fish. They used hooks and

lines that they dangled from their porches. They also ventured out on water in boats. The saddle-shaped houses of the Batak of Sumatra are thought by some historians to represent the prows of oceangoing ships, signifying the boating heritage of the Bataks. Coastal fishing was common, with the Philippines alone having more than 2,000 species of fish near shore.

Among the Hindus and Buddhists of India slaying animals was supposedly forbidden, but their culture provided numerous exceptions for killing animals for food. In the case of fishing, any fish caught with a hook was thought to have chosen to bite the hook and therefore it, not the fisherman, was responsible for its death. Consequently, someone who caught a fish or two by hook could eat them without guilt. Even so, some professional fishermen operated on large rivers and along the coast, using not only lines and hooks but nets and baskets as well. They would gut and clean the fish and even cook the fish before sending it to market.

India had a very ancient tradition of replenishing its forests. A class of worker, the forester, was required to manage the forests on behalf of the monarch, who supposedly owned all the forests within his or her domain. The foresters picked what trees were to be logged, and they planted new trees where logging had taken place. They tended to plant trees that were useful to people, thus modifying India's forests to favor nut-bearing and fruit-bearing trees as well as good timber trees. There were several other classes of workers who used the wildlife resources of India. There were people who collected honey, wandering through woodlands and tapping trees to hear which ones were hollow and might contain a beehive. There were people who gathered sticks from the forest floor, bound them up into bundles, and sold them to housewives in towns for use in cooking fires.

Professional hunters lived near forests. Their tools included bows and arrows, spears, blowpipes, and traps. They hunted to sell meat in towns and to capture animals for the hunting parks of monarchs and aristocrats. Tough little hunting dogs who tracked down game often accompanied hunters in their work. Fowlers were a separate occupation from hunters, and they specialized in hunting birds. They used bows and arrows and nets. They sometimes captured birds alive to sell to the parks of the monarch and aristocrats.

A monarch's hunt tended to be a big production. If monarchs could find time free from the requirements of statecraft, they would go hunting in a royal game preserve that would have deer, wild pigs, and many game birds. The monarch would go with professional hunters, who would beat animals in his direction. Other attendants made sure the monarch was refreshed with food and drink and kept cool. The ruler would show off his skills with the bow and arrow. The animals that were killed often were used as offerings in religious rituals.

The peoples of Oceania had widely varied habitats. Small atolls might have only vines and grasses with just a few shrubs or trees. Larger ones with more freshwater available could have banana, breadfruit, and taro plants. People often brought coconut trees to atolls. Even on the large island of New Guinea people had to learn to raise crops in order to survive. For most Pacific islanders fishing was essential for survival. Atolls usually had hundreds of species of fish near their shores. There were also turtles, lobsters, oysters, snails, sea cucumbers, octopi, and squid near shore. When enough wood was available to build boats or rafts, islanders often fished far from shore, using nets to catch tuna and other large fish. They hunted dolphin with harpoons.

The climates of Australia were varied, which meant that not all medieval Australians hunted, fished, or gathered in the same way. In general, medieval Australians hunted and gathered everything they ate. Clothing, bags, and spiritual objects all derived from something found rather than cultivated. There was a division of labor reflected in their tools. Women had digging sticks, usually of hardwood with a point at one end or both ends, used to burrow out roots and delicacies such as small frogs that retained water while hiding underground during dry spells and, thus, served as sources of hydration. The roots of the mallee tree also contained water. The blood of kangaroos and wallabies were drunk by some Australians to ease thirst, although many found the blood too salty to drink.

Men had bows and arrows, spears and spear-throwers, and nets. They hunted kangaroos, wallabies, possums, flying foxes, snakes, lizards, tortoises, emus, and mallee hens. They would drive emus and other birds into outstretched nets, entangling the animals. Australians knew when different species of birds laid their eggs and would visit nesting grounds at the right time to gather them. Australians foraged for yams, peaches, figs, berries, and nuts. Mussels were hunted in inland ponds and rivers. Fish were hunted with spears, harpoons, and nets. Some Australians hunted in boats along the coast for turtles, stingrays, fish, and dugongs, and they killed beached whales. They gathered clams, oysters, lobsters, and crayfish.

## EUROPE

BY GEORGE HAMBRECHT

Almost all types of hunting, gathering, and fishing were heavily regulated by medieval legal codes, with overlapping jurisdictions of unwritten customary law (tradition), secular or common law, and canon law all competing for the right to order “wild,” or uncultivated, natural resources. By the High Middle Ages many such resources were under the control

Badge showing huntsman with bow and hunting horn, British, late 1300s (© Museum of London)

of elites, whether noble or ecclesiastical, leaving few uncontested “wild commons.” The word *forest* had a specific legal definition in many medieval law codes that designated such areas, whether wooded or not, as those where all game belonged to the king or to local secular or ecclesiastical nobles. Moreover, several parties could each have rights of collection for different materials within the same area. Forests, for instance, were multi-use places where herbs, fruit, nuts, mushrooms, building materials, firewood, medicinal materials, and food were gathered. Wild animals were also hunted there, and even domestic animals, especially pigs, were allowed to graze forest areas (a practice known as pannage in English law). Each of these rights could have been, and probably would have been, held by different people, households, and communities.

The activities of hunting, fishing, and gathering in the European medieval period were generally directed toward two ends: for the “pot,” or the use of wild resources for personal or household consumption, and for trade, or the provisioning of larger households and towns. It is harder to find documentary evidence for the former, although archaeologi-

cal evidence can be of help in understanding the extent and quality of such activities. Activities of the latter type, however, show up in both documentary and archaeological evidence.

Pot hunting was obviously widespread in the medieval period and, with the exception of relatively small urban populations, was practiced from the Byzantine lands in the Balkans to Islamic and Christian Spain. Given its popularity, hunting both reflected and revealed certain ideological and social conditions in medieval Europe. The hunting of big game, such as deer, European bison, and elk, was thought of as the preserve of the nobility and was an important part of the aristocratic self-image. Scenes of the nobility hunting are portrayed in countless tapestries and paintings and on decorative objects. In addition to supplying the noble table with meat—believed, especially by the nobles of Christendom, to be the appropriate diet for the aristocracy—hunting was thought to keep martial skills sharp in times of peace as well as offering recreation.

Zooarchaeological analyses of middens (refuse heaps) from medieval Belgium reveal that hunting and fishing reflected the medieval European social order of the three estates: the nobility, the ecclesiastics, and the commoners. Archaeofaunal assemblages, or groupings of the remains of animals, associated with the nobility show a preponderance of wild game, especially big game such as red deer. Assemblages associated with the ecclesiastic estate, or clergy, show great numbers of fish and next to no big game at all. Assemblages associated with commoners, though few in number, contain very little game at all, and what evidence of meat is present comes from domestic animals.

Forests and other nonagricultural lands often were reserved specifically for the noble hunt. In almost all medieval law codes poaching and other non-noble encroachments had severe punishments attached to them. These lands frequently were protected physically as well. In England before the Black Death (bubonic plague), for example, where growing populations resulted in an increase of cultivated land and a converse shrinking of the “wild” lands, several forests were literally walled off in order to preserve timber and game for the nobility. The Robin Hood stories might be a reflection of the growing tension between noble hunting and forestry prerogatives and the common encroachments upon them.

Hunting was also used to gather valuable trading goods. Archaeofaunal assemblages and documents both show that the republic of Novgorod was actively engaged in fur hunting for trade in networks stretching from the Arctic regions of Scandinavia and Siberia to western Europe, Byzantium, and the Islamic lands to the south. The Norse Greenland colony was likewise very active in walrus hunting to obtain ivory, a prized material for decorative art throughout medieval Eu-

rope. So important was the substance to the Greenland colony's economy that some have hypothesized that it was the increased and cheaper availability of ivory from Novgorod and Africa that made the Greenland colony no longer economically viable and hastened its fatal isolation from continental Europe.

Fishing was a ubiquitous activity for many people living near water in medieval Europe. Freshwater fishing was a basic part of medieval household subsistence for most (though surprisingly not all) of those near such resources. Many monasteries established fish farming ponds on their properties. Marine fishing and shoreline gathering were important elements in the subsistence of many coastal populations. In many areas there was a difference between what a community saved for its own consumption and what it processed for export. Fishermen in medieval Iceland, for instance, consumed haddock while saving cod for export, just as they generally do in the 21st century. In northern Norway halibut generally was consumed domestically, while cod was saved for export.

Intensive fishing for export took place in both the medieval Mediterranean Sea and the Atlantic Ocean. The Mediterranean saw tuna fishing in Sicily, Catalonia, and the Ionian islands, when the tuna happened to appear, with much of the catch pickled in brine or vinegar for export. Other, more humble fishing operations, such as the eel fishery at Lake Bolsena in Italy, were possibly more dependable. These eels were salted and then exported, some for great distances, such as those that were sold to the 14th-century papal court in Avignon. Garum, a fish paste beloved by the ancient Romans, continued to be produced in the medieval Mediterranean region.

The Atlantic Ocean was even more fertile than the Mediterranean in terms of exploitable fish populations. As early as the eighth century in Arctic Norway, the catching and drying of fish, mainly members of the cod family, has been seen through archaeological research. This fishing and processing supplied large chiefly households in the Arctic region around the Lofoten Islands. Dried fish, along with beer, allowed chiefs to attract and sustain large groups of retainers, who functioned largely as private armies, with which they broadcast their own power. This fishing and processing knowledge was carried with the Scandinavian settlers of the Viking Age to Iceland, the Faeroe Islands, and the British Isles. Coastal settlers of Iceland, for example, were clearly processing cod and trading them far inland. It can be argued that these initial trading networks are the origin of the medieval trade in stockfish, which was such an integral part of the Hanseatic League and the later early modern European world trading systems. The Hanseatic League likewise controlled the herring fisheries in the Baltic and North seas.

Gathering was ubiquitous in medieval Europe, as it is today in any rural community. Seasonal berries, fruits, nuts, and mushrooms were collected by people throughout medieval Europe for the purposes of food, medicine, and, very likely, recreation. Archaeological and documentary evidence, in the form of medieval cookbooks, herbariums, and books on medicine, illustrate this. For example, the plant *Angelica officinalis*, a species found from Iceland through Scandinavia and into the Baltic regions, was gathered for culinary and medicinal uses. High in vitamin C, it was a valuable in preventing scurvy in northern regions, where the diet might make people vulnerable to the disease.

Salt was a highly prized resource in the medieval period. In the Mediterranean it was collected in estuarine areas that also contained large and exploitable numbers of fish. This pairing allowed for the preservation of fish through salting, leading to the export of salted fish as a trade item. This pairing of salt extraction and fish preserving also was found in the Black Sea region after the sixth century, around the mouth of the Danube, and at the mouths of the Russian and Ukrainian river systems in the Black Sea. Salt was later collected in the coastal regions of the Atlantic as well.

Wood, of course, was valuable as a resource for building materials and fire. Charcoal burners are noted in documents as well as in archaeological remains throughout medieval Europe. Charcoal was used both for domestic consumption and as fuel for metallurgy and other craft industries. Forestry rights were often legally defined. Commoners might have the right to gather certain amounts of fallen wood for domestic purposes, while others might hold the right of live timber harvesting. In areas where wood was scarce, the right to collect driftwood was regulated strictly. In Iceland, where such debris can come in the form of large, whole Siberian trees, the medieval Icelandic Church retained the right of ownership to driftwood appearing on many specific beaches throughout Iceland.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

In much of the medieval Islamic world, hunting was not important for supplying food. In general, people much preferred the foods they could find in markets. Such foods were almost always inspected and approved as *halal* (“that which is permitted” in Islamic law). The farther away from cities people lived, the more likely they were to depend on hunting for some of their food. In some areas hunting was essential to supplying protein in people’s diets.

The rules for hunting were much debated by religious and legal scholars who tried to define what was *halal* and

what was *haram* (“that which is forbidden”). In different places at different times the rules varied, but in general hunters were mindful of an injunction in the Koran against wasting what God provided. God provided all the world’s blessings for humanity and therefore should be thanked for what he made available. This meant, for example, that a sultan hunting with his falcon or hunting dogs were required to invoke God’s name when dogs were let loose or a falcon was released. Failure to speak God’s name made whatever was killed *haram*.

There were rules for how hunters were to conduct their kills. Hunting weapons were supposed to be decisively effective. Bows and arrows and spears, for example, were permissible because they were designed to penetrate a vital organ and thereby kill quickly. Hunters should focus on taking the animal only for good use, and it should have as merciful a death as possible. If hunters used hunting dogs, they were to be only trained dogs that understood their duty. Animals killed by untrained dogs were *haram*.

The rules could be very detailed. For instance, if a hunter came upon prey that had been bitten by his hunting dog, he could use it for food if it had plainly been killed by his dog, even if the dog had eaten some of it. If the prey was still alive and the hunter waited for the prey to die, then he could not use it for food. To make the prey *halal*, he had to kill it himself with a blow that fatally penetrated an internal organ of the animal. Authorities were divided on the matter of an animal found soon after it was wounded and then quickly slain. Most seem to have believed that the prey would still be *halal* provided the hunter did not hesitate but quickly dealt the fatal blow. Others thought the prey was already *haram* because of its suffering and because it had bled. Failure to penetrate a vital organ, thus sometimes allowing prey to bleed to death, made the animal unacceptable as food. Prey that was killed by a hunting dog but lay overnight before the hunter found it could not be eaten.

Many passages from the Koran and the Hadith (the record of Muhammad’s sayings and proscriptions) were cited by scholars to support this point, but in sum it was considered wrong for the prey to suffer a lingering death. The same rules applied to the use of falcons and hawks. Prey that was knocked out of the air by trained falcons or hawks or that had been taken down by hunting dogs had to be killed the instant the hunter came upon it. Again, hesitation could make the prey *haram*.

Unlawful prey included all pigs at all times. Animals that had once been domesticated but had become wild, had died of disease, or had been killed by wild animals were *haram*. A distinction was made for animal skins. Pigskin was unlawful to touch. Some scholars believed that it was *haram* for

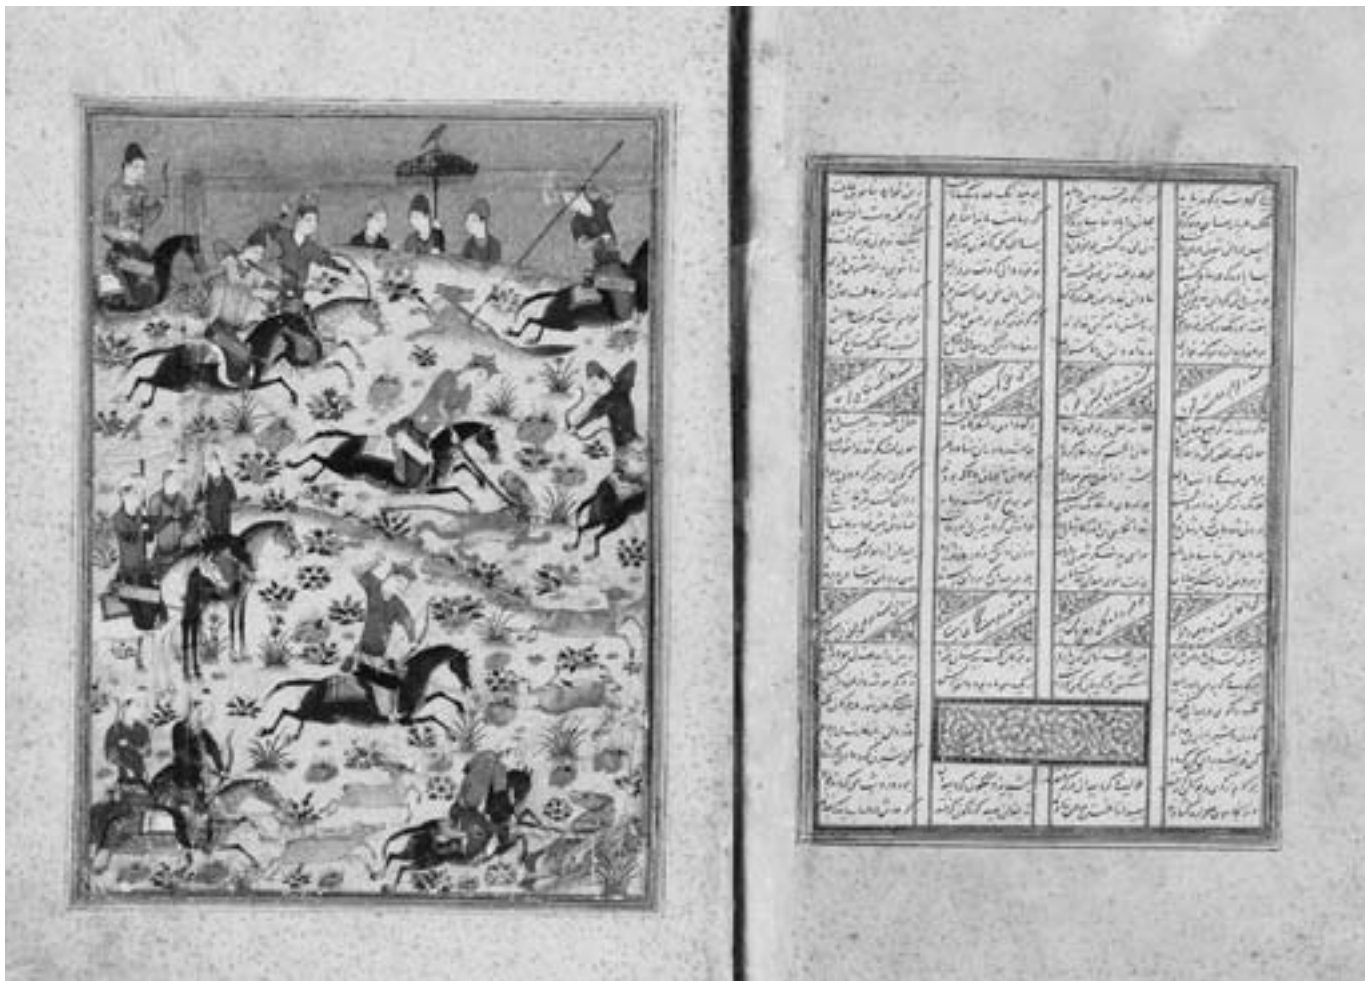

Muslims even to handle a container holding any parts of pigs. Most, however, seem to have believed that as long as Muslims did not themselves actually touch the parts of a pig, handling the container was acceptable, although the person might have to fast for a day as penance. For animals that were forbidden as food, it was acceptable to use the wool or skins. The tanning process was thought to purify animal skins, except for those of pigs.

During the hajj (the pilgrimage to Mecca that was the religious duty of all Muslims) it was forbidden for pilgrims to eat wild game but acceptable for them to eat fish. Animals from rivers, lakes, and the sea fell under different rules from animals of the land and air because, in the Koran, God declares all things from the sea to be pure. Thus, even carrion of a sea animal washed onto shore could be lawfully eaten, whereas carrion of land animals and birds could not be lawfully eaten.

Lines and hooks and nets were used to fish. These could be used in any stream or body of water, provided it did not lie in lands belonging to someone else. Professional fishermen plied the waters of the seas surrounding the Islamic world and large rivers, most significantly the Nile. The common fishing boat was a dhow, which had the classic triangular sail that is still found on boats in the Middle East and Africa. Small fleets of boats owned by merchants or groups of investors used nets to troll for fish in the eastern Mediterranean Sea; sometimes they were protected by galleys against pirates and fleets from rival European lands such as Italy.

The grandest Muslim fishing fleets may have been those of Morocco and Andalusia. The first fishing boats of these fleets were dhows. Their sailors were truly intrepid, sailing into the Atlantic to find fish out of sight of land. In the medieval Islamic world, the Atlantic Ocean was known as the Sea of Darkness, and it was the locale for tales of the

*King Khusraw and Princess Shirin in the hunting field*, by Nizami, ink, opaque watercolor, and gold on paper; Iran; 15th century (Freer Gallery of Art, Smithsonian Institution, Purchase, F1931-33)

supernatural and terror. Even during the first centuries of the development of Andalusia, however, Muslim boats sailed as far as the Canary Islands, and daring explorers sailed to Ireland. During the 1300s the boats with triangular sails were slowly replaced by much larger ships equipped with square-rigged sails, better suited to big ships than was the triangular sail. Fleets set sail from fishing ports in Lisbon in western Andalusia and Morocco and seem to have so regularly sailed far out to sea that trips to places such as the Azores, Canary, and Cape Verde islands were almost routine. The Muslim fishing fleets sailed north to fish in the ocean west of Brittany and south to fish off the African coast south of the Canary Islands. They brought back huge hauls of fish that were then cooked, dried, or salted for transport throughout much of the Mediterranean.

Hunting as a pastime was a favorite sport of the wealthy and the well connected in the medieval Islamic world, and hunting took place in wild places in mountains and deserts. Medieval Islamic literature often depicts the hunter as an adventurer astride his horse. Although hunting for sport could involve the usual weapons of bows and arrows and spears, most sportsmen seem to have preferred using trained falcons and hawks. In the 1100s the wealthy elite of Syria hunted in mountains near the coast, where some lands were known to be good for hunting hares and others for game birds such as partridges, geese, and quail. Although hunting dogs could be used to scare prey out into the open, falcons and hawks brought the prey down. The hunter typically sat on his horse, spoke the name of God, and released his bird of prey.

Gazelles were native to much of the Near East and often were hunted for both food and sport. Among the social elite far from cities, the hunting of gazelle could be a festive affair, with the animals slain by arrow or spear from a rider on horseback whose race at breakneck speed, often over obstacles, impressed onlookers. Slain gazelles would be prepared, cooked, and eaten on the spot after retainers moved tents and other gear to the grounds where the gazelles were slain.

One hunting animal popular among the wealthy was the cheetah. It was native to Africa and was exported from Africa to much of the Islamic world. In areas where lands were fairly open with few trees and shrubs, trained cheetahs were set loose on swift prey such as deer and hares. Their kills seem to have been treated like those of hunting dogs.

The use of trained falcons and hawks by hunters for sport was popular throughout most of the medieval Islamic world, with possible exceptions being sub-Saharan Africa and southern wetlands in southern Asia, where little is known about Islamic hunting practices. Wealthy hunters sent emissaries to Istanbul, Italy, and other exotic places to find the best-

trained, most-capable birds for use in hunts. The falcons and hawks were shipped with a supply of pigeons to feed them. People in the country often used nets to capture falcons and hawks, caged them, and took them to market or sold them outside their homes or along roads.

Among the most favored birds were those that came from the Bulgars—Muslim Turks who lived along the Volga and Kama rivers near the northern extremity of the Islamic world. Beginning perhaps in the late 900s the Bulgars had a major industry of forest products that they traded for the manufactured goods of the Islamic world to the south. They exported falcons, honey, and nuts, but they mostly hunted for furs. As long as they did not transgress the rule forbidding waste and killed the animals for a useful purpose, the hunting was halal. The animal's furs were to be used in clothing, and in some cases, such as squirrels, the meat of the prey could be eaten. The Bulgars hunted foxes, sables, martens, and beavers for their furs.

## ► illumination

---

### INTRODUCTION

Managing light was of concern to many medieval cultures. With some variations, there were five main sources of light: the sun, fires, candles, oil lamps, and lanterns. In China people sometimes placed fireflies into lanterns, but lanterns usually had candles inside them. Lanterns were made of bamboo, wooden, or metal frames, around which paper or cloth was wrapped and glued. Decorated coverings would shine when the candle was lighted.

Oil lamps consisted of two main parts: a vessel for holding the fuel and a notch or nozzle for placing a wick. Oil lamps were used in many different parts of the world, and as a consequence the sorts of fuels varied according to available sources. North Americans sometimes used tar or petroleum that had risen into pools on the surface. Most people used either animal fats or oils from plants. In the Americas and eastern Asia fish oil was often burned. In India oils came from cinnamon and other plants, in Africa it came from palm nuts and animal fat, in the Islamic world it came mostly from olives, and in Europe it came from animal fats, grain, and olives.

Candles were not as widely used as were oil lamps. They were made from boiled animal fat or from molten beeswax into which a wick was dipped. When lighted, it was the burning fuel that provided the flame. A pool of oil or wax would pool at the candle's peak, and it was this that was burned.

Sometimes candles were used to tell time; the candle would be marked with numbers or other indications of the time. In religious institutions it was important that the person in charge of the candles replaced it each day, usually at dawn, just after he or she awakened.

Fires played central roles in many people's lives. In Indian homes married couples had fires in their hearths that were meant never to be allowed to go out, because the fire represented their marital union. If it did go out, the married couple had to go through several rituals before the fire could be relit. For people living outdoors, fires could be the centers of their community. For instance, Australians would tell stories and pass on information about their religion or their daily techniques of survival to the young. In Europe travelers would gather around campfires and share their stories.

Sunlight was both friend and enemy. It provided much better light than did lanterns, lamps, candles, or fires, but its light could become oppressive and could be so bright as to be blinding. Many cultures tried to find ways to manage sunlight to their benefit. In the Near East people often used latticework in their windows to soften the sunlight that passed through. Other people built courtyards that would be bathed in sunlight, but the people would do their business in shadows cast by overhanging eaves or verandas.

All these sources of light often had religious significance. For those people who believed that the sun was a god, finding ways to incorporate the sun into their religious rituals was important. Many religions used sunlight to heighten the effects

of temples and shrines. Buddhist temples often had a statue of the Buddha in an otherwise dark room, with shafts of light from windows or entryways cast directly on the statue. Muslims used sunlight to create an air of mystery in many of their mosques; by allowing light to be cast in the center of a prayer room with the rest of the room in darkness, they created the effect of a room with no walls, as if it were an expression of the infinite spirituality of God.

In homes and private businesses artificial lighting meant that people could make use of hours when the sun was not in the sky. They built niches for lamps into their walls, had metal stands to hold their candles or lamps, and hung lamps, lanterns, and candles from the ceiling in metal frameworks. These methods of lighting after dark were hazardous. They could strain the eyes of people trying to read or work. Another hazard was fire. In Europe and China there were instances when the careless use of a candle or lamp resulted in fires that burned large sections of cities. In China the imperial government created a curfew, after which all lights were to be extinguished on pain of criminal prosecution. Nevertheless, medieval people found artificial lighting so valuable for extending the days into the night that they pressed on with its use despite the dangers.

## AFRICA

BY AMY HACKNEY BLACKWELL

Throughout most of medieval Africa the main source of illumination was the sun. The hours during which the sun shone varied from place to place. At the equator days were the same length as nights year-round, and the sun shone with more or less equal intensity regardless of the month. Farther south days varied according to the calendar, with days growing longer during December, January, and February and shorter in the months that correspond to summer in the Northern Hemisphere. People did most of their work outside by the light of the sun. Cooking, farming, hunting, fishing, building, and other jobs were mostly done in daylight hours. The light of the sun was essential for growing plants, which need sunlight to perform photosynthesis.

Medieval Africans had no sources of nighttime light as bright as modern electric lighting, but the lack of lighting did not pose a major problem for them. Human eyes are quite adapted to seeing in low light, and medieval Africans were accustomed to functioning with available light. Artificial light sources, including fires, disrupt the eye's natural adaptation to dark, so people who had to travel at night often preferred to move with no light sources at all.

The moon and stars provided a natural source of nighttime light. In open areas without trees the full moon could

*Bronze lamp, Coptic, ca. 500–1000* (Los Angeles County Museum of Art, Gift of Robert Blaugrund, Photograph © 2006 Museum Associates/LACMA [M.80.196.74])

be quite bright. The number of visible stars in the night sky was much greater than in modern areas with large amounts of artificial light. The Milky Way and the planets Jupiter and Venus shone brightly enough to cast shadows on the ground.

Some parts of Africa were very dark at night, and people could not take advantage of the light of celestial bodies. The dense forests of central Africa, for example, contained tall trees and thick undergrowth that blocked the light of the moon and stars. The small people who inhabited these forests, such as the people now known as the Mbuti, were accustomed to functioning with little light, walking forest paths without any artificial assistance.

Medieval Africans used natural light sources as a foundation for religious belief and as a topic of study. In southern Africa, for example, people used the moon's phases to create a calendar. Farmers throughout Africa used the light of the stars to determine the seasons and to predict the likelihood of rain. Because it provided light to grow crops and live, the sun assumed great spiritual importance for some African peoples. Many Africans recognized a sun god, often as the father god or the supreme deity of their cosmology. In many cases the sun god was said to be married to the moon goddess. In Sudan ancient people erected stones in alignment with the sun's placement at different seasons. The !Kung believed that all celestial bodies, including the sun, the moon, the stars, and the planet Venus, were symbols of the deities. In medieval Mali scholars observed the moon and the stars and used their findings to write books about astronomy. They also engaged in astrology, using the stars to make predictions about the future.

The main source of artificial nighttime lighting throughout sub-Saharan Africa was fire. Most African peoples used open fires for cooking, and if they were to have any light at all at night, it had to come from the fire. Each family might have its own fire, usually burning outside the house, and the group might build a larger central fire as well.

Fire had several disadvantages as a source of illumination. It was smoky, making it inconvenient indoors. It was also dangerous, and children had to be watched constantly to ensure that they did not fall into it. Gathering fuel for fires was a daily operation. In order to keep the fire going day and night, people had to collect wood or other sources of fuel, picking up dry wood that had fallen in the forest or cutting down trees as needed. Depending on a person's location, gathering wood could take nearly all day and required hard work. !Kung women, for example, would sometimes walk for hours looking for wood and carrying it home in their leather bags.

To start a fire, medieval Africans might use friction of wood on wood, using a device to make a pointed rod spin rapidly and create heat. They might also use flint and steel, hitting the stone and metal against each other to create sparks. Because starting fire was difficult, many people tried to keep their fires going constantly, banking the hot coals when they went to bed and stirring them up again in the morning.

In many cases the fire became the geographic center of social life. Families gathered around their own fires at mealtimes and during relaxed evening hours. An entire band or village might gather around a fire for a festival, music, dancing, or storytelling. Fire was so important as a source of heat and food as well as light that many African peoples considered it the province of a deity, such as the Yoruba warrior god, who was also the god of fire. Among the !Kung people of the Kalahari Desert, the fire was the gathering place, where people came together to sing, dance, tell stories, and socialize. When the group suffered misfortunes, the !Kung healers performed a "healing dance" around the fire, dancing around the fire until they fell into a trance and began performing healings for everyone sitting around the fire. In western Africa people believed that ancestors became fire spirits.

The small people of the central African forests typically kept a large fire burning in the center of their temporary camp, gathering wood to fuel it every morning. This fire would burn all night, serving as a source of warmth and light and defining the boundaries of the encampment. Often the central fire was considered the territory of men only, and men and boys sang and danced around it while women and children stayed in their own huts.

Fire was an important component of the Ethiopian festival known as Meskel, which commemorated the finding of

the True Cross by Helena (ca. 248–ca. 328), mother of the Roman emperor Constantine the Great (r. 306–37), and its arrival in Ethiopia during the 15th century. People celebrated by building pyramids of poles covered with flowers and then setting them on fire. Revelers carried torches through the streets and sang, danced, and drank around the giant bonfires. The high point of the night was the moment when the bonfire collapsed.

Most medieval African dwellings did not make much provision for illumination, artificial or natural. Maasai women, for example, built small, temporary huts whenever they settled in one place; these huts had no windows, so the only light that entered came through the doorway or the small hole in the roof that functioned as a chimney. Somali houses were made of animal skins and likewise did not contain windows. Even in areas where people built more permanent houses, such as the mud hut settlements of the Hausa people of northern Nigeria, not much light entered dwellings. A window in a house was by necessity simply an opening in the wall, allowing rain to enter, so it was not entirely desirable. Consequently, people did much of their work outside their houses. In many areas women cooked in the yards in front of their houses.

Aside from open fires, the main sources of artificial illumination were lamps and torches. These had the advantage of being portable but still could not produce large amounts of light. A lamp could produce a flame about as bright as that of a modern candle. Like fires in fireplaces or on the ground, lamps and torches could be smoky and required a source of fuel.

To make a torch, a person would soak a rag in some sort of flammable material, such as pitch or oil, and wrap it around the end of a stick. Medieval lamps typically consisted of a small reservoir that held oil and a place for a wick made of flax, rushes, or any other fibrous material that could hold a flame. The simplest lamps were clay bowls with pinches on the sides that could hold wicks. More elaborate lamps featured handles, spouts, and decorations. Yoruba women specialized in making lamps to burn palm oil. In Nigeria historians have found a number of iron lamps consisting of bowls set atop stands or tripods. Africans who traded with North Africa, Europe, and Asia occasionally acquired lamps from those areas. Most oil lamps were made of clay, though expensive imported ones could be made of bronze.

Many types of fats will burn to create light. In areas where olive oil was available through trade, people used that in lamps. Other people used animal fats. Palm oil was the only lamp fuel and ointment available in most of western and central Africa, and the trade in palm oil was brisk. Caravans traded salt and cotton cloth for oil and transported the fuel throughout their trade routes. During the late 1400s Europe-

ans discovered western African palm oil and began purchasing it as a provision for sea voyages.

To make palm oil, people would first collect palm nuts and then follow one of two main methods. In one approach they would ferment the nuts for several days, adding water as necessary to keep the mixture moist. Then they would pound the nuts in a mortar to remove the fibers and mix the mash with water. The oil would float to the surface of the water, where it was skimmed off and boiled to remove all water. The other method involved first drying the nuts in the sun and then boiling them until they were soft. The people would then pound the nuts in a mortar, mix the pounded nuts with warm water, strain the liquid to remove solid pieces of shell and fiber, and boil the liquid to separate the oil. Once the oil was extracted, it was poured into bottles and allowed to cool to room temperature, at which point it became solid.

## THE AMERICAS

BY MICHAEL J. O'NEAL

The technologies that pre-Columbian Americans used to illuminate their world differed little from those their distant ancestors had employed in ancient times. Without electricity, early Americans shed light on their surroundings with fire at night and relied almost entirely on the sun during the day. When the moon was full, it also provided a certain amount of illumination.

Illumination was a vital issue, particularly for people who lived the farthest away from the equator. The Inuit, the sub-Arctic people of the North, lived in a region where the amount of daylight differs dramatically depending on the season of the year. During the summer the Northern Hemisphere is tilted toward the sun. The days are so long that it never really becomes fully dark at night and the sun shines long after it has become dark in more southerly regions of North America. At night the sun barely dips below the horizon, so a kind of twilight persists until the sun begins to rise just a couple of hours later. During the winter, though, the opposite occurs. The Northern Hemisphere is tilted away from the sun, so daytime is short, with the sun barely peeking above the horizon for at most a couple of hours and then setting to begin a long night.

While people who lived close to the sea were able to burn driftwood to help them through these winter nights, the supply of driftwood was limited. Some southerly groups burned wood for fires, but since the territory of the Inuit has historically been north of the tree line, wood was not a widely used commodity. The Inuit obtained most of their resources from the sea. Among those resources were whales, which provided food, bones used to make tools, and the oil for cooking and

heating as well as for illumination in the long Arctic winter. Whale oil, along with oil from walruses, seals, and other sea mammals, was the most widely used fuel. These sea mammals typically have a thick layer of fat, called “blubber,” that conserves body heat and provides buoyancy. Oil was extracted from the blubber and burned for both heat and light in shallow stone bowls with moss wicks around their edges. Seal oil was particularly valued because it gave off a warm, honey-colored light. A seal-oil lamp was called a *kudlik*.

To make maximum use of natural light, houses made of snow, commonly called igloos, had windows of sorts. These windows consisted of sheets of clear ice taken from the tops of bodies of water. The sheets of ice were inserted into the walls of igloos and functioned like clear panes of window glass to admit light.

Native Americans throughout North, Central, and South America burned whatever was available. The Eastern Woodlands nations of North America had no shortage of firewood, for the regions they inhabited were generally dense with forests. On the Plains, where wood was somewhat less plentiful, animal dung was a primary fuel. Among the Indians of the Southwest and Mesoamerica, firewood was available, but in many desert areas firewood was in short supply. Sometimes sticks from low-growing plants and trees, such as juniper, could be used for fuel, but this type of firewood would have to be scavenged over a wide area. Thus, corncobs were also burned for heat and light. Typically, fires were started by spinning a spindle in a block of hard wood until enough heat was generated by friction to ignite tinder. It was common for fires to be maintained perpetually. In the American Southwest food was stored in caves and fires had to be maintained in them so that those accessing the food could find their way around. It was also common for a communal fire to be maintained; individual families in a community could then take live coals from the fire to start their own fires for light and cooking.

People had to deal with the smoke given off by fires used for illumination. Many Indians, especially those on the Plains, lived in tepees, or conical tents made of animal skins and supported on a framework of poles. These tepees had an opening at the top that functioned much like the flue of a chimney. As heat from the fire rose, it carried the smoke out through the hole. Even among those tribes that lived in more permanent structures, such as the Woodlands tribes, smoke was carried out through a hole in the roof.

Fires for lighting were typically built in one of two ways throughout the Americas. One way was to build the fire in a fire pit, a depression in the ground surrounded by a ring of stones. The fire provided illumination, and the rocks retained heat for warmth; hot rocks could aid in cooking when food was covered by them. The ring of rocks also ensured that

hot embers would not blow about, posing a fire danger. The other way was to build a fire on a flat stone hearth. This was the method used primarily indoors. Again, the stone hearth could serve a dual purpose, not only supporting the fire but also retaining warmth, which it would give off during the night as the fire died down.

Fuels also included fish oil, fat from game animals, and various vegetable oils. Vegetable oil had the advantage of not being as smoky as oil from animal sources. In some places people burned tar and crude oil that had risen to the surface—the same crude oil modern engineers pump out of the ground to make gasoline and other petroleum products. These fuels were burned in lamps made of stone and sometimes copper. Additionally, evidence suggests that North American tribes, as well as the Aztecs, discovered petroleum and burned it and also used it for medicinal purposes. The Aztecs likewise found seams of coal that were exposed and burned the coal for light and heat.

People did not always illuminate their personal living spaces, at least not on a regular basis. Often they relied on communal, ceremonial fires, built to honor the gods, and these fires were a source of community for people, who gathered around them to dance, celebrate harvests, listen to stories and legends about their ancestors, and take part in similar ritualistic activities. The bonfire was the community's hearth, a place where people found a sense of belongingness to the group and to its history, gods, and ancestors. The flames of a bonfire, flickering in the dark, were a source of great comfort to those who gathered around.

## ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Both historical and archaeological records for illumination in Asia and the Pacific are spotty, with the continuity of development during the medieval era murky even for such places as China, where there are historical records for some eras but not for others as well as archaeological discoveries of lamps in some parts of China from different periods. Historical records can be frustrating because if they mention illumination at all, they do so usually to praise a city or a palace for its lights without describing what the lights were like.

Medieval Chinese people used oil lamps, candles, lanterns, and torches to bring light to darkness. Oil lamps were common in China from ancient times, and bronze lamps in the shapes of animals and fantastic creatures, such as dragons, are known from medieval China's cities. Oil lamps were used to illuminate rooms and halls, and usually burned hemp oil or oil from the fat of whales and seals as well as fish oil. These were typically clean-burning fuels; other animal fats

were believed to produce smoke that would damage eyes. Fish oil seems to have been preferred to produce light bright enough to see details, because it was used to illuminate looms when women were weaving at night. Those who could not afford fancy bronze oil lamps had shallow metal or ceramic pans into which oil was poured. A rush wick was placed in the oil with part of the rush hanging over the side to prevent it from sinking into the oil.

Candles were made from animal fats mixed with beeswax, with berries or fragrances sometimes added. The fragrant candles were affordable only for the wealthy. These candles were placed in holders made of metal or wood and often were burned in a bedroom while its occupant slept, providing a pleasing smell during the night. Some candles were marked so that as they burned down, they would show the passage of time. These candles were narrow because the flame of candles came from a pool of melted wax or fat at the top; wide candles, with their bigger pools, burned more fuel faster than narrow ones, making the burning of narrow candles easier to control for long periods of time.

Lanterns had wooden or bamboo frames around which silk or paper was wrapped and glued. Candles were placed within the lamps. Wooden torches were used to illuminate streets and outdoor festivities, and military units carried them on nighttime patrols. Those who used boats to patrol waterways often used oil lamps. All of these means of illumination had in common the use of fire. Buildings in Chinese cities tended to be made of wood, and fires caused by someone's carelessness sometimes devastated them. This vulnerability resulted in laws that forbade people to have lights in their homes after certain hours of the night. Police patrolled cities at night, looking for light coming from windows.

This curfew was lifted for the Lantern Festival, held for three days on the 14th through the 16th days of the first

*Oil lamp, unglazed earthenware, Southeast Asia, sixth to 11th centuries* (Arthur M. Sackler Gallery, Smithsonian Institution, Gift of Osborne and Gratia Hauge, and Victor and Takako Hauge, S2005.182)

moon. The festivities in Ch'ang-an were wonderful to watch, with the emperor, aristocrats, and the wealthy competing with each other to display the best lamps. The lamps were decorated with silk, jade, and gold. In 713 one emperor had a 200-foot-tall wheel of lamps set up outside Ch'ang-an. It contained 50,000 lamps. Another display was an 80-foot-high tree blanketed with lamps. Lanterns were painted with images of landscapes, bamboo, flowers, birds, animals, and people and were hung outside homes and shops.

Religious institutions made extensive use of lamps and candles. Buddhist monasteries burned devotional lamps and candles night and day in their shrines. For instance, in Tibet monks placed candles made from yak butter before images of the Buddha. Pilgrims would give yak butter to the monks for making candles. The flames of the candles represented the spirit of light in a person as well as the driving of darkness out of one's heart. Buddhists would bring flowers and burn incense as well, with the aromas serving as reminders that the light is nurtured by moral behavior. During prayer the candlelight, flowers, and incense served to help focus the worshipper's mind on the verses to be recited. In Chinese homes lamps would be lighted in front of tablets bearing the names of deceased family members as a way of honoring the dead. This practice was especially important during festivals in which the dead were celebrated.

Korea seems to have followed the illumination practices of China, but Japan went its own way. Candles were uncommon in Japan in medieval times. They were usually made of pine resin, which did not burn well or give off much light. The Japanese did not use wax, not even beeswax, for their candles. Much preferred in medieval Japan were oil lamps, which shone more brightly than candles. These typically were plain pans for oil with a rush wick hanging over the edge or a cotton wick floating in the oil. Camellia seed oil and sesame seed oil were most often used for the fuel in the lamps, although other vegetable oil was sometimes used. Oil sellers were like traveling salesmen, hauling their oil in cylindrical tubs. An oil seller would carefully measure out the volume of the oil and then pour it into a kettle or another container for a purchaser.

Medieval Japanese lanterns had wooden frames covered with paper, which could be coated with lacquer. The lanterns displayed during festivals were decorated with images of temples. Lanterns with wooden frames could be folded up for storage. The Japanese made another sort of lantern out of stone. Stonemasons manufactured these lanterns in their workshops for use in temples, monasteries, and gardens. For nighttime processions, torches were used for light. For large gatherings of people for festivals, bonfires were used to provide light. Shintoists believed that a bonfire during a festival could be inhabited by a spirit.

Many Japanese could not afford candles, lamps, or lanterns and therefore did without artificial light at night. In general, Japanese houses were built to take advantage of daylight. They not only had windows but also walls that could slide open, allowing both light and air into a home. Shops were often outdoors to take advantage of sunlight. These would have overhanging roofs held up by posts, with workers underneath.

In contrast, medieval Indian housing was designed to keep out sunlight. An ordinary home in a country village would have only one window or no windows at all. The window, when there was one, tended to be narrow, with latticework making the light cast into the house shadowy. City houses were usually more than one story tall. The top floor typically had windows under the eaves or gabled windows called *kapotapalika*, meaning "pigeon cote," a reference to pigeons' habit of roosting in the windows. These windows had frames that were painted bright colors. The windows were covered by wooden latticework, curtains with bright patterns, or mats. They typically had solid shutters. The light of the windows illuminated a space where the family kept its valuables and food reserves.

Most houses had niches in the walls for the placing of oil lamps. The lamps tended to be small, with wicks dipped in ghee placed in them. Ghee was clarified buffalo butter. Sometimes lamps were hung from the ceiling in metal frames. This practice seems to have been more common in large areas, such as halls in monasteries or palaces, than in ordinary small homes. Interior lighting was also supplied by torches. Used mostly at night, the torches were held by servants in the households of the wealthy. Few palaces survive from medieval times because they were made of wood, but some stone fortresses survive, and the importance of torchlight for them can be seen by examining them. The outer walls and the walls of interior buildings were very high, with windows dozens of feet above the ground; the lower reaches would have been very dark without torchlight. Lamps and torches were used to illuminate city streets. The light cast from some city palaces was sometimes said to be dazzling.

Lamps were important to the spiritual lives of Indians. An Indian would typically awaken before sunrise and would ignite a lamp in a niche in the bedroom. If he was a man allowed to read the Vedas, he would sit cross-legged before the lamp and rest in his lap a copy of the Vedas, from which he would read passages. Lamps themselves could carry symbolic power. For instance, some bronze lamps had bulges in the middle representing male and female sexual organs. The light of such a lamp represented the life force. Small, circular lamps called *diyās*, which were made of terra-cotta, had cotton wicks and were shaped to be cupped in a hand. *Diyās*

were used for many religious ceremonies and were placed in shrines.

*Deepastambhas* were lighted in front of temples. These were metal frames in which many lamps were placed. *Deepastambha* means “tower of light.” Very popular for homes that could afford them were *deepavrikshas*, meaning “trees of light.” These were metal frames with arms like branches with lamps held in them.

Lighting elsewhere in Asia and the Pacific is harder to account for, perhaps because wood was used for lamps and wood is perishable, and candles, after all, disappear during their use. Most of Southeast Asia seems to have imitated Indian uses for lamps, except for northern Vietnam, where Chinese practices prevailed, and for the islands of Indonesia and the Philippines. On these islands the use of torches seems to have been common, although some cultures on Java and Sumatra adopted the ways of India.

It seems that for the Pacific islands, the intrusions of Europeans may have affected customs of illumination so much that the practices of the historical era may have had little to do with the practices during the medieval era. For instance, illuminated wooden masks may have been created more for sale to outsiders than for actual illumination. Torches may have been common. They were used by fishermen to attract fish to their boats at night and probably were used for people to see their way onshore or at sea at night.

Medieval Australians used fire sticks. These were sticks kept smoldering all the time. They were carried while Australians traveled, often held by children. These sticks were used to ignite campfires, to ignite torches to light the way at night, and to start range fires that would drive game animals out of hiding and toward Australian hunters.

## EUROPE

BY JULIE-ANN VICKERS

Lighting technology underwent few advances in the Middle Ages. All the forms of illumination used in this period had been known to the ancient world. The source of every type of artificial light was the flame, produced by burning various fuels. Although the basic technology changed little over the course of the period, the types of light used varied from region to region. These differences were dictated by the local availability of fuels and the poor performance of some fuels under certain climactic conditions. Individual wealth also affected the quality and quantity of light in each household. Illuminating a room after sunset was an expensive task, and for the very poor it remained an infrequent extravagance. Regardless of social class, artificial lighting at this time was often polluting, messy, and dangerous. The most easily and

*Oil lamp with six spouts, similar to the traditional Jewish Sabbath lamp, Britain, 12th century* (© Museum of London)

readily available forms of light were still the sun and, to a lesser extent, the moon.

Medieval society was structured to make optimal use of natural light. Daylight was the only light source in which most forms of productive labor could be performed. The number of hours that could be worked in a day, therefore, varied from season to season, with the advent of summer heralding long days of work. In wintertime monastic rules allowed for monks to sleep longer, in recognition of the limited hours of daylight available to them for work. The wealthier groups in society designed their buildings to maximize the amount of daylight entering rooms. For instance, monastic scriptoria, the rooms where monks copied manuscripts, were built with a large number of windows and often were situated around an interior sunlit courtyard. People also took note of the waxing and waning of the moon, as a full moon on a clear night was another viable source of natural light, particularly for travelers. Such was the dependence on natural light at this time that for many of the poorer people sunset signaled the time to go to bed.

For those who could afford them there were two different ways to artificially light their rooms, enabling them to extend

their waking hours. The largest source of illumination was the hearth fire, which also acted as the primary source of heating for warmth and for cooking. Although the fire could light a fairly large area, the quality of light it emitted was poor. Spot-lighting was the other main type of illumination. This method used the light of a smaller flame, for example a candle flame, that provided a higher intensity of light but only for a very small area. The relative limitations of both main area lighting and spotlighting meant that people's activities at night generally were restricted to the most basic and routine tasks. In the later Middle Ages some guilds went so far as to ban craftsmen from laboring after dark because of the deterioration in the quality of the work produced then.

The hearth fire was for many the sole source of lighting, with spotlighting used only on rare occasions. In the earlier Middle Ages the fire was a bare, open hearth located in the center of the room to ensure the maximum dispersal of light and heat. Since many buildings were made of wood, the central location of the fire away from the walls also acted as a safety measure. A hole in the roof helped guide some of the smoke out of the room, while open windows provided an extra form of ventilation. Nevertheless, soot and smoke accumulation were constant problems. In the 11th and 12th centuries the construction of buildings with an upper story led to the shifting of the hearth fire to the peripheral wall. The hearth in this period was typically made of stone, brick, or tile. In time the hearth was incorporated into the peripheral wall itself and developed into the chimney fireplace. The type of wood burned in the hearth fire greatly affected the quality of light it radiated. Older, dry wood was the best and was in high demand. Poorer people often had to make do with green, moist wood, which burned less brightly and created far more smoke.

Gradations in quality and affordability in the different forms of spotlighting available meant that some were more widely used than others. Candles were one of the least common types of small-area lighting employed in the Middle Ages. They were made either of beeswax or tallow. Beeswax candles were highly valued as they produced a bright flame, were not smoky, and smelled sweet. The wax for making these candles was collected from the cells of honeybee hives. However, demand for this material far outstripped supply, making the beeswax candle a luxury item that even the wealthy used sparingly. By far the largest consumers of these candles were the medieval clergy, who used them extensively in church ceremonies. Throughout the Middle Ages the light of a beeswax candle was endowed with important religious significance.

Far more common than beeswax candles were tallow candles. Tallow was produced by rendering animal fat, usually from sheep or cattle. Rendering was a process of boiling

and straining fat in order to produce a more purified form. Compared with beeswax candles, the light from tallow candles was of poor quality. Tallow candles also burned with a strong, acrid smell; sputtered hot fat; and produced a lot of smoke. In the warm climate of southern Europe they were never commonly used because they had a low melting temperature. In addition to these disadvantages of tallow candles, the cost of the rendered fat remained higher than the price of meat, so they did not constitute a viable source of lighting in the homes of the poor.

Medieval peasants turned to more readily available forms of lighting that could be produced very cheaply. Rushlights were one of the most popular forms of illumination in peasant households. These lights were essentially a type of candle in which the wick was replaced by a rush. Rushes were plants that grew abundantly in marshy areas. Once they were harvested, usually in late summer, the outer skins were peeled to expose their pith and they were then laid out to dry. When sufficiently dry, the rushes were coated in tallow or grease. The great advantage of the rushlight was its low cost. Rushes were free, and enough fat could be gleaned from family meals to supply the coating. Their main disadvantage was that they required constant attention. The burning time of a rushlight was maximized by holding it at an upward angle. To accomplish this, rushlights had to be supported in clamp holders and manually shifted forward to ensure continuous burning.

Another cheap variation of the rushlight was the splinter. Splinters were sticks of resinous wood such as boxwood, birch, or pine. They were coated in tallow and then burned either in clamp holders or simply wedged into an appropriate surface. The use of rushlights and splinters was determined largely by geography. England, for instance, had a plentiful supply of rushes, ensuring that rushlights were the most commonly used form of lighting there throughout the Middle Ages and into later centuries. In contrast, resinous wood was easily found in parts of continental Europe making splinters a common form of lighting there.

Lamps were widely used to light the homes of both the wealthy and the poor. The most basic type of lamp was produced by placing a wick in the mouth of a fatty or oily animal, which was then burned. Oily birds, such as stormy petrels, were used in this way. A more sophisticated lamp consisted of a vessel with a lip that could hold a reservoir of oil and a wick. The lamp itself was typically made of ceramic, metal, or stone; glass was sometimes used as well but was very expensive to produce. Like other forms of lighting in this period the type of fuel affected the quality of the lamplight. Olive oil, fish oil, and grain oil were the main lamp fuels. Olive oil provided the cleanest flame but was readily available only around the Mediterranean. Wicks for lamps, as well as candles, were usu-

ally made of linen, hemp, or cotton. Of these, cotton burned the best and soon became the dominant material. To use the lamp the wick was floated or secured in the oil and set alight. Lighted lamps were then placed on the table in dishes or hung from the ceiling by chains. Lamps were used everywhere in Europe during the Middle Ages. However, the low melting point of candles and other tallow-coated lights meant that in the warmer areas of southern Europe lamps were the main source of lighting after the hearth fire.

Outdoor lighting during the period was extremely limited. It was difficult to produce a light bright enough to illuminate a sizable area for any length of time. Firelight provided the best source of light but lacked portability. The other main types of outdoor light were torches and cressets. Torches were made from bundles of dried grasses and dried sticks that were then set alight. They were highly combustible and sent off dangerous sparks. The extent to which they were used remains largely speculative, as they left no trace in the archaeological record. Cressets were baskets made of metal or stone, which were then filled with fuel such as resinous wood or oil. The baskets were mounted on poles so that they could be carried around. These portable forms of light were commonly used by night watchmen on guard in villages and towns.

In the Middle Ages artificial light sources not only were of poor quality, they were also messy and dangerous. Soot and smoke were constant pollutants, while hot oil and molten animal wax were capable of causing serious injury. In addition, most domestic dwellings were made of wood. This meant that there was a constant risk of local or widespread fires. In order to minimize the damage to property and life from unattended flames, hearths had to be covered or extinguished at a certain hour of the evening. A bell was rung to signal this hour, which was known as the curfew. The name derives from the Old French *couvre-feu*, meaning literally “cover fire.”

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

People of the medieval Islamic world had an ambivalent relationship with sunlight. On the one hand, they depended on the sun to provide light for working and reading, but for much of the Islamic world, sunlight brought with it wearisome heat and blinding glare. For nomadic Muslims, these conditions meant that they spent much of their time in their pavilions, out of direct sunlight. Women did much of their work within the tents, cooking and weaving. Both of these activities required an ability to see small details, implying that lamplight was almost certainly used within the tents.

The development of Islamic architecture reflected various efforts to come to terms with sunlight. Homes in the country

often were walled enclosures with buildings within them. The buildings, which were homes and storage houses, might have no windows at all, allowing for people to escape inside from direct sunlight, or they might have small windows that allowed enough light inside for people to avoid bumping into each other or furnishings; these windows could be covered by curtains or shutters. In early Islamic cities homes usually consisted of courtyards around which the living quarters were built. Most daily activity took place in the courtyard, which could be shaded on the edges by eaves or verandas. In large homes of well-to-do people the courtyards were surrounded by roofed colonnades, among which people could enjoy the benefits of shade while having enough sunlight by which to work or to read. Medieval Muslims valued family privacy highly, and their cities developed multistory houses, each house with only a single door facing the street or alley outside. There were no windows on the outside walls; instead, windows were in the walls facing the inner courtyard. Thus, lighting emphasized the importance of the family home over the outside world.

The relationship of sunlight to religious observances was similarly ambivalent. For many builders, lighting the prayer hall was important so that people could see the direction to Mecca and see the cleric leading prayers. The oldest great Islamic monument, the Dome of the Rock in Jerusalem, had five windows for each side of its octagonal lower story, making a total of 40, and another 16 windows in the drum of the dome, allowing sunlight to bathe the designs on the walls of the interior. Lamps were added for further illumination of the interior. Another approach was that of the Great Mosque of Damascus (706–15). It was one of many courtyard mosques. In these a courtyard surrounded by walls or colonnades served as the prayer hall. Nevertheless, some designers seem to have wanted an air of mystery in their mosques. The Great Mosque of Córdoba is the most famous example. Its prayer hall is a forest of pillars of varying designs. In sunlight from high windows these pillars cast numerous shadows, darkening the walls and producing the effect of a wall-less interior, with people inside being surrounded by infinite space.

The Koran asserts that “God is the Light of the heavens and the earth” and compares the light of God to a lamp encased in glass in a niche, with the glass shining like a star. Thus, lamps could symbolize the light by which God attracts the spirits of people who wish to be good and moral. When the Islamic world began, lamps were already the preferred form of artificial illumination in the Near East. In Egypt candles made of beeswax had long been made, but under the Byzantine Empire oil lamps predominated in homes and public places. At first Muslims used the sort of lamps that were already being made, mostly those of the Samaritans and of

the Byzantines, before going on to create lamps that were not only serviceable but also often wondrous works of art.

By the seventh century the use of molds had long been the primary method of producing lamps. Ceramic lamps could be made on potter's wheels or shaped by hand, but molds allowed for mass production of metal lamps. Molds were made of plaster, clay, or stone. Stone molds were difficult and time-consuming to make; therefore, they were rare. Plaster molds dried quickly and retained their size and shape during drying, providing potters with molds that would reproduce exactly what they had modeled. One drawback was that plaster contained numerous small bubbles that appeared as speckles on the finished product. Because plaster molds deteriorate quickly, many more clay molds have survived from the medieval Islamic world than have plaster molds. Archaeologists can identify lamps made with plaster molds by the speckles on them, so it is known that plaster molds were often used. Clay molds were much more durable than plaster molds, and they were easier to make than stone molds, but clay molds sometimes shrank while drying or being fired, at times resulting in distorted shapes for finished products.

Typically, an archetype—a model—would be carved into stone or modeled in clay and fired. Plaster or clay would be pressed around the archetype. Most molds were made in two parts, one for the lower half of the lamp and another for the upper half. Into the completed mold would be poured molten metal; the upper and lower halves of the mold could be separated from each other after the metal had cooled. The lamp

could be sold as it was, but it was often smoothed with files and rubbed with sand. Lamps of copper, silver, and gold were most popular, but lamps of tin, brass, and iron were made as well. Almost all lamps of the medieval Islamic world were fueled by olive oil, except in India, where other vegetable oils, such as sesame oil, were more commonly used.

From 500 to about 700 probably the most popular lamps in the Near East were made in Samaria, part of ancient Palestine in an area now in the west of Jordan. Even though Jews, Christians, and others lived among the Samaritans, the Samaritans had their own culture and decorated their lamps with their own religious symbols as well as with the images of plants. The lamps from Samaria were used in temples and homes. The use of lamps in mosques is undocumented and may have contravened Islamic injunctions against pagan images. Samaritan lamps almost always had nozzles that were somewhat like spouts on jugs, into which wicks were inserted. The wicks soaked up oil from the lamps so that the flame burned more of the oil than the wick. When first sold, a lamp from Samaria usually had a closed nozzle that would require opening by its new owner; the closing of the nozzle's hole apparently symbolized the purity of the vessel of the lamp. Jews of the region especially valued Samaritan lamps that were decorated with plants and that had two nozzles. For the Jews of the medieval Islamic world, grapes on their lamps symbolized the entrance to the long-destroyed second temple of Jerusalem, the center of the Jewish faith.

Byzantine lamps were typified by their slipper-shaped style. Elegantly simple, these lamps were often highly polished. They typically had more than one nozzle and had handles. This style lingered for centuries, perhaps because Byzantine craftsmen set up shop in Muslim cities. These lamps were found in ordinary homes. The Byzantine-style lamps of the first two or so centuries of the Islamic world featured images of the cross, flowers, trees and other plants, and birds and other animals. These images were gradually replaced by geometrical designs, probably so as not to irritate iconoclasts, who objected to living things being portrayed in art.

Early Muslim variations in lamps included narrow nozzles, broad bases, and elegant, sometimes flared, handles or handles shaped like knobs. Writing in Arabic sometimes appeared on early Islamic lamps but does not seem to have become common until the era of the Mamluk Dynasty (1250–1517). The mature form of Islamic lamp tended to be large and rounded, somewhat pear shaped or sometimes slipper shaped. The nozzles of these lamps tended to have grooves in them. Lamps with pear shapes and flared handles were made in the 12th century. In the Near East these were followed by lamps with twisted handles, which were followed by lamps with long, twisted handles that were common during and after the 13th century.

*Candlestick, brass inlaid with copper, silver, and black organic material; Afghanistan; ca. 1150–1200* (Freer Gallery of Art, Smithsonian Institution, Purchase, F1951-17)

In Muslim homes such lamps were placed in niches in the wall, not only for convenient lighting but also as a subtly symbolic act in which the lamp in its niche reminded one to seek God's light. Lamps were sometimes placed on stands. It is likely that lamps were also hung from ceilings in a manner reminiscent of Indian customs. Such lamp holders could have several branching arms, each holding a small lamp. In palaces and mosques lamps were often ornate and could be hung singly or in groups over hallways and prayer rooms. The palaces of caliphs and sultans were dazzling sights at night, aglow with thousands of lamps cared for by dozens of servants.

Candles may have seen more use in the eastern reaches of the Islamic world, as is evidenced by the many fine examples of candlesticks that survive from Afghanistan and Iran. They often gave metalsmiths the opportunity to display their skills. From Afghanistan came candlesticks of hammered brass in the shape of a drum with a candleholder on top. The record of candlesticks from Iran is more complete, with specimens including sticks of bronze with gold and silver inlay. Such ornate candlesticks could be afforded only by the wealthy and may have been intended either for their homes or as gifts to mosques.

## ► inventions

### INTRODUCTION

Many inventions of medieval times have no known inventors. Much of the technology and economic and spiritual life of the medieval era were created by people working without notice or credit, improving their tasks in many small ways and oc-

asionally large ones. The rope bridges of the Andes may have been group creations, inventions developed by communities rather than individual people. Many other inventions may have developed out of earlier practices in a manner that from the hindsight of hundreds of years of history seems logical, almost inevitable, although the inventors may not have found the developments either logical or inevitable. Indeed, they may not even have noticed that they had invented anything new.

For example, was the North American tepee the inspiration of one person, who contemplated the mobile society's need for portable shelter and came up with the idea of a frame of wood around which animal skins were wrapped? As simple as the tepee may look at first glance, it was the composite of many technologies as well as improvements that may have come with use. The choosing and cutting of poles may have evolved out of techniques for building huts. The skins came from skills in skinning animals and tanning their skins. These skills, in turn, required skills at making the knives used in the skinning as well as for identifying and applying the tannins for the tanning process.

Was the hole at the peak of the tepee obviously required from the first, or did people suffer from smoky tepees until they hit on the idea of allowing the smoke from a hearth inside to escape upward? Perhaps people originally made fires only outside, and the making of hearths and holes in the roof occurred simultaneously. Looking at all that it took for people to figure out how to secure a tepee and make it portable must inspire awe at the inventiveness of its creators, or at least admiration for how they solved many problems to make their technologies succeed at the tasks they set. Looking at invention for the thousand years of the medieval era, we see the wonderful ability of ordinary people as well as geniuses to invent what they needed to make their lives better.

That last may be crucial to understanding medieval inventiveness. Pure scientific inquiry as it is known today was rare in medieval cultures. It is possible to see times and places where people pursued knowledge just out of the desire to *know*, as in the case of many Islamic astronomers in the first 500 years of the Islamic world, but even during those centuries of invention, most astronomers were motivated by religious faith—the belief that they were pursuing the wishes of God, who created a universe for people to know.

In general, invention had a purpose. In the medieval Islamic world, though, inventors faced a problem. There were people who object to their inventions on religious grounds, arguing that the world of Muhammad was the ideal world and that change was therefore bad. Even though invention seems to be a fundamental part of human nature, so is a desire to keep the world familiar, to discourage changes that make one feel uncomfortable or out of place. In China the magnificent

sailing expeditions of perhaps the greatest ocean-going vessels of the medieval era were ended just as sailors were on the verge of discovering a way to the Atlantic south of Africa. Imagine what the world might have been like had Chinese ships sailed into Lisbon in al-Andalus. It is often noted by historians that the voyages of discovery, which involved many small and large advances in the technology of shipbuilding, ended because factions in the imperial government argued that the Chinese empire had everything it wanted and therefore voyages of discovery were a waste of time. A more fundamental reason was that the voyages were costly and the money spent on them was wanted for other projects in the empire.

This touches on another aspect of invention: Not even the most famous of inventors acted alone. They required help. During the medieval era can be seen the development of centers of invention. These required three elements: the inventors, the skilled workers who aided the inventors, and people to pay the inventors and protect them. Having a patron was common in much of the world. Inventions such as that of the crankshaft made by al-Jazari in the 1100s were not organic developments naturally arising out of older practices. They required thought and the application of mathematics. Thus, in the medieval world, the mixing of cultures played a vital role in inventions. The early Islamic scholars thirsted for knowledge, usually believing that every morsel of truth they uncovered was a testament to their faith in God, because God wanted them to seek the truth of his world. They translated Greek books on science and engineering; they absorbed the mathematics of India; they incorporated the technology of China, such as papermaking, into their everyday lives. Yet they were practical people, motivated like inventors elsewhere in the world by the desire to solve problems.

Support often waxed and waned for inventors and their inventions. Wars or changes in governmental leadership could shut down the work of engineers. Indian mathematicians went to China to find work, where they were honored. Arabs looked for work as far away from home as England; Syrians moved to Europe and made glass, advancing European glassmaking with their innovations as they did so. The inventions of the medieval era did not arise in vacuums; they came out of the complex interactions of creative minds and their societies.

## AFRICA

BY BRADLEY SKEEN

Anyone living in the 21st century has been conditioned to expect life to change constantly because of new inventions and the advancement of technology. But this expectation is very different from the reality of life during the Middle Ages

in sub-Saharan Africa. In that time and place, life was static, and its rhythms and character might not change for generations. When change did come, as, for example, when a new invention was introduced, it was likely to be something from one of the cosmopolitan civilizations that existed in North Africa rather than something entirely new created in the isolation of southern Africa. The greatest stimulus of change in Africa was contact between cultures. For instance, many of the Khoisan peoples of Africa made the most sweeping, fundamental cultural change in human history—from being hunter-gatherers to being farmers and herdsman—but it happened because they took up the ways of their Bantu neighbors, not because they invented new technologies.

It is important to keep in mind that inventions are rarely entirely new. More often someone sees something in a new light or is able to put together existing things in a new way. An example can be seen in a new type of architecture invented in medieval Ethiopia. According to biographies of the emperor Gebre Mesqel Lalibela (r. 1189–1229) written later in the Middle Ages, after he had been recognized as a saint, he was inspired in a dream to invent a new kind of architecture, and there is no denying that he did so. After the Christian crusaders lost the city of Jerusalem, Lalibela was constructed a new version of the city at his hometown of Roha, which he renamed after himself. In it, he constructed several churches, all of which were carved out of solid rock. Huge outcroppings of stone had trenches cut down into them to reveal the square shape of the buildings, which were then carved out room by room so that they were in every way like ordinary buildings—except that they were made of solid stone forming a single piece with their foundations in the mountainsides, rather than constructed in the usual way.

This was a completely new style of architecture, but it was not without precedent. Some of the rock-cut churches originally may have been carved out of the mountainside for use as fortresses by the earlier Axumite kings of Ethiopia. Also, some of the Ethiopian royal tombs in the city of Axum had tremendously large tombstones carved to resemble the facades of buildings. These existing structures and designs must have been in Lalibela's mind when the inspiration for the new form of the rock-cut church came to him. Thus Lalibela created something quite new out of traditions that were available to him.

Another innovation coming out of medieval Ethiopia was the domestication of the coffee bean. No one knows any details about how this was done, but it seems to have been completed not earlier than the ninth century C.E. In general, domestication of a new variety of plant takes many generations of patient breeding to move from a wild variety to one that can be grown as an agricultural product. The coffee

plant, with its bright red berries, originally grew wild in the Ethiopian highlands. Its domestication probably took place in the Ethiopian kingdom of Kaffa—hence the name *coffee*; in Ethiopic the bean is called *buna*. There is, however, a commonly told legend that a simple goatherd named Kaldi first noticed the properties of coffee by observing that his goats begin to dance after eating the distinctive red berries of the coffee plant. Despite this colorful discovery story, the domestication of the coffee plant was a process carried out by generations of Ethiopian farmers. The beans, however, were eaten raw by native Ethiopians. They did not roast them or brew coffee with them.

Sometimes inventions and discoveries must be made in order to adapt new technology acquired from elsewhere to local conditions. Sub-Saharan Africa received the process of iron smelting through cultural diffusion from North Africa and the civilizations of the Nile Valley. A very early form of iron technology penetrated into Africa. It was centered on a type of smelting furnace called a bloomery. The iron ore was smelted inside a large ceramic jar, in which it was mixed with charcoal and clay to produce a pure wrought-iron bloom, a mass of iron that “grew” from the chemical actions of the iron inside the furnace. This mass later had to be hammered into shape to make tools, weapons, and other ironware. The wrought iron did not have a sufficient carbon content to harden when quenched or to form an outer layer of steel.

Iron smelting probably did not become very widespread in southern Africa until the Middle Ages. African iron technology was for the most part limited to the northern Bantu-speaking region from Lake Victoria west into Nigeria along the equator. It was by far the most advanced technology mastered by the peoples of sub-Saharan Africa. Although it was an acquired technology (the process was probably developed in the ancient Near East), Africans made certain refinements that can be considered inventions. These had to be made to improve the process, which developed in different ways than it did in the Mediterranean or Asia, and to adapt it to African conditions.

The African inventions in iron-smelting technology begin with the process of finding and processing ore. Without a systematic understanding of geology, miners had to look for traces of iron ore on the surface of the ground. The Toro people (in the mountains west of Lake Victoria) did this by examining the balls of cow and elephant dung made by the dung-beetle or scarab. These beetles often combined soil excavated from their burrows with the soil on the surface of the ground. If iron ore was present in the immediate vicinity, the balls most likely would contain small, shiny black granules of iron ore that could be seen easily. Once these were discovered, the miners could start digging for iron ore.

This technique appears to be a unique invention of sub-Saharan Africa.

A more readily accessible source of iron ore is the black sand that accumulates in riverbeds. This consists of particles made up of minerals that have a high iron concentration. The particles tend to gather together, especially after floods, because they are heavier than ordinary quartz particles. Black sand cannot be smelted in a bloomery furnace. It is usually necessary to melt the sand in a crucible so that the impurities can be skimmed off the top, but this is possible only at very high temperatures. (Iron melts at 2,795 degrees Fahrenheit, while a bloomery rarely reaches temperatures above 2,192 degrees Fahrenheit.) Thus, black sand ore could not have been used in Africa. However, if the black sand contains hematite, or magnetic iron, the mutually attractive magnetic iron particles can be separated and concentrated by washing the ore to produce an aggregate of iron that can be smelted at lower temperatures. This process was not known in antiquity and appears to have been an African invention. It may have been suggested by the relatively shiny, metallic appearance of hematite particles compared with ordinary black sand ore. Although no one knows who is responsible for this process, it is especially common in cultures where the collection of ore is assigned to female family members of the smith, such as the Mafa people in Cameroon.

An innovation in iron smelting among the Haya who live on the western shore of Lake Victoria was the use of a blow-pipe in the production of wrought iron. Ordinary iron-smelting furnaces of the bloomery type are given drafts of air from bellows, blown into the furnace through a pipe (tuyere) leading into the bottom of the furnace chamber. The bellows used in African ironworking are very inefficient. They consist of simple leather bags mounted inside clay pots that are pulled up and down by means of an attached stick. This type of bellows goes back to ancient Egypt and was originally designed for working copper, which requires much lower temperatures than iron. The bellows must have been disseminated up the Nile Valley before the invention of ironworking. For whatever reason, when sub-Saharan Africans began to receive ironworking technology, they did not use the more sophisticated bellows associated with it. They instead improvised a system by which the smith would use a second pipe at an earlier stage of the process than the bellows to blow air into the furnace with lung power. This preheating allowed the furnace to reach the necessary temperatures for smelting.

Some anthropologists have suggested that iron smelting was not borrowed by sub-Saharan Africans from the culture of the Mediterranean but was invented independently. Their reasoning is that the African practice was culturally integrated into African civilization (meaning that it was ac-

accompanied by a social network based on iron production and possessed a number of ritual links to the worldview of African culture at large) and that it was technologically adapted to the African environment by the inventions mentioned as well as others. The persuasiveness of this argument is diminished, however, by the observation that iron-smelting technology (which originated in the Near East) was certainly borrowed by European cultures, and yet by the medieval period it had been culturally integrated into European civilization and been technologically adapted to the European environment. The technological process of using a bloomery furnace to make wrought iron was essentially the same in both African and European cultures with minor variations and improvements made on the original iron-making process developed in the ancient Near East.

## THE AMERICAS

BY LAWRENCE WALDRON

By the first millennium of the Common Era the native people of the Americas had developed numerous inventions to suit their unique needs and environments. Still isolated from contact with the peoples and technologies of the other continents, American Indians sometimes devised machines, techniques, and materials that could be either startlingly different or surprisingly similar to those of Europe. It is difficult to say exactly when many of these inventions, processes, and technologies came about because most American peoples carried their history verbally. Tragically, written records that American Indians did keep of their histories were lost in the bitter struggles that characterized the European conquest of native lands. Nevertheless, many original inventions in the fields of medicine, sports, and agriculture have been passed down to the modern world from the people who inhabited the American continents before the European conquests.

The Aztec city of Tenochtitlán is in many ways an ideal sample of preconquest American achievements in architecture and urban planning. To Spanish conquistadors, Tenochtitlán must have seemed like a floating city, with water surrounding it on all sides; raised causeways connecting the city to the lakeshore; and islands of food growing in the nearby *chinampas*, the raised earthen beds emerging from the lake bottom. The city proved to be just as inventive within as without. It had many of the conveniences, virtues, and vices of a modern city, including grid-patterned streets; monumental buildings; and plazas full of performers, vendors, and even barbershops. The Aztec city also had waterways teaming with prostitutes, who were identified by their unusual hairstyles and their habit of constantly chewing chicle, the original form of chewing gum. The emperor Mon-

tezuma I and his ancestors had established various facilities either for his or the public's enjoyment, including botanical gardens, a zoo, and public schools. Indeed, schooling was mandatory for Aztec children. There is evidence that both boys and girls were required to board at "youth houses," where they were instructed in arts and letters.

The Aztec's Inca contemporaries devised a census system that worked in conjunction with taxation based on both goods and labor remittance. Citizens of the Inca realm were required to pay their labor tax by working on various public works projects. The Inca are also known to have had a legal code that recognized and protected the rights of disabled citizens. Taxes were used to offer assistance to those and other disadvantaged people, but the disabled also were selected for jobs that fit their disabilities so that they too were taxpayers. The Inca had a less-egalitarian system of public schooling in that only nobles received an education in mathematics, literacy, and martial arts.

In the Inca Empire couriers and messengers maintained communications among distant population centers. They sometimes faced perilous river and valley crossings. With their characteristically advanced textile arts, the Inca devised several kinds of cantilevered, suspension, and pontoon bridges. Most spectacular were the large suspension bridges that spanned more than 100 feet. Such bridges were anchored into posts driven 20 feet into the ground and suspended from enormous ropes. Incan law protected bridges with the threat of the death penalty for anyone who tampered with one. Be-

*Ceramic vessel with glyphic text, Mayan culture, Guatemala, 400–550; the Mayans developed a complex pictographic system of writing.* (Los Angeles County Museum of Art, Museum Acquisition Fund, Photograph © 2006 Museum Associates/LACMA [AC1992.129.1])

cause of their fine construction and their protection by Indian and later colonial authorities, many of these bridges have survived into the modern era.

Indigenous Americans are known to have originated several unique architectural forms in the first millennium of the Common Era. Exact dates are impossible to ascertain because of the lack or loss of written or traditional accounts. The tepee of the Plains Indians and the igloo of the Alaskan Inuit may have ancient antecedents, but the connections are difficult to prove because both structures are made out of highly perishable materials that could not survive in the archaeological record. A tepee was a large tentlike structure, some 15 to 20 feet across, made of animal hide stretched over a somewhat conical frame of wooden poles. It featured an adjustable vent hole and smoke flaps to circulate and clean the air inside. The tepee could be assembled or dismantled in a few hours and could be carried by an able-bodied teenager when folded up.

Igloos were the ultimate in ephemeral or disposable architecture in that they were made of snow cut into sloping blocks. These blocks were arranged in circles of decreasing size until they resolved into a dome. With the installation of a keystone-shaped snow block at the top, the structure became extremely stable. If igloos have a prehistoric ancestor, then their domical construction predates the Roman dome. Inuit Igloos could be 6 feet tall and 10 to 15 feet in diameter. They could be built by two men in an hour, with one worker on the inside adjusting the installation angles of his partner outside. The temperature on the inside of an unheated igloo was still considerably warmer than it was outside. But when Arctic Indians lit fires within the igloos the interiors became quite comfortable. Since the entrance to the igloo was a smaller dome creating an indirect passage inward, it remained warm inside even as blustery winds blew outside the insulated structure.

Pyramids are perhaps the most acclaimed architectural invention of Native American peoples, culminating in the grand construction complexes of Cahokia, the Yucatán Peninsula, the Andes, and central Mexico. Based on even earlier prototypes, some being the oldest pyramids in the world, Common Era pyramids like those at Tenochtitlán, Palenque, and Chichén Itzá were used either as temples or as burial places. The function of the structures depended on the religious affiliations of the kings who commissioned them. On these impressive pyramid structures Mesoamericans inscribed a vast range of imagery. Some inscriptions were not merely pictorial representations but written language.

Like temples and stelae, pyramids often featured mythic, religious, or royal hieroglyphs. Classic Mayan scribes used a complete system of hieroglyphic writing with syntax, grammar, subjects, objects, and most other devices needed to

make sentences. This written language used pictographs that represented sounds. Hieroglyphs were inscribed on pyramids from Copán to Yaxchilan and at dozens of other sites during the apogee of the Maya civilization. The hieroglyphs spoke of military exploits, lines of heredity, or mythic episodes. This phonetic form of writing was not the only kind of hieroglyph, however. The later Aztec employed a more logographic form of hieroglyph (symbols representing entire words) that did not translate into any particular pronunciation but whose meaning was recognized visually.

Mesoamerican writing was not only inscribed in stone but also painted in beautiful calligraphy in bark-paper books, almanacs, calendars, accounts ledgers, and sacred scripture. Unfortunately, most of these documents were burned during the Spanish conquest and Christian evangelization of the Americas. However, archaeologists can still guess the wealth of Mesoamerican writing arts from the thousands of painted and inscribed ceramic vessels that remain from the classic civilizations of that region.

The Mesoamericans also seem to have originated forms of sign language that spread northward to the Great Plains and Pueblo Indians, such as the Kiowa, Comanche, Cheyenne, and Lakota. North American Indians used sign language for trade with other linguistic groups but also employed this quiet means of communication in the pursuit of animals, where it enabled hunters to communicate without frightening the quarry away.

Perhaps the most unique form of recording information came from the great civilizations of the Andes. The 11th-century Incan method of recording information employed a system of different-colored strings tied into various kinds of knots, each representing a number, noun, or verb. These encoded knot bundles, or quipus, illustrate the ingenuity of the preconquest Indians. Free from the homogenizing effects of their neighbors, the Inca or perhaps their Quechua-speaking ancestors developed this revolutionary method of encoding and retaining data. Recent research suggests that quipus, in fact, not only were used to record numbers and other aspects of mercantile accounts but also may have contained the grammar and syntax necessary to write fully detailed government documents, histories, and even poetry.

While ancient Indians had many elaborate religious rituals that took the form of athletic events, their Common Era descendants seemed to have enjoyed many sporting activities in a more secular setting. Many American sports played today originated in these games. Early versions of both soccer and lacrosse were played by the Indians of eastern North America. Although the games varied considerably in terms of the number of the players, they bore distinct resemblance to their modern versions. Many ball games were played by

women. Games like hackey sack and various forms of kickball were played by teams of Plains Indian women strenuously competing for accolades and prizes.

Inventions that might be more readily associated with Asia, Europe, and Africa were sometimes developed separately in the Americas. The abacus, a counting machine usually attributed to the Chinese, was used by both Mayan and Aztec mathematicians. Similarly, various sleds, snowshoes, and toboggans developed by Arctic American peoples had their analogues in other parts of the world. The sled pulled by teams of trained dogs remains a uniquely American vehicle. Because riders of these sleds could become snow-blind on their long journeys across white expanses, Indians of those climes devised goggles to cut down on the glare from the snow. The goggles fit over the eyes and let light through only a long, narrow slit.

Another ingenious Arctic American invention was the bow drill. This small tool consisted of a string looped around a friction stick, and it was used to start fires with the rapid back and forth motion of the stick being turned by the string. Bow drills could also function like early power tools, in that they enabled the user to rapidly make holes in other tools and weapons. The Maya used bow drills in sculpture and even in dental procedures.

In the field of weaponry South American warriors developed an impressive array of projectiles. Amazonian Indians possessed a frightening arsenal of poisoned blow darts, which, fortunately for their enemies, they used mostly on birds, monkeys, and other prey high in the rain forest canopy. Besides the standard arrows, spears, clubs, maces, and fighting sticks, soldiers in the Andes and southern South America used bolas to fell or strangle their adversaries or prey. These stones on strings opened like propellers when flying through the air but then rapidly tangled once they hit the legs, arms, or necks of their intended victims. Bolas were made famous by Argentine gauchos in later colonial history.

Inca warriors also heated stones until they glowed red, wrapped them in tarred cloths (which caught on fire), and hurled them at their enemies. The detrimental effect of these burning missiles was equaled only by their fearsome appearance raining through the air like meteorites. With their invention of metal casting in ancient times, the Andeans might have ensured that they had among the hardest and sharpest weapons used in close combat. However, Andeans used their metallurgy mostly to produce art, not weaponry. In any case, the Aztec battle-ax would have surpassed any metal implement the Inca could make since it was edged with obsidian, a hard volcanic glass that could be more than razor sharp. In the Great Basin states of Idaho, Oregon, Utah, and Wyoming, prequest Indians devised a bow laminated with

animal sinew that greatly increased the tensile strength of the weapon. This bow sent arrows flying as much as twice the distance of enemy arrows.

Many scientific and medical innovations arose from the Americas following the beginning of the Common Era. While Native North Americans developed a wide range of antibacterial and antiviral medicines, Mesoamericans created a system of vigesimal math, mathematics based on cycles of 20 rather than 10 that fostered increasingly complex astronomical and calendrical computations. Advanced obstetrical practices were developed, probably based on already sophisticated ancient techniques. Prenatal care, methods of inducing labor, gravity-assisted birthing, sedation and pain killing, regulation of uterine bleeding, and induced expulsion of the placenta were part of North, Central, and South American obstetrics. Additionally Mesoamericans had techniques for correcting breech presentations and even performing cesarean sections.

Central and South Americans developed several tools to aid in their medical procedures. For instance, the Inca created stretchers for carrying disabled patients, and both the Aztec and Inca developed surgical forceps for removing bone fragments. In fact, such forceps may have been used in brain surgery, a technique independently invented in several American native societies and known to have been performed in triage conditions after warfare. Aztec surgeons also attached wooden nails deep into the center of broken bones that were difficult to reset.

In a unique use of unmodified natural tools, Amazonians used the jaws of large leaf-cutter ants as surgical staples to close wounds. The insects were held and made to bite the opposite edges of the patient's wound so that their strong jaws would contract and close the laceration. Once these powerful pincers were locked in place, the surgeon killed the ant, breaking off his body and leaving the locked jaw in place as a surgical staple. These natural clasps were removed once the wound had healed. Much of prequest American medical knowledge seems clustered around emergency and obstetric procedures. However, a wide range of preventive medicines, quarantines, holistic health foods and herbs specifically chosen for the patient, and even plastic surgery and talk therapy were practiced by the Aztec and some North American Indians, including the Chippewa and the Iroquois.

Among the medicines invented or discovered by Native Americans in the prequest Common Era were quinine from the bark of the *quina* (cinchona) tree, used by the Andeans to treat fevers (and later malaria in the colonial period); coca, primarily used by Andean workers as a stimulant to increase resistance to fatigue and cold but also used as an anesthetic in surgery; stone seed and dogbane, used by the Sho-

shone, Potawatomi, and other Great Basin North American groups as oral contraception; kelp, used by Indians throughout the Americas to treat goiters and other iodine deficiencies; and ipecac, used by Mesoamericans and Amazonians to induce vomiting and cleanse the intestines of parasites.

The American peoples were generally conscientious in their observance of personal hygiene. Locating their residences near fresh or running water was an intentional decision, but Indians went far beyond bathing in their daily cleansing rituals. Most North American peoples washed and removed stains from their clothes using various forms of vegetable and herbal detergents; Mesoamericans used both copal and fragrant oils as underarm deodorants; and both the Inca and Aztec used frayed, fibrous tree cuttings to brush their teeth. People on all the American continents used some manner of toothpaste, usually made of a mildly abrasive mineral, such as salt, charcoal, or ash.

From maple syrup to salsa and tortillas, most modern Americans are familiar with the legacy of Native American foods to the colonists that followed. Less familiar are the facts that Caribbean Indians invented the barbecue method of cooking meat sometime in the first millennium and that the indigenous people of Canada and Alaska were the first seafarers to engage in open-sea whaling. Fishing methods were particularly unique in the Americas. Many Indians from California to the Caribbean used poisonous chemicals to capture fish. Derived from plant sources like yams and manioc, the poisons had no effect on people, making this chemical fishing technique both expedient and safe. Ice fishing, with spears through holes in the Arctic ice sheets, was yet another unusual method of fishing pioneered by Native Americans.

Some Indian agricultural innovations, such as the domestication of corn, were already millennia old by the advent of the Common Era. But Native Americans continued to experiment with plant species, not always to increase their food supplies. Many centuries after domesticating corn, American Indians began to domesticate cotton. The Mexican variety would go on to out-compete all other varieties of cotton on the modern world market. Other Native American innovations were in methods of cultivation rather than the crop itself. Increasingly, archaeologists have begun to speculate that perhaps the Amazon rain forest, for all its wild, “virgin” appearance, may be partially anthropogenic, that is, influenced by humans. Indians may have selected certain tree species for planting in specific areas of the Amazon, thereby increasing the density of useful species while maintaining the appearance and ecology of the original rain forest. Concentrations of fruit-bearing species or trees that attract certain types of animals favored in hunting would be made to grow together, all for the harvesting convenience of the Indians who lived

nearby. These deliberately planted trees are discernible only when counted, which is precisely how some scholars have concluded that certain groups of Amazonian trees are the result of human agency.

Other recent studies provide evidence that precolonial Amazonians manipulated their environment in this inconspicuous way. *Terra preta* is a dark soil with extremely high fertility that Amazonian farmers seem to have developed through a process of phased mulching, whereby a reproducing bacterial cycle is set in motion, causing the soil to remain perpetually fertile. Modern farmers have located sites that repeatedly yield this rich soil and have begun either selling the *terra preta* or trying to reproduce its mysterious recipe. Because pottery and other centuries-old human products have been found in *terra preta* deposits, archaeologists are without doubt that this self-replenishing soil was purposefully engineered by Indians for use in the raised-bed agriculture of the Amazon.

## ASIA AND THE PACIFIC

BY CARYN E. NEUMANN

Arguably the most important inventions of the medieval era originated in Asia and the Pacific. These inventions appear to have been entirely empirical rather than rooted in scientific theories—ad hoc creations and not the products of large numbers of technicians dedicated to the process of invention. Until Europe advanced after the 13th century, China led the medieval world in technological advancements. The compass, mechanized printing, and gunpowder all are Chinese inventions that proved critical to the growth of the modern world. As Chinese culture spread throughout Asia and the Pacific, these major Chinese inventions spread as well.

One of the greatest Chinese inventions, the compass, removed much of the power of weather from travel. With the compass a mariner could set sail at any time, since clouds that obscured the sky were no longer a factor to consider. The compass could always identify the position of Polaris, the primary star used in navigation. The device is built on the magnetic power of the lodestone, which had been identified by both the ancient Greeks and the ancient Chinese. The lodestone consists of magnetite, a natural oxide of iron that exhibits magnetic properties. By the sixth century the Chinese scientifically passed the Europeans by discovering the phenomenon of induced magnetism. A piece of metal could be magnetized by stroking it periodically with a lodestone. The Chinese discovered the declination as well as the polarity of the magnet by the eighth century. These developments made the invention of the compass possible. By the 11th century the Chinese were using the compass for navigation. This

early form of compass consisted of a magnet inserted into a piece of wood cut in the shape of a fish and set afloat on water. The Chinese compass spread by travel and trade throughout the Pacific, thereby aiding mariners in Japan, Indonesia, and Korea, among others.

Merchandise and technological ideas spread freely throughout Asia. The Chinese developed boats propelled by paddle wheels in the seventh century. A musical instrument called the fiddle bow appeared first in Java in the late eighth century and migrated through India before reaching Europe in the 10th century. Other musical instruments that were invented in Asia include the transverse flute and the two-ended drum. The Malay blowgun, or *sumpitan*, followed a route similar to that of the fiddle bow. When Buddhism came to Japan in 552, Chinese culture and science followed in its wake. Chinese balances for weighing and tiles for the roofing of temples were introduced into Japan about 590. The paternoster pump (a type of pump using a chain), the vertical-axle windmill, the horizontal loom, the spinning wheel, and the trebuchet all are Chinese inventions that subsequently became popular in medieval Europe.

Several Chinese military inventions enjoyed enormous worldwide popularity. The trebuchet first appeared in China in the third century. This military weapon consisted of a long beam pivoting on a frame. A sling rested at one end of the beam to hold a missile. Ropes at the other end of the beam would enable soldiers to pull downward simultaneously upon a signal, thereby raising the sling and hurling the missile toward the enemy. The Chinese first used gunpowder in the seventh century for fireworks. By the end of the 10th century gunpowder was well established as a propulsive agent in war weapons in China. The earliest references to its use in war occur in the 1044 *Wu ching tsung yao* (Compendium of the Military Arts), by Tseng Kung-Liang and others. The first projector using bullets, the *t'u huo ch'iang*, had a bamboo barrel and was made in 1259. Metal gun barrels were developed soon thereafter. The medieval Chinese were the first to use rockets as signals and as weapons.

The dissemination of all of these newly discovered inventions was aided by the advent of mechanized print. The first references to the use of block printing in China are found toward the end of the Tang Dynasty, about 900, in the *Chia hsun hsu* (Family Instructions) of Liu Pin. A Chinese version of the Diamond Sutra, a Buddhist text, dated May 11, 868, is long thought to be the earliest extant printed book. The book appears to be the result of a long experience in block printing; consequently, the skill must have originated years before its printing. A Buddhist charm printed in Japan about 770 and a charm printed in Korea about 751 also have been located, giv-

ing further support to early medieval origins for mechanized printing.

About 1040 movable type printing began in China. According to the 11th-century *Meng ch'i pi t'an* (Dream Pool Essays), written by the Chinese scientist and government official Shen Kua (1030–93), sticky clay was cut in characters as thin as the edge of a copper coin. The characters were then baked to be hardened. The printer then prepared an iron plate by covering it with a mixture of pine resin, wax, and paper ashes. When ready to print, the printer set an iron frame on the iron plate. The type was placed on the frame, set close together. When the frame was full, the whole made one solid block of type. The printer then placed the frame near the fire to warm it. When the glue was slightly melted, the printer took a perfectly smooth board and pressed it over the surface so that the block of type became even. As a rule, two frames were kept going continuously to speed the printing process. While the impression was being made from one frame, the type was being set on the other. Type of burnt earthenware was sometimes replaced by type made of other materials. Tin type became popular in the early 14th century. Koreans were known to use bronze in the early 15th century. However, because of the large number of Chinese characters, block printing survived despite the advent of movable type.

Papermaking is another Chinese invention that developed before the eighth century and spread throughout Asia. The Chinese were the first to invent a printed paper currency, and such money was in common use by the 12th century. The circulation of Chinese currency to Europe probably served as the first introduction of printing to Europeans.

After enjoying a period of enormous invention, China effectively entered a state of scientific hibernation soon after the 13th century. With the engine of Asian science stilled, the development of inventions through Asia and the Pacific precipitously declined. In the 16th century China began to acquire scientific instruments from the Europeans, the new leaders of invention.

## EUROPE

BY SHANA WORTHEN

The Middle Ages was a time of widespread technological development. Many inventions were developed in Europe, including the heavy plow, the mechanical clock, and guns. Others, including gunpowder and the magnetic compass, were imported from the Near East, India, and China via traders and travelers and adapted to new uses.

Falling population numbers led to the end of slavery over the fifth to seventh centuries and thus encouraged the development of more-efficient methods of farming. The heavy

plow opened up new lands for cultivation in the early Middle Ages, especially in northern Europe. It was three tools in one: The coulter was a vertical blade that broke the soil ahead of the plowshare, the plowshare cut through the earth behind it, and the moldboard turned over the cut earth, loosening and aerating the soil for planting. The earlier form of plow had only a plowshare.

Other agricultural technologies that were either medieval inventions or at least rarely used earlier include the scythe (to cut hay) and the pitchfork (to move hay around). Hay became a much more important crop after use of the heavy plow and the resulting large number of oxen became widespread. The wheelbarrow first appeared in China in the third century and in Europe in the 13th century.

Greater efficiency in farming, among other factors, led to population growth starting in the 10th century. More people living in northern Europe's colder climates increased the need for supplies of warm clothing. Wool from sheep became a prime commodity. But the process of turning raw wool into wearable clothing was long and labor intensive. Two 13th-century innovations hastened some parts of the process. The metal-toothed comb sped the task of carding, or combing, the wool, but the cost of efficiency was quality; it produced shorter fibers and a rougher feel. The spinning wheel, brought to Europe from the Near East in the late 13th century, helped make quicker work of turning raw wool into thread.

The versatility of the horse was heightened by several medieval inventions. The padded horse collar enabled farmers to hitch horses to plows, although horses were never used as widely for plowing as were oxen. Nailed horseshoes were first imported into Europe from Asia in the eighth century, around the same time as the stirrup. The stirrup made possible a new style of combat. With their feet securely braced in stirrups, riders in combat could use battle-axes and, when it was later developed, the heavy lance. The heavy lance was used in jousting, a sport that employed the mass of the horse, rider, and lance as a weapon to knock the combatant off of his horse. It is not clear whether the lance was ever used in actual combat.

The medieval crossbow was developed in Italy in the 11th century to pierce metal armor. Unlike earlier, rarely used versions, the medieval crossbow was loaded by bracing the bow against the ground with a footrest and pulling back the bowstring with a hook attached to the archer's belt. It fired arrows at faster velocities than could a regular bow, although it was slower to reload. Likewise, the trebuchet, a weighted lever used for hurling stones several hundred yards, was developed to do damage to the heavy masonry walls surrounding fortifications. Originally powered by human force, a revised trebuchet developed in Europe around the end of the 12th century replaced human effort with a heavy counterweight.

The lack of a cheap labor supply led to widespread adoption of the water mill, a late Roman invention, and the development of the windmill. Both tools enabled millers to grind grain, or meal, more quickly than they could with the quern, the most basic kind of hand-operated mill. The typical upright post mill, a kind of windmill, was developed in the 12th century in England, although it may have been adapted from a seventh-century Persian variant that had a vertical axis for the sails and was used in tunnels to funnel the wind. Windmills, water mills, and querns all were used over the course of the Middle Ages, none ever fully replacing the others and each used in a unique location. Water mills were the most widely employed; windmills were put on the tops of hills and in other places without a regular watercourse, where water mills could not operate; and querns could be used cheaply at home to produce small batches of meal.

By the 14th century the trip-hammer, a Chinese invention, was being used in European mills to power machines for forging iron. The blast furnace, another Chinese innovation, employed waterpower to blow air via bellows into a thick-walled hearth to superheat the temperature within, allowed European iron production to increase dramatically starting in the mid-14th century. The new supplies of iron were used for making farming tools like scythes and spades, domestic tools like pots and baths, and combat technologies like cannons and guns.

Gunpowder was first imported from China to Europe around 1260. Used for fireworks and rockets in China, gunpowder in Europe became a tool of war. The first record of a cannon in Europe is from Florence in 1326. The earliest cannons were small, on the scale of guns rather than the wall-battering giants developed and widely used in the 1400s.

In the 13th century the mechanical clock was developed in Italy, France, or England. The earliest mechanical clocks were large, heavy devices, and because they were used only in church towers to ring bells, they did not need faces. Clock hands and faces became increasingly common in the 14th century, but it would be several centuries before they became standardized: most only had an hour hand; some ran counterclockwise; some started at the top, others at the bottom; some showed 24 hours, others 12. Mechanical clocks spread rapidly across Europe. Towns erected their own bell towers, competing with churches for control over their citizens' work schedules. As clocks became more common, smaller and smaller versions were made. By the 15th century wealthy families were buying clocks for their households. Hourglasses and other kinds of sand timepieces are also medieval inventions; none are known of before the middle of the 14th century.

Spectacles, or eyeglasses, were invented in the late 13th century, approximately 30 years after the magnifying glass.

*The Hurbeck hoard of knives and tools used in farming, including four scythes, Anglo-Saxon, ninth to early 10th centuries* (© The Trustees of the British Museum)

Reading glasses were originally made with horn or boiled-leather frames and rock crystal lenses, although ground glass soon replaced the crystal. Glasses for nearsightedness were not developed until the mid-15th century. Among other wearable goods, buttons dramatically changed fashion in Italy in the 13th century and made necessary another innovation, close-fitting underwear.

The eating fork was first developed in the Byzantine Empire and started to appear in Europe by the 11th century, although it was not a common implement until the 14th century. Alcohol distillation was invented by Persian or Arab chemists in the eighth or ninth century, enabling for the first time the regular production of spirits. By the 12th century stills were in use at the medical school in Salerno, Italy. Both in the Near East and in Europe spirits were initially used as a base for perfumes and for medicinal purposes.

The fireplace was developed in the 12th or 13th century, helping to direct the smoke rising from domestic fires away from people using the fire. Before the fireplace and its chim-

ney, smoke was vented with a small hole in the roof. Another household change occurred in the late 14th and 15th centuries, when glass windows were first used. Individual windowpanes were small but were pieced together with lead to form larger windows that let in more light than the waxed cloth previously used.

Not all medieval inventions were practical in nature. Playing cards were invented toward the end of the 14th century in western Europe. The elaborate designs of the four suits—scimitars, polo sticks, cups, and coins—would become the basis for tarot cards later used throughout Europe for divination.

The magnetic lodestone, long known in China and the Near East, was used by 13th-century European navigators in the form of the compass. Sailing by compass directions, dramatically opened up trade and travel options, by obviating the need to sail within sight of coastlines. The earliest-known canal locks date from the 14th century in what is today Belgium and the Netherlands.

The first carriages started to be used from the 1370s, possibly earlier. Rocking carriages originated in what is today Hungary; the body of the carriage was suspended by leather straps from the frame, a design that helped smooth out bumpy rides. By the 15th century they were common in western Europe.

The numerous technological developments that occurred over the course of the Middle Ages were primarily the work of unknown inventors. People were only just starting to focus on contemporary inventions as something of interest in their own right. This lack of interest in the subject of invention means that the identities of very few medieval inventors are known.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

In the medieval Islamic world there was a tremendous desire to learn about the world. Learning about nature and how it worked seemed to many people to be a godly pursuit, because it involved understanding God's creation. In the process of making discoveries about nature, Muslims learned how aspects of the physical world worked, and out of this knowledge came new ways for keeping time, new methods to move water efficiently, and perhaps new sciences, such as pharmacology and agriculture. Medieval Muslims would not have used the term *science*, which they reserved only for the study of religion and religion's application to living; nevertheless, Muslims developed what modern people would call natural science. From the 10th century to the 12th century Islamic inventing flourished: Numerous mathematicians, astronomers, and chemists hit upon fresh ways of thinking about and seeing the world.

In the Islamic world there was always conflict between those who wished to invent and those who resisted change to their way of life. This conflict manifested itself in two major ways. One manifestation was in a division between theologians and philosophers. In general, the philosophers viewed the secular world as existing apart from the religious world. They believed that the Koran applied only to spirituality and that the Hadith (comprising accounts of Muhammad's life and sayings) was too fragmentary to supply guidance to research into the natural world. They were opposed by theologians, who insisted that all of life was religious and that the study of the natural world and the study of God were the same thing, indivisible.

The other division had become a powerful social force by the 12th century and came to dominate much of Islamic teaching. This division involved the belief that just as the Koran was the final revealed word of God, given to God's last

prophet, Muhammad, and just as Arabic was the one language in which to read and understand God's word, so too the world in which the word was revealed was the only proper world in which to live. In sum, this point of view held that nothing not existing in the age of Muhammad—that is, the seventh century—should exist in the world thereafter.

These views—that there was no secular world, only a religious one, and that the seventh century represented the ideal level of human advancement—had real-world consequences. Great observatories were torn down because clerics declared them to be too secular. Financial support by governments and private donors was often withheld from inventors, and some scientists and inventors had to travel from place to place to find sites where they could do their research and even teach in schools. It is because of the general, but not complete, curbing of invention in the Islamic world after the 12th century that some historians refer to the period from 900 to 1200 as a golden age for Islamic science and invention, and historians also use it to account for why the civilization of the Islamic world outshone many other cultures in scholarship and invention in the 12th century but eventually fell behind Christian Europe in technology and scientific research.

There were also divergent views on medicine, creating a long-term tension within Islamic medical circles. One view was *tibb nabawi*, meaning “prophetic medicine.” This philosophy developed as a reaction against ancient Greek learning, which in translation had spurred much growth in medical practices in the Islamic world. *Tibb nabawi* looked to what the Hadith said about how Muhammad and those close to him dealt with health and medical issues. In general, it disregarded what the ancient Greeks, Indians, and Chinese had to say about medicine. The majority of Islamic physicians followed another point of view—that they as medical professionals were searching for truth and that it did not matter where the truth came from. These physicians were notable for their keen observation of symptoms. One such physician, Ibn al-Khatib (ca. 1313–74), through empirical observation, learned how contagious diseases spread, especially plague. His work may have led to the invention of inoculating people against diseases, which peoples of the Near East seem to have been doing before Europeans took up the practice.

Although the Islamic world may have lagged behind the Far East in surgical practices, its inventors created numerous surgical instruments, including types of saws and scalpels that are similar to instruments of modern surgeons. In other ways, physicians of the Islamic world may have been unsurpassed in the medieval era because they invented a way of thinking about treatment of patients, based on observation. Rather than relying on tradition, even the tradition of the ancient Greeks, they observed and noted how medicines affected

## ARABIC POETRY

Not all inventions, and certainly not all Arabic inventions, fall within the sphere of engineering and the physical sciences. Some of the most important and most influential Arabic inventions were made in literature. Rhyming poetry, and even the sonnet, perfected in English by William Shakespeare, all begin in Arabic. Although rhyme has been downplayed in English poetry in modern times, it was an important element in the poetry of all the European languages during the Middle Ages and after. But it was not always so. Poetry written in ancient Greek and Latin did not rhyme. In Old English poetry the device of head rhyme, in which the beginnings of words at the beginning of poetic lines had the same sound (alliteration), was actually the main stylistic ornament.

The tradition of poetry in Arabic took a unique form. Going back even to the oldest Arabic poetry in pre-Islamic times (from the sixth century C.E.), the poetic line consisted of a particular pattern of stressed and unstressed syllables. Lacking in Greek and Latin, versification based on stress is a precondition of rhyming poetry, since for two words or phrases to rhyme their stressed syllables must have the same ending and all following syllables must be identical: “quickly” and “prickly” rhyme, but “quickly” and “swiftly” do not make a good rhyme because the stressed syllables are too different. Rhymed verse in Arabic consisted of a series of couplets (a group of two lines). Originally the last word in the second line of the couplet was the same throughout the poem. Over time, this requirement was loosened so that the couplets only needed to rhyme.

This form of stressed, rhyming poetry was picked up by the troubadours, an influential group of poets in southern France during the 11th to 14th centuries. Moving between the courts of different noblemen in many countries, they encountered Arabic verse in Spain at the same time that European scholars were traveling to Spain to translate Arabic scientific literature into Latin. Using Arabic verse as their model, the troubadours soon made the rhyme schemes they used more varied. They developed new forms, such as the sonnet, which became popular all over Europe and dominated poetry in the vernacular languages down to the 21st century.

people. By carefully observing which substances affected people in which specific ways, they created a large pharmacopoeia, a catalog of medicines. An Islamic engineer's invention of a distillation process expanded the kinds of medicines that could be used. In distillation, substances were separated by using their different boiling points to evaporate one substance while leaving the other behind. This process is now well known in the manufacturing of alcoholic spirits, but in the medieval Islamic world it resulted in the identifications of the precise active ingredients used in many medicines, allowing physicians to prescribe ever more precise treatments for their patients. Another engineering feat was the development of the syringe by Ammar ibn Ali al-Mawsili in Iraq in the ninth century; this instrument was developed to extract cataracts from the eyes.

Among the most famous fields of invention in the Islamic world were astronomy and mathematics, two disciplines that in Islamic practice were almost inseparable. The early motivation to find better ways to look at the sky and to use numbers to quantify what was seen stemmed from the desire to be able to identify the exact direction of Mecca from anywhere on earth, because facing Mecca was an important part of daily prayers. Better ways for telling time

stemmed from a similar desire, in that prayers were supposed to be said at certain times of the day. For instance, the sundial had been in use since ancient times, but Muslim mathematicians used what they had learned from Indian trigonometry to calculate tangents to the circles on sundials, making it possible to calculate small divisions of time; in the process they added to and further developed trigonometry as a mathematical science. They adapted the Greek astrolabe, used to calculate the altitudes of celestial bodies, and in the 14th century they invented spherical astrolabes for more precise calculations. By the 12th century circular astrolabes that were small enough to fit in a pocket had become available North Africa.

The most precise astronomical measuring devices were big—the bigger the device, the more finite the calculations could be—and these were built as parts of large observatories. Many historians of science credit the Islamic world for inventing the first true observatories, places where scientists could gather to observe the heavens and record what they found. The observatory built by Ulugh Beg (1394–1449) in Samarqand was particularly famous, with part of its huge sextant dug into the ground. Little of the observatory survives because it and other places of learning were destroyed at the

behest of clerics who saw such places as too secular. In about 1015 in al-Andalus, Abu Ishaq Ibrahim ibn Yahya al-Zarqali (1028–87), known to the Western world as Arzachel, invented the equatorium, a device for finding the positions of celestial bodies.

Probably the most famous inventor in the medieval Islamic world was Ibn Ismail Ibn al-Razzaz al-Jazari (1136–1206). He was the chief engineer for the sultan Nacer ed-Din Muhammad Ibn Qura of Diyarbakir, who commanded al-Jazari to write a book about what he knew. In this book, the *al-Jami Bain al-Ilm Wal-Amal al-Nafi Fi Sinatat al-Hiyal* (*The Book of Knowledge of Ingenious Mechanical Devices*, 1206), al-Jazari describes approximately 60 mechanical devices, most of them derived from other inventors but with modifications of his own, with the others probably being his creations. Among the best known are his water clocks, including portable ones. These were portable not in the sense that they could be carried in a person's pocket but in the sense that a couple of people working together could wheel or carry them from one place to another without harming the mechanism. Perhaps the most significant invention of al-Jazari from an engineering point of view was the segmental gear, which appeared in his timepieces and in another of his inventions, a programmable robot consisting of humanlike figures that resembled musicians. It was intended to entertain the sultan's guests at parties and was a boat that floated in a lake or a pond. Gears in it had pegs that could be removed and moved. During operation these pegs struck levers that moved the automatons. The tunes varied according to the placement of the pegs.

Another of al-Jazari's inventions was one of many the Islamic world created to help move water for agriculture. The Islamic world's contributions to agriculture tended to be in many small aspects that may have been inspired by developments in India, China, and ancient Egypt. The changes were practical, created by anonymous people who probably hit upon modifications of such lifting devices as the block and tackle (pulley blocks with cable for lifting) as part of their everyday work. A nettlesome problem was moving water from one level, perhaps a low river, to a higher level, such as an irrigation canal. This process tended to be labor intensive. For example, along rivers people built recessed tiers into the riverbank. On each tier stood men, each man controlling a large bucket swaying from a crossbar that was attached by a hinge to an upright post, allowing it to sway up and down and to be turned to face the river or the next tier up. Water was dipped out of the river by a man on the first tier, who pivoted his crossbar to pour the water from his bucket into the bucket of the man next higher up, with this process continuing until the water could be poured in the canal.

An alternative was the Archimedes' screw, a screw-shaped device in a tube or a tunnel that when turned would raise water upward. Al-Jazari was probably inspired by the Archimedes' screw when he invented the crank mechanism and the crankshaft. This device took rotary motion and turned it into linear motion, much the way an automobile's crankshaft converts motion from an engine into motion that turns wheels. This invention has many applications in the modern world, but in al-Jazari's time it allowed people or domesticated animals to turn a wheel by walking against it or pulling it; their force was transferred to a wheel outfitted with scoops or buckets that continuously dipped into a source of water, such as a river or a lake, and carried the water up to be poured into an irrigation ditch or a canal. The flywheel, invented in al-Andalus, smoothed out this transfer of force, making the turning of the wheel with scoops smooth, even if the turning of the rotary wheel was uneven.

## ► language

### INTRODUCTION

Two factors account for the changes in world languages during the Middle Ages: migration and conquest and isolation. Arabic, along with Bantu and Turkish languages, were spread across continents as their native speakers left their homelands. Other languages, most notably the Romance languages descended from Latin, developed because populations found themselves cut off from contact with the larger world.

The Middle Ages saw three great migrations. One was of the Bantu-speaking peoples from the region of the upper Congo. They swept across southern Africa, bringing a new culture marked by agriculture and ironworking technology as well as the proto-Bantu language, and they supplanted or absorbed local cultures, many of whom were hunter-gatherers. After this expansion, the forces of isolation differentiated proto-Bantu into many of the modern languages of central and southern Africa. In another wave of conquest Arab groups occupied the Near East and the Mediterranean coast of Africa, replacing many local languages with Arabic. Speakers of Altaic languages (Turkish and Mongolian) poured out of inner Asia at the beginning of the Middle Ages in raids and conquests fueled by the invention of the stirrup and the military supremacy this brought to their cavalry. Turks dislodged Hunnic peoples to the west, who in turn brought pressure to bear on the Germanic tribes that as a result broke into and

destroyed the Western Roman Empire. Mongols conquered China and India as part of the same outward migration. While these migrants absorbed the languages of their subject peoples, a later wave of Turkish tribesmen conquered much of the Islamic world and established the Ottoman Empire, bringing Turkish as the new dominant language of Asia Minor (Turkey).

The most profound linguistic effects were felt in the West. The political cohesion of the Western Roman Empire was destroyed, and regional dialects were allowed to develop in isolation, becoming within a few hundred years early versions of the modern Romance languages: Portuguese, Castilian, Catalan, Provençal, French, Italian, Romanian, and others. The Germanic languages of the conquerors were also quickly lost (except in Britain). Even these languages existed as smaller groups of dialects. Only with the invention of printing at the end of the Middle Ages did the modern national languages emerge in western Europe.

Isolation was also the main factor in the development of language in the Americas. Whether or not the initial Asian immigrants who populated America across the Bering Strait all spoke languages of the same family, by the Middle Ages the isolation of small populations and the restless movement of tribal groups had given birth to an amazing diversity of languages with nearly 150 distinct language families (each equivalent to Indo-European or Semitic), not individual languages, in South America alone and nearly 100 more in North America.

Scholarly languages exerted their influence. In the West, Latin was no longer spoken as a primary language but was studied and used as a display of learning and social position. In China there were many native Mandarin speakers, but the writing system of that dialect was adopted for reasons of prestige by speakers of other dialects and even by Japanese speakers. In Korea, Mandarin enjoyed a status more like that of Latin in the Western world, and no serious literature or important documents were composed in any other language.

The dispersal of the Jewish people throughout Asia, Europe, and Africa, living everywhere in isolated minority communities among speakers of radically different languages, had interesting linguistic consequences. Jews' their sacred text, the Bible, is written in Hebrew, which was a spoken language in early times. But already in antiquity Hebrew had ceased to serve as a living language for everyday use (though a form of it has been revived recently in the modern state of Israel). Most Jews in the Roman Empire, for instance, spoke Aramaic or Greek. At the same time, the learning of Hebrew was a cultural ideal of scholars (rabbis) and indeed of the entire Jewish community. In particular, Jewish boys had to learn the Hebrew alphabet and at least some Hebrew, since they were required to be able to read and interpret certain portions of the Bible in Hebrew during religious ceremonies. As a result, in the Middle Ages, Jews spoke the language common to wherever they happened to live, but they developed their own dialect (with many Hebrew loanwords and a Hebrew accent) and their own form of writing the language in the Hebrew alphabet. Thus, throughout much of the Arab world, Jews spoke Arabic but transcribed the spoken language into Hebrew, rather than Arabic, letters, creating the language known as Judeo-Arabic. In Spain, too, Jews wrote Castilian Spanish in Hebrew characters, a combination known as Ladino (from Latin). Likewise, Jews in the Rhineland developed Yiddish, a Germanic dialect written in the Hebrew alphabet. Oddly, when the Spanish and German Jewish communities fled anti-Semitic persecution, they kept Ladino and Yiddish as their languages rather than adopting the Turkish or Slavic languages of their new homelands.

## AFRICA

BY HAIG DER-HOUSSIKIAN

With regard to medieval Africa the lack of a written tradition or archaeological evidence indicating times of dispersal of language families makes a historical discussion of these families and the subgroups within them difficult, if not impossible, to fully verify. Nevertheless, certain instances of dispersal are clearly verifiable, and others are supported either by circumstantial evidence or by educated assumptions

drawn by the scholarly community. (Notably, since comparative studies intended to reconstruct parent languages and establish chronologies of expansion and dispersal no longer preoccupy the discipline of linguistics, little was added to this historical discussion through the end of the 20th century.)

The one concrete case of dispersal is the spread of Arabic, a major Semitic language, from the Arabian Peninsula into North Africa concurrent with the spread of Islam and Arabization in the eighth century. The countries involved are now known as Egypt, Libya, Tunisia, Algeria, and Morocco, including the western Sahara. In this region Islamization and Arabization progressed concurrently, although indigenous languages were not completely eradicated. Nubian, a Nilo-Saharan language, continues to be spoken as a community or home language in southern Egypt and northern Sudan despite efforts by the Egyptian and Sudanese authorities to discourage its use. Coptic, a member of the Afro-Asiatic family and a derivative of ancient Egyptian, disappeared as a language of communication sometime in the 19th century. Another such language that remains in use in modern times is Berber, a Semitic language with several dialects. Beyond the countries of North Africa—including through southern Sudan, Chad, and Mauritania—Islamization progressed, but Arabization gradually slowed and ended.

Cases of dispersal that depend on circumstantial evidence for candidacy during the medieval time frame include the spread of Fulani, a western Atlantic language, eastward from Guinea to Nigeria and the westward spread of Yoruba, a member of the Kwa family, from southwestern Nigeria along the coast to the southeastern corner of Ghana. The evidence for the medieval spread of Fulani is circumstantial in that the Fula are known to have partially Islamized the Sahelian countries as they moved east from their home base of Fouta Djallon, in Guinea; since the eastward movement involved Islamization, the spread of Fulani must have occurred after Islam arrived in Guinea, which must have occurred after the Islamization of North Africa. Yoruba evolved through its dispersal into distinct but verifiably closely related languages, including Fon in Benin and Ewe in Togo and southeastern Ghana, while also leaving small pockets of Yoruba-speaking communities in Benin and Togo. Although the very close relationships among Yoruba, Fon, and Ewe are well demonstrated, the timing of this movement also remains uncertain.

The most prominent case of language dispersal in sub-Saharan Africa was the spread of Bantu languages into regions south of the equator. Three competing hypotheses attempt to locate the geographic point of origin of these languages. Harry H. Johnston, who finished publishing his study in 1922, placed the probable origins of Bantu in two distinct geographic locations. The first is on the modern-day boundary

*The Shenute Codex, an account of the life of a holy man, written in the Sahidic dialect of Coptic; Egypt, seventh century* (© The Trustees of the British Museum)

between northeastern Cameroon and northwestern Central African Republic. The second, a much larger point of dispersion, is in the northeastern corner of the modern Democratic Republic of the Congo, very close to northwestern Uganda. The first probable origin attests to Johnston's early assumptions regarding a connection between the sub-Saharan western African languages and the Bantu languages. He provides an elaborate map of migratory patterns but fails to give either a time frame or a chronology.

Malcolm Guthrie, writing in 1962, placed the origins of Bantu in the central and southern regions of the Democratic Republic of the Congo. Guthrie engages in a very elaborate examination of word roots to verify a common Bantu ancestry for those languages presumed to be members of the Bantu family. Through these examinations, he discovers that languages spoken in central and southern Congo and in northern Zambia, adjacent to the Congo, have the highest percentages of common Bantu roots (in the range of 50–54 percent). Time alone would play a role in degrading the lexical integrity of the parent language; on this basis Guthrie considers central-southern

Congo to be the geographic source of the Bantu languages, but he, too, fails to provide any reference to a time frame.

Joseph H. Greenberg, writing in 1966, placed the source of Bantu in the general area of southeastern Nigeria and southwestern Cameroon, to the east and south of Johnston's locations. Greenberg fully develops Johnston's early references to a relationship between the Bantu languages and the sub-Saharan West African languages, under the broad family heading of Niger-Congo. He places Bantu under a subfamily called Benue-Congo, one of six subfamilies. He does not deal with the issue of how Bantu spread southward.

Guthrie questions the possibility, implicit in Greenberg's hypothesis, that the speakers of Bantu languages could have physically moved through the prohibitively large and dense forest region immediately south of Greenberg's location. Guthrie also presents a second argument against the dispersal implications of Greenberg's hypothesis. The northernmost Bantu languages have very low percentages of common Bantu word roots (in the range of 14–20 percent). Guthrie argues that these are Bantu-speaking communities that spread northward and in the process lost large percentages of their Bantu word roots. He makes the same claim for the southernmost Bantu languages, including Zulu and Xhosa, which demonstrate very low common Bantu word roots (in the range of 26–30 percent). The implication here is that the source of a language family would presumably contain the highest proportion of the lexical and grammatical characteristics of the parent language. As individual speech communities disperse in various directions, they continually lose these characteristics. In the case of Bantu the loss is highest at the extreme peripheries of the northwest, toward the southern Cameroon-Nigerian border, and the south, at the southernmost tip of South Africa.

Circumstantial evidence suggests that a significant movement of Bantu speakers into southern Africa, specifically modern-day South Africa, displaced the vast majority of Khoi-San speakers. The circumstantial evidence in this case consists of the controversial and conflicting histories of the respective arrivals in South Africa of the mix of European immigrants (including Portuguese, Dutch, Belgian, French, and British) during the 15th century and of Bantu speakers. During the conflict to end apartheid, the system of racial discrimination established under white European dominance, both sides claimed to have arrived in South Africa before the other. These claims appeared important in attempts to establish "native" status for one group and "settler" or "colonist" status for the other; however, these claims were in fact entirely inconsequential because the anti-apartheid argument was based on the need for democratically elected majority rule. Regardless, it is reasonable to conclude that the Bantu

arrival in South Africa took place before the 15th century, based on the reliable hypothesis that speakers of Bantu languages replaced the predominant Khoi-San speakers over a very vast area, covering much of southern Africa beyond the borders of present-day South Africa. The hypothesis that Bantu replaced Khoi-San is reinforced by the continuing presence of two small Khoi-San-speaking communities in central Tanzania called Hata and Sandawe. It is reasonable to conclude that this linguistic transition must have taken quite some time and continued into the period of European arrival in South Africa.

## THE AMERICAS

BY MICHAEL J. O'NEAL

Several challenges prevent the compilation of an accurate inventory of the languages in use in the Americas during the centuries before the arrival of the Europeans. The first is that with the exception of Mayan, from Mesoamerica, none of the languages of North, Central, or South America was written down. The second challenge relates to the definition of a *language* as opposed to a *dialect*, a definition that is based on the degree of difference between sets of spoken words and is thus often a matter of judgment. Third, as communities spread throughout the Americas, they were separated by distance and geographical barriers that isolated them from one another—to the extent that peoples who lived just 100 miles apart could not understand each other's language. Nonetheless, linguists can trace similarities between the grammars and vocabularies of languages, and these similarities suggest that languages can be grouped into families. Languages belonging to a family descended from the same earlier community of speakers and then developed differences in much the same way that American and Australian English diverged from that of England.

A fourth challenge in the tallying of American languages is that no sharply defined borders separated language speakers. Rather, the outer edges of the territories in which peoples lived were ill defined and often overlapping; over the centuries, communities of speakers moved to new territories. In a number of cases, language families spread out over areas that were not geographically continuous; a good example is the Muskogean language family, which is spoken in much of the southeastern United States, including northern and southern Florida but not the central part of the state. Finally, while most of the languages spoken by Native Americans early in the second millennium continue to be spoken in the third millennium, the number of people who speak them is small and shrinking, with often only hundreds or dozens speaking a given language. Until recently, one such language was spoken by only two surviving people who happened to be sisters.

Historians estimate that late in the pre-Columbian period, about a thousand languages were spoken in the Americas—perhaps 220 or so in North America, nearly 300 in Mesoamerica and Central America, and almost 500 in South America. In North America, Mesoamerica, and Central America were some nine major language families (with linguists disagreeing about the precise number) as well as an assortment of other smaller families and individual languages that have yet to be classified and may have been unique. The northernmost one is called Eskimo-Aleut, spoken by people who inhabited the Alaskan coastlines and a band of coastal land that stretched across northern Canada into Greenland. To their south was a large area of modern-day Alaska and Canada (including the Northwest Territory, the Yukon, and the northern portions of British Columbia, Alberta, Saskatchewan, and Manitoba) that was home to speakers of the Athabaskan languages, a group of at least 45 languages generally divided into the northern, central, and southern branches. The northern group has been a particular challenge for linguists because the people were largely nomadic.

The largest North American language family geographically was Algonquian, a group of 30 languages spoken by numerous groups in a large swath that extended through most of southern Canada to northeast Canada and down through the eastern half of the American Midwest and large portions of New England. The speakers of languages in this group included the ancestors of numerous peoples whose names are well known, including the Cree, Algonquin, and Blackfoot. This language region surrounded a region in which the Iroquoian languages were spoken, a group of 11 languages spoken by such nations as the Iroquois, Mohawk, and Cherokee primarily in western New England, parts of lower Canada, and small regions of the upper American South. Largely in the western portion of the Midwest and into the Rocky Mountain region, 17 Siouan languages were spoken by the Sioux, Crow, and numerous other groups. The most prominent of these languages remains Dakotan. A more eastern Siouan branch included languages spoken as far to the east as the Ohio Valley and as far south as Mississippi.

In northwestern America and southwestern Canada the Salishan (or Salish) languages predominated, a name taken from a specific language spoken in Montana. These languages, some dozens of them isolated from one another by the region's rivers, inlets, and islands, were spoken by numerous other peoples, including the Coeur d'Alene and Spokane. To the south were the Uto-Aztecan languages, spoken by groups in parts of California and throughout Nevada, Utah, and other portions of the American Southwest into Mexico.

The names of numerous U.S. states are taken from these Native American languages and language families. These

states include Alabama, Alaska, Arizona, Arkansas, Connecticut, Illinois, Iowa, Kentucky, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nebraska, New Mexico, North and South Dakota, Ohio, Oklahoma, Tennessee, Texas, Utah, Wisconsin, and Wyoming.

The final widely recognized language family in North and Central America is Mayan, spoken in the regions of southern

Mexico and Central America dominated by the Maya—and spoken still by some 6 million people. Because the Maya used a system of hieroglyphs to write the language down, Mayan is the best documented of the pre-Columbian American languages. Much of this writing was produced during the Maya Classic Period, from about 250 to 900. Mayan, which descended from a common language that linguists simply

## THE MAYAN LANGUAGES

Describing a language that evolved during the pre-Columbian period is a difficult undertaking. Linguists—those who study languages—have their own set of tools and their own vocabulary for analyzing and discussing the languages they study and preserve. Moreover, the fundamental structure of non-European languages is radically different from European languages such as English. The Maya, in common with other peoples throughout the world at this time, perceived and considered their world in ways that may be unfamiliar to those living in the 21st century. Thus, the grammar and vocabulary of their language was markedly different.

One aspect of the Mayan language that merits discussion is word order. In modern English, the usual order of an action-oriented sentence is subject–verb–object. This order reflects a basic sense of “a person (or thing) does something to someone (or something) else.” In the Mayan languages, though, the basic word order was verb–object–subject, making the emphasis more on “what was done to whom (or what)” and reducing the subject to a subordinate role in the sentence. Also, word endings were used to mark relationships, so that in sentences such as “The man has arrived” and “The man saw the boy,” the grammatical ending of “the man” would be different. In the first, “the man” would be regarded as the receiver of the action of “arriving”; in the second, “the man” would be regarded as the initiator of the action of “seeing.”

Another fundamental aspect of the Mayan language was the relative absence of prepositions. Prepositions include words such as *in*, *on*, *over*, *under*, *to*, *inside*, and others used to indicate where and how things are located in relation to one another in space and time. Thus, a dish is *on* a table or dessert is eaten *after* dinner. The Mayan languages did not use prepositions. Rather, they used positional words that in many cases were based on the human body. Thus, a phrase such as *u-wach ulew* is usually translated into English as “on the earth,” but a more literal translation would be “its face the earth,” indicating that something “on” something is literally its “face.” Similarly, the word *ti’ na* is translated as “door,” but it literally means “mouth of house.” In the same vein, *chirupam* is translated as “inside” but literally means “mouth its stomach.” Thus, the notion that something was “inside” something else was expressed by reference to the stomach, which is “inside” the mouth.

Counting in pre-Columbian Mayan also had unique characteristics. In English a number word such as *one* or *two* can stand alone or can be used to enumerate any noun, such as with “one dish” or “two trees.” The Mayan counting system was more complex. First, the number word could not stand by itself; it had to be attached to the “class” of the noun that was being counted. Classes might include such characteristics as animate, inanimate, flat, round, or human. Thus, for example, English speakers would say “one jahuacte tree.” Mayan speakers said *untek wop*, which literally means “one-tree jahuacte,” with *un-* meaning “one,” *-tek* meaning “plant,” and *wop* referring to the specific type of tree. A speaker who wanted to refer to a branch of the tree said *unts’it wop*, literally meaning “one (*un-*) long, slender object (*ts’it*) jahuacte tree (*wop*).”

Yet another noteworthy characteristic of Mayan relates to the concepts linguists refer to as alienable and inalienable possession. In English the phrase *my photo* can have two meanings: “a photo of me” (inalienable) or “a photo that I possess” (alienable, or able to be taken away). The Mayan language distinguished between the two forms of “possession” grammatically.

These are just a few of the differences between pre-Columbian Mayan (as well as Mayan languages as they continue to be spoken) and modern-day English. Numerous others could be cited, including distinct grammatical forms that indicate such things as verb tense, commands, and the direction in which objects are moving.

call Proto-Mayan, comprised numerous dialects and languages spoken throughout the region. Through painstaking comparative analysis, linguists have been able to reconstruct Proto-Mayan and trace the changes the language underwent in many of the dialects.

South America was much more linguistically diverse than were North America and Mesoamerica. While these areas had nine major language families, South America had at least 37 as well as at least 70 languages that have yet to be classified. While the number of distinct languages spoken in North America was some 220 and the number in Mesoamerica and Central America was nearly 300, the number spoken in South America was at least 448.

Scholars offer a number of possible reasons for this greater linguistic diversity. One is that during pre-Columbian times, no empire in South America extended its influence, and therefore its language, over a large region. Another reason is geographical: While North America and Mesoamerica provided terrain that generally allowed people to move about freely, South American language communities were isolated from one another by dense and impenetrable jungles, high mountain ranges, and immense rivers. These factors, combined with the absence of written records, have made it difficult for linguists to determine how South American languages are related, whether they all descended from a common tongue, and whether or not certain “languages” are really just dialects of the same language. Partly offsetting these difficulties is the fact that a great many of these languages are still spoken alongside the official state languages—Spanish and Portuguese—of South America.

At least 10 South American language families included 10 or more languages. Some 64 Arawakan languages were spoken throughout regions of northern South America and the Caribbean and even in a portion of Florida. The Carib family consisted of 32 languages spoken in northern South America and by some communities in the Caribbean. The Chibchan family, comprising 22 languages, was spoken in the border areas between Central and South America. The largest family was Tupi-Guarani, comprising 78 languages spoken in the southern part of the continent. Other families with 10 or more languages included Choco (12), Macro-Ge (32), Panoan (28), and Tucanoan (25). Additionally, 46 languages made up the Quechuan language family, spread later by the Incan Empire.

## ASIA AND THE PACIFIC

BY KENNETH HALL

Frequent migrations of many ethnic groups before and during the medieval era and the cultural mixing that resulted

from these migrations produced diverse oral and written linguistic traditions in Asia and the Pacific. Written languages developed as a mixture of pictorial and symbolic representations of concepts. In India as well as in Southeast Asia these early written forms gave way to an alphabet in which each character represented a spoken sound. In China, Korea, and Japan pictographic and ideographic scripts evolved from characters representing entire words and ideas to a system that included characters representing sounds. A pictograph is a pictorial representation, whereas an ideogram is a symbolic representation.

South Asian languages are written and read horizontally from left to right. In contrast, Chinese and other Chinese-derived East Asian language characters are printed vertically and are read top to bottom, starting from the right-most column and moving left. Therefore, vertically printed books start from the “back,” from the point of view of a Westerner, and each column of text is read until the book finishes at the “front.” If, however, the Chinese language characters appear in horizontal lines, they are read left to right, as in English.

Scholars believe that the foundational languages of southern Asia, Southeast Asia, and the Pacific were versions of Proto-Austronesian, a tongue still spoken by pockets of aboriginal populations in India, Southeast Asia, Taiwan, and Australia. By the medieval era there were two dominant southern Asian language families. Most northern Indians spoke regional languages (which included Marathi, Gujarati, Bengali, Urdu, and Hindi) that had evolved from the Indo-European Sanskrit language spoken by Aryan seminomads from central Asia, who migrated into northern India from roughly 1600 B.C.E. In southern India, however, as well as among isolated populations throughout central and northern India, earlier Dravidian languages (which by the medieval era included Tamil, Kannada, Malayalam, and Telugu) prevailed. Inclusive, during the medieval era the Aryan and Dravidian language families matured from spoken languages into sophisticated written languages. In the foothills of the Himalayas on southern Asia’s northern borders, medieval populations spoke a mixture of indigenous Sino-Tibetan, Tai-Kadai, and Austronesian languages.

Southeast Asian and Pacific island languages had their origins in a series of migrations into and within the region that were continuous through the medieval era. As in southern Asia, spoken languages developed writing traditions during the medieval age. Tagalog (in the Philippines), Malay, Indonesian, and the languages of the Pacific basin belong to the language family called Austronesian (which used to be called Malayo-Polynesian). Mainland Southeast Asia had three language families: Austroasiatic (Khmer, Mon, and Vietnamese), Tai-Kadai (Thai and Lao), and Sino-Tibetan (Burmese).

By the medieval era central Asians spoke mixtures of Indo-European (Turkish and Afghan) and Ural-Altaic languages. The Chinese spoke languages in the Sino-Tibetan family, but the roots of Japanese and Korean languages are subject to debate. Some linguists consider Korean to be an Altaic language, derived from early migrations from or contact with northern central Asia. Others categorize it as an independent language, not affiliated with any other language group. A similar debate surrounds Japanese, with some scholars arguing that it has Altaic roots and others claiming that it is a unique language. The latter group label Japan a “Japonic” language, along with the Ryukyuan language, named for the southern Japanese island on which it is spoken. During the early medieval era the Japanese, Korean, and Ryukyuan languages became separate and unique. The Japanese and Korean languages selectively incorporated Chinese loan words and Chinese written script, in contrast to the Ryukyuan language, which did not incorporate these elements. Ryukyuan did not develop an independent written script tradition but selectively borrowed the variety of scripts used by its Japanese neighbors.

Sanskrit and Pali, the Sanskrit-derived language of Buddhism in south Asia, were used in the recording of India’s most important early literature in the Gupta Period (ca. 320–ca. 480). Like the people in Korea and Japan, during the medieval era Southeast Asians modified the languages and scripts from the variety of Indian and Chinese options to meet their own cultural needs.

Written script was late to develop in India because religious texts were memorized and recited orally (with an elaborate instructional methodology to assist in the memorization and recitation of these texts), making written language of little importance initially. Through the medieval era each Brahmin priest was required to memorize one of the classical Sanskrit (the language of Hinduism) and Pali (the language of Buddhism) religious texts. In the third century B.C.E. the Mauryan king Asoka (r. ca. 265–238 B.C.E. or ca. 273–232 B.C.E.) posted his pillar inscriptions using a version of Sanskrit known as “Old Magadha,” which was written in Brahmi script. Brahmi script became the basis of the regional scripts used in India through the 12th century. In the 12th century the numerous variations of the Brahmi script were replaced by the universal Devanagari script, which is the script still used in the writing of Sanskrit.

The eighth-century Pallava rulers in southern India, who selectively drew on the cultural achievements of their northern neighbors as their new state emerged, adapted the northern Indian Brahmi script in their Grantha script Tamil language inscriptions. Grantha script has remained the standard among subsequent southern Indian language family

writings that proclaim the achievements of regional southern Indian dynasties and civilizations.

Both northern Indian Devanagari script and southern Indian Grantha script, in common with the earlier Brahmi script, distinguish between consonants and vowels. In Devanagari script a symbol for the vowel is added to the consonant symbol, or failure to use a “stop” symbol attached to a consonant adds an “ah” vowel sound to the consonant. In such southern Indian languages as Tamil, the vowel characters are added before or after a consonant. Like northern Indian languages, Tamil uses a “stop” symbol to denote no vowel ending; failure to use a stop symbol adds a final “ah” vowel sound.

Chinese writing evolved from pictographs into more linear representations coincident with the emergence of China’s first functional dynasties in the first millennium B.C.E. The *lishu* (clerkly) script became the norm after 500 B.C.E. because it was better suited for rapid sketches using fewer strokes. The new script was more efficient for government bureaucrats, in an era that marked significant increases in governmental authority and bureaucracy. Then, as today, China’s regional spoken languages used different words in association with common script representations. For example, the southern Chinese might speak Cantonese, while the northern Chinese spoke Mandarin—the spoken language of Chinese government—but both used common script symbols to express the spoken Cantonese and Mandarin words that had the same meaning. Chinese script in compound represented phonetic sounds. Additional symbols, called “radicals,” further clarified these sounds.

The continuing evolution of Chinese script was consequential to the development of Chinese calligraphy, which emphasized a disciplined and continuous brush style in a contained space. By the medieval era *kaishu* had become the standard script. *Xingshu* (running script) was a cursive version of *kaishu*, and *caoshu* (grass script) developed among calligraphers as a continuous flowing brush script.

Korean language script was heavily influenced by the Chinese language, reflecting China’s strong cultural influence in the region. The earliest Korean script (*hanja*) came into existence in the first centuries C.E. as an adaptation of Chinese characters in association with local language sounds as well as meanings. This ambiguity was rectified in the 13th century, when *kugyol* script distinguished between sound and meaning. However, at that time classical Chinese was the preferred language in Korean literary culture. King Sejong (r. 1419–50) of the Yi Dynasty (1392–1882), in his attempt to reassert an independent Korean culture, commissioned the development of a new Korean script, *hangul*, which used signs in segments of consonant and vowel combinations. In writing words the

hangul signs were grouped by syllables into squares. Despite the king's attempts, Korean literature was still composed almost exclusively in Chinese until 1945, and if hangul appeared at all, it was paired side by side with Chinese.

Writing came to Japan from China during the fifth century, as Chinese characters (*kanji*) were used in a system called *kanbun*, "Chinese writing." This system used Chinese characters to represent both ideas and syllables. Eventually the *kanbun* system used Chinese characters as representations of Japanese words using Japanese rather than Chinese grammar. When the Japanese imperial state came into existence, to facilitate communication between the court and the countryside in the seventh century, a new writing system, *kana*, developed, which continued to use Chinese characters (*kanji*) in representations of things or ideas; a simplified version of Chinese characters was used to represent sounds.

In *hiragana* writing, which developed in the eighth century, *hiragana* characters better represented Japanese words. Often literate Japanese continued to use the older *kanji* system (as the language of government and as a statement of cultural and intellectual superiority), while *hiragana* was associated with less philosophical women's compositions, such as the *Tale of Genji* (ca. 1010), the world's first novel, written by Lady Murasaki Shikibu (ca. 978–ca. 1014), a resident of the Kyoto court (795–1192). *Katakana* ("part *kanji*"), which used a Japanese script to depict syllables, was another option. It was originally developed in the ninth century to aid in the pronunciation of Chinese Buddhist scriptures, but by the 14th century it was in common use in representing suffixes, particles, and postpositions in compound with *kanji* root words, or in simplified representations of exclusively *katakana* single syllables, which were used in compound to sound out words.

Medieval Southeast Asian societies drew from either the southern Asian or the Chinese language tradition. The Vietnamese modified Chinese ideographs into their own Sinoform (Chinese-like) script, known as *chu-nom* or *nom*. Other Southeast Asian societies adapted either the northern Indian Brahmi or southern Indian Grantha script into their syllabic rather than Chinese ideographic characters, because of the lesser number of Indian script symbols, their better representation of sounds, and their association with the sophisticated Indian cultural tradition. Commonly, the southern Asia-derived scripts depict consonants that have the inherent vowel "ah," with the exception of Cambodia's Khmer, which has two sets of letters, one that carries the vowel sound "ah" and the other the vowel sound "oh" (for example, *ka*, *ko*).

Burmese and Thai languages are tonal, meaning that the speaker raises or lowers the voice when pronouncing words, thus allowing any word to be pronounced a different way and

have its own unique meaning. For example, in Vietnamese the same syllable can mean "mother" or "ghost," depending on the tonal emphasis. Thai letters associate tonal sounds with the letter appearance at the start or end of a syllable. Burmese tones are represented by diacritical markings that are added above or below the written consonant.

In the eighth century the Java modified the Pallava Grantha script in their Old Javanese Kawi court script and then in the 13th century developed a new Brahmi-derived Javanese script, which was the model for neighboring Philippine Tagalog populations in their 14th-century Baybayin script.

## EUROPE

BY ANNE BERTHELOT

As the medieval era began, Latin was the common language of western Europe, and it remained so for centuries. In fact, Latin was almost the only factor of unity that remained in a world fractured by the fall of the Roman Empire. By the close of the Middle Ages Latin still had a dominant place as the language of the church and affairs of state. It was only in 1539, for instance, that Francis I (r. 1515–47) of France passed the Ordinance of Villers-Cotterêts, making French instead of Latin the official language of France. For centuries there were no grammar books for any language other than Latin, and even the first English and French grammars were written in Latin.

Nevertheless, the Latin of the 16th century would not have been recognized by Latin speakers of the early medieval era. Very early on, probably well before the fall of Rome, Latin started to change under the influence of new people entering the Roman Empire. Furthermore, church Latin rapidly became a language in its own right. New languages began to emerge from Latin in most of the Western Roman Empire (France, the Iberian Peninsula, Italy, North Africa, and the Mediterranean islands). Older languages, which had been stifled by Latin as the official language of the military and civilian power, reemerged in both oral and written forms.

The turning point may be located in the ninth century. In 842 the kings Charles II (r. 840–77) of France and Louis II (r. 843–76) of Germany entered an uneasy alliance against the emperor Lothair I (r. 840–55) of Italy, and the oaths they took on this occasion, known as the Oaths of Strasbourg, represent the first written testimony of two vernacular languages, French and German, in addition to the official Latin version. Each king pronounced the oath in the language of the other's soldiers, thereby suggesting that Latin was no longer understood by the people.

Latin was still, however, invaluable as the language of the church. For centuries most people believed that the Bi-

ble, known only through the Vulgate version translated by Saint Jerome (ca. 347–419 or 420), was originally written in Latin. Additionally, until the 16th century Renaissance Latin remained the learned language of schools and universities. Scholars and students from every part of Europe could communicate in Latin—hence the name Latin Quarter given to the area around the Sorbonne, the Parisian university.

Philosophy, theology, and the sciences were expressed only in Latin; vernacular languages were not considered noble enough to address serious issues. Translations of these texts from Latin were rare before the 14th century. After the Great Schism of 1054, when the Eastern Orthodox Church and the Roman Catholic Church separated, access to and knowledge of Greek were very limited in western Europe; to some extent, philosophers like Plato (ca. 428–347 or 348 B.C.E.) and Aristotle (384–322 B.C.E.) were rediscovered through Arabic translations during the 13th century, after the conquest of Constantinople by the crusaders and the contacts with the eastern world through the Crusades. If there were debates about and comparisons of the three “philosophical” languages—Latin, Greek, and Arabic—they were reserved to some intellectual circles and did not have any influence on the evolution of languages in Western Europe.

The vernacular forms of language arose in varying manners. The first languages of western Europe were of Celtic origin, but in part for religious reasons these languages were not written down. In some remote regions of the empire Celtic languages, such as Gaelic and Welsh, survived. Long before the fall of Rome a large movement of populations weakened the empire’s borders and brought inside the empire people who did not know Latin. Pushed forward by the next wave of invaders, these people settled and founded kingdoms in regions that are now western Germany, France, Italy, Spain and North Africa. The Visigoths occupied most of Aquitaine and the Iberian Peninsula, the Lombards occupied northern Italy, and the Franks occupied Belgium and northern France.

The Romanized populations considered these people barbarians, and the name of the society that crossed the Mediterranean to North Africa, Vandales, became synonymous with *barbarian*. The newer populations spoke their own languages, which belonged mostly to the same subcategory of Indo-European, the Germanic languages. There was relatively little interaction between these languages and Latin, although a few Germanic words entered the Latin lexicon, were given Latin declension or conjugation, and went back to enrich a new vernacular.

Eventually these Germanic languages and, to a lesser extent, the Scandinavian languages became dominant in Germany, most of the Netherlands and Belgium, northern Italy, and Great Britain. In the fourth century the Angles and the

Saxons started to push back the Celtic people toward the sea of Ireland, triggering a secondary migration wave to Ireland and Brittany. These invaders spoke Germanic languages closely related to those of the Continent. Indeed, Old English and Old High German are very similar.

France, the Iberian Peninsula, and Italy had been more deeply Romanized than the rest of Europe. There the basic language was Latin, not only among the elite classes but indeed throughout the whole population. (Despite the Saracen presence in Spain and southern France, the Arabic influence on these areas’ languages was comparatively limited to a few hundred words at most.) This Latin, however, quickly evolved and differentiated into several languages, such as Castilian (the ancestor of Spanish), Catalan, Old French, Italian, and Old Provençal. Old French was the name for the language spoken in France north of the Loire River; Old Provençal, closer to the Latin original, was spoken in the southern part of France; and between the two regions there was a so-called linguistic crescent where people spoke a mix of Old French and Old Provençal called Franco-Provençal.

These were the first Romance languages, so called because they stemmed from the Roman language, if not actually from Latin; Proto-Roman is the intermediary stage between Late Latin and the Romance languages of the first vernacular texts. They were not unified languages but were composed of many dialects; to some extent they were closer to each other than to the modern languages that evolved. Old French was especially fragmented. The same could be said about the Germanic languages, where the distinction between High and Low German was mainly geographic.

Another twist in the repartition of European languages happened when William of Normandy became William I (r. 1066–87), king of England, after winning the Battle of Hastings in 1066. The Normans were of Scandinavian origin but, having settled in Normandy during the 10th century, had adopted the local dialect of Old French. They now transported it to England, and the resulting Anglo-Norman dialect was the language of the aristocracy for more than a century. When English came to the fore again after a period of almost complete disappearance in written form, it was as Middle English, still a Germanic language but including a fair number of French words and Latin roots.

Around the 14th century dialectal differences started to fade. The lexicon and morphological characteristics (inflection, for example) of the modern languages were mostly stabilized, and their syntax had grown more sophisticated, allowing them to translate nuances and complexities that until then had been better expressed in Latin. Middle French and Italian, for instance, experienced an influx of Latinized forms even though the pre-Renaissance scholars tried to return to

an earlier pure or authentic language. This tendency would continue during the Renaissance, when most European languages settled into their modern forms after eliminating superfluous neologisms (extended meanings of existing words) and atypical syntax. On the whole, the medieval era was an unprecedented flourishing time for languages.

## THE ISLAMIC WORLD

BY ALASDAIR WATSON

Arabic, Persian, and Turkish, each from different language families, are the three major languages that have been the main vehicles for Islamic culture and government at various times and places in the medieval Islamic world. From the nucleus of the Hejaz in the Arabian Peninsula, Arabic-speaking Muslims spread out gaining territory that a century after Muhammad's death in 632 encompassed North Africa and the Iberian Peninsula in the West and Transoxiana and the gates of China in the East. This territory, which was to form the backbone of the Islamic world until the 15th century, was home to a vast array of spoken languages and several major languages of high culture and government. The rise and fall of these languages reflect demographic events such as large-scale migrations of people as well as the coming to power of one language-speaking group or another in various parts of the Islamic world.

Arabic, the language of the Koran, is classed, like Aramaic and Hebrew, as a Semitic language, so called as speakers of these languages are said, according to the Bible's book of Genesis, to be descendents of Shem, the son of Noah. Semitic languages form one branch of the Afro-Asiatic language family. According to Islamic tradition, Arabic was the divinely revealed language Adam spoke in Paradise (compare this with Jewish traditions about Hebrew). Modern Western scholars, however, state that Arabic is the latest of all Semitic languages to appear and posit that at one time a Proto-Semitic existed and was the origin of all Semitic languages. In common with other Semitic languages, Arabic is largely based on a triconsonantal root structure (one composed of three consonants) but with a complex, highly formulaic system of derivation using prefixes, suffixes, and infixes, or formative elements placed in the middle of words.

The initial Arab conquests of Syria and Palestine (633–40), Egypt (642–46), and Iraq and Iran (633–51) brought Muslim rule to these areas that had been formerly controlled by the Byzantine and Sassanian Persian empires. However, the Arabic language did not immediately displace the existing administrative languages of Greek and Coptic in the West and Pahlavi (Middle Persian) in the East. Indeed, Arab governors frequently maintained existing administrative

structures and often employed local clerks. In Syria, for example, John of Damascus succeeded his father as one such Greek-speaking Christian administrator in the service of the Muslim caliph. The Arabization of the administrative offices began in 697, apparently on the initiative of al-Hajjaj ibn Yusuf, the Umayyad governor in Iraq. This was soon to be emulated in Syria (700) following the reforms of the caliph Abd al-Malik (r. 685–705) and in Egypt (705). It was not until 742 that Arabic became the administrative language of Khurasan in eastern Iran. Thereafter, Arabic gradually became the lingua franca and certainly the intellectual and cultural language of the entire Islamic world. As this process went on, other languages, such as the Aramaic spoken in Syria and Palestine and the Coptic spoken in Egypt, went into gradual decline, but there is evidence to suggest that bilingualism was common as an intermediary stage.

Further excursions to the Maghreb (North Africa) in the seventh century brought Arabs in contact with Tamazight/Berber-speaking peoples, who, despite going on to embrace Islam and play a prominent role in the conquest of Andalusia, were often hostile toward the Arabs. It was not until the Hilali invasions of 1052 that the Arabization of the Maghreb really began in earnest.

In Islamic Spain, Spanish Arabic was the language of the Arab ruling class but also of the growing number of *muwalladun*, people of mixed ancestry who were Spanish converts to Islam. They assimilated themselves into Muslim society, often preferring the new Arab-Islamic culture and language to that of their Gothic or Iberian roots, although bilingualism was widespread among all sections of society. The Jews of the Iberian Peninsula and the Islamic world in general also often wrote in Arabic using Hebrew characters, and there exists a considerable body of this so called Judeo-Arabic literature. The Arabic script also was used in the Iberian Peninsula to write the local Hispanic Romance languages of Aragonese, Castilian, Catalan, Galician, and Portuguese. This type of literature is known as *aljamiado*.

In the eastern areas of the Islamic world, in the lands formerly controlled by the Sassanian Empire, a number of Iranian languages were spoken, most notably forms of Persian. Persian is classed as belonging to the southwest Iranian branch of the Indo-European language family, a large family that includes Germanic, Latin, Slavonic, and Greek. The earliest archaeological evidence of Persian dates back to the late fifth and early sixth centuries B.C.E. and takes the form of Achaemenid cuneiform inscriptions in what is commonly called Old Persian. It is thought that the oldest parts of the Avesta, a collection of sacred texts of the Zoroastrian religion, date from even earlier than the sixth century B.C.E. and represent a more archaic form of the language.

Middle Persian in the form of Pahlavi was the official language of the Sassanian government until it was superseded by Arabic as the administrative language. Arabic remained the literary and cultural language in Iran for about 150 years, until the emergence of “New Persian” in the ninth century of the Common Era. Even so, Persian continued throughout this period as a vernacular language, especially east of Iran. As other territories became part of the Islamic world—among them, Afghanistan and Transoxiana and later even parts of India, where in time a new language, Urdu (a mixture of Arabic, Persian, and Indian languages), would arise—Persian, in the form of Dari, spread and became the common spoken language of these regions, replacing another widely spoken Iranian language, Sogdian. The form of Persian spoken in parts of Afghanistan today is still known as Dari. With the waning of power of the Abbasid Caliphate in the East and the emergence of the new local ruling dynasties of the Samanids (819–1005) and the Saffarids (867–1495), Persian in its new form found patrons that ensured its continuous flourishing as the new literary language of south-western Asia. The major innovation for the language was the adoption of the Arabic script as well as the assimilation of numerous loanwords from Arabic, including much religious and philosophical terminology.

Turkish represented by its “Old Anatolian” and “Ottoman” forms, the third main language of the medieval Islamic world, belongs to the Oghuz, or southwest group of the Turkic language family, which is a branch of the Altaic language

grouping and is made up of a large and diverse number of languages and dialects all of which are structurally strikingly similar. Turkish first appeared as an Islamic language in the 10th century in Transoxiana and eastern Turkestan, which were then ruled by the Karakhanids, a dynasty with Turkish origins. Although the Karakhanids adopted the Perso-Islamic style of government normal to the eastern regions of the Islamic world, they did retain a strong sense of Turkishness, and during their rule a particularly Turkish Islamic literature developed, especially in east Turkestan.

The beginning of the 11th century marked the start of a series of large-scale migrations of various Turkic-speaking peoples into the lands of Islam, which was to continue for 400 years and have a profound effect on the Islamic world. Since Umayyad times Turks had had a presence in the Islamic world, where they were used as domestic servants, and in Abbasid times Turkish troops formed an increasingly large part of the caliph’s armies. Hence, it is often said that Turkish was the language of the army, Arabic the language of the law, and Persian the language of refined society.

The first major migrations began in the first decades of the 11th century around the time of the rise to power of the Seljuks, who were descended from the Oghuz clan of Turkic peoples. They became the sultans of a great empire stretching from Transoxiana to Anatolia. Like the Samanids and Saffarids before them, the Seljuk court adopted Persian as their language, and they were great patrons of Persian and, to a lesser extent, Arabic belles lettres, even in the non-Persian

parts of the empire such as Anatolia. However, with the large influx of Turkish-speaking peoples bringing their languages with them, it was inevitable that the linguistic map would be changed. In the late 11th century the Seljuks must have introduced what is known as “Old Turkish” to Anatolia, and by the end of the 15th century with the coming to power of the Ottoman Turks (1293–1922), who made Turkish the court language, this had developed into a refined literary language written in the adopted Arabic script and with copious Arabic and Persian loanwords.

## ► laws and legal codes

### INTRODUCTION

People have been very creative in their formation of laws, the rules that govern the activities of human beings within a community. In most cases, laws have been intended to maintain order and civility among people within a society. The laws could favor the rights of individual people over society or the rights of society over individual people. Studying medieval laws and legal codes offers the chance of gaining an understanding of the ways in which human beings viewed themselves as individual people, the relationship between community and themselves, the roles of their governments, and responsible behavior within their communities. Understanding these roles and relationships in turn offers insight into the human condition.

It is tempting to suggest that the larger a society (the more numerous the people within it), the more complex the laws. The medieval era is close enough to the present age for many of the laws of nonliterate societies to have survived in oral traditions, and the oral traditions have revealed that even small communities could have elaborate laws. For example, many western African communities had neither a formal government nor lawgivers; their laws were transmitted orally and were subject to revision when times and circumstances changed. One aspect of the laws dictated gender roles, with some tasks relegated to women and others to men. This did not prevent a man from assuming a woman’s role or a woman from assuming a man’s role, but when people of one gender took on a role that the law said belonged to the other gender, they would sometimes be required to dress and behave as the opposite gender. Keeping track of who was supposed to be behaving like a woman or a man took a community-wide effort. A continent and a couple of oceans away, the medieval peoples of Australia had their own complex rules, such as ones for who had access to which territory and under what circumstances. In North America law often was a matter of community consent, fluid and flexible for changing circumstances and therefore complex.

Laws often were intended to govern personal morality rather than just public behavior. Some of the most important legal codes of medieval times were developed out of concern for morally acceptable conduct. In ancient times laws frequently were thought to derive from gods and goddesses, and they focused on how people should properly behave toward their gods. One of the significant aspects of the biblical Ten Commandments was that its focus was on how people should conduct themselves toward other people. Muslims built a culture out of this idea, with Islamic laws emphasizing such rules of conduct. For instance, laws often required people to give

some of their income to charity; by helping others less fortunate than themselves, people simultaneously fulfilled the law of the government and the wishes of God. Yet such laws were subject to disagreement, because they were constructs of words and people could vary the words to suit themselves. Often, such overarching laws as those of Islam or the Tang Code of China were made subject to local customs, which often carried more weight with individual people than did legal codes. Islamic law, for example, insisted that women be modest, but in medieval Mali in Africa, women often wore no clothing in public. Then, too—much to the shock of visitors from other Islamic lands—both men and women had sexual companions outside marriage and saw nothing wrong with it.

Laws rarely existed to liberate people. Often, they were intended to oppress people in order to preserve the privileges of the ruling elite or to perpetuate the power of government. In the Byzantine Empire, the lives of people were closely governed by laws that reached into how they worked and with whom they associated. The laws governing farmers were so oppressive that they discouraged farmers from trying to be the most productive they could be and may have been one reason why the Byzantines were willing to accept the rule of invading Muslims without much fuss. Laws also could be weapons used to keep certain social groups subject to the demands of others, such as in India, where caste laws required some people to live blighted lives in the service of people of higher social castes. Among such people Buddhism made headway because it held everyone to have equal spiritual opportunities. Islam was attractive because it regarded everyone as equal before God. These and other aspects of law shaped people's lives and behavior, and a way to measure the success of a legal code is to observe how well it served the needs of people and their communities and how often people and communities sought rescue from their laws.

## AFRICA

BY KIRK H. BEETZ

The laws and legal codes of medieval Africa are the subject of controversy and are intensely studied by historians, archaeologists, and anthropologists specializing in the study of Africa. This stems from the practice of slavery, which existed in many African societies, though there were many others for which it was an alien institution. After the medieval era millions of Africans were enslaved and transported out of Africa and to Europe, the Americas, and Asia. One of the hard facts of the practice was that some Africans profited immensely from selling their neighbors or their own people into slavery. Most Africans were sold to outsiders by other Africans, and the slave trade existed throughout the medieval era. Some

historians want to uncover medieval laws that reflect a humane attitude toward slaves.

One result has been the compiling and publication of two documents: the Charter of Mandé and the Charter of Kurukan Fuga. Both purport to be medieval but are at least partly modern creations. Some publications state that the two are one and the same, but the Charter of Mandé was compiled from the oral history of the Mandinka and was published in 1991. Its compilers claimed that the oral tradition for the Charter of Mandé dated to 1222, though other scholars believe the date to be imaginary, and it was presented as a set of laws or a constitution for the medieval Mali Empire. The Charter of Kurukan Fuga was compiled from oral histories from Mali, Senegal, and Guinea during a meeting in the late 1990s and was reformatted to make it look like a constitution in 1998; the new format may misrepresent its actual status in medieval Mali. It was dated to 1236 and was attributed to an emperor of Mali. Some scholars propose that these documents contain defenses of human rights as well as other modern notions of liberty, and a few suggest that the documents prove that Africans of the 1200s had contemporary attitudes toward human liberty, making medieval Mali the inventor of present-day concepts regarding human rights and the people of Mali benign slave owners. That Mali sold slaves abroad does not seem to enter into the discussion.

It would be wise to remember the people who gave rise to such laws. For them, slavery was an everyday practice—to be avoided if possible but to be found in the form of household servants and colonies of slaves established by emperors of Mali to serve as farming communities producing food for the emperor and his government. Terms such as *human rights* would likely be unknown to them and would require explanation. On the other hand, they did have strong notions about social rights. Their laws tended to emphasize the rights of communities of people rather than of individual people; people had rights through their families, marriages, crafts, and religions.

In the Charter of Kurukan Fuga it is easy to find much that corresponds with what historians believe is true about the laws of Mali, Ghana, and Songhai, empires that arose during the medieval era in western Africa. As seems to have been typical in most of medieval Africa, the laws are closely tied to ideas about moral and immoral behavior. For example, one law states that an entire community, not just the immediate family, is responsible for the welfare of its children. Another declares that people are not allowed to offend women. Yet another asserts that people must keep their word of honor. Others regard the organization of society. For instance, everyone who was neither too young nor too old was supposed to be allowed to participate in the making of decisions about

public policy—a practice common among many of the cultures encompassed by the Mali Empire. Other laws seem to represent criminal law. For example, anyone who attempted to murder another person was to be put to death. Mali tended to use Muslims as judges, and it seems to have had an appeals system in which people convicted of crimes could petition a higher authority to void the conviction, but how this worked has yet to be figured out.

That Mali was a nation of laws seems evident from the accounts of visitors, mostly Muslims. Ghana in the 1100s and Mali in the 1300s were praised by visitors for their strong sense of justice. Travelers on Mali's roads appear to have been remarkably safe and secure. Still, the rule of law as embodied by the imperial government often did not reach throughout the empire. Especially in remote provinces, the laws that were enforced tended to be local ones that derived from long-standing regional customs. Villages and towns often were allowed to make and enforce their own laws, which tended to take precedence over imperial laws within local communities. The remarkable safety of travelers noted in the 1300s may have derived in part from imperial laws that forbade the molesting of travelers but also from ancient rules of conduct in which banditry or theft was punishable by exclusion from the community, a fate that may have been worse than death for the perpetrators, who within their cultural outlook would lose all sense of personal identity without their places in their communities. Further, people could gain status in a community by treating strangers well, because in their view the strangers would be obligated to them until the good treatment was repaid. From this perspective, the Charter of Kurukan Fuga seems to be in harmony with medieval African customs and remote from modern controversies.

Written laws and even ones from oral history are hard to find from medieval Africa. In part this is because in many cultures laws were memorized by scholars trained for the purpose, as seems to have been the case in Benin. It is also partly because written documents may have been lost, as may be the case for the city-states of East Africa. Archaeologists often seem optimistic that they will someday uncover legal documents from city-states such as Kilwa or Mogadishu, as they are also hopeful for the Christian kingdoms of Nubia and the kingdom of Kanem. All were places with literary traditions.

One place where some records survive, although much revised over many centuries, is Ethiopia. The leaders of Ethiopia took pride in keeping records and even had libraries in which scribes were perpetually kept busy copying decaying books in order to maintain a continuous record of history and thought. Further, the Solomonid Dynasty of Ethiopia lasted from medieval times to the end of the 1900s, helping to

preserve documents that might otherwise have been lost had their government been overthrown by invasion.

Legal historians usually refer to two Ethiopian works in particular: the *Kebra Nagast*, meaning the “Book of the Glory of Kings,” and the *Fetha Negast* (also spelled *Fetha Negest*), meaning the “Law of the Kings.” The first contains accounts of the rulers of Ethiopia, and the second includes a body of legal precedents. The *Fetha Negast* was first written as a single work perhaps in about 1450, though it may have been as early as the 1200s. It was revised often as times changed, but in 1450 it still represented the legal practices of Ethiopia from the early medieval era. Its laws drew on the Bible, ancient Roman laws, and traditional Ethiopian customs.

The emperor was embodied in the law as having the final say on all matters of law. The only people allowed to interpret the law and to advise the emperor on legal matters were scholars trained at the *Matshaf Beit*, meaning “House of Books.” The *Matshaf Beit* served not only as a repository for writings about the law but as a sort of graduate school of law, where students would study 30 years to memorize the empire's laws and even foreign laws and to understand the commentaries on the laws.

Medieval Ethiopia had a system of courts and lawyers. Cases were tried before a judge, called a *dania*. The *dania*s were usually *debterras*, who originally were clerics committed to transcribing documents. They became respected for their knowledge of literature and law and often became government officials. Judges were not required to be *debterras*, so village chiefs or leading community figures, including women, could become judges. Judgments were based on both imperial and local laws, with local laws usually prevailing over imperial laws. The application of the law required judges to combine Roman laws, Greek philosophy, traditional laws, and biblical laws, especially from the Old Testament. People who lost their cases were able to petition regional or provincial tribunals and ultimately the emperor, whose decision was final. Enforcement of the law fell to the Ethiopian nobility and through them to village chiefs.

There were kingdoms in central Africa and southern Africa, but their laws are little known. Travelers of the late medieval era reported being able to travel from west Africa all the way to southeastern Africa through two large kingdoms where the rule of law seemed to prevail. Merchants and others travelers from outside the kingdoms were required to pay homage to the kings and pay duties; if they did so, they had legal protection on the roads of the kingdoms. The merchants would have been traveling to the city-states of East Africa or to Great Zimbabwe, where the nation of Zimbabwe is today. The city-states were of African origin, and their basic social structure was local. Yet they were heavily influenced

by merchants from Indonesia, India, and the Islamic world, with most of their rulers becoming Muslims. It seems that the city-states were fairly conservative societies. Most historians suspect that their laws were influenced by Islamic laws, particularly those governing trade, which would have been especially useful to the city-states that prospered from international trade. The laws of Great Zimbabwe may also have been influenced by Islamic law, although this is not certain. What little was recorded of Great Zimbabwe's laws focuses on how people were expected to behave toward its monarch.

Elsewhere in Africa were societies that did not have imperial governments, or if they did have them, the governments did not last long. Many may have arisen, survived a few generations, and then fallen apart because of economic failure, invasion, or lack of support from the subject peoples. Remarkably, chaos did not necessarily follow. Instead, African communities had an intricate and powerful set of customs that called for giving and receiving from family, neighbors, and communities; this linked people together in a common interest to ensure the survival of their social groups. These customs encouraged people to behave toward one another respectfully, to give help as well as to receive it, and to care for the well-being of their families. Just as the Charter of Kurukan Fuga asserted that children were the common responsibility of all in the community, so African traditions among farmers and hunter-gatherers in stateless cultures required that community members be responsible for one another's welfare.

## THE AMERICAS

BY MICHAEL J. O'NEAL

It is risky to make generalizations about the systems of law that governed Native Americans in the pre-Columbian era. First, few legal codes were written down or formalized. Rather, codes of behavior were agreed on by a community and passed to subsequent generations through oral traditions, particularly in North America. Even within one a group or in neighboring communities, however, law could be administered in different ways. The immense diversity of Native American peoples also makes difficult any attempt at forming generalizations. North America, for example, encompassed 8 million square miles and was home to at least 400 to 500 distinct groups, each speaking its own language. Thus, nothing in the way of a common legal code existed.

Nonetheless, a few generalizations about North American groups are possible. First, law and government tended to be administered by consensus. While a chief or headman nominally ruled a community, in that capacity serving as its chief judicial officer, in general chiefs were not absolute rul-

ers who governed by divine right. Rather, they were selected for their leadership abilities, and while chieftainship could be partly hereditary, inheritance was by no means a foregone conclusion. Thus when a leader adjudicated legal issues, he did so in consultation with elders or a council as a way of building consensus. Often the leader's wife also might have a say in legal and other matters.

A second generalization is that North American groups did not recognize property ownership as it pertained to land. Land was regarded as an asset owned in common by the community, a gift given to it by a higher power. Individuals did not own title to the land their families worked, and land could not be bought or sold. With regard to personal property, the concept of ownership was sometimes fluid. An individual could own, for example, personal items of clothing, but agricultural implements were regarded as family or clan property rather than the property of one person. Sometimes this view of ownership led to disputes, which were resolved by chiefs and elders with an eye to the good of the entire community rather than to the legal rights of individuals.

A third generalization is that laws and legal codes tended to emphasize harmony and preserving the social fabric of the community. A good example is provided by the Inuit. When people crowded into winter camps, it was not uncommon for disputes to break out. Arguments often escalated into fistfights and occasionally into murder. The Inuit developed a unique way of dealing with these matters—the song duel. Singing was a highly valued art form in the dark, frozen regions of the far north. When a dispute erupted, the people gathered to witness a “duel” in which the disputants sang long, elaborate songs that detailed the vices and flaws of their opponents. The duels could go on for the entire winter season or even longer. The purpose of the song duel was to get the disputants to forget their grudges in the general hilarity of the event. In that way social harmony could be restored. In extreme cases the Inuit put to death people who were insanely aggressive, making sure that members of the person's family carried out the sentence to ensure that a feud did not erupt between families.

Another example of the emphasis on harmony was the Harmony Ethic of the Cherokee. The purpose of the Harmony Ethic was to avoid conflict and the expression of anger toward others. In the case of a legal dispute the tribal leader listened to both sides, often calling in another person to help resolve the conflict. The disputants were ordered to withdraw until judgment was rendered. The goal of judgment was to restore harmony and resolve the dispute by requiring one or both parties to exercise generosity and to give up belongings. Food was the most common item given up. The Cherokee had separate words for stinginess: one applied to food and one

to any other good. People who violated the Harmony Ethic were subjected to gossip and ostracism. In more extreme cases conjurers were enlisted to make the offender seriously ill or even cause his death. In all cases, though, a person not involved in the dispute was brought in to render judgment, thereby reducing face-to-face conflict.

Some North American groups had slightly more formal legal codes. For example, the Poncas of the Midwest enforced seven fundamental laws: have a single god, do not kill, do not steal, be kind to others, do not gossip about others, be generous to others, and revere the Sacred Pipe. When a person violated one of the laws, the victim or the victim's family usually handled enforcement. The Chickasaw, part of the Mississippi culture that flourished from about 800 to 1600, dealt with legal transgressions within the clan, a common practice among many Native American tribes. If a legal dispute involved members of different clans, elders from the two clans met to reach some kind of resolution. Usually the emphasis was on restitution. In the case of a serious crime such as murder, the victim's family had the right to demand the life of the murderer; however, if the murderer was a person of much lower social status than that of the victim, the victim's family had the right to claim a life of equal social status. This appears to be simple revenge, but for Native Americans it was a way to restore cosmic order and put to rest the lingering spirit of the murdered person. Similarly, among the Choctaw who lived in modern-day Mississippi, if a person found guilty of murder fled, the victim's family had the right to demand a substitute for execution.

Among the Mesoamerican Aztec, law was much more formalized than it was in North America. The Aztec word for "justice" was *tlamelahuacachinaliztli*, literally translated as "straight line to a point," or "to straighten that which is twisted." One Aztec ruler, Nezahualcoyotl of 15th-century Tetzaco in the basin of Mexico, created a legal code with 80 statutes. His successors expanded the code, which was designed in large part to maintain respect for authority, given that the Aztec state was militaristic. Because the Aztec state had no legislative body, judicial authority resided in the hands of the emperor, who ruled by decree.

The Aztecs had a judicial system that resembled the one that would be developed in the United States centuries later. Legal disputes were heard at a local court (*barrio*), and cases could proceed to appeals courts. The lowest court was the local court, which dealt with relatively minor criminal and civil offenses. Assisting the local court were neighborhood watchmen, who reported crimes to authorities but themselves had no enforcement powers. Higher-level courts in the capitals of the Aztec provinces dealt with more serious criminal offenses. An appeals court heard petitions from verdicts in

lower courts in the case of commoners; the same court, however, was the "court of first instance" for members of the nobility. Thus cases involving nobles went directly to the higher courts. An important case could be referred to the emperor, who would hear the case in concert with several advisers. Special courts existed for commercial matters, domestic affairs, the military, artisans, and other groups. A special court in the emperor's palace dealt with crimes committed by foreign dignitaries; one such crime was adultery, punishable by death throughout Aztec-controlled lands. In an Aztec court parties had to take an oath to the god Huitzilopochtli. They did so by touching first the ground and then their lips to symbolize that lying offended the gods and was punishable by death.

A unique feature of Aztec law was the law of the marketplace, which regulated the activities of the merchant guilds. Merchants were, in effect, a state within a state, worshipping their own gods, marrying within their caste, and inheriting their positions. The Aztec had a complex economic system consisting of a web of marketplaces. To ensure that merchants behaved legally and ethically, the merchant guilds themselves regulated the marketplaces, judged legal cases having to do with the marketplaces, and even issued death sentences.

Several regulations applied to market behavior. For example, it was against the law for merchants to trade on their way to the marketplace; they could sell their goods only at designated places. Inspectors mingled with the crowd to ensure that goods were being sold at the proper prices (based not on currency but on units of exchange determined by the value of cloth and cacao beans). These inspectors also ensured that scales and measuring devices were accurate. A nearby court rendered immediate judgment on thieves or people selling stolen goods. Any vendor guilty of violating the laws could be fined. Those guilty of serious violations were beaten to death in the middle of the marketplace.

Judges were specially trained and held in high repute. Most were members of the nobility, but some were members of the priestly class. The latter were feared persons, for they often walked the streets after a night of ritual bloodletting, during which they painted their bodies black. The state set aside special lands from which judges drew their income. It was believed that this method of payment made judges less susceptible to corruption. Any judge found guilty of corruption was put to death. Judges ruled swiftly, and Aztec justice was harsh.

In South America, the greatest empire was that of the Inca, who originated in Peru in the 13th century and quickly rose to power. Unfortunately, little is known about the Inca legal system, for no written records survive. What information historians have is fragmentary and incomplete. It is known no prisons existed. Although the Inca overall were

very warlike, within the state life was very peaceful, and crime was infrequent. One possible reason for this apparent internal tranquility is that punishments for crimes were swift and brutal, and the state specified numerous capital offenses, such as treason, disobedience to the ruling Inca, and thievery. A thief was beaten with stones for a first offense and beaten to death for the second.

Laziness was regarded as a crime—a form of stealing from an employer and from the state. Disabled people were required to work within the limits of their disability, as were the elderly. It is also known that land was divided into thirds: one parcel was dedicated to the use of the gods, a second to the ruling Inca, and the remaining to the landholder. The landholder was expected first to work the land dedicated to the gods and then to focus on the ruling Inca's land before finally paying attention to the personal share of the property. It is also known that the Inca required men to marry by the age of 20 and people with disabilities to marry people with the same disability.

## ASIA AND THE PACIFIC

BY KENNETH HALL

During the medieval era the Asian court elite codified prior legal practices into written legal codes. Chinese dynasties shared the legal values and customs that complemented the formal law and procedures as contained in the Tang Code (624). The Tang Code, which became the basis for judicial codes in neighboring Korea, Japan, and Vietnam, contains 502 articles. The initial 57 articles establish the basic principles of justice and judicial procedure; the remaining 445 articles define specific offenses. South Asia and most neighboring Southeast Asian countries based their legal codes on the multiple Dharmasastra Hindu-Buddhist texts that were codified in the era of the Gupta monarchs (320–550). The Dharmasastra texts, which outline the Indian system of jurisprudence, define universal obligations and penalties, but they were always subject to local caste, religious, and civil codes that prescribed appropriate local behavior.

These Chinese and Indian legal codes were modified to accommodate local needs and common practices in the law codes of their neighbors. Since issues of social justice were universally regarded as foundational to civil order, they took precedence in Asian law. Laws reinforced and defined the privileges of social hierarchy and regulated landholding, property rights, taxation, and service relationships. Criminal law included elaborate lists of appropriate penalties. Commercial law established the standards of the marketplace. Religious law defined appropriate ritual traditions and practices.

### THE ABOMINATIONS OF THE TANG CODE

The Tang Code was one of the most influential set of laws in the medieval world. It was established in 624 but did not take on its final form until 737. Out of this immense work in 12 sections and 502 articles, medieval Chinese legal scholars identified criminal laws that were “abominations” because they disrupted the order and the peace of society. These laws concerned depravity, family life, the conduct of government, and the security of the emperor. Mass murder, which was the slaying of three or more people at a time who had not committed capital crimes, may have been chief among depraved crimes. Another depraved crime was the use of sorcery to harm others, especially to murder them. The burning or dismembering of murder victims before or after death was an abomination.

Physically harming elder family members was an abomination. It was illegal for someone to beat or murder a parent, and aunts, uncles, and elder siblings were also protected by the law. On the other hand, it was legal for a parent to beat a child, though the law might punish a parent if the harm done to the child was too excessive for the offense for which the child was beaten. Treason was an abomination. This crime included switching sides during a war, joining a rebellion, or giving allegiance to a foreign ruler. Murdering a government official was treason. The penalties for these offenses varied from loss of social rank to exile to the hinterlands of the empire to death, usually by beheading.

In general, most reprehensible were violations of the laws protecting the emperor, because the emperor both represented the government and was the father of all the Chinese people. Deliberate efforts to harm him were forbidden. Other abominations included failing to carry out duties, such as properly tasting his food before it was served to him, or failing to follow dietary laws or to prepare healthful food when cooking his meals. Physicians who did not follow appropriate procedures when treating the emperor also committed abominations.

Chinese law was shaped by two conflicting approaches to maintaining societal order. China's humanistic tradition was more optimistic in its hopes for humanity and was thus more tolerant of transgressions than the Confucian legalistic tradition. The Confucian legalistic tradition was based in a

detailed written legal code that was considered to be foundational to political power, which derived from a social and moral order that resulted from social control. Thus the Chinese legal code defined inappropriate conduct as this was a detrimental threat to societal harmony. The legal code dictated obedience. Disobedience resulted in severe penalties, including public humiliation, mandated labor, physical mutilation, community expulsion, slavery, or death. Above all, the code demanded proper conduct (*li*) as appropriate to one's social standing in a family, community, or state hierarchy. Since the family and community were ultimately considered to be accountable for individual misconduct, legal penalties were regularly imposed on an inclusive group rather than exclusively on the offender.

Families, clans, and village organizations promoted proper behavior through education and example. Aggressive selfish behavior was unacceptable; yielding to the interests of others was expected. Conflicts were resolved by compromise, frequently through the intervention of respected family elders and community leaders. A magistrate's court was the last resort and was to be avoided if possible, since courts were not aware of local circumstances and threatened to impose legal decisions that would ruin reputations, alienate property, and impose a variety of physical punishments, including a possible death sentence.

For minor offenses, the sentence required public humiliation, with the criminal wearing a heavy collar bearing the inscribed record of the crime. Since the collar was too large to allow access to the criminal's mouth, the criminal would starve if not fed by others, a symbolic gesture of the community's accountability for the criminal's rehabilitation. Minor offenses might also result in exclusionary penalties, as members of an elite family might be barred from future government appointments, and monetary fines. Those unable to pay their fines worked off their sentence as "debt slaves." Labor penalties of one to six years were normal judgments imposed on those guilty of theft or other civil crimes. Those of wealth and status could have their labor service performed by servants or younger family males. More serious offenses resulted in mutilations, such as publicly shaving the offending man or woman's hair or beard; branding; or, in more extreme cases, cutting off a body part, such as a nose, ear, hand, foot, or sex organ. Decapitation and hanging were the normal executions of death sentences, but there were unusual executions, as when a criminal was sentenced to be torn apart by horse-drawn chariots or to be buried with the exception of the head, to die a slow death. The heads of executed criminals were displayed on poles, to deter other would-be criminals and to increase the shame of the criminals' families and neighbors.

Chinese magistrates were state appointees who were accountable to the emperor rather than to the local community. A magistrate was both the judge and the chief prosecutor, required to investigate a case thoroughly before assigning a fair verdict. As a statement of respect, those attending a legal proceeding were required to kneel before the magistrate and could be whipped if they were not reverential. Private lawyers were prohibited, since they were seen as self-serving individuals who were more interested in prolonging the legal process to run up their fees than in working toward a quick resolution that was in the best interests of the community.

Magistrates were subject to regular legal reviews conducted by their bureaucratic superiors or, in rare cases, the Chinese civil system's censorate, which reported directly to the emperor. These investigations evaluated the magistrate's record keeping, supervision of subordinates, management of penal law, legal investigations, and interactions with and management of the local public. A magistrate was held accountable for mistakes of law or fact, regardless of his good intentions. Offending officials might be fined, removed from office, reassigned, or, in rare cases, executed. There was also substantial consequence to an offender's family, which was subsequently ineligible for bureaucratic appointments and barred from lucrative imperial commissions. The severe consequences of wrongdoing encouraged Chinese officials to mediate local settlements to avoid courtroom litigations.

Chinese magistrates were forbidden to receive anonymous accusations; personal testimony had to be given, subject to in-court questioning. Knowingly providing false testimony led to severe consequences. As a check on legal decisions, there was an automatic new trial if the convicted criminal refused to sign an acknowledgment that the judgment was valid according to both the law and the facts. A case could be reopened if one party claimed to be the victim of injustice. Family members could appeal any conviction all the way to the emperor, but they were subject to the risk of punishment if their appeal was ruled to lack merit. The Tang Code mandated three reviews of a sentence of death before an execution.

In Chinese justice the criminality of an act had to be proved: Had a law been broken, and had the violator intended to break the law? The system was sensitive to the state of mind of the offender; an accused might be free of prosecution or receive a reduced sentence if, feeling remorse for a lapse in judgment, he surrendered voluntarily prior to the issuing of an arrest warrant. The judicial system also considered traditional cultural practices and beliefs, such as the claim of spiritual possession and detrimental ancestral interventions that were responsible for a criminal act. Among the acceptable allowances was the ignorance of the accused

or other family members in avoiding an inauspicious day or failing to adequately perform ancestral rituals, funerals, and marriages. Any of these acts would cause demons and malign spirits to impose their reprisals and thus lead to the human crime.

Indian law was based in the moral codes of the Hindu and Buddhist religious traditions. Law was conceived as dharma, the duty or obligation of proper conduct relative to the needs of society over those of the individual. The Dharmasastra texts prescribe the obligations and penalties appropriate to caste and social status. Like Chinese justice, Indian justice encouraged local resolution, through community tribunals based in caste, trade, artisan, family, sect, and village society. Each community could establish and apply its own customs and procedures; in theory, there was no hierarchy among these frequently overlapping, community-based institutions.

Indian Dharmasastra law was the ideal rather than an absolute, and it was above all intended to make practical legal decisions based on common usage rather than on a written

code of law. Legal decisions were in the best interests of the community, to maintain local societal harmony consistent with the community's political, economic, religious, or hereditary hierarchy. As did the Chinese, Indians believed that in an orderly hierarchical society, if members behaved according to what was expected of their social rank, righteousness would surely prevail. Physical penalties were rare, and there are few records of severe fines. Instead, legal decisions mandated restitutions or public admission of wrong and recommitment to acceptable behavior. Subsequent offenses resulted in boycotts or expulsions. Rare death penalties were subject to a king's review before an execution.

Kings involved and asked the guidance of Hindu and Buddhist clergy, scholars of Dharmasastra, before making legal decisions. In the absence of an inclusive bureaucrat system, Indian kings might exercise their legal authority directly, or more commonly through their delegated agents who would travel the countryside on their behalf. A royal agent's local judicial intervention resulted from a community's failure to make their own resolution. If a legal appeal reached the court, a court tribunal sent officials to gather the facts of a case, and to determine the common practice of the groups involved. From the local community's perspective, such royal legal intervention was undesirable, since the king's justice ultimately served the king's rather than the community's interests. Legal interventions frequently discovered local improprieties that resulted in unintended fines, penalties, or additional taxes. Thus, as in China, state interventions were infrequent, and local resolution was the norm.

Six text-based traditions of law developed in Southeast Asia during the medieval era. In each case the legal system localized either Indian or Chinese legal culture. The Burmese *dhammathat* (dharma) and *Thai-Lao thammawat* legal traditions consisted of numerous texts that incorporated India-derived Buddhist modifications of Dharmasastra law according to local needs. Cambodian law developed in the era of the Angkor-based court (eighth to 14th century) and made similar local modifications of the Indian Dharmasastra Hindu and Buddhist legal codes. Numerous Sanskrit and Khmer temple inscriptions highlight issues of landholding and labor rights as they relate to royal patronage of Hindu temples and Buddhist shrines. In Vietnam the 15th-century Hong Duc code marked a Confucian departure from previous reliance on Buddhist codes of law. The new secular law code, in common with the old, included significant local modifications that were consistent with prevailing Vietnamese social practice, with notable concern relative to local landholding, social, and ritual practices as these related to royal authority.

Javanese law, which was codified in the 14th-century Majapahit court, was also Indic inspired with local variation.

Folio from a *Khamsa of Amir Khusrau Dihlavi*, showing a priest bringing a marriage document; ink and color on paper, Sultanate Period, India, 1450–1500 (Freer Gallery of Art, Smithsonian Institution, Purchase, F1959-2)

Javanese law was inclusive of assorted local legal traditions that are documented in charter and temple inscriptions dating from the eighth century and 11th-century through 15th-century literary adaptations of the Indian Mahabharata and Ramayana epic poems. Java's texts and inscriptions go beyond the Angkor court's inscriptions in their variety of concerns relative to land, property, societal, political, and ritual rights. In contrast to Java, from the 13th century the rulers of the neighboring Malay Strait of Malacca region modified their previous legal practices in keeping with local conversions to Islam. The most complete account is supplied in that era's court chronicle (*Hikayat*) tradition, as these texts detail issues of law and contract and the legitimacy of the law as a derivative of the Muslim ruler, the "shadow of God on earth," who had been empowered by divine revelation.

The legal culture among the Pacific basin islands was based in family bloodlines and ranking of the different branches of ancestors. Rank-based legal consequence was often related to previous islands of residence and favored the earliest settlers over those who arrived later. Legal culture was respectful of the realm of nature and penalized those who were disrespectful of or abused the natural realm due to belief that such disrespect would alienate the spiritual forces and bring negative human consequence. The center of the community was a communal building or a central space, where justice was dispensed by a chief, village or family elders, or a meeting of all the local society's adult members, who would reach a judicial decision based on the community's best interests and to ensure the community's continuity. Among the most extreme options of punishment was banishment of the offender from the community or from the island itself.

## EUROPE

BY JULIE-ANN VICKERS

The history of laws and legal codes in the Middle Ages is intricately bound to the fragmentation of political systems that occurred after the fall of the Roman Empire. From the fifth to the 11th centuries laws and the processes upholding them were characterized by diversity and local autonomy. This was a reflection of the decentralized nature of political power at the time. In the 12th century a resurgence of Roman law coupled with increasing consolidation of monarchical power led to the development of more cohesive bodies of legal thought. Significantly, those laws applied to whole societies rather than particular groups or communities.

The most important influence on the development of law in the Middle Ages was the body of legal knowledge that medieval society inherited from ancient Rome. From 529 to 533 the Byzantine emperor Justinian I (r. 527–65) issued the

Corpus Iuris Civilis (Body of Civil Law). This set of texts was a collation and codification of the legal knowledge of classical Roman jurists. Beginning in the late fifth century, however, western Europe became increasingly isolated from the Byzantine east, both politically and culturally. As a result only incomplete sections of Justinian's Corpus Iuris Civilis, along with fragments of Roman law that predated it, were known to western Europe in the early Middle Ages. In Byzantium this document continued as the core of the legal code until the end of that empire in 1453.

The Germanic tribes that settled in western Europe after the fall of Rome brought with them their own legal culture. This culture differed in several respects from the principles that informed Roman law. Traditionally, Germanic law—sometimes referred to as barbarian law—was oral and customary in nature. Their laws were not written down but were based on the customs, developed over generations, of specific tribal groupings. The societies also subscribed to a principle known as the personality of the law. According to this principle, birthright law, which was dictated by ethnic grouping, governed individuals regardless of where they lived. Thus individuals of different ethnic origins living in the same region fell under different legal customs. In contrast, Roman law was written and territorial, which meant that the same body of law governed all the inhabitants of a region. The substance of Germanic law also differed markedly from Roman law. Germanic law was primarily concerned with regulating the complex system of fines and compensations used to end feuds when an infringement of customary law occurred. But owing to their nomadic past, the German populations had few provisions for contract or property law, both of which were highly developed in Roman law.

In the Germanic kingdoms of the early Middle Ages inhabitants coexisted under different bodies of law. Roman law continued to apply to the native inhabitants of the former Roman provinces as well as to all members of the clergy, who automatically came under its ruling. Meanwhile, the Germanic rulers and their people adhered to their own systems of customary law. Soon, however, the Germanic laws began to change, reflecting the influence of Roman law. Faced with the written legal tradition of Rome, the German kings began to write down or codify their own laws—a process that also worked to strengthen the authority of their rule. The codification of Germanic laws began in the late fifth century and continued into the ninth century. These codes were written in Latin, which remained the language of learning and law throughout the Middle Ages. When specific laws were lacking, such as in the area of property law, the German codes simply borrowed from Roman law. The more notable of these codes are the Codex Euricianus (Code of Euric, ca. 475) of the

Visigoths, the Lex Salica (Salic Law, ca. 500) of the Franks, and the Edictum Rothari (Edict of Rothari, 643) of the Lombards. Collectively these laws are known as the *leges barbarorum*, or barbarian laws. Some Germanic rulers issued separate codes, adaptations of Roman law, for their Roman subjects. Of these, the most comprehensive is the Lex Romana Visigothorum, also known as Breviarium Alaricianum (Breviary of Alaric), issued in 506. The Roman codes issued by the Germanic kings are often referred to as Roman vulgar law.

Having several legal systems in one territory was complicated and often confusing. Some rulers, like the emperor Charlemagne (r. 800–14), attempted to impose legislation that applied universally to people under their dominion. These attempts were only partially successful, however, and personal law continued to be cited when it was expedient. Over time the various populations of local communities integrated. As a result, each community came to subscribe to its own body of customary law, which was applied equally to all inhabitants of that community. In this way the Roman principle of the territoriality of law began to encroach on personal law.

From the eighth century onward power and authority became increasingly tied to land ownership. Rulers granted land to freemen in return for military service and other obligations. Freemen, or vassals, gained autonomous authority over their estates; they were also free to grant parts of their land to other freemen in return for specified services. Land grants and the authority they bestowed could be inherited by successive generations. The laws governing these complex mutual obligations and transfers of property were customary and for centuries remained unwritten. Eventually, in the

later half of the 12th century, the first written collection of land grant laws appeared. It was called the Liber Feudorum (Book of Feudal Laws). Feudal relations continued to play an important role in medieval society for the remainder of the medieval period.

In the early Middle Ages an entire community was responsible for enforcing the law. Lacking a professional law-enforcement agency, the local assembly, or court, had to deal with transgressions of the law. Similarly lacking in professional judges, the community turned to a local nobleman or a representative of the sovereign to preside over court proceedings. He was assisted by freemen from the community. The primary purpose of the court was to maintain law and order through consensus rather than coercion. Thus the main role of the presiding authority was to facilitate an agreement between the two sides of a case, rather than to sit in judgment. If an agreement was reached, it had to have the approval of the community. Various types of courts were available to accommodate the diverse legal codes that could apply to disputants. The church also had its own courts. For serious crimes and grievances, particularly those involving the higher classes, another avenue of appeal was the king's justice in the royal court.

After the eighth century the organization of agricultural society around specific economic and territorial units called manors or seigneuries led to the development of manorial justice, also called seigneurial justice. Under this system landlords gained autonomous jurisdictional authority over their estates. They held court and made rulings on a case-by-case basis according to a mixture of public and customary law.

The extent to which lords respected the customs and traditions of the communities under their jurisdiction, as opposed to asserting their own judgments in cases, varied greatly. In general, however, the principle of communal consensus still dominated proceedings. The manorial system of justice developed in conjunction with the increasing application of territorial law and the emergence of feudal law.

In the late 11th century two developments occurred that reshaped the legal culture of Europe for the remainder of the Middle Ages and into the early modern period: the consolidation of church law, known as canon law, and the rediscovery in the West of the complete version of Justinian's *Corpus Iuris Civilis*. In the early Middle Ages the clergy lived under the authority of Roman law, but during this time they developed it to suit their requirements. Most important, they added new laws based on scriptural tenets, the decisions of church councils, and papal decrees. In the late 11th century these accretions began to be worked into a cohesive body of ecclesiastical law using the principles of Roman law as its basis. From this emerged canon law. The jurist Gratian issued the first commonly accepted collection of canon law known as the *Decretum Gratiani* (Decrees of Gratian) in the middle of the 12th century.

At the same time that canon law was forming, western Europe gradually recovered a complete version of Justinian's *Corpus Iuris Civilis*. Historians have not determined precisely how this happened. It is likely that one or more manuscript traditions ensured the transmission of the text through the early Middle Ages. Then, in the second half of the 11th century, the significance of the subject matter was recognized and subjected to intense study. The recovery of the *Corpus Iuris Civilis* is one of the most important developments in the legal history of western Europe. By studying its contents, medieval scholars gained access to a comprehensive and systematic body of written Roman law.

The first formal legal studies were taught in Bologna at the end of the 11th century, giving rise to legal experts and the development of legal principles, both of which allowed the law to be applied in a consistent and accountable manner. Canon law also became increasingly sophisticated as a result of the recovery of the *Corpus Iuris Civilis*. A combination of Justinian law, Roman law, and canon law formed the *ius commune*, or common law. This was the formal system of law that dominated western European legal thought from the 12th century onward. In conjunction with local variations of customary law, the *ius commune* also came to be the applied law, except in England, which developed along its own trajectory.

The application of the *ius commune* as a common system of law in continental Europe was assisted by the consolidation of monarchical power that occurred in western Europe

at the same time. In the 13th century a strong papacy also extended its political and legal power via the Roman Curia, a centralized ecclesiastical court that dealt with all administrative and legal matters of the church. In England the process of unification that William the Conqueror started in 1066 assisted the development of that country's system of common law, instigated by Henry II (r. 1154–89) in the following century. Under Henry II the royal court made decisions based on an amalgamation of local customs. The king's representatives were sent out to judge cases all over the land according to this common custom, and in this way local variations of customary law were gradually eradicated. The English common law in use today evolved directly from these medieval precedents. Likewise, the *ius commune* lies at the foundation of the contemporary legal systems of continental Europe.

## THE ISLAMIC WORLD

BY PERI BEARMAN

Islamic law is composed of both divine revelation and interpretations of it by skilled jurists. The divine revelation is fixed and incontrovertible and is made up of two elements. The first element was revealed by the angel Gabriel to Islam's messenger, the prophet Muhammad, and is contained in the Koran, Islam's holy book and first source of law. The second element consists of the Sunna, a large corpus of writings by the prophet's contemporaries, who demonstrate his example by reporting what he did, said, and failed to do during his lifetime. These two sources of Islamic law, known collectively as the *sharia* ("path to water"), define the path that God laid out for humankind to attain salvation. They guide the believer in all matters, both religious and nonreligious. Muslims regard the *sharia* as holding universal truths and covering all of human life.

Because the two sources of Islamic law are finite, they do not treat every situation that might arise in a legal arena. Therefore, they are supplemented by a very large body of legal rulings elaborated by scholars based on their understanding of the moral teachings of Islam and on textual exegesis of the two divine sources. As a product of human intellect rather than divine revelation, this collection of legal sources is not canonical or above critique. The tension between the sacred and the human elements of Islamic law, and thus between the proponents of each element, has formed a continuous thread throughout the 1,400 years of the law's existence.

When Muhammad died in 632, the small Muslim community was left without a leader. The prophet had been the lawgiver, judge, general, and chief executive of the immature Islamic polity. It was left to the caliphs who succeeded Muhammad to expand the realm of Islam to outlying areas and

create institutions, including those required by a legal system, that the prophet had not established. Just 100 years after Muhammad's death, Islam had spread from the Arabian Peninsula, where it had begun, through Mesopotamia to the east as far as India and to the west across North Africa as far as southern Spain, bringing its social and religious message to many diverse peoples and cultures.

The Umayyad Caliphate (661–750) is largely credited with the establishment of a judicial class of government officers. The caliph dispensed justice in accordance with his legal authority—judicial, administrative, and legislative—but the expanding empire demanded that he delegate his authority to governors and judges, whom he appointed to act on his behalf in resolving legal disputes in an official tribunal setting. Because the textual canons of the Koran and the Sunna were not yet finalized, much of the caliphal law was based on a combination of customary, Roman, canonical, Jewish, and Sassanian law. The personal judgment of each adjudicating official, based on his sense of equity and his knowledge of Islamic moral teachings, also played a role in the development of this practical body of law that some call Umayyad judicial practice. This law formed part of the much larger corpus of Islamic law developed by religious scholars who, unlike judges, remained independent of the official administration.

By the time of the Abbasid Caliphate, which followed the Umayyad and ruled until 1258, individual scholars who were revered for their vast religious knowledge had become an important source for laypeople in matters of law, religion, and ritual. Rapidly expanding numbers of Muslim converts sought to know the correct practices of their new faith—everything from the right way to worship to permitted financial transactions—and they asked for advice or legal opinions (*fatwa*) from these scholars, many of whom began articulating a body of legal rules that entailed more than just judicial practice. In doing so they attracted circles of students who learned and transmitted their masters' teachings, starting schools of legal thought that differed from one region to the next in both substance and method. Whereas, for example, one school would place more emphasis on custom in determining a correct ruling in a legal matter, another would rely more on reason.

Islam teaches that God is the ultimate judge and the knower of all things, and human fallibility in the understanding of what ultimately is only knowable to God is a given. Hence all sincere and conscientious interpretations of God's message to humankind are accepted as possible and legitimate. In this way many divergent legal rulings prevailed. No religious or judicial institution, such as a church or a supreme court, was established to determine the proper way for the community of believers to obey the divine will. Classic Islamic law is the culmination of great intellectual effort, free

from the authority of the state, and various opinions and debates among scholars are the seeds from which it sprang.

Nevertheless, the number of legal rules and methodologies increased to such an extent that in the ninth century an effort was made to organize them under one theory. Abu

Abdullah Muhammad ibn Idris al-Shafii (767–820), one of the foremost legal scholars of the time, proposed a hierarchy of sources that would grant the stamp of orthodoxy to the growing jurisprudence. He named the Koran as the first and highest source of law, followed by the corpus of prophetic custom, consensus of the topmost scholars, and analogous reasoning stemming from the clear rules of the foundational texts, in that order. All other principal sources used at that time—such as the customs of local communities, independent reasoning of scholars, the “preferred” view, and the public good—were disparaged. Of the hundreds of schools of law that existed then, only a small number accepted the imposed hierarchy. By the 12th or 13th century only a handful of those schools were left, and those lasted until the legal codification process of the 19th and 20th centuries erased most of their influence.

The schools of law that adopted the new legal theory and survived into the premodern period were the four orthodox, or Sunni, schools of Hanafi, Maliki, Shafii, and Hanbali, each named after a prominent master in the early history of the school. These were the legal schools of choice for most Muslim believers inhabiting regions from Morocco to Indonesia. The most widespread school of law was the Hanafi school, since it became the doctrine of choice of the large Mongol and Ottoman empires and spread accordingly throughout the imperial lands.

Two schools of law emerged apart from the Sunnis. An early heterodox movement called Shiism, which later broke into numerous sects such as the Twelvers, the Seveners, and the Zaydis, formulated its own theological and legal doctrines. A small percentage of the Muslim community followed the Jafari school of law of the Twelver sect, which forms the law

Four Sunni schools of law—Hanafi, Maliki, Shafii, and Hanbali—became the legal schools of choice for most Muslim believers inhabiting regions from Morocco to Indonesia. The most widespread school of law was the Hanafi school, since it was adopted as the official doctrine during the Mongol and Ottoman empires and spread accordingly throughout the imperial lands. By the end of the medieval period the Hanbali school had few followers, although it experienced a revival in the 18th century with the rise of the Wahhabi movement.

of modern-day Iran. An even smaller minority followed another independent school, the Ibadiyya, which remained very small and prevails now only in Oman.

Thus classical Islamic law did not have one code; in both theory and practice, the various rulings of each school of law were regarded as authoritative. Nor was classical Islamic law drafted by appointees of the state; rather, it was the product of an intellectual tradition, the vision of the scholar-jurists who promulgated it. Within a school certain texts and teachings of foremost jurists from that school were given canonical status. Throughout the centuries, however, when they could not reach a consensus on a particular rule of law, scholars would formulate new law based on their understanding of the foundational texts and in line with their school's methodology. Despite the lack of codification, a measure of consistency in the law was thus assured, despite its being predicated on diversity.

From the perspective of the jurists, Islamic law sought to fulfill the ideal presented to them by divine revelation: happiness in this life and salvation in the next. The jurists were most concerned with the pious conscience in the law—that is, with matters that touched on preserving Islam and its social and moral teachings. The areas of the law that preoccupied jurists the most were family law, the laws of sale and hire, contracts, torts (the law of damages), inheritance, property, and criminal law (especially crimes considered offenses against God, like brigandage, theft, sexual intercourse outside of marriage, false accusation of adultery, drinking alcohol, and apostasy, or repudiation of the Islamic faith). Other areas of the law, which today would be called public law, were relegated to the local ruler. Beginning in the Umayyad Caliphate, matters that affected the state or the community as an entity, whether con-

stitutional, administrative, financial, or criminal, fell more to the relevant governing body. The primary concern of the jurist, on the other hand, was that the ruler's law not contravene the *sharia*. The two legal arenas, with their own institutions and officials, functioned side by side for many centuries, yet a tension between them always existed.

The tolerated diversity in doctrine and the parallel religion-based legal system were both assailed during the later medieval period, especially under the Ottoman Empire (1281–1924), which ruled over much of the Middle East, North Africa, and the Balkans. The Ottomans leaned toward standardization and codification. Reform began with the Hanafi doctrine being declared the favored law of the empire and some Hanafi texts prescribed over others for reference. In the end the entire legal system was refitted, with codes adopted from European civil law substituted for much of the Islamic legal doctrine and with the establishment of secular courts to apply the new codes. Vestiges of codified Islamic law still function in the area of family law, but only a handful of modern states have either preserved Islamic law as the basis of their legal system (Saudi Arabia, Oman, and Yemen) or re-applied it (Iran, Sudan, and northern Nigeria).

Europe

~ Justinian: Excerpts from the *Corpus Iuris Civilis*  
(sixth century) ~

**THE DIGEST: PROLOGUE**

The Emperor Caesar, Flavius, Justinianus, Pious, Fortunate, Renowned, Conqueror, and Triumpher, Ever Augustus, to Tribonianus His Quaestor, Greeting:

With the aid of God governing Our Empire which was delivered to Us by His Celestial Majesty, We carry on war successfully. We adorn peace and maintain the Constitution of the State and have such confidence in the protection of Almighty God that We do not depend

upon Our arms, or upon Our soldiers, or upon those who conduct Our Wars, or upon Our own genius, but We solely, place Our reliance upon the providence of the Holy Trinity, from which are derived the elements of the entire world and their disposition throughout the globe.

Therefore, since there is nothing to be found in all things as worthy of attention as the authority of the law, which properly regulates all affairs both divine and human, and expels all injustice; We have found the entire arrangement of the law which has come down

(continued)

(continues)

to us from the foundation of the City of Rome and the times of Romulus, to be so confused that it is extended to an infinite length and is not within the grasp of human capacity; and hence We were first induced to begin by examining what had been enacted by former most venerated princes, to correct their constitutions, and make them more easily understood; to the end that being included in a single Code, and having had removed all that is superfluous in resemblance and all iniquitous discord, they may afford to all men the ready assistance of true meaning.

After having concluded this work and collected it all in a single volume under Our illustrious name, raising Ourselves above small and comparatively insignificant matters, We have hastened to attempt the most complete and thorough amendment of the entire law, to collect and revise the whole body of Roman jurisprudence, and to assemble in one book the scattered treatises of so many authors which no one else has herebefore ventured to hope for or to expect and it has indeed been considered by Ourselves a most difficult undertaking, nay, one that was almost impossible; but with Our hands raised to heaven and having invoked the Divine aid, We have kept this object in Our mind, confiding in God who can grant the accomplishment

of things which are almost desperate, and can Himself carry them into effect by virtue of the greatness of His power. . . .

We desire you to be careful with regard to the following: if you find in the old books anything that is not suitably arranged, superfluous, or incomplete, you must remove all superfluities, supply what is lacking, and present the entire work in regular form, and with as excellent an appearance as possible. You must also observe the following, namely: if you find anything which the ancients have inserted in their old laws or constitutions that is incorrectly worded, you must correct this, and place it in its proper order, so that it may appear to be true, expressed in the best language, and written in this way in the first place; so that by comparing it with the original text, no one can venture to call in question as defective what you have selected and arranged. Since by an ancient law, which is styled the *Lex Regia*, all the rights and power of the Roman people were transferred to the Emperor, We do not derive Our authority from that of other different compilations, but wish that it shall all be entirely Ours, for how can antiquity abrogate our laws?

From: *The Digest of Justinian*, ed. C. H. Monro (Cambridge, Mass.: Cambridge University Press, 1904).

### ~ The Institutes of Justinian: Sources of Laws ~

Justice is the set and constant purpose which gives to every man his due. Jurisprudence is the knowledge of things divine and human, the science of the just and the unjust. . . .

The precepts of the law are these: to live honestly, to injure no one, and to give every man his due. The study of law consists of two branches, law public and law private. The former relates to the welfare of the Roman State; the latter to the advantage of the individual citizen. Of private law then we may say that it is of threefold origin, being collected from the precepts of nature, from those of the law of nations, or from those of the civil law of Rome.

The law of nature is that which she has taught all animals; a law not peculiar to the human race, but shared by all living creatures, whether denizens of the air, the dry land, or the sea. Hence comes the union of male and female, which we call marriage; hence the procreation and rearing of children, for this is a law by the knowledge of which we see even the lower animals are distinguished. The civil law of Rome, and the law of all nations, differ from each other thus. The laws of every people governed by statutes and customs are partly peculiar to itself, partly common to all mankind. Those rules which a state enacts for its own members are peculiar to itself, and are called civil law: those rules prescribed by natural reason for all men are observed

by all people alike, and are called the law of nations. Thus the laws of the Roman people are partly peculiar to itself, partly common to all nations; a distinction of which we shall take notice as occasion offers. . . .

Our law is partly written, partly unwritten, as among the Greeks. The written law consists of statutes, plebiscites, senatus consults, enactments of the Emperors, edicts of the magistrates, and answers of those learned in the law. A statute is an enactment of the Roman people, which it used to make on the motion of a senatorial magistrate, as for instance a consul. A plebiscite is an enactment of the commonalty, such as was made on the motion of one of their own magistrates, as a tribune. . . . A senatus consult is a command and ordinance of

the senate, for when the Roman people had been so increased that it was difficult to assemble it together for the purpose of enacting statutes, it seemed right that the senate should be consulted instead of the people. Again, what the Emperor determines has the force of a statute, the people having conferred on him all their authority and power by the *lex regia*, which was passed concerning his office and authority. Consequently, whatever the Emperor settles by rescript, or decides in his judicial capacity, or ordains edicts, is clearly a statute: and these are what are called constitutions.

### The Islamic World

#### ≈ Extract from the Sunna (ca. seventh century and later) ≈

##### OF JUDGMENTS

The first judgment that God will pass on man at the day of resurrection will be for murder.

Whosoever throws himself from the top of a mountain and killeth himself is in hell fire forever; and whosoever killeth himself with iron, his iron shall be in his hand, and he will stab his belly with it in hell fire everlastingly.

No judge must decide between two persons whilst he is angry.

There is no judge who hath decided between men, whether just or unjust, but will come to God's court on the day of resurrection held by the neck by an angel; and the angel will raise his head toward the heavens and wait for God's orders; and if God orders to throw him into hell, the angel will do it from a height of forty years' journey.

Verily there will come on a just judge at the day of resurrection such fear and horror, that he will wish, Would to God that I had not decided between two persons in a trial for a single date.

##### OF WOMEN AND SLAVES

The world and all things in it are valuable, but the most valuable thing in the world is a virtuous woman.

I have not left any calamity more hurtful to man than woman.

A Muslim can not obtain (after righteousness) anything better than a well-disposed, beautiful wife: such a wife as, when ordered by her husband to do anything, obeys; and if her husband look at her, is happy; and if her husband swear by her to do a thing, she does it to make his oath true; and if he be absent from her, she wishes him well in her own person by guarding herself from in chastity, and taketh care of his property.

Verily the best of women are those who are content with little.

Admonish your wives with kindness; for women were created out of a crooked rib of Adam, therefore if ye wish to straighten it, ye will break it; and if ye let it alone, it will be always crooked.

(continued)

(continues)

Every woman who dieth, and her husband is pleased with her, shall enter into paradise.

That which is lawful but disliked by God is divorce.

A woman may be married by four qualifications: one, on account of her money; another, on account of the nobility of her pedigree; another, on account of her beauty; a fourth, on account of her faith; therefore look out for religious women, but if ye do it from any other consideration, may your hands be rubbed in dirt.

A widow shall not be married until she be consulted; nor shall a virgin be married until her consent be asked, whose consent is by her silence.

When the Prophet was informed that the people of Persia had made the daughter of Chosroes their queen, he said the tribe that constitutes a woman its ruler will not find redemption.

Do not prevent your women from coming to the mosque; but their homes are better for them.

O assembly of women, give alms, although it be of your gold and silver ornaments; for verily ye are mostly of hell on the day of resurrection.

When ye return from a journey and enter your town at night, go not to your houses, so that your wives may have time to comb their disheveled hair.

God has ordained that your brothers should be your slaves: therefore him whom God hath ordained to be the slave of his brother, his brother must give him of the food which he eateth himself, and of the clothes wherewith he clothes himself and not order him to do anything beyond his power, and if he does order such a work, he must himself assist him in doing it.

He who beats his slave without fault, or slaps him in the face, his atonement for this is freeing him.

A man who behaves ill to his slave will not enter into paradise.

Forgive thy servant seventy times a day.

### ► literature

#### INTRODUCTION

The Middle Ages saw the end as well as the partial preservation of many traditions of oral literature through the spread of writing. At the same time, many vernacular languages developed in the Middle Ages and, with them, modern literary forms. While people in the modern world inevitably think of

literature as tied to writing, the composition of literature was originally oral. Before the invention of writing (or before a culture's acquisition of writing) poetry was inextricably tied to the performance of song. But once writing was introduced, the written document became the locus of literature and performance quickly vanished. Instead of performing poetry, one read it aloud.

In many preliterate cultures the most prestigious performer of poetry was the bard, who sang epic poetry at the courts of royalty and nobles. From studying and working in his tradition, the bard had memorized the great stories and myths of his people and also thousands of specific oral formulas equivalent to a line or half of line of verse that might consist, for example, of the name of a hero and some descriptive epithet or a vivid description of some typical action of fighting in a battle. During a performance the bard told his chosen story by recombining all of these elements, spontaneously arranging the formulas to make a poem in much the same way that individual words are arranged in ordinary speech. The singing of the story could be fitted to the length of time available (from an hour to the two days it would have taken to perform a long poem, such as the *Iliad*), and its details could be fitted to circumstances. For instance, the role of the special god or ancestor of the bard's patron could be expanded. There was no standard text of the poem but rather a new creation with each performance.

Once a language becomes literate, however, it will at first seem important to record the poetry of the bard in writing. This paradoxically destroys the bardic profession, since he is no longer an integral part of the poetry that is now written. By the same token, however, bardic poetry of the past can have been preserved for us only at the moment of a culture's transition from illiteracy to literacy. This happened in antiquity in the case of the Homeric poems. The *Iliad* and the *Odyssey* were recited by two prominent but now anonymous bards for written transcription in the early sixth century B.C.E., and within a generation the profession of the bard had died in Greece and was replaced by *rhapsodes*, who merely recited the written text of those two poems from memory.

The Middle Ages was another period productive of the recording of bardic epics because many cultures on the fringes of the classical Mediterranean world gained literacy at that time. This is true of the peoples of Scandinavia, for instance. Bards were there called *skalds*. Their tradition produced two great epics that were written down in the early Middle Ages. One was *Beowulf*, composed in Old English, perhaps for the Danish rulers of England. Another is the *Elder Edda*, composed in Old Norse and eventually transcribed in Iceland. By the mid-14th century, the *skalds* were dying out, and a third epic, the *Prose Edda*, merely contained the themes of

epic verse without the poetic form. Other bardic traditions originated in the Middle Ages and concern the exploits of historical figures from that era. An example of this is the tradition that flourished in the mountain villages of Serbia (with a cycle of stories about the battle of Kosovo in which Serbia was conquered by the Ottoman Empire) that flourished into the 20th century and which modern scholars study to learn the characteristics of oral composition.

Bardic traditions of oral poetry composition were not limited to Europe, however. A form of bardic verse seems to have existed in both Mayan and Aztec culture, some remnants of which were recorded shortly after the Spanish conquest. Something similar probably existed in the Inca Empire as well. Performance there was based on knotted and beaded strings. While detailed knowledge of this system was quickly lost after the Spanish conquest, probably each different-colored bead and differently spaced knot referred to some element of bardic performances and allowed performances to be composed in advance. Epic also developed in the royal courts of western Africa, where the bards were called *griots*. The *griot* tradition survived into colonial times. India also produced an old epic literature that was written down in medieval times.

Europe is a special case in the Middle Ages. As literacy came to the vernacular languages, it eventually produced a mature literature represented by the Italian poets Petrarch and Dante, by the French Arthurian cycles, by German poets like Wolfram von Eschenbach, and in English by Chaucer. At the same time, Europe inherited the Latin literature of antiquity, and until very late in the Middle Ages conducted all of its intellectual and official life in Latin, which was a purely learned language with no native speakers. India also had a venerated ancient language, Sanskrit, ancestral to several medieval vernaculars; only a few, but nevertheless important works of a religious character, such as the Vedas and some early Buddhist literature, were written in it.

Like those of Christendom and Judaism, the culture of Islam is based on a religion of scripture. The Koran—the content of which was said to have been revealed by God to Muhammad—was the dominant factor not just in Arabic literature but indeed in every aspect of Islamic life. Much of the most important Arabic literature of the later Middle Ages was devoted to commenting on and interpreting this seminal work. Another important Arabic literary activity in the Middle Ages was either translating Latin and Greek works into Arabic or developing poetic genres closely related to classical literature.

East Asia had writing from very early times, so by the medieval period literary compositions were more like those of the late medieval period in Europe in recognizably modern literature genres. China, in particular, produced a great deal

of Confucian and Taoist philosophical text. Poetry was composed for publication rather than traditional bardic performance. One of the dominant genres was the novel, such as the Chinese *Journey to the West* and the Japanese *Tale of Genji*.

## AFRICA

BY TANURE OJAIDE

Like music and art, literature is a cultural production. It is an artistic expression of a people's verbal and imaginative talents. For this reason, the literature of a people is as old as the people themselves, because a people always have a way of life that involves "literary" production. Long before Europeans came to Africa and colonized the continent, African ethnic groups had a vibrant literature of their own. During the Middle Ages, spanning from about 500 to 1500, Africans had a literature informed by the nonliterate and oral nature of their society. Because African society of that time placed a premium on passing information by word of mouth from one person to another and from one generation to another, the literature was oral. That literature has been passed from medieval times to contemporary times and thrives together with modern-day literature, which is written down.

Literature can be oral or written; what makes literature is not the mode of its preservation but its artistic and imaginative expression through verbal words of individual or human experience. A poem or song remains poetic because of the imaginative, witty, and innovative use of language—it matters not whether it is written or oral. At the same time, a story is interesting because of its humor, wit, irony, foreshadowing, suspense, and other narrative techniques and not because it is written down. Thus, oral African literature of medieval times entertains and educates its targeted audience in ways that are different from written literature.

It is significant to note that many African groups were still on the move during the Middle Ages and that many were inhabiting places different from where they are today. In the process of moving to seek fertile land and fishing waters or to escape ethnic conflicts, the groups carried along their forms of oral literature ("orature") and in the process created variants of songs, folk tales, legends, and epics in their new environments. New experiences encountered during the process of migration also informed the literature. For instance, during the reign of the Ogisos in Benin in the 13th through 15th centuries migrations of different groups (such as the Urhobo, Igbo, Ishan, and Afenmai) created their separate legends of Ogisos, which are still told today. The contemporary writer Isidore Okpewho's *Once upon a Kingdom* deals with the tyrannical Ogiso legend among the Asaba group of Igbo people. Similarly, different groups of the western African savanna

belt have their versions of the story of Sundiata, founder and hero of the medieval Mandingo epic.

## THE NATURE AND FUNCTIONS OF AFRICAN MEDIEVAL LITERATURE

African literature of medieval times relied on memory to be preserved. It is for this reason that there are numerous variants of many tales—the human memory is not perfect. A storyteller might forget some parts of a story and spontaneously improvise others. The "oral" text changes according to the mood of the storyteller, the time of the telling, the place it is told, the environment in which it is told, and many other factors that make oral literature an evolving text. For example, the folktale of a beautiful young woman who wants to marry a "spotless man," or a complete gentleman, has variants that change according to the environment, social trends, and historical circumstances. While the story today involves a young man dressed in a suit and carrying an attaché case, in traditional societies of medieval times the beautiful young woman yearned for a man dressed in traditional attire, with a hat and a walking stick. In this way one can say that an oral text is an evolving text.

The literature of Africans in the Middle Ages was integrated into the daily lives of the people. It was in the songs that men and women sang at home or on farms or while fishing, hunting, or traveling on lonely roads. A woman sang as she weeded her yam or cassava patch, while pounding her millet, as she lulled her baby to sleep with poetic lullabies. At the same time, a man clearing and planting a farm or preparing palm oil in a press sang songs to revive his energy. Unlike Western literature, which demands leisure and formal education, traditional African literature of the Middle Ages was a people's literature. The literature was woven into the different stages of people's lives: There were songs at births, naming ceremonies, initiation into different age grades, marriages, and deaths, among others. Oral literature was also performed at festivals and social gatherings to the accompaniment of drums or other musical instruments.

African literature of the Middle Ages was a very functional literature that catered to the needs of the traditional society. In communalistic societies literature in various forms helped maintain a healthy social ethos that bound people together. One of the advantages of traditional African literature is that it is cohesive in bringing people together to share verbal imaginative expressions in the forms of poetry, songs, chants, narratives, and performances that took place in a very live atmosphere. It is a literature with its own aesthetics and manifests in different forms.

In medieval times Africa had no formal schools, but there were avenues for teaching young ones about life, society,

and the environment and for imparting language and literary skills, which the oral tradition brought about. Usually at the end of the day's work parents and elders gathered their young ones by the fireside to tell them stories. Such sessions were a part of the growing process of young boys and girls, and they looked forward to these informal fireside "schools" with enthusiasm. They not only listened to others but also learned to tell such stories and sing the songs themselves.

African oral literature, as thrived in the Middle Ages, manifests in the following forms: folktales, folk songs, specific types of chants, myths, legends, epics, proverbs, riddles, and tongue twisters. There is no clear-cut division of the genres of narrative, poetry, and drama, as in modern Western literature. Literature is integrative in the sense that a good narrative involves poetic songs and chants, with the minstrel wearing a mask and a costume and performing to the accompaniment of music supplied by drums and other musical instruments. Oral literature as practiced by Africans of the period was a multimedia event.

### ORAL NARRATIVES

The folktale is one of the commonest forms of traditional African literature. It is anonymous because it is a product of the common imaginative genius of the group. It is different from specific songs that are owned by individuals or groups. Often folktales are narratives with animal characters that behave and act like human beings. Although the stories feature animal characters, the elders telling the story and the young ones listening know that the tales are reenacting human behavior and actions. Folktales are usually didactic, teaching moral and ethical lessons. Growing up in a traditional African environment, one is taught not to steal or do other bad things indirectly, through folktales. One learns to be selfless and to desist from immoral behavior through the lessons learned from folktales. Whoever is like the tortoise—self-centered and greedy—is punished for their bad actions, which destabilize society. Traditional African folktales teach a person to be a constructive individual in a communal unit. There are hundreds, if not thousands, of folktales in Africa of the medieval period, all geared toward moral and ethical lessons.

As indicated, different animals are involved in folktales. The tortoise (and its water equivalent, the turtle), the hyena, the fox, the elephant, the lion, the rat, birds, and others are often characters in folktales. Many of these stories, such as the tortoise tales, are trickster tales, in which weak or small animals outwit bigger and stronger animals. For instance, the small rat often outwits the big elephant to teach the lesson that the small can overcome the big with wit. There is a folktale, for example, in which a tortoise rides a hyena without being hurt.

A typical folktale, however, recounts the action of one animal as it relates to others and highlights the consequence of such action. An example is the tortoise tale, one Igbo variant of which the Nigerian writer Chinua Achebe uses in his *Things Fall Apart*. In this variant, Tortoise hears that the Sky God is going to throw a party to which all are invited. Since Tortoise has no wings to travel to Sky God's party in the heavens, he asks birds to lend him feathers and to go along to the party. Many birds lend Tortoise feathers with which he can fly, and they all set off for Sky God's party.

When they arrive and are offered food and drink, Tortoise asks Sky God for whom the bounty is intended. God answers, "For All of You." But Tortoise claims the food is for only him. After eating and drinking to his satisfaction, he asks his followers to take the leftovers. His followers feel humiliated and treated like slaves; out of anger they take their feathers and leave for home. The last bird takes pity on Tortoise and, before taking his feather, asks Tortoise what message he should give to Tortoise's wife. Tortoise asks the bird to tell his wife that she should place soft things, like cotton, on the ground below so that he can fall from the sky without being hurt. To punish Tortoise for his greed and self-centeredness, the bird tells Tortoise's wife to place pieces of rock, stones, knives, machetes, and hard items on the ground. From the sky Tortoise does not see well but thinks that his wife has prepared the ground for his fall; he dives down only to fall on the hard things and break his back. Ants take pity on him and glue together the different pieces—hence the patched body of the tortoise today.

That story, with many variants in the Africa of the Middle Ages, is a typical folktale; it teaches a lesson and also explains a natural phenomenon—why the tortoise's shell looks like a patched body. Many such tales seemingly explain why things are the way they are. This particular tortoise tale the lesson is also that in a communal society in which the tortoise has to borrow wings from others, he has to share with them, too. The tale shows that humans are interdependent.

Other stories feature human beings, like the many variants of the beautiful princess who wants to marry a "spotless man" or a "complete gentleman." Often the girl falls in love at first sight with an ogre or snake that has transformed himself into a handsome man after hearing of the finicky girl; she marries the stranger in haste and follows him away to his home. On the way to the stranger's home, he gives back the borrowed body parts and once more becomes an ogre or a snake. The woman finds herself stuck with him until she is rescued by one of the local men she had earlier rejected, who is rewarded with her hand in marriage. A folktale common in many African patriarchal societies, it tells how humans have a desire for an ideal that often is nonexistent.

Myths have always been an integral part of Africa's oral literature, and many were told in medieval times. Myths are common in traditional African literary repertory, and they, too, often explain natural phenomena. They are sometimes described as "etiological" tales. Among Africans, there are myths about why the sky is so high. The mythical explanations vary: A woman pounding millet knocks God with a pestle, and he withdraws to the heavenly heights. Or humans pester God with complaints that cause him to ascend to the heights to avoid them. There are myths about why the fowl drinks only in drops, why the pig always looks down, why some birds cry the way they do, and so forth.

One myth concerns the reason that men and women are always quarreling but cannot live without each other. In the Urhobo version of this myth, which dates back to the time some groups of Urhobo people migrated from Benin in the 14th century, the Supreme God, Osonobrugwe, first creates a man and gives him the whole world. However, the man wants a companion with whom he can share his happiness, and God obliges by giving him a woman as companion. They start quarreling, and Man goes back to tell the Creator: "When I was alone there was peace, but since I got this companion there has been no peace; please take her so that I will enjoy my peace." But Man had become so used to Woman in one night of lovemaking that he could not do without her the following night. The next morning he goes back to ask God to give her back. The to and fro goes on for six days; on the seventh day God tells Man and Woman to go and solve their problems themselves because he is tired of them. He withdraws to an impossible height, where they could no longer reach him. This myth explains the relationship between man and woman in society.

Other forms of African oral literature are legends and epics. The legends are often exaggerated truths in the sense that they often seemingly explain natural aspects of the landscape or manmade features. In Benin City (a town in Nigeria), for example, a giant is said to have used his toe to circle the city three times; this story is meant to explain the presence of three moats that act as defenses around the city. In a myth from Borno State (Nigeria), Lake Alau is said to be the spot where a heroic warrior died and left for the afterworld. In another myth, from the Ughelli group of the Urhobo people, a bride is said to have turned into a tree when she returned to a lake to fetch her forgotten belongings after being warned not to look back.

Many epics in Africa today date back to medieval times. The best known are the epic of Sundiata (ca. 1217–ca. 1255), the founder of the Mali Empire; the saga of Ozidi, a folk hero of the Niger Delta Izon people (Nigeria); and the epic of Mwindo, the legendary chieftain of the Nyanga nation

(present-day Democratic Republic of the Congo). Generally, in these epics the hero saves his or her people from oppression, exploitation, harassment, enslavement, and humiliation by another group. The epic tends to expose the noble qualities, courage, and other virtues of a people. The rule of the epic hero ushers in an era of peace and plenty as was not seen before and would not be seen after him; hence derives the nostalgia for the period of the hero. Often, as in the epics of Sundiata and Ozidi, there are many versions performed by the minstrel, called a griot in the Senegambian and Mali areas of western Africa. In traditional African society the epic often is performed during a festival to reenact and dramatize the heroism, peace, and abundance of the past as a reminder to the present generation of its proud heritage and as a guide toward heroic deeds of its own. Young ones have their mentors and aspire to contribute to society and learn to make sacrifices for the general good. The epic would have had a special appeal in medieval Africa because of the youthfulness of many of the ethnic groups that were trying to establish their separate identities at the time.

### FOLK SONGS AND OTHER TYPES OF SONGS

Folk songs and other types of songs are integral to the African oral tradition that thrived in the Middle Ages. These simple, common songs involving repetition were sung by men, women, and children alike. Sometimes they are found integrated into folktales. Many such songs are associated with festivals and rituals. In addition to folk songs are other types of songs and chants in traditional Africa, among them, songs of praise such as the *ijala* chants of the Yoruba people of Nigeria and Benin Republic, who sang the praises of hunters for their bravery in confronting wild animals in the bush. *Ijala* recitals are common at the burials of hunters as the last sign of respect for fallen comrades.

From South Africa, especially among the Zulu and the Sotho, come the impromptu praise chants called *izibongo*. The poet is a colorfully and flamboyantly costumed man who recites his praise of important personalities on special occasions. He often praises kings and their chiefs and is expected to know the history and genealogy of those being praised. Since the position frequently is inherited from father to son, certain formulas and praise epithets tend to run in one family's recitals. The *izibongo* requires a sharp memory, wit, and finely honed dramatic skills from its practitioner.

Just as there are praise songs and chants in traditional Africa, so are there also abuse and satiric songs. There are varieties of such songs in Africa, but the most elaborate traditions seem to be the *udje* dance songs of the Urhobo people in Nigeria and the *halo* among the Ewe of Togo and Ghana. *Udje* is a unique type of performance in which, on an appointed

day, rival quarters or towns perform songs composed of exaggerations about the other quarter or town. Central to the concept of *udje* are the principles of correction and deterrent through punishment with “wounding” words. Rival groups used these performances to maintain their rivalry during peaceful times. By exaggerating undesirable behaviors or characteristics, *udje* dance songs also were used to establish and maintain social norms. These songs attack negative behaviors and characteristics, such as adultery, flirtation, greed, harshness, laziness, miserliness, prostitution, overzealousness, stealing, and vanity.

In the *udje* tradition the poet composes the song, which is later taken to a communal workshop for editing and then given to a sweet-voiced person to sing. The poem or song is not complete until it is performed before a large crowd; consideration of their performance informs the compositions of the poetic songs. *Udje* performers wear costumes that will enhance their appeal. Being an integrative art, *udje* fuses song, music, dance, and other dramatic and theatrical features. Various poetic and gestural features enhance the song quality of *udje*. Doubtless other types of songs exist in Africa but the folk songs, praise songs, and abuse songs are the most vibrant.

### PROVERBS, RIDDLES, AND TONGUE TWISTERS

While the oral narratives of folktales, myths, legends, epics, and songs have their role in society, proverbs, riddles, and tongue twisters are also very important. They cater to the intellectual and language-building aspects of individuals in society, especially youngsters. A proverb is a wise saying that expresses an idea in a concise and succinct manner. It is a traditional trope, or saying that is highly figurative. It tends to have a central image that is expanded upon to convey meaning.

Most of the proverbs that exist today date back hundreds of years, to medieval times. For instance, in the saying “A dog with bells will not be lost in the bush,” the central image is of a dog wearing bells whose ringing will always expose the dog’s whereabouts. This image would have made sense in medieval Africa, where hunting was a major occupation. The proverb generally exhibits wit and is usually anonymous in the sense that it cannot be attributed to a single person. Its origin is always ancient, even though some proverbs appear to be much older than others because of the conditions of the time in which they were introduced into the language. Proverbs are based on language and ethnicity and often result from generations of observation or experience. Every proverb appears to emanate from experience over a very long period and seems at a particular time to be incontrovertible truth or perceived truth from observable reality.

Proverbs are deeply rooted in traditional culture, in which they play many roles, such as advising, cautioning, and entertaining. They arise from the people’s experience and sensibility and reflect the character of a people or an ethnic group in that they affirm acceptance of what the proverbs entail. Proverbs corroborate the way of life or lifestyle acceptable to a people. The ethics, morality, and virtues of a people are enshrined in their proverbs. Over the ages, proverbs became, for nonliterate traditional Africans, the memory of their common experience as a people. With African peoples, the strength of their language lies in their proverbs, which are not only expressive and communicative tools but also agents of the perpetuation of their entire culture and its values.

A people’s culture and experience are dynamic and change with time. As time passes, new proverbs arise to express and reflect the new realities. Proverbs are the summations of keen observations and lessons learned from different facets of life. In the small ethnic world the observations that make the proverb tend to be narrow in scope; with new sensibilities some could be challenged, like the gender-based views of the patriarchal African society. Proverbs continue to be formed by people about their experiences. The proverb is an integral part of the language, which carries it to enrich and strengthen itself. It is amazing that proverbs are never assigned to a person, and it is rare to know specifically from where in the language belt it derives. A people’s experience involves their environment, history, culture, society, politics, character, sensibility, and worldview, and proverbs relate to these diverse and broad manifestations of human experience. Proverbs are used to register the people’s ethos and affirm faith in their own ways of life.

Riddles and tongue twisters also form parts of the African oral literature tradition. Riddles are like far-fetched metaphors and create meaning in the group. Since riddles in a particular ethnic group or area have set answers, one gets them either right or wrong. Even before the person asking the question completes the question, the young ones who are listening compete to answer it. Riddles demand a sharp imagination for answers. A traditional Nigerian Hausa riddle asks: What is an egg with thorns? The answer is a pineapple.

Tongue twisters are common in African languages. They test the child’s acumen in repeating fast sentences that contain clusters of alliteration. In Urhobo, a Nigerian language, this is one sample tongue twister: Kua kp’ Ekrebuo, kua kp’Ekrebuo, Ekrebuo be kua ra (meaning “Move to Ekrebuo; move to Ekrebuo; Ekrebuo is not difficult to get to”). Speed is the essence of pronouncing a tongue twister.

The oral tradition of medieval Africa was of particular help in the nonliterate society of medieval times in playing the role of educator, entertainer, and role model to establish

a peaceful, happy, and warm human community. Through the oral tradition, the individual understood his or her place in the social fabric. At the same time, communal living did not restrict individual freedom and sense of worth. The oral tradition carried the hopes and fears of the people of the time, and through it contemporary Africans can peep into the lives of the past with a view to imbibing what can strengthen modern life. The oral tradition shows the roots of modern Africans and carries the values, worldview, philosophy, and experience of their ancestors. One can glean from the oral tradition the African world as the people lived it. The changes that Africans have encountered over the centuries are reflected in various forms of the orature. Above all, the oral tradition affirms faith in communal living and creates cultural identity.

## THE AMERICAS

BY ALESSIA FRASSANI

No written record of literary text survives from pre-Columbian indigenous America. The rich poetic, epic, and historical heritage of American native cultures was almost entirely oral and substantially relied on recitation for transmission and preservation. At the moment of contact in the 16th century, on the other hand, the Spanish eagerly recorded native literary and historical tradition using the Latin alphabet. These European documents, together with archaeological evidence and contemporary oral tradition, enable scholars to reconstruct the role, major features, and content of pre-Columbian literature. Archaeological evidence includes painted vases and murals, which depict scenes from mythology or scribal activity, and a few pictographic codices from Mexico. (A codex is an unbound manuscript of a classic text.) Linguists and anthropologists, supplementing the work of archaeologists, study living traditions that still follow ancient customs of storytelling, record keeping, and divination in different parts of the Americas.

The lack of written records from the pre-Columbian Period does not mean that other devices were not employed to help in the memorizing and reciting of literary texts. Pictography relies on pictures rather than words and was particularly developed in Mesoamerica (a region including modern-day central and southern Mexico, Guatemala, Honduras, Belize, and Salvador), where the system was used to record tribute payments, genealogies, and religious information (the latter in special relation to timekeeping and the calendar). In South America the Incas continued in the 15th and 16th centuries the millennial Andean tradition of using knotted threads of varying colors and shapes to keep records of imperial affairs, from taxation to historical events.

A phonetic (sound-based) writing system was developed by the ancient Maya in the Preclassic Period (1000 B.C.E.– 150 C.E.) and was widely employed throughout the Classic Period (until 900 C.E.) to record historical events, mostly royal successions and battles, and astronomical and calendar information. By tying royal deeds to the movements of the stars, the Maya created a type of history that was highly mythical and cast factual reality into a cosmic realm. The glyphs found on pottery or carved in stone were meant as a springboard for oral recitations either in a courtly setting or in the open spaces of large public plazas. These recitations had a double function: they entertained the audience while at the same time fostering a sense of communal identity through historical, mythological, and highly moralizing storytelling.

The main features identified by scholars in American indigenous literatures are common to all the great epic traditions of the ancient world—for example, the *Iliad* and *Odyssey* in Greece. Several stories develop around a known and fixed set of characters. The stories are very long and usually evolve through tens if not hundreds of years. There is no linear structure. The narrative usually begins in the middle of the story, and the plot can be better described as a series of unrelated segments with recurrent personages and themes. A certain familiarity of the audience with the stories and characters is therefore expected, and the success of the performance rests on the ability of the storyteller to give a lively delivery.

Not all literary production was epic and grand. Highly educated nobles produced courtly and refined lyric poetry, often engaging in philosophical thinking. This meditative poetry was concerned with the nature of the divine, the mystery of death, and the duty of war and political leadership. Finally, religious and ethical issues were addressed in poems that spoke about good and proper behavior toward the elderly and the rulers, in societies strongly divided by gender and class. Sacred hymns also elaborated on respect and honor owed to the supreme beings, such as gods and natural forces.

Memorization of long and intricate stories, as well as complex poems, was achieved by employing specific rhetorical devices. Actors and poets often relied on established metaphors and poetic associations, and what might be perceived by 21st-century ears as being obscure was rather plain and understandable to pre-Columbian listeners. Parallelism is the most common and recurrent feature in indigenous poetry. It involves the repetition of sentences in couplets with only slight wording variations. This device can be considered equivalent to the rhyme and metric system in Western poetry because it created the basic musical structure of the poetic verse. A common elaboration on the two-verse parallelism is the triplet, in which a third verse concludes the preceding couplet by breaking the established pattern. In this way, the

performer is able to change pitch and stress before starting again with new sets of parallel verses.

### PAN-AMERICAN ORIGIN MYTHS AND HISTORICAL NARRATIVES

Despite chronological and geographical differences, similar origin myths appear throughout the pre-Columbian Americas. The Maya (from the Guatemala highlands) book of the Popol Vuh, the Aztec *Leyenda de los soles* (Legend of the Suns), the Mixtec (from southwestern Mexico) Codex Vienna, Andean chronicles from South America, and indigenous North American folklore tell the story of the creation of the world, humankind, maize (the staple food of the societies that practiced agriculture), and civilization. Frequent is the idea of many creations, either as a series of failed attempts on the part of the gods to create worthy human beings or as a cycle of creations and destructions due to disastrous natural phenomena. According to all these myths, before creation there was only darkness and mud. The sun (and therefore the passing of the days and time) did not exist, and water and earth were not divided and united again cyclically by the rain and the seasons. Priest-gods' offerings of tobacco or incense caused mountains to rise from water, the emergence of the sun, and the beginning of day counting.

According to traditional Aztec lore, the Aztec were living in the fifth sun, that is to say, the fifth cycle of creation, after four previous eras that had been ended by devouring jaguars, wind and hurricanes, rain and volcanic eruptions, and flood, respectively. Vestiges from previous eras were still visible in the present world: Boulders were giants of the first era turned into stone by the new rising sun; monkeys were nothing more than a failed attempt to create human beings; butterflies, dogs, and turkeys were the survivors of the third creation; while human inhabitants had been turned into fish at the end of the fourth sun.

In Andean lore the world originated in the region of Lake Titicaca. Before creation everything was in darkness. The god Viracocha created the first race of humankind. These people were eventually turned into stone by the god, who was dissatisfied with them. They were at the time of the Inca identified with the stones and ruins of Tiahuanaco, a powerful center that originated and flourished in the highlands not far from Lake Titicaca a thousand years before the Inca. The god eventually created the sun, moon, and stars from the lake and still in the 21st century indigenous people celebrate the recurrence of this important cosmic event by visiting Titicaca annually. The different cycles of creation were known as *pachacuti*, literally a "revolution or turning upside down of time and space." According to one chronicle, there had been five previous creations, during which humankind progres-

sively approximated the final state. The gods Viracocha and Pachacamac were already worshipped, and agriculture, metallurgy, and other social institutions still practiced at the time of the Inca were also a legacy of previous eras.

Culture heroes also play a crucial role in creating the defining features of American civilizations. Their deeds always revolve around the defeat of death, with braveness and deftness, the creation of humankind with bones of the ancestors, and blood self-sacrifice. This is the case of the legendary god known in Nahuatl (the language of the Aztec) as Quetzalcoatl, or Feathered Serpent, and Coqui Savi, or Rain Serpent, among the Mixtec. Among the Maya he is known as Kukulcan, in Yucatán, and Gukumatz in the Guatemala Highlands. Although the god is represented frequently in Mesoamerican art from the Preclassic Period (as early as 700 B.C.E.), especially as a powerful animal double for priests and rulers, extensive documentary data exist only from the Late Postclassic Period (ca. 1200–1521 C.E.). An exemplary wise man, Quetzalcoatl, according to Aztec mythology, agreed to descend into the Underworld for the sake of defeating the Lords of Death. He successfully overcame the challenging tasks that they posed to him, let his blood fall on the ancestors' bones, and brought the world out of obscurity. He was also responsible for giving maize to the people by turning himself into an ant and stealing a few kernels from the womb of the earth. According to other myths, Quetzalcoatl was a Toltec ruler. The Toltec dominated central Mexico before the Aztec and were regarded as the inventors of writing, poetry, and the arts. Quetzalcoatl was a devout and pious king who fasted and lived in chastity, only to flee away to the east, the region of the sun, when the golden age of the Toltec came to an end.

In the Mayan Popol Vuh, the twins Hunahpuh and Xbalanque, skilled ballgame players, went to Xibalba (the Mayan Underworld) to retrieve the remains of their father who had been sacrificed by the Lords of Death. They played and danced for the gods of the Underworld, ritually killing and bringing back to life each other, until they tricked the Death gods, sacrificed them, but did not revive them. They eventually revived their father, who came back to life sprouting as a young corn plant. This last aspect is very relevant metaphorically, as it indicates the importance of sacrifice, death, and renewal in Mayan agricultural society.

Tricksters, in some ways similar to the Mayan Hero Twins, are probably the most common culture heroes in Native North America. They are—most of the time—animals or children, smart and deft. Stealing is the typical way by which these heroes create the living and natural things of the world. Coyotes, spiders, and ravens are among the most common tricksters. They are rather ambivalent figures, with the creative power of the gods but all the moral limitations of

humans. The unpredictability and instability of their personalities make them outcasts in their own societies. They are unsettled characters, always wandering in a rather unpredictable way. In many ways, trickster stories provided good moral lessons, exemplifying the type of behavior that should not be followed in society.

Caves were mythical origin places for indigenous people in the Southwest, Mesoamerica, and South America. Pueblo and Navajo stories usually tell of mythical origins from a hole in the earth, or a cave, where the ancestors lived for many generations, escaping floods and other natural disasters. The emergence from the cave takes the shape of an epic journey through different ascending worlds, where the people face different challenges and create social institutions and order out of a primordial state of barbaric chaos.

In the case of the Aztec, the society that would eventually dominate central Mexico originated from Chicomoztóc, “place of the seven caves,” together with six other groups. Besides historical reality (the Aztec did in fact enter the Valley of Mexico from a place to the north) the myth explains the power relation between the dominating Aztec and other culturally related, but eventually subjugated societies. Similarly, in the Andes, the Inca were said to have originated from a place called Pacaritambo, “inn of dawn or origin.” They migrated northward and settled to found the city of Cuzco as the center, literally the navel, of their empire. Other different Indian nations that allied with the future imperial family of the Inca also originated from Pacaritambo.

### NORTH AMERICAN INDIAN LORE

Despite the vastness, diversity, and long history of the North American continent, literature, almost entirely known through oral tradition, has come down only from modern times. Few stories were recorded during the first European encounters of the 16th and 17th centuries, and it was only in the late 19th and early 20th centuries that American ethnographers began to collect and study Native American folklore. There is a general understanding among Native Americans that there are two different literary genres: the sacred stories, also referred to as “old” and “true,” contrasted with the “young,” narrated or “false” stories. From the Western perspective, these two categories would be “myth” and “fiction,” respectively. The former touches the deep core of community identity and history, while the latter is meant mostly for entertainment.

### AZTEC HISTORY AND LITERATURE

Aztec literature is relatively well known. Different genres are documented that clearly anchor this central Mexican tradition to wider Native American lore. The myths about different cycles of creation and the culture hero Quetzalcoatl are

Stone bust of Quetzalcoatl, a god associated with the Aztec creation myth; Mexico, ca. 1325–1521 (© The Trustees of the British Museum)

known as *teotlahtolli* (divine words). Specifically, Aztec is the story of the migration from Aztlán to the Valley of Mexico that recounts in rather epic fashion the geographical and chronological journeys that shaped the past and present cultural identity of the clan. Although no pre-Hispanic document has survived the Spanish conquest, many paintings and chronicles produced after 1521 were meant to leave a testimony of the grandeur of Aztec past and empire. According to these sources the Aztec had entered the basin of Mexico (where today the national capital of Mexico City is found) after leaving and wandering for some time in the northern part of Mexico. The glorious history of the Aztec from a “barbaric” and nomadic lifestyle to the founding of the imperial city of Tenochtitlán centers on the myth of their patron deity, Huitzilopochtli (Hummingbird of the Left, or Hummingbird of the South). The deity’s birth at Coatepec (Hill of the Serpent) is a pivotal event in Aztec cultural and political history. Huitzilopochtli was the miraculous son of the goddess Coatlicue (She of the Serpent Skirt) and had to kill his own brothers and sister, who were infuriated at their mother for her shameful pregnancy. This myth probably coincides with actual historical events that led to the Aztec rule over their neighbors and former allies in the Valley of Mexico.

Another important literary genre is constituted by the *huehuetlahtolli* (“ancient words”) compositions learned and transmitted in the *calmecac*, priestly schools, by members of the nobility. They are speeches from mothers and fathers to sons and daughters, emperors to their subjects, and supplications to the gods in times of drought, famine, or other natural disasters. They also include official speeches of ambassadors and merchants. They chiefly address the moral concerns of a traditional society preoccupied with maintaining the established authoritarian order.

### MIXTEC BOOKS AND EPIC LORE

The literary tradition of the Mixtec of Oaxaca, in southwestern Mexico, is expressed in the famous codices, or painted manuscripts, that were produced a few decades before the conquest. The Codex Vienna (from the city where it is currently located) recounts the origins of the Mixtec, the major geographical features of their land, their cultural traits, and their lineages. Aspects common to the rest of Mesoamerica include the primordial creation myth and the culture hero Quetzalcoatl, or Coo Savi.

A series of other manuscripts, however, depict an epic story that is peculiar to the region. Manuscript painting was a courtly activity and therefore reflects the ideological concerns of the ruling class. Although lineage reckoning and legitimization were important goals of these codices, a strong literary component is also present in the epic story of a legendary Mixtec general who, during the 11th century, is able, albeit temporarily, to unify the different city-states of the Mixtec. Son of a priest, and therefore not destined to political leadership, Lord 8 Deer Jaguar Claw achieves an unprecedented power in the region thanks to military campaigns, political alliances, and ritual pilgrimages. His quest and ambitions eventually take him to central Mexico, where he is crowned sovereign ruler, and to a place in the east where he meets the sun god. His life nevertheless is ended by murder, killed in revenge by the son of a former lover whose execution he had ordered. This story, present in fragments in the different manuscripts, has a highly moral tone, besides entertaining the audience with grand historical events, love stories, and political intrigues.

### POPOL VUH, A QUCICHE MAYAN COUNCIL BOOK

The single most important text surviving from ancient Mesoamerica is the so-called Popol Vuh from the Guatemala highland. The term means the “Book of Council” and refers to the fact that the text was consulted by Mayan kings in making important political decisions. The book, which was an anthology of hieroglyphs, survives in the 21st century in the Latin alphabet and was written down between 1554 and 1558.

The original painted manuscript probably included extensive illustrations, such as astronomical tables and calendars to accompany the textual parts. It is stated in the available version that there are two different ways of reading the Popol Vuh: divinatory and narrative. Priest-diviners consulted the book as a springboard for oracular deliberations that were often uttered in obscure form. The narrative part, on the other hand, is the version that has come down to us and that was only partially represented in the text and pictures of the original manuscript, basically relying on oral tradition. The story is divided into three sections. First, there is an account of the creation of the Mayan world and humankind by the gods. Second, there follows the epic journey of the Hero Twins to the Underworld that gives rise to the life cycles of death and renewal and agriculture through sacrifice. Finally, the manuscript takes a more historical turn and recounts the first lineages that populated the various Mayan regions, from the Guatemala highlands to the tropical lowlands of Guatemala and Mexico and the desert region of Yucatán.

### INCAN WRITING AND MYTHOLOGY

Native-language sources abound in Mesoamerica, but few texts in Quechua (the language of the Inca) about Andean native mythology, literature, and history have survived. Pictography, the art of painting symbolic pictures on animal skin, cloth, or paper was flourishing in Mesoamerica at the time of the Spanish conquest. Spanish missionaries probably saw similarities between the production of books in ancient Mexico and medieval manuscript illumination. In the Andes, on the other hand, knowledge was chiefly preserved and transmitted by means of knotted strings stored in large bundles. Although many examples of quipus, as they are called in Quechua, survive, their decipherment and interpretation is highly controversial. Perhaps the lack of any writing system that vaguely resembled the Latin script was a restraint to translating traditional literature into an alphabet. From colonial sources it is known that quipus were used in narrating stories about the Incan past as well as for collecting statistical information, such as census and tribute accounts. Information was encoded in the different colors and combination of colors of the strings and in the variation and positioning of the knots. Every *quipucamayoc* (“knot maker” or “knot keeper”) probably developed a personalized system of encoding information. Spanish chronicles of Incan history and mythology are the literal translation of original Quechua accounts made by the *quipucamayocs* during the “public readings” at ceremonial occasions.

The Inca, from a valley in the south-central Andes, came to dominate a vast region that includes modern-day Peru, Ecuador, northern Chile, and western Bolivia. Their power

stemmed from the natural resources of the fertile highlands and maritime coast, but they also maintained contacts with people living in the Amazonian forest. Their empire rested on a strong centralizing political and economic ideology that centered on the region of Cuzco.

Oral tradition stresses the imperial view of the Andean past and its heritage, but the Huarochirí manuscript offers a complementary view of Incan history and lore. It balances the typical Andean vision of creation and history focused on Lake Titicaca with a view from the coastal region. Just outside the modern Peruvian capital of Lima lies the pilgrimage center dedicated to Pachacamac. Although the ethnic group of the Yauyos of the province of Huarochirí, where the manuscript was produced, said that they recognized Viracocha as the sun deity of the highlands (the Lake Titicaca region), Pachacamac was the supreme creator deity. He was credited with the creation of the first human couple. He gave corn to the people by sacrificing and planting the teeth of one of the sons of the first couple. He planted the boy's ribs and bones and created yucca tubers. Eventually, Pachacamac was defeated by a son of the sun deity, Viracocha, and disappeared into the sea in front of the place where the temple dedicated to him still stands in the 21st century.

## ASIA AND THE PACIFIC

BY KENNETH HALL

The spirituality, ideals, experiences, fears, and hopes of medieval Asia are contained in its sophisticated philosophical, moral, epical, and religious texts. Literacy and learning were prestigious; even Japan's samurai warriors were literate and composed poetry. Despite the fact that women did not attend regular schools and were not tutored as boys were, some were taught to read and write by their family members. Such was the case especially in imperial Japan among court ladies, such as Lady Murasaki Shikibu (ca. 978–ca. 1026), the author of the *Genji monogatari* (*Tale of Genji*, ca. 1010). In India, where religion was a focal part of life, most of the early literature was associated with India's Hindu and Buddhist traditions. In China the Confucian tradition favored philosophical texts that focused on human existence in this world rather than speculating on a life everlasting. By the sixth century China's acceptance of Buddhism encouraged new works of fiction and poetry, countering the Confucian view that creative works were wasteful, self-indulgent exercises.

### INDIAN LITERATURE

Earlier oral compositions transitioned into Sanskrit, Prakrit, Pali, and Tamil written texts in the medieval era. In contrast to earlier religious literature, which records the mythology,

rituals, ritual chants, magical spells, and philosophy of Indian society, medieval literature shifts the focus from the worship of mythological divine to consideration of a universal celestial creative force, Brahma, and proposes ascetic and mystical ways to realize wisdom and eternal truth. This philosophy was foundational to the development of Hindu law, as contained in the Dharmasastra legal texts that address good and evil, human morality, and societal duty.

Medieval Buddhist teachings, popularized in the Jataka folktales concerning the previous lives of the Buddha, provided an alternative commentary on a middle way between Hindu ritual and withdrawing asceticism. These themes are developed in contemporary and subsequent Hindu literature, notably Indian epic literature and poetry. The Bhagavad Gita, a Gupta-era (320–550) addition to the Mahabharata epic poem, became the philosophical base for new Hindu devotional (bhakti) cults, which focused on the veneration of numerous intercessory divine beings that were represented in stone and metal icons and addressed in an assortment of post-10th-century bhakti poetry and literature celebrating the Hindu gods Vishnu and Shiva.

### INDIAN EPICS

The Mahabharata and Ramayana epic poems were the first secular literature of south Asia and evolved in their oral forms over centuries from Vedic times (ca. 1600–800 B.C.E.). Initially they were martial ballads of heroes in India's ancient past, but later the Brahmin priesthood added long passages on theology, morals, and statecraft. The epics, which transitioned from oral tradition to writing during the Gupta era, continued to evolve in medieval times, with additions and innovative compositions inspired by the epics in India and in Southeast Asia.

The Mahabharata is the world's longest poem, with 90,000 stanzas. The Mahabharata's diverse plot centers on a great civil war between two rival factions of heirs to the throne in the Vedic-era kingdom of Kuru in northwestern India. On one side are the Pandava brothers, Yudhisthira, Bhima, Arjuna, Nakula, and Sahadeva, who are the rightful heirs; on the other are the Kaurava brothers, led by Duryodhana. After a long series of earlier intrigue and conflict, including a period in which the Kaurava brothers leave the kingdom and travel among various other courts as soldiers of fortune, all the kings of India and surrounding regions join one side or the other to form two huge armies, which meet in a decisive battle on the plain of Kurukshetra. In an 18-day battle, all of the important chiefs die except the five Pandava brothers and their companion Krishna (Lord Vishnu in one of his alternate identities), who had become Arjuna's charioteer-adviser. The eldest Pandava brother, Yudhisthira, becomes the new king,

and when he retires, he names Arjuna's grandson Parikshita as his heir. The five brothers, with their joint wife Princess Draupadi, the daughter of the king of the Panchala, who had selected her mate from among an assembly of potential marital partners, then go on foot to the Himalayas, where they climb Mount Meru to enter the realm of the gods.

The five Pandava brothers and other characters represent the various personalities of humankind. Yudhisthira is pious, righteous, and gentle but a little negative in character; Bhima is physically imposing, rough, and gluttonous but very intelligent; Arjuna is the great warrior—principled, generous, and brave; Draupadi, their wife, has spirit and is not afraid to speak her mind to her husbands when she has issues with them. The villain, Duryodhana, and his followers are not totally evil; they have noble qualities and courage, and are worthy opponents of the Pandavas. Among the key subordinate episodes are the Santi Parvan, a philosophical discussion on statecraft and ethics, and the Bhagavad Gita, the sermon of Krishna to Arjuna on dutiful behavior before the climactic battle. Other notable narrative subsidiary episodes tell legends of the gods as well as the stories of numerous secular characters from Kuruksetra or its neighboring regions.

In contrast, the Ramayana epic poem is about one-fourth the length of the Mahabharata and is a later composition. Its story is based in Ajodhya, the capital of the neighboring kingdom of Kosala, east of Kurukshetra. The plot focuses on Rama, one of the king of Kosala's four sons, and his wife, Sita, the daughter of the king of Videha, whom Rama had won in an archery contest. Later versions of the poem add that Rama is really an incarnation (avatar) of the god Vishnu, who takes an earthly form (as he does as Krishna in the Mahabharata) to right a wrong in the realm of humankind. Owing to a disagreement with his father, Rama voluntarily goes into exile with Sita and his brother Lakshmana, and they live as hermits in the forest of Dandaka, where Rama destroys many demons who are attacking ascetics and villagers.

Ravana, the demon king of Lanka (Sri Lanka), intent on avenging his fellow demons' deaths, comes in disguise while Rama and Sita are on a hunting expedition and kidnaps Sita, carrying her off to his Lanka home in his magical flying chariot. In an attempt to find Sita, Rama and his brother ally with Sugriva, the king of the monkeys, and his general, the brave and loyal Hanuman. Hanuman discovers Sita in Ravana's palace and leads his great army of monkeys and bears across a bridge of stone that Rama had magically built from India to Ravana's island kingdom. There Rama, Lakshmana, Hanuman, and their allies kill Ravana and his followers and rescue Sita.

While Ravana has not mistreated Sita, nor has Sita in any way yielded to Ravana, under Hindu sacred law Rama

must refuse Sita as his wife. In anguish, she throws herself on a funeral pyre, but the fire god Agni refuses to accept her. This rejection is interpreted to be a sign of Sita's innocence, allowing Rama and Sita to renew their marriage vows and return to Ajodhya to rule righteously as king and queen for the remainder of their lifetimes. In a later addition, Rama responds to continuing criticism from his subjects that his queen is impure, and to satisfy the will of the people, despite his belief in her true innocence, he banishes her to a monastic hermitage. There she gives birth to twin sons. Rama eventually discovers Sita and her sons and acknowledges that her sons are his. Sita calls on her mother, the earth goddess, to intervene to make a final proof of her innocence. The earth opens and swallows Sita; soon Rama returns to heaven, to resume his form as Lord Vishnu. In yet another later addition to the text, Rama and Sita are finally reconciled in heaven, in their divine forms.

There were other medieval regional epics, the most notable being those of southern India and the court literature of Java. Among the Tamil-language compositions that blend southern Indian and northern Indian Sanskrit culture are the erotic, heroic, and religious-themed *Cilappatikaram* (The Jeweled Anklet) and the *Manimekalai* (The Girdle of Gems), which date to the early medieval era. Both works are set in the capitals of the three Tamil kingdoms: Chola, Pandya, and Chera. The first tells the story of a young Chola merchant, Kovalan, who is married to the virtuous Kannagi but is in love with the courtesan Madhavi; he is punished by being exiled to the Pandya realm, where he is executed when he tries to sell his wife's ankle bracelet. Kannagi comes to redeem her husband's name and in rage tears off one breast and throws it at the city of Madurai, which goes up in flames as demonstration of the supernatural powers of a faithful wife. In death, Kannagi becomes the goddess of chastity.

The second example, the *Manimekalai*, continues the story of the *Cilappatikaram*. The heroine is Madhavi's daughter, Manimekalai, a dancer and a courtesan like her mother. Manimekalai is torn between her desire for a princely lover and her spiritual needs—the first encouraged by her grandmother, the second by her mother. She flees from the attentions of a prince, and while he pursues her, she achieves magical powers: She changes forms and survives prison, lecherous villains, and other dangers. She converts the queen and finally goes to the Chola capital, which is being destroyed by ocean storms; worships Kannagi; and arrives in the Chera capital city to provide famine relief and to perform "penance." Unlike the *Cilappatikaram*, which is a local blend of Hinduism and Jainism, the *Manimekalai* mixes Buddhism with local supernatural and naturalistic beliefs common to early south Asian society.

### SANSKRIT KAVYA AND CLASSICAL DRAMA

India's early literary tradition culminated in the classical Sanskrit compositions of the Gupta era, notably the *kavya* poetry and drama of Gupta-era authors. These writings on love, nature, and morality were intended for recitation and performance, to elicit an emotional response from their audience. Human emotions are personified in seasonal and day and night settings, as well as in birds, beasts, and flowers. *Kavya* compositions follow a rigid set of grammatical rules. The unit of poetry is the stanza, which has four quarters, each of varying length from eight to 21 syllables; epics employ the *sloka*, with eight syllables to the quarter.

By general consensus, the compositions of the court poet Kalidasa (fifth century) are the best. One of his most popular remaining works is *Meghaduta* (The Cloud Messenger), whose central character is a young man who is banished to the mountains for a year for a civil offense. The poem expresses the anguish of his separation from his beautiful wife; he finally gives a cloud his message of love to take to his wife. Subsequently, the 10th-century popular bhakti devotional poetry, composed in India's regional languages, addresses the intense emotions of the individual devotee who distances himself from the secular world to embrace an intense desire to become one with the divine and to fulfill the human potential for love that becomes possible when one totally commits to Lord Shiva or Lord Vishnu.

Kalidasa and other Gupta-era authors also set the standard for subsequent Indian drama; among them are the works of the eighth-century central Indian dramatist Bhavabhuti (fl. 700), who is considered to exceed Kalidasa in his portrayal of sorrow. Many medieval Indian dramas are filled with melodrama that brought medieval audiences to tears, but they always have a happy ending. Women are exiled from their homes by their fathers and husbands, who later realize the injustice; lost or banished children are eventually reunited with their families; and at the last moment noble heroes are always saved from death. Plots were borrowed from earlier and contemporary sources, such as dramatizations of the epics, legends of gods and ancient heroes, folklore, and tales of historic figures. There were 12 recognized categories of drama, ranging from allegorical plays to light comedies. Indian dramas commonly feature a hero, a heroine, a villain, a comic relief, and a cultured but shallow parasite who befriends the hero with negative consequences.

### JAVANESE KAKAWIN LITERATURE

Java's *kakawin* poets, whose patrons were kings and their courts, composed Javanese-language versions of epic stories set in the Java landscape (1000–1500 C.E.). Their stories told

about the activities of a court. Heroes were courtiers whose behavior was refined, and they were equally accomplished in the arts and in warfare. Their opponents were crude, intellectually unstable, and self-centered. Courts were not isolated but networked with their countryside. Men and women of the court regularly traveled beyond the court, where they had contact with commoners and foreigners, gods and goddesses, demons and priests. Courtiers especially sought harmony among several realms of existence, in the realm of humanity and in those of the divine. Humans lacked the preeminence of divinity and nature. In their travels courtiers encountered romance, fought in great battles, and paused to receive instruction from the gods on the meaning of human existence, all of which allowed the elite to bring prosperity to their subject humanity.

Kings established the standards of acceptable conduct appropriate to Java's hierarchical society, from courtiers to commoners; in common with the theme of Indian epic literature, proper behavior insured society's success. In the minds of the poets, a king's power ultimately depended on his alliances with his nobles and his ritual leadership in partnership with Hindu or Buddhist priests, who were his intermediaries with the Supreme Divine. The initial *kakawin* poets hoped for a future golden age, which later poets claimed was achieved by Java's 14th-century Majapahit court (1293–ca. 1500). While early-14th-century poets thought of kings and priests as intermediaries whose special relationships with the gods was essential to their subjects' success, by the 15th century poets symbolized the declining fortunes of the courts by asserting that Java's prosperity was by then less the consequence of the kings and their priests than it was their subjects' actions in this life, notably family rituals that honored the memory of deceased ancestors.

### CHINESE LITERATURE

In contrast to medieval south Asian literature, which generally has a religious context, China's early literature focuses on secular existence and addresses the necessary conditions for successful governance. Confucian tradition dictated that early Chinese literary compositions conform to rigid standards and have some secular value. The era of the Han Dynasty (202 B.C.E.–220 C.E.) was notable as a period of literary transition. This period featured the development of Chinese governmental record keeping and the use of these records to provide documentation for the writing of official dynastic histories, which were written by the subsequent dynasty, and the composition of essays that apply Confucian logic and the historical past to the resolution of current societal needs.

Chinese poetry reached its fullness in the Tang and Song eras of the seventh to 12th centuries. While earlier poetic ex-

pression was constrained by Confucian structure and poetry was expected to have some secular value, by the Tang era Chan Buddhism made it clear that literary creativity was an appropriate exploration of the human mind. Writing was an act that brought self-discipline, which perfected the individual, who might then be a more productive member of society. Tang poetry began to make this transition but was still hesitant, and most of that era's poems have some purpose. Song-era poets fully embraced creativity for its own sake, and their poems openly indulge in the subtle pleasures of life. Song poets believed in a limited role of government leadership, stressing the need to believe once again in the moral capacities of humanity, and thus they argued for a less regimented society as the means to inspire greater creativity.

Tang and Song texts were printed using carved woodblocks, a practice that made written works widely available among an increasingly literate Chinese urban public. Among these were popular new *huaben* stories and earlier *shuo hua* oral stories that were printed and widely sold. There were also popular accounts of Buddhist pilgrims, printed encyclopedias, interpretive histories, and neo-Confucian philosophical essays. Tang-era writings were still hesitant, and most had some purpose, but Song-era authors fully embraced creativity for its own sake, even to the point of openly indulging in the subtle pleasures of life, which Confucian scholars regarded as dangerous to the welfare of humanity.

## CHINA'S NOVELS

Chinese authors finally produced novels during the Yuan Dynasty (1279–1368), when two of China's four great classic novels, *Shuihu zhuan* (Water Margin; also known as *Outlaws of the Marsh* and *All Men Are Brothers*) and *Sanguo yanyi* (Romance of the Three Kingdoms), were published. *Xiyouji* (Monkey: Journey to the West, ca. 1590) and *Shitou ji* (Dream of the Red Chamber, 1791) are the other two, to which many add a fifth major composition, *Jin Ping Mei* (The Golden Lotus, 1610). In each of these stories the lead heroic characters all end as immortals or supernatural beings with magical powers.

*Shuihu zhuan* depicts the lives of outlaws and their defiance of the imperial government in late Song China to the founding of the Southern Song in 1127. It is loosely based on the historical Song Jiang and his 36 companions, who were active in the Huai River region and surrendered to government troops in 1119. The bandits' exploits became the basis of Chinese folktales, in the Robin Hood tradition of the West. From the 13th century, under the Yuan Dynasty, *Shuihu zhuan* collects previous folk and literary works, becoming the basis of popular Yuan drama. There are frequent brawls, passionate brotherhood, and emphasis on physical strength over philosophical logic. In these stories the villain Kao Chui

forces each of the heroic bandits to become outlaws. They join his rebel band, which lives on the water margins of Kiang Shan Po, where they and others become Kao's opponents and eventually overthrow him. Along the way, their adventures, sword fights, plots, and counterplots against seemingly insurmountable opposition offer commentary on Chinese philosophy. Over time, the qualities of the central characters change: Lin Chung, ever the conscientious army officer, becomes the greatest hero; the small-time petty crook Kao Chui becomes his empowered opponent. The heroes, who were initially respectful of legal authority and are forced into banditry in their troubled times, always maintain their moral integrity and ultimately rebel against their corrupt government.

In contrast, *Sanguo yanyi* presents the sophisticated treachery of individual elite characters subtly manipulating others to achieve their own self-interests. The plot centers on the intrigue of the late Han Dynasty and its aftermath, from roughly 150 to 280. This novel also was composed in the Yuan era, in the 14th century, and compiles various folk and official traditions. The stories blend traditional Chinese culture with Buddhism, in their acceptance of the notion of reincarnation and karma (action) that leads to the fate of the individual at death. Like the *Shuihu zhuan*, this novel is a string of numerous stories within the story, in this case the decline of the Han Dynasty. The main story begins at the end of the Han Dynasty, when the last Han emperors place their trust in their eunuchs (castrated male courtiers) and do not pay attention to the advice of their able officials. Generalized corruption at the top leads to the decline of the Chinese economy and personal security. In the reign of the next-to-last Han emperor the Yellow Turban popular revolt breaks out (184), under the leadership of Zhang Jiao, who practices Daoist wizardry and holds immortal powers. The emperor's brother-in-law, He Jin, leads the imperial forces quickly to suppress the revolt but is subsequently murdered by the eunuchs. He Jin's loyal elite followers successfully deal with the eunuchs. Among them, Dong Zhuo, governor of Western Liang, takes the opportunity to depose Emperor Ling and place Emperor Xian, who is his puppet, on the throne. Dong Zhuo's subsequent tyranny causes the other nobles to unite and drive him from power. Dong Zhuo's foster son, Lü Bu, the mightiest warrior of his time, eventually kills his father over Diao Chan, a beautiful woman they both want.

By this time the imperial government has collapsed, and the elite return to their provinces and begin to fight each other. After an initial series of battles three centers of power emerge, coincident with a prolonged war among the Wei in the north, the largest, with their capital at Yuoyang (220–65). The Wei force the last Han emperor, Xian, to abdicate in their favor in 220. The kingdom of Shu Han (post Han) emerges

in the lands west of the Yangtze Gorges to Yunnan in the southwest (221–65), its capital at Chengdu (Sichuan Province), claiming legitimacy based on its inheritance of the Han bloodline. The independent kingdom of Wu emerges in the southeast (222–80), its capital at Jianye (Nanjing Province), which is controlled by a powerful southern family. Eventually the three are absorbed into one, after the conquest of Shu by the Wei in 263, followed by a successful palace coup by the Wei general Sima Yan, who establishes the Jin state in 265 and then absorbs the Wu in 280.

The text is a window into the Chinese past as well as a commentary on Chinese political philosophy and ultimately a reflection on politics in the Yuan era. Several of these historic figures had become deified heroic figures widely worshiped in Yuan Dynasty and Ming Dynasty times, owing to their celebrated past bravery and extreme loyalty to the imperial throne. *Sanguo yanyi*, however, portrays them as overconfident, of questionable integrity, and less than worthy of the divine status the Yuan rulers had granted them. The lead characters of the epic came to be known by all Chinese: Cao Cao, the founder of the Wei, is the classic villain. The three early Shu heroic champions are Liu Bei, who fights to uphold the traditions of the past, and his able and loyal generals Zhuge Liang, who defeats Cao Cao at the Battle of Red Cliffs, and Guan Yu, who becomes Guan Di, the Chinese god of war.

## JAPANESE LITERATURE

The foundation of the Nara imperial court in 710 created the conditions and audience for the development of a literature based on Chinese models. In fact, the Chinese system of ideographic writing was used in these early literary efforts, but the characters were used phonetically to record sounds rather than the meaning they represent. A conscious effort was made to transfer historical folk tradition to a written form that would bolster support of the claims of the imperial house to sole rule in all of Japan. This resulted in the first written histories of Japan, the *Kojiki* (Records of Ancient Matters) and the *Nihon shoki* (Chronicles of Early Japan).

Poetry was also produced at the court, generally short pieces expressive of piety, love, or the meaning of nature for the human condition. This poetry, like the court itself, helped to strengthen the importance of the traditional Shinto religion. This literature is known through a collection of 4,516 poems compiled in about 760, the *Man'yōshū* (Collection of Ten Thousand Leaves). In 952 a group of poets transcribed the *Man'yōshū* into the newly created kana phonetic script, which was designed to represent the sounds of the Japanese language in roughly the same way Western languages use the Latin alphabet. The relative ease of using this new script

promoted a wider growth of literature in the Heian Period (794–1185).

One popular form of Japanese poetry known throughout the world is haiku, which uses two stanzas of 17 (with lines of 5-7-5) and 14 (7-7) syllables, respectively. This form has its origins in *renga* poetry, developed in the 15th century. *Renga*, however, was a collaborative form, in which attendees at a party would create a lengthy poem by writing alternating stanzas, usually rapidly improvised. Its main purpose was to encourage sophisticated camaraderie.

Two important early novels were produced around the year 1000 by ladies of the court: the *Makura no soshi* (Pillow Book) of Sei Shonagon (965–ca. 1010) and the *Tale of Genji* of Murasaki Shikibu (ca. 973–ca. 1025). The earlier of these novels was *Makura no soshi*, by Sei Shonagon, who served as a lady-in-waiting to the empress Teishi between 900 and 1000. The form of this work is more nearly a diary than a novel and seems to refer to historical personages as characters. Its miscellaneous style is also diaristic, containing a compilation of character studies, short stories, and random notes. The author's primary interest is in romantic relationships. She describes the arranged marriages common among the nobility, based on family interest rather than romantic love, and the system of male polygamy common at the court. In fact, she and Murasaki were supposedly personal rivals because they were maids to two different wives of the emperor (Murasaki of the empress Shoshi).

The noble women that are characters lived independently in their own quarters with their children and would be visited for romantic liaisons by their husbands and lovers. It was a common practice (known as *tsuma toi kon*, or “visited-wife marriage”) that once a married man had sired an heir by his first wife, he was free to take on whatever other relationships he chose—whether supporting a lifelong mistress or pursuing a single liaison. Sei's female characters have an equal range of freedom with respect to their relationships; they range from vampiric man-eaters to tragic heroines wounded through abandonment by a husband or lover. One may compare to this state of affairs the ideology of courtly love in the medieval West.

Murasaki's *Tale of Genji* had the same courtly setting as Sei's work but is a psychological novel approaching the modern type. This in itself is a rather startling achievement, since it has no clear precedent in earlier Japanese or Chinese literature and is far more like the modern novel perfected in the West but now popular throughout the world than were the romances composed in Roman antiquity or by European courtly writers of the medieval period. The main character is Genji, a minor courtier and the son of the emperor and a concubine, who may be based in some degree on the author.

While of relatively unfortunate birth, Genji distinguishes himself as master of courtly arts and manners in speech, poetry, and music. He is handsome and is pursued by both men and women. The plot concerns Genji's movements through various romantic entanglements, while the metatext of the novel explores the meaning of every kind of human relationship as well as the philosophical idea of Confucianism and Buddhism. The imperial court itself, however, is in some ways the main character of the work. While the Fujiwara clan exercised temporal power, the emperor and his entourage were free to devote themselves to *mano no awari* ("subtle manners"). Their introverted concern is with understated perfection in dress, speech, and art.

*Heike monogatari* (Tale of the Heike) is an epic poem based on a tradition of oral performance among mendicant Buddhist monks. The chief version that we have was compiled in 1371 by Kakuichi, a monk trained in the tradition. Kakuichi is said to have been blind, but the key figures in epic traditions are often presented as blind (such as the Greek poet Homer), so this may itself be a folkloric element, as though sight were traded for poetic inspiration. The three sections of the poem are each long enough to be recited to accompaniment of the *biwa*, or Japanese lyre, during a single night's entertainment, recalling the work's origin in oral performance. The poem concerns the Genpei war fought in 1161 and 1185 between the Taira and Minamoto clans for control of the Japanese state. But just as the subject of the *Iliad* is not the Trojan War but the wrath of the hero Achilles, *Heike monogatari* concerns the destructive force of emotion in human life, pointedly given a Buddhist moralizing reading. The first section has to do with Taira no Kiyomore, whose wrath turns victory into defeat. The second section concerns two cousins of the Minamoto clan, Yoshinaka and Yoritomo, whose rivalry even in victory brings about the destruction of Kyoto and the shaming of the emperor. The third section develops the story of Yoritomo's betrayal of his brother Yoshitsune. The tradition, not necessarily mediated through the written version, also inspired a number of Noh dramas and woodblock prints throughout the feudal period. It continues to be referenced in modern Japanese comic books and video games.

## KOREAN LITERATURE

As in Japan, the contemporary Tang-era court culture of China inspired Koreans to create their own written literary works during the seventh-century reign of the Silla court. The *hyangga*—short, four-line folk ballads and nursery songs and 10-line philosophical commentaries by priests and emotional writings by warrior-aristocrats—are the first uniquely Korean poetic form. *Hyangga* were recorded in the *hyangchal* script, in which the Korean language was written using the "sound"

(*um*) and "meaning" (*hun*) of Chinese characters. The *Samguk yusa* (Memorabilia of the Three Kingdoms) contains 14 poems from the Silla period; other surviving 10-line *hyangga* poems are collected in the *Kyunyo chon* (Tales of Kyunyo), *Seo Dong yo* (Ballad of Seo Dong), *Che mangmae ka* (Song of Offerings to a Deceased Sister), and *Ch'an-Kip'arang-ga* (Song in Praise of Kip'arang). The 13th-century literature of the Koryo court period is marked by the increased use of Chinese letters, the disappearance of *hyangga*, and the creation of *Koryo kayo* (Koryo songs), which were first transmitted as oral literature until they were written after the founding of the Yi court in 1392. Other Koryo-era compositions include *Samguksa-gi* (Chronicles of the Three Kingdoms) collection of folktales, the *Legend of Tangun* (a recollection of the founding of the legendary Old Choson Dynasty), and *King Tongmyong* (a legendary account of the Koryo Dynasty's founding).

In the Yi Dynasty (1392–1882) Korean authors finally composed in the first Korean script (*hangul*). This era's poetry had two forms: the "short-stanza form" (*tallyonch'e*) single-stanza works and the "extended form" (*yonjangch'e*) that was separated into many stanzas. The "Chong Kwajonggok" (Song of Chong Kwajong) and the "Samogok" (Song of Maternal Love) are examples of the short-stanza form, but in the more representative *Koryo kayo*, which include "Ch'nongsan pyolgok" (Song of Green Mountain), "Sogyong pyolgok" (Song of the Western Capital), and "Tongdong and Ssangh-wajom" (Twin Flower Shops), poems were written in the extended form, each divided into four to 13 stanzas.

## EUROPE

BY ANNE BERTHELOT

The medieval era traditionally starts with the fall of Rome to Theodoric (r. 474–526), king of the Ostrogoths, in 476 C.E. and ends with the fall of Istanbul to the Turks in 1453. This represents almost 1,000 years of literature to take into account, when usually literary periods or fashions are envisioned on a much smaller scale. The situation is complicated by the linguistic picture of the Middle Ages. It may be described as a kind of generalized bilingualism, with Latin as the medium for philosophy, theology, and all serious matters and various vernacular languages (languages of the common people) for less-weighty literature.

## MANUSCRIPTS AND BOOKS

The conditions for the production and diffusion of books were drastically different from those in the modern period. The first printed books date back to the last two decades of the 15th century. Before that time there were only manuscripts. Manuscripts are very expensive and take a long time to copy,

so books were few at the best of times. Manuscripts are fragile, too. Very few existing manuscripts are older than the 13th century, although the works contained in some date back to the 12th century or earlier. Furthermore, one cannot be certain that the written version reproduces faithfully the oral version that was sung or played 200 or 300 years earlier. For instance, the *Four Branches of the Mabinogi*, a Welsh manuscript that dates to the end of the 13th century, transmits stories dating from the ninth or 10th century.

Because the written version may be quite different from the original—whether transmitted orally, written in a different dialect, or transcribed at a different stage of linguistic evolution—it is somewhat hazardous to date texts. There was no concept of “copyright” until at least the 14th century, and it was very difficult, without the technical support provided by printing, to make exact copies of long texts. Moreover, the meaning of words changed over time, and scribes may have substituted new expressions for old ones; alternately, they may have provided explanations, or glosses, for facts or ideas that were no longer current or may have added to the original text a passage that seemed fitting.

The notion of “author” presents similar problems. Many texts are simply anonymous because there was no centralized system preoccupied with remembering the identities of those who wrote them. What mattered was not the name of the person who composed a text but the authority that could be invoked to give weight to the work. In some cases a text was attributed to a much earlier and respected author; conversely, an older text may have been adopted by a contemporary writer who considered it no problem to erase the original author’s name and substitute his own. Furthermore, numerous authors used pseudonyms, relying heavily on puns and word games.

The existence and quality of manuscripts depended on the scribes who copied them; for a long time these scribes were almost exclusively clerics, who considered only Latin a respectable language and only religious matters worthy of being written down. Many antique texts were lost during the Middle Ages, some forever and others to be recovered at the dawn of the Renaissance. Many new texts were not considered valuable enough to be copied and collected by the aristocracy. Archaeologists must take into account a considerable attrition rate in trying to estimate the popularity of a text on the basis of remaining manuscripts. Criteria that have been honed during the last two centuries do not necessarily apply to medieval productions.

Similarly, modern categories defining certain types of literary works simply cannot cover the medieval corpus. The texts themselves very often address this issue, using various words to describe what they are; however, it is difficult to

establish a clear-cut typology. Some medieval genres disappeared by the end of the 15th century or even earlier. Others, like romance literature, underwent such changes that they barely can be considered as the same anymore.

## RELIGIOUS LITERATURE

Throughout the medieval era Latin remained the primary literary language of philosophy, theology, and science. While there were attempts to translate the Bible into vernacular beginning around the fourth century—Bishop Ulfilas (ca. 311–ca. 382) produced a Gothic version of it, and the Anglo-Saxon abbot Aelfric (ca. 955–ca. 1010) translated the book of Genesis into Old English—the famous theologians of the Middle Ages wrote their treatises in Latin. These authors included Saint Anselm of Canterbury (1033 or 1034–1109), Peter Abelard (1079–ca. 1144), Thomas Aquinas (1225–74), and Roger Bacon (ca. 1220–92).

Although predication (preaching) long had been done in the various vernaculars of any Christian audience, the common language for moral teachings and edification remained Latin. Priests, abbots, and bishops were prone to use fables, often borrowed from antique tradition, or brief anecdotes with a moral point, called *exempla*. These came to represent a body of popular wisdom that got translated into the vernacular languages, sometimes as part of a larger allegorical construct. The linguistic and philosophical theory of the four meanings of the scriptures (a belief among medieval scholars that each biblical verse had four meanings), enlarged to secular pursuits, influenced such works as the *Roman de la rose* (Romance of the Rose, 1225–70), which plays on the complementary literal and secondary meanings of an apparently straightforward love story.

Allegory also was present in the important body of literary visions or dreams describing the Christian afterlife. From the ninth-century *Navigatio sancti Brendani* (The Voyage of Saint Brendan) to the 14th-century *Divina commedia* (Divine Comedy) by Dante (1265–1321), vivid descriptions of hell and purgatory (less so of heaven) bore testimony to the eschatological preoccupations of medieval Europeans.

In the 13th century arose an encyclopedic ambition to charter the whole world. Whether in theology, the sciences, or history, scholars tried to gather all the information pertaining to a subject in one work; such books are called in Latin *specula*, “mirrors” of the world, or *summae*, “sums” of knowledge, such as Thomas Aquinas’s *Summa theologiae* (Summary of Theology, 1265–74). Many of them were written in Latin, but the encyclopedic trend spread to vernacular texts and even to romances like the Lancelot-Grail, a series of volumes describing the romance of Lancelot and Guinevere and the search for the Holy Grail.

Apart from predication, Latin was the language of everyday liturgy, with the growing handicap that the people attending mass did not understand the language. Religious pageants seem to have stemmed directly from an effort to make the Holy Scriptures understandable to the people. Reenactments of scriptural events (called *plays* in English, *jeux* in French, and *Spiele* in German) took place outside the church, encompassing secular and even farcical elements, although most of them preserved a strong religious component. During the 14th and 15th centuries the large mystery plays, which engaged a whole population for several days, were spectacular affairs striving to give a global rendition of scriptural history. Meanwhile, a secular theater emancipated itself from any religious influence: Middle German *Fastnachtspiele* (Carnival plays) were presented during the festival of Carnival preceding Lent but were hardly related to the liturgy. Similarly, French farces, such as *La farce de Maître Pierre Pathelin* (The Farce of Master Pierre Pathelin, ca. 1470), were not even remotely religious.

The so-called legends of the saints were edifying tales that were meant to be read during mealtime in an abbey. The tradition of Latin hagiography continued until the end of the Middle Ages; the most famous example was the huge *Legenda aurea* (Golden Legend) in which the Dominican brother Jacobus de Voragine (1228 or 1230–98) gathered all the hagiographic material pertaining to the saints honored during the Christian year. This ambitious work soon was translated into various vernacular languages. In fact, several of the first vernacular literary texts are religious, such as the *Cantilène de Sainte Eulalie* (The Cantilena of Saint Eulalie), a late-ninth-century biography, and the Old German *Heliand* (Savior), a ninth-century telling of Christ's life. Loosely in the same category are the moralized Bibles, which were commentaries to specific books of the Bible.

Religious and secular literature was not mutually exclusive. The anonymous author of *Pearl*, one of the most famous Arthurian romances in Middle English, also wrote the 14th-century works *Cleanness* and *Patience*, which are prime samples of allegorical musings. Even earlier, in the first half of the 13th century, the French poet Raoul de Houdenc (fl. ca. 1200–30) wrote both *Le songe d'enfer* (The Dream of Hell) an allegorical vision of a pilgrim's journey to hell, and *La vengeance Raguidel* (The Vengeance of Raguidel), an Arthurian verse romance.

## HISTORIC LITERATURE

Latin was the language of historiography until at least the 12th century, mainly because those who took it upon themselves to write a chronicle of past or contemporary events were almost always clerics. Some monks painstakingly gave an ac-

count of the entirety of world history starting with the fall of Adam and ending with the dealings of their own abbey and its secular neighbors. (Sometimes the linguistic choice was reinforced by the literary style; while most Latin chronicles are in prose, numerous vernacular chronicles are in verse.)

This tradition was maintained for a long time, from the sixth-century *Historia Francorum* (History of the Franks), by the Frankish bishop Gregory of Tours (538–94), and the eighth-century *Historia ecclesiastica gentis Anglorum* (Ecclesiastical History of the English People), by the theologian known as the Venerable Bede (672 or 673–735), to the 12th-century *Gesta Danorum* (Deeds of the Danes), by the Danish historian Saxo Grammaticus (ca. 1150–after 1216), and the 13th-century *Chronica majora* (Major Chronicles), by the English historian Matthew Paris (d. 1259). Most vernacular chronicles date to the late 13th or 14th century; sometimes, as in the case of the mainly anonymous *Great Chronicles of Saint Denis*, the language begins as Latin but ends in a vernacular (here, French), the turning point happening during the reign of King Philip II (r. 1179–1223) of France. The Holy German Empire boasts a long tradition of vernacular chronicles, from the 12th-century *Kaiserchronik* (The Book of Kings) to the 15th-century *Weltchronik* (World Chronicle, also known as Nuremberg Chronicle) by Hartmann Schedel (1440–1514).

Vernacular chronicles or histories tended to become more secular and to give up offering a summary of the Bible as a foreword to contemporary events. This tendency is especially illustrated by the two *Conquêtes de Constantinople* (Conquests of Constantinople), one by Geoffroi de Villehardouin (ca. 1150–1213), one of the chiefs of the ill-advised Fourth Crusade (1204), and the other by Robert de Clari, one of the knights who went to fight for the freedom of the Holy Land and ended up besieging Constantinople. In effect, the apologetic tone of Villehardouin foretells the “new history” as Philippe de Commines (ca. 1447–1511) later presented it at the end of the 15th century in his *Mémoires* (Memoirs).

## ROMANCE AND EPIC LITERATURE

At times it is difficult to identify a work as either history or romance. Perhaps the most famous instance of this ambiguity is found in the *Historia regum Britanniae* (History of the Kings of Britain), by the English bishop Geoffrey of Monmouth (ca. 1100–54). Geoffrey goes back to the Trojan War to introduce the founder of Britain, Brutus, a descendent of the Trojan hero Aeneas; he then proceeds, generation after generation, until he comes to the modern period. In this manner he was the first writer to coherently organize scattered annalistic or legendary material pertaining to the great figure of King Arthur.

His book was greatly successful, though perhaps less as a truthful historical account of past events than as a tool of political propaganda. Two verse translations of his work were written in vernacular languages: the Anglo-Norman *Roman de Brut* (Romance of Brutus, ca. 1155–60) by Wace (ca. 1100–after 1174) and the Middle English *Brut* by Layamon (fl. ca. 1200). Both translations introduce numerous modifications in Geoffrey's storyline, not the least being the invention of King Arthur's legendary Round Table. Wace's octosyllabic text clearly refers to elements of a nonhistorical, perhaps oral tradition concerning King Arthur.

The epic is another genre that may be difficult to distinguish from either a historical work or a romance. Among the first written works of the Middle Ages appear a number of so-called heroic poems that tell of the prowess of some larger-than-life characters and of the wars fought by Christians against enemies of faith. The Middle High German *Nibelungenlied* (Song of the Nibelungs, 12th century) borrows the material of thinly Christianized pagan legends, and the Old Norse sagas tell of seafaring expeditions and feuds between landed families in Norway and Iceland. The Old

English *Beowulf* (ca. 700–1000), however, is more about the fundamental conflict between good and evil, represented by monsters and dragons the civilizing hero must conquer. In their turn, the Old Spanish *Cantar de mio Cid* (Song of the Cid, written down in 1207) and the Old French *Chanson de Roland* (Song of Roland, ca. 1090) offer a polarized vision of the world where Christians are right and pagans are wrong.

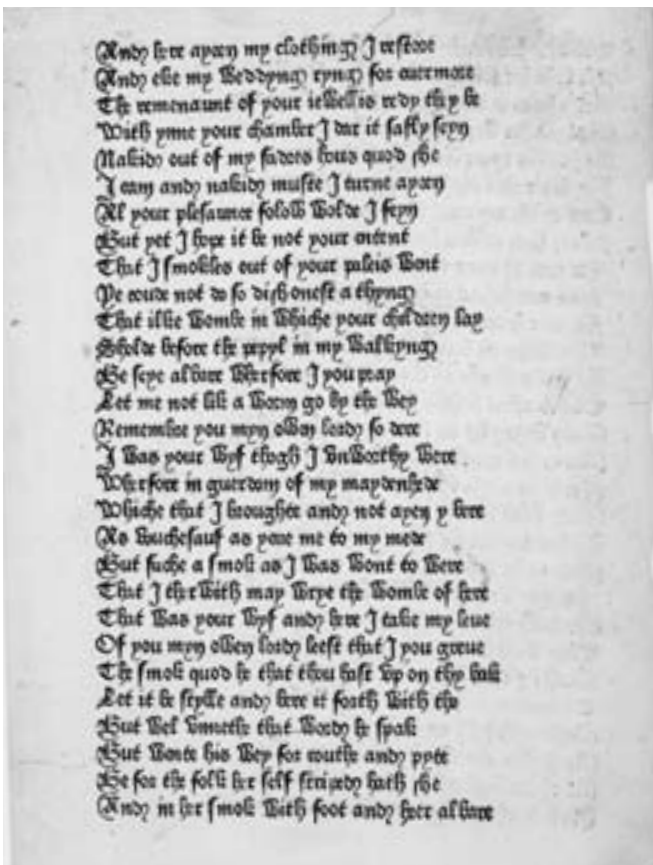

Most of these epics are anonymous; the manuscripts that preserve them represent probably the last stage of a prolonged creative process wherein cantilenas, or songs, were written down either by clerics intent on gathering these testimonies of popular faith or by literate performers interested in building a repertory of works. Little is known about the production, transmission, and performance of these songs. After they were put into writing, however, the individual epics were organized in cycles, or works grouped according to theme, such as the French William of Orange cycle, and evolved toward romance or chronicle.

While most French and Italian epics revolve around the figure of Charlemagne, some focus on more contemporary characters or events. There are some *chansons de geste* (songs or tales about heroic deeds) about the historical Crusades. One, the *Canso de la Crozada* (Song of the Crusade) in Old Provençal, is about the early-13th-century crusade against the Cathar sect in southern France; it was written shortly after the fact by two authors whose perspectives are very different. Although the modern reader would not consider these epics trustworthy sources for historical information, at a later date in the medieval era many of these texts were rewritten in updated language and presented as chronicles.

## COURTLY LITERATURE

War songs about great heroes of the Christian faith performing exceptional deeds (*gesta* in Latin) seem to have catered mainly to a male, war-oriented, feudal audience. During the 12th century new ideas from a whole new culture were imported from southern France and Arabic Spain first into northern France and then to England. A few decades later they reached Germany and the northern parts of Europe and eventually spread throughout western Europe and beyond. In many respects, Eleanor of Aquitaine (ca. 1122–1204), the queen of France and then, after her divorce from King Louis VII (r. 1137–80), queen of England as wife to Henry II (r. 1154–89), was instrumental in the diffusion of what came to be called courtly culture.

This culture was indeed found at court, originally among the great lords of Provence and Aquitania and later at the courts of Blois and Champagne, where Eleanor's daughters by her first husband had married powerful counts whose courts rivaled the royal courts in Paris or London. It implemented a new set

A leaf from William Caxton's edition of Geoffrey Chaucer's *Canterbury Tales*, printed at Westminster, Britain, in 1476 (© Museum of London)

of values that were more refined than the feudal ones and often at odds with the teachings of the church. Women were given a more important place in this new system; they were the ladies for whom the knights would accomplish great deeds. In the new game of *fin'amor* ("perfect love," often roughly translated as "courtly love") women were the dominant figures.

Whether *fin'amor* and courtly manners ever were more than a parlor game for the aristocracy is debatable. In literature, however, a large number of texts, probably intended mainly for feminine audiences, develop the tenets of this new ideology. Courtly romance was a very successful genre in the 12th and 13th centuries. It encompassed a number of topics; evolved from verse to prose; included short lays, or ballads, as well as huge narratives; and remained characterized by the association of weaponry and love (*arma et amor*) along with a very un-Christian acknowledgment of adultery or a secret relationship between a lady and her knight.

### THE THREE "MATTERS"

In a French polygraph from the late 12th century the poet Jehan Bodel (ca. 1167–1210) identifies three "matters," or main topics, in narrative literature. The "matter of France" describes factual epics about Charlemagne and the Crusades. The "matter of Rome" deals with stories borrowed from antiquity; the writings of the ancient Greek writers Homer (eighth or ninth century B.C.E.) and Virgil (70–19 B.C.E.) are the models of various medieval romances, such as the Old French *Roman d'Eneas* (Romance of Aeneas) and *Roman de Troie* (Romance of Troy) and the Middle High German *Eneit* (Aeneas) by Heinrich von Veldeke (ca. 1145–before 1210). The richest and most famous topic is the "matter of Britain," which regroups stories about fairy lovers (both male and female), the Tristan and Isolde legend, and the Arthurian tales.

Oral tales probably were told first by itinerant minstrels and later evolved into short poems and then romances. The doomed love story of Tristan and Isolde was widely read in the 12th and 13th centuries. Among the many versions are ones in Old French by Bérout and Thomas of Erceldoune (fl. 1220–97) and the anonymous *Prose Tristan*; in Middle High German by Eilhart von Oberge (fl. 12th century) and Gottfried von Strassburg (fl. 1210); in Middle English (*Sit Tristrem*); and in Old Norse (*Tristrams saga ok Isöndar*).

The Champenois writer Chrétien de Troyes (fl. 1170) was the first to compose Arthurian romances. He created, as a response to the not-quite-courtly Tristan-and-Isolde story, a new couple of courtly lovers: Lancelot of the Lake and Queen Guinevere, whose love was to become the core of the huge 13th-century *Prose Lancelot*. Chrétien was also the "inventor" of one of the most enigmatic and fascinating literary objects ever created, the Grail, soon to be the Holy Grail. King Ar-

thur, Merlin, and the knights of the Round Table associated with the Grail in huge romance cycles that came to include Tristan and Isolde and even Alexander the Great (356–323 B.C.E.), who was presented as an ancestor to Arthur.

Despite the obviously British origin of the Arthurian material, Arthurian literature was primarily French until the end of the 13th century, when its fashion began to wane on the Continent. With the notable exception of *Parzival*, by Wolfram von Eschenbach (ca. 1170–ca. 1220), Germany showed little interest in King Arthur and his entourage, but the whole story was translated and adapted several times into Middle English during the 14th and 15th centuries. The famous early-14th-century poem *Sir Gawain and the Green Knight* develops an original motive, but Sir Thomas Malory (fl. 1470) gives in his *Morte d'Arthur* (Death of Arthur) the definitive version of the legend that was remembered into the modern period.

The three "matters" do not cover the whole range of narrative texts during the golden age of medieval literature (roughly 1150 to 1470); many romances or short stories, in verse or in prose, cannot be restricted to specific categories. On the comical side, the 13th century brought the development of the *fabliaux*, short texts exploiting sexual and scatological motives and taking the counterpoint to courtly ideals. At the end of the Middle Ages, starting with the Italian *Trecento*, a new fashion appeared: the collection of short stories. These were organized loosely under various headings: *Decameron* (ca. 1349), by Giovanni Boccaccio (1313–75), is one of the first, followed by the *Canterbury Tales* (ca. 1386–1400) of Geoffrey Chaucer (ca. 1342–1400) and the 15th-century Middle French *Cent nouvelles nouvelles* (One Hundred New Tales). This tradition continued deep into the 16th century, and many humanists enjoyed the freedom of familiar conversation among the different narrative voices and the eclectic quality of the material.

### POETRY

Latin poetry represents an uninterrupted tradition from ancient to medieval times. Religious poetry was dominant, and love poetry became a minor trend that was associated with other Epicurean themes, such as the pleasures of drinking, gambling, and wandering freely instead of being confined in a cloister. The so-called Goliards were presented as wild monks at odds with church hierarchy, ancestors to numerous bon vivant churchmen satirized in various literary productions of the Renaissance. Conversely, songs of love for and praise of the Virgin Mary represent an important repertory that later influenced the vernacular languages, as in the *Cantigas de Santa Maria* (Songs of the Virgin Mary, ca. 1270–84) of Alfonso X (r. 1252–84), king of Castile and León.

During the first half of the 12th century a new kind of poetry arose in southern France. This reflected the ideology

of courtly love and depicted the poet-singer (*trobador*) as a lover entirely subservient to the whims of his (usually cruel) lady. The *trobadors* developed a sophisticated and refined code of behavior resolutely contrary to the teachings of the church. The love expressed in their songs is of necessity adulterous; it places the woman above her lover and gives her the freedom of choosing whether to yield or to resist his prayers. Even when the would-be lover and poet is in fact one of the most powerful princes of the time, as in the case of William IX (1071–1127), the count of Poitiers and duke of Aquitaine and Gascone, this notion of womanly superiority is maintained. (In a slightly different genre, however, William also composed erotic poems that do not fit in the usual frame of *fin'amor* discourse.)

*Trobador* poetry is more formal than passionate, although modern readers tend to interpret it as the expression of deep and sincere feelings. This is the case with Bernard de Ventadour (d. ca. 1195), considered the greatest of the *trobadors*, who was instrumental in importing this type of poetry into the northern courts. There the poets were called *troveors* or, in 13th-century Germany, *Minnesänger* (“love singers”), but the topics and ideology remained the same. Conon de Béthune, Thibaut IV de Champagne (1201–53), Walther von der Vogelweide (ca. 1171–ca. 1230), Ulrich von Lichtenstein (ca. 1200–75), Petrarch (1304–74), and Dante (1265–1321) all sang of the joys and pains of love for a perfect and unattainable lady.

Lyrical poetry did not disappear with these courtly lovers. While the courtly ideology lost favor toward the end of the 13th century, love remained an important poetic topic in, for instance, the works of Guillaume de Machaut (ca. 1300–77). Other trends also appeared and gradually gained prominence. Political and satirical poetry, which had begun in the 12th century with the atypical *trobador* Bertran de Born (d. ca. 1202–15), bloomed during the Hundred Years War (1337–1453). The rise of didactic poetry was facilitated by the separation of music and text as new types of verse, closer to the rhetorical model than to the lyrical one, became fashionable.

At the end of the medieval era the theme of courtly love had vanished, but first-person poetry remained. The supposedly personal confessions of, for instance, François Villon (1431–after 1463) open the door to modern poetry and, despite the formal changes introduced by the Renaissance, stand in perfect continuity to those of 16th-century poets.

## THE ISLAMIC WORLD

BY SUHAIL MOHIUL ISLAM

The early authors during the formative period of Islamic thought lived during the era when Arabic was the written language of Islamic culture and literature (seventh century

to 10th century). The new Persian language had just begun to emerge as the language of literature at the end of this period, and Turkish would not appear for a century or so. As for medieval Islamic literature, whether it should be called “medieval” is debated by those who object to the application of European periodization to other cultures, but no other alternative term has yet been suggested. The cultural advancement of Islam began with the collection and translation into Arabic of many of the classical Greek and Roman works.

Islamic literature is subdivided by works in the following main languages: Arabic, Persian, and Turkish. The main languages are quite different from each other. Although Islamic literature is very diverse, it has a coherent thematic unity that is striking and justifies the term *Islamic*. The religious foundation of Islam has contributed to this homogeneity. There are two basic strands in Islamic literature: the classical *adab* literature and the popular “folk” tradition.

### THE RANGE OF ISLAMIC LITERATURE

The Muslim influence spread far and wide; it included a diverse mix of peoples, many of whom had preserved their own traditional cultures and languages. Initially, for a long period Arabic was the literary language for many regions of the Islamic world, from Spain to central Asia; as time passed, however, local influences blended with Islamic culture, and native languages came into use. Such was particularly true in Persia and Turkish central Asia, where the Arabic alphabet was adapted to the Persian and Turkic languages.

By the 11th century the northwestern Indian subcontinent and the area that is now Pakistan had become a flashpoint of Islamic literature in the Persian language and, to some extent, in the Turkic languages. Persian retained official language status in Muslim India until it was replaced by English in 1835, while the common language of literature became Urdu, which was mainly derived from Persian sources in its early period.

Another geographic region, central Asia, came under Islamic rule after 711. With the cultural and literary cities of Samarqand, Bukhara, and Fergana, central Asia was the center of Islamic literature and scholarship of the time, much of it in the Arabic language. A substantial portion of the literature of central Asia was also written in the Turkic languages; in later centuries, when the Seljuk and Ottoman Turks conquered much of the Islamic world, their languages displaced Arabic in some regions. After the 14th century, for example, a sophisticated classical Turkish literature took root, highly influenced by Persian diction and poetics.

In Islamic Spain, at the western front, the Muslims created a highly developed culture that reached its zenith in the 10th century and continued to prosper until the Muslims

were defeated by Christian rulers in 15th century. Many of the major Arabic and Islamic works in literature, philosophy, and the sciences reached the academic institutions of medieval Europe through Spain, Cyprus, and Sicily.

### PERIODS OF ISLAMIC LITERATURE

Three successive caliphates ruled the Islamic world: the Rashidun (“Rightly Guided” or “Pious”) Caliphate (632–61), the Umayyad Caliphate (661–750), and the Abbasid Caliphate (750–1258). In 1258 the Ottoman Turks invaded and sacked Baghdad, the capital city, ending Islamic rule in the eastern section of the empire. However, a weak Abbasid Caliphate survived in Egypt until 1517, while in Spain and the western part of North Africa various factions and dynasties continued to rule until the 15th century.

#### *The Prophet and the Pious Caliphs*

After the prophet Muhammad’s death the problems of ruling the young Islamic community were immediately complicated by apostasy and military attacks. However, Abu Bakr (ca. 573–634) and his immediate successors, the “pious caliphs,” were able not only to consolidate the community but also to expand beyond the Arabian Peninsula into Syria, Mesopotamia, and Egypt. The fourth of the pious caliphs, Ali (r. 656–61), was opposed by Muawiyah, the governor of Syria. In the battle of Siffin, Ali was defeated and was forced to negotiate with Muawiyah. A few years later Ali was murdered; after his death a group, the party of Ali, who believed Ali’s descendants to be the rightful rulers of Islam, formed the Shia sect.

Heroic narrative verse was prominent in early Arabic poetry. Owing to the warlike character of ancient Bedouin society, feuding goes back as far as history can record and was so deeply rooted in the tribal structure that Islam was able to keep it under control only during the era of the Prophet and the four pious caliphs.

In the context of Islamic literature the Koran (the recitation) must be analyzed both as a work of art and as religious scripture. In fact, the two aspects overlap and complement each other. Therefore, the first fact of Islam is the Koran. It declares itself to be the word of God and its authenticity to rest on the matchless eloquence of its language, classical Arabic. The risk of losing this language, felt by Muslims who mixed with conquered peoples, gave impetus to literary and philological studies. There was a massive effort to collect and record the language of the Arabs and what they still remembered of the pre-Islamic prose and poetry of the ancients. The reason for this effort was to preserve and practice using the classical language in order to understand the sacred scripture.

To Muslims, the Koran is not an ordinary book; it is considered to have been revealed to the prophet Muhammad by the angel Gabriel (called Jibrail) during the last 23 years of the Prophet’s life; however, it came down in totality on the so-called night of power (Laylat al-Qadr). The revelations came in rhymed prose style (*saj*), and they are regarded as God’s words, the message, the one of the *Umm al-kitab*, the prototype of all revealed books kept near God’s throne. The Koran is clear regarding humanity’s exceptional worth and teaches *bayan* (eloquence): The word *bayan*, applied only to God and to human beings as taught by God, is not an attribute of any other creature, not even of the angels. The words of the Koran are not Gabriel’s or Muhammad’s but are God’s, given to help Muslims organize their lives for their good here and hereafter and for the benefit of other human beings.

Historically, the Koran is divided into two sets of chapters, or suras. The Meccan suras, which were revealed to Muhammad before the Hegira (the Prophet’s migration to Medina), are short, strong, and full of hope for reward and warnings of punishment, dealing mainly with love, faith, loss of faith, misery, and the essence of God and his attributes, very rarely giving details about life in this world. The Medinite suras, on the other hand, are longer and cover all aspects of human life on this earth. After establishing a community based on religious, spiritual, and moral principles, Muhammad needed direction from God as to how to organize the lives of the people in a comprehensive Islamic state and system. Muslims believe that there cannot be two separate aspects of life, one secular and the other religious, as divine guidance from the Koran integrates the two parts into unity.

Muslims believe that the instructions in the Koran come directly from God, and any additional instructions from the prophet Muhammad were termed Sunna, the way of the Prophet. For example, the command to pray and the times for prayer are stipulated in the Koran, but the prayer positions are not. Muslims believe that the prayer positions were taught to Muhammad by the angel Gabriel and that the Prophet passed them on to his companions. The prayer positions, then, come from the Prophet’s Sunna, not from the Koran.

The Sunna can be learned from two sources: the Hadith collections and the *Sirah* (a biography of the Prophet). The most important was the Hadith, the record of the sayings and deeds of Muhammad through *isnad* (the chain of supporting authorities). The death of the spiritual and political leader within a few decades made it necessary to preserve all of Muhammad’s words and actions, since they were believed to have been inspired. The Hadith collections are the original source of the Sunna, though they contain not only the Prophet’s sayings but also reports about his practices and the practices of his close companions (*Sahabas*). By the ninth

century the Hadith had been solidified into a body of material to which no new traditions were added. Today the Hadith is revered as a major source of religious law and moral guidance, second only to the Koran.

The other source of Sunna is the *Sirat un-nabi* (biography of the Prophet), in which scholars started to gather together all of the information available about the Prophet's life. The *Sirat un-nabi*, of Muhammad ibn Ishaq (ca. 704–67), apart from being the earliest-surviving full biography of the Prophet and the earliest-existing history of Islam, also contains the stylistic influences of pre-Islamic literature. However, ibn-Ishaq's work and, to some extent, Ibn Hisham's abridged life of Muhammad give us historical circumstances of the Prophet's birth and early years. Ibn Ishaq also tells of miraculous signs and events connected with Muhammad's birth and childhood, such as trees bowing down to him and the Christian monk Bahirah's recognizing signs of prophethood in Muhammad.

Another collection that was begun at the same time consists of the sayings of Ali, Muhammad's son-in-law and the fourth caliph, whose followers later established a major division in Islam, Shia. Finally compiled in the 10th century, the collection is called the *Nahj al-balaghah* (Road of Eloquence). It is a masterpiece of Arabic prose that has inspired numerous commentaries and imitations in other languages.

### **The Umayyad Caliphate**

After the death of the pious caliphs, Muawiyah (r. 661–80) assumed the caliphate, and his victory was significant as it established into power the prophet Muhammad's family, who were relatively late in accepting Islam. It also marked the beginning of the hereditary caliphate and moved the capital to Damascus, Syria. Most of the classical forms of Islamic literature originated during this period. Initially, the passion was for collecting and editing poetry from the oral tradition; together with the Koran this literature represented the classical, or "old style," strand in early Islamic literature. The enormous corpus of pre-Islamic poems associated with feuding and battles is almost entirely of the "heroic" type, in which the recurrent themes are the perseverance of the poet-hero, his defense of his tribe's reputation and his own prestige, and his fight for a worthy cause.

With the advent of Islam, the hero's adversaries are not just from hostile tribes but in fact become national enemies. From this perspective, *maghazi* poetry (about the Prophet's military expeditions of 623–30) is dominated by narrative impulses, as is *futuh* poetry (about Islamic conquests of 633–62). The wars against the powerful Byzantines and Persians, the efforts of Muslims to spread Islam, and the intermingling in the conquered lands of converts from vastly different cul-

tures supplied rich material for fascinating stories. The legends associated with Muslim heroes like al-Qaqa b. Amr, Abu Mihjan al-Thaqafi, and Amr b. Madikarib reveal the fantastic elements in the adventures of these poets.

The other major theme of epic poetry, worldly love, is also common in pre-Islamic poetry, especially in the works of Imru al-Qays (d. ca. 550) and al-Asha (before 570–ca. 625). The social and economic developments of the Umayyad Period helped foster and popularize the worldly love poetic genre of *ghazal*, or ode. The wealth resulting from the Arab conquests provided an easy and leisurely life for the people of the Arabian Peninsula. Wealthy and well-bred and living in opulence, security, and ease, most of the Arabian poets devoted their lives to wine, music, and flirtation.

A remarkable poet from Mecca, Umar ibn Abi Rabiah (644–712 or 719), was unquestionably the most illustrious love poet of his time. His youth, good looks, and wealth endowed him with the reputation of being a lady-killer, a breaker of hearts, a seducer whom no beautiful woman could resist. The various themes that Umar develops are more or less the stylized narration of real events. He contributed to the development of the *ghazal*, a love lyric consisting of five to 12 verses that probably originated as an elaboration of the *qasida's* opening section (a *qasida* being an elaborate ode). His poems sing of amorous adventures with the ladies who came to Mecca on pilgrimage. Using the same literary form, one of the last Umayyads, al-Walid (r. 705–15), gained a greater reputation as a poet than as a warrior. His poetry is characterized by frivolous love verses and odes praising the virtues of wine.

In Medina the vogue was highly idealized love poetry akin to the chivalric romances of medieval Europe. This genre was invented by Jamil (d. 701), who sings of lovers who become martyrs, dying in their total surrender to the force of true love.

The political unrest, the civil wars, and the development of sectarian rivalries gave rise to the *naqa'id* ("poetic slander"), a form of poetry that became a favorite genre for expression of the divergent points of view. The three eminent poets of the Umayyad Period were all polemicists who used their verses to support or attack various political groups.

The *naqa'id* was used by Jarir (ca. 650–ca. 729), Tammam ibn Ghalib Abu Firas (al-Farazdaq; ca. 641–ca. 730), and al-Akhtal (ca. 640–710), a Christian, who was a strenuous supporter of the policies of the first Umayyad, Muawiyah I. Jarir and al-Farazdaq were active at the courts of the Umayyad caliph Abd al-Malik (r. 685–705), still keenly aware of pre-Islamic tribal feuds and of the prowess of their ancestors. Jarir and al-Farazdaq, however, were enemies, and they delighted rival tribesmen with their biting satires against each other.

The work of these two poets has furnished historians with a rich vein of material on the social and political climate of Islam during the early eighth century. They used the traditional *qasida* form, an elaborately structured ode consisting of 20 to 100 verses, which maintains a single end rhyme throughout the entire piece to great effect, incorporating a wealth of vocabulary and imagination.

### **The Abbasid Caliphate**

Although the Umayyads ruled ably enough initially, the caliphate survived for a very short 90-year period. During the early part of eighth century opposition to their rule mounted; Shiites were opposed to them from the very outset, and others accused them of worldliness and incompetence. By contrast, the Abbasid Caliphate ruled for more than five centuries. The Abbasid caliphs proclaimed the end of worldly and secular Arab rule and the beginning of a religious and pan-Islamic state. During the Abbasid Caliphate, led by Caliph al-Mansur (r. 754–75), with the capital at Baghdad, the flowering of Islamic literature began. The reign of al-Mansur's grandson, the fabled Harun ar-Rashid (r. 786–809), came to be regarded by later generations as the golden age of Islam. In Iraq all of the cultural currents of the ancient Near East, especially Persia, came together, adapting and reworking elements from all of the earlier cultures.

The most original development of the early Abbasid Caliphate was the emergence of the “new style” in Arabic poetry to accommodate the realities of court patronage, the religious spirit fostered by the state, the needs of the administrative secretaries, changes in socioeconomic conditions, and contact with other cultures, such as Persian and Turkish societies. The “new style,” in contrast to the “old style,” was distinguished by the use of novel similes, an innovative and bold approach to eulogy and satire, lucidity of style, and avoidance of strange words and ornamental padding. More artful prose was fostered by translations into Arabic of outstanding foreign literary works, a growing desire for systematic accounts of early Islamic times, and the more sophisticated cross-fertilization of taste and style with Persian and central Asian Muslims. To serve the tastes of a new courtly culture in which skill in Arabic literature was highly esteemed, the form known as *adab* was developed. It was a highly mannered, anecdotal, very didactic, and vastly entertaining form, aimed at instilling a pattern of cultivated living. Al-Jahiz (ca. 776–868 or 869) is usually credited with having established it in its paradigm form; its influence spread all over the Islamic world, affecting all forms of Islamic prose.

Al-Jahiz of Basra wrote treatises raising Arabic prose to heights of elegance and sophistication. The *Kitab al-bayan wa al-tabyin* (Elegance of Expression and Clarity of Ex-

*The Persian epic hero Rustam; stone paste painted with enamel, Iran, 12th century* (Freer Gallery of Art, Smithsonian Institution, Gift of Charles Lang Freer, F1911-319)

position) deals with literary style and the effective use of language, known as *adab* literature. As a founder of *adab* literature, al-Jahiz experimented with various styles and genres. His *Kitab al-bukhala* (Book of Misers) is a collection of stories about the avaricious. Although he was an intellectual free spirit, al-Jahiz supports government policy in his “*Manaqib at-turk*” (“Exploits of the Turks”), an essay on the military qualities of Turkish soldiers, upon whose strength the government depended. His *Kitab al-hayawan* (Book of Animals) is a mine of information on Arab proverbs, superstitions, and traditions.

The major poets of the Abbasid Caliphate were Abu Nuwas (ca. 747 to 762–813 to 815), al-Mutanabbi (915–65), and al-Maarri (973–1057). The greatest of these was Abu Nuwas, a boon companion of Harun ar-Rashid and of half-Persian origin, who had an incomparable command of language and imagery. Abu Nawas's witty, cynical verses and delightful drinking songs scandalized the religious and ascetic Muslims, however. Close contacts with the high life of aristocracy provided Abu Nawas with the motifs of the poetry for which he is most renowned. He also composed poems with traditional themes of love, satire, and the chase, and he even composed religious poetry.

Al-Mutanabbi, one of the greatest Arab poets, took the panegyric form to its perfection. He was the main poet patronized in the Hamdanid court and followed the mainstream tradition of classical *qasida* poets, but his work surpasses that of his predecessors in imagination. Al-Mutanabbi did not follow the poetics of the “new poets”; rather, he went back to the

older meters and forced them to bend to his art. His compositions are noted for their exaggeration, sound effects, and formal perfection. Many of the poems are addressed to Sayf ad-Dawlah (916–67), the ruler of Aleppo, whose friendship al-Mutanabbi enjoyed for a decade and whom he eulogized in brilliant verses.

By contrast, almost two centuries later al-Maarri (973–1057), orphaned and blinded in his childhood, was deeply religious, disturbed by the shallowness of worldly life and the uncertainties of time. The dominant theme of his poetry is the expression of his philosophical ideas about his own faith and other religions in which pessimism, asceticism, and fatalism are the main traits. Although al-Maarri's poems are cynical and sad, they do not equal the cynicism of Abu Nuwas. One can detect, mostly in al-Maarri's talk of love, dogged traces of a faith and hope in justice for humanity.

During the reign of the Abbasids literary prose also began to develop. Writers were consumed by an insatiable curiosity for all kinds of knowledge, a curiosity that led them to compile and translate scholarly and philosophical works from other cultures. Ibn al-Muqaffa (d. ca. 756), a Persian, translated Persian works into Arabic, the most notable of which is the famous book *Kalilah wa Dimnah* (Kalilah and Dimnah), a collection of fables, folktales, and legends derived from the Sanskrit fables of Bidpai, an Indian sage. These stories provided Islamic culture with a seemingly inexhaustible fund of tales and parables from the animal world, comparable in some respects to the fables of Aesop and Jataka. Al-Muqaffa also introduced into Arabic the Persian *Shahnameh* (Book of Kings), a type of pre-Islamic mythology that sophisticated Muslims preferred to the rather meager accounts of the Arab pagan past. Al-Muqaffa's translations of writings on ethics and the conduct of government are the prototype of the "Mirror for Princes" literature that flourished during the late Middle Ages in both Iran and the West.

The rhetorical style of rhymed prose (*saj*) found its best expression in the *maqamah*, a literary term usually translated as "assemblies" or "séances." The twin strains of Arabic folk literature and the more sophisticated *adab* never came closer to fusion than they did in this genre. Full of wit and learned allusions, the *maqamahs* presuppose a knowledgeable audience that can appreciate them. This art form was invented by al-Hamadani (969–1008) in his *Maqamat*, in which the leading character is Abul Fath of Alexandria, the wandering Muslim scholar.

The greatest writer in *maqamah* form, however, was al-Hariri (1054–1122) of Basra, whose 50 *maqamahs* are closer to the Western notion of the short story than anything else in classical Islamic literature. Clearly imitations of al-Hamad-

hani's works from the century before, they decidedly surpass the works of their predecessor in skill and virtuosity.

## SPAIN AND NORTH AFRICA

The processes by which the Islamic caliphate disintegrated into many separate states were diverse and complex. In two areas decentralized rules were established. The first of them was in Fatimid Shiite Egypt; the second was in Spain, where a lone survivor of the Umayyad Dynasty and his successors had established a respectable empire. The caliphate proper lasted from 929 to 1031, although Islamic power in Spain lasted for several more centuries. Despite being at the far end of Islamic hub, Spain experienced a simultaneous flourishing of literature during its Muslim period, one that prospered under its own Umayyad Caliphate. The culture of Muslim Spain contains some of the greatest names in Islamic literature. Outstanding in the discipline of philosophy were Ibn Hazm (994–1064), Ibn Sina (980–1037), Ibn Tufayl (d. 1185 or 1186), Ibn Rushd (1126–98), and al-Ghazali (1058–1111).

The theologian Ibn Hazm was called the greatest scholar and the most original thinker of Islamic Spain. He drew upon personal experiences to compose his *Tauq al-Hamama* (The Ring of the Dove), a prose work, interspersed with poetry, on pure love. Apart from being a perfect example of highly developed Arabic *adab*, it is considered a frank treatment of romantic love in addition to being the author's anthology of amatory poems.

The brilliant work of Ibn Sina in philosophy, science, and medicine was highly regarded in the rest of Europe. Ibn Sina also wrote a philosophical allegory in *Hayy ibn yaqzan* (The Living One, the Son of the Awaker). Ibn Sina portrays Hayy as the symbol of the eternal sage, at once youthful and old, seeker and guide. In the latter capacity, Hayy discourses with the author and his companions on the knowledge he has gathered and reveals to them its esoteric meaning.

Ibn Tufayl, a physician and a philosopher, was born near Granada. Ibn Tufayl's *Hayy ibn yaqzan* differs from Ibn Sina's work in character as well as in concept. Ibn Tufayl's Hayy is himself the self-taught seeker of wisdom who was washed to a remote island and raised by a doe; he reasons methodically toward an ordered cosmology and eventually a philosophical recognition of God, a far cry from Ibn Sina's Hayy, who is a sage guiding the ignorant through his immense knowledge and wisdom.

Ibn Rushd, court physician of the Berber kings at Marrakech in Morocco, was the Arab translator and commentator on Aristotle whose work helped to lay the foundation of medieval Christian theology and scholasticism in Europe. Ibn Rushd was also famous for writing an attack on the Islamic mystic al-Ghazali, whose *Tahafut al-falasifa*

## THE INCOMPARABLE IBN HAZM

Ali ibn Ahmad ibn Saeed ibn Hazm was born to a wealthy family in Córdoba in al-Andalus. His family claimed descent from Persians who had served in Islamic governments early in Islamic history, but it is possible that this pedigree was an invention, with ibn Hazm's family having Iberian Christian ancestors who converted to Islam. His father and grandfather held positions in the court of the Umayyad caliph of al-Andalus. Ibn Hazm's early teachers were women family members who conveyed to him the basic principles of rational thought and literary technique and helped him memorize the Koran. He eventually studied under Abu al-Hasan ibn Ali al-Fasi, a scholar who emphasized piety in his thinking.

Ibn Hazm lived during the period of the breakup of al-Andalus. His father was arrested by opponents of the Umayyads, and some of his wealth was confiscated by his enemies. When one of the Umayyads, Abd al-Rahman ibn Muhammad, tried to claim the throne, ibn Hazm joined him at Valencia. Abd al-Rahman was defeated in battle and ibn Hazm was captured and imprisoned until he was 25. The Umayyad prince Abd al-Rahman ibn Hisham and then Hisham ibn Muhammad gained control of Córdoba, and ibn Hazm served in their governments, rising to the rank of vizier. Hisham ibn Muhammad was toppled from power in 1031, ending the Umayyad line. Ibn Hazm's enemies confiscated much of his wealth, although he retained ownership of farmland and enough money to live comfortably.

He moved to Majorca, whose governor, Ahmad ibn Rasheeq, was a friend, but the governor died in about 1048, and ibn Hazm's enemies, both scholars and political opponents, chased him away. He then settled in Seville, where he had a difficult relationship with the governor, al-Mu'tadhid ibn Abbad, who claimed to rule by the authority of Hisham. When ibn Hazm said this claim was nonsense, the governor had ibn Hazm's books burned. During this period, ibn Hazm's writing became ever-more bitter.

He moved to his farm in Córdoba, where many students came to study Islamic law, philosophy, and literature with him. He was much admired for his strong will, exceptional scholarship, and brilliant literary style. Many in his time and since have disparaged him for the harsh criticisms in his writings about rival thinkers, but he was friendly and good humored.

(*Incoherence of the Philosophers*) is directed against Muslim theologians and their attempts at saving religious beliefs by casuistry and dialectics. The work elicited from Ibn Rushd the counter treatise *Tahafut al-tahafut* (*The Incoherence of the Incoherence*). Al-Ghazali, however, has a well-deserved reputation as the most influential of the mystic writers; his chief work is *Ihya ulum al-din* (*The Revival of the Religious Sciences*), which establishes his system of harmony between mysticism and theology.

Known to his disciples as a great master, the prominent mystic Ibn al-Arabi (1165–1240) was educated in the Spanish tradition but wrote poetry and prose that shaped large parts of Islamic thought for centuries afterward. His chief work is *al-Futuhat al-Makkiyah* (*The Meccan Revelations*), which establishes a complete system of Sufism based on his mystical experience. He also wrote a volume of love poems entitled *Diwan* (*The Interpreter of Desires*), in which he pours the sacred mysteries of “love” into profane phrases but in an esoteric sense, as symbols of spiritual experience; wisdom is the true object of his quest.

Perhaps the greatest world traveler of his time was Ibn Battuta (1304–68 or 69), a native of North Africa who explored the Far East, India, Sri Lanka, the Maldives, and the region of the Niger in Africa. In all, it is estimated that he traveled and visited nearly every Muslim country. His *al-Rihlah* (*Travels*), written in about 1353, is filled with information about the cultural state of the Muslim world of his time. The account of travel is vivid, full of his personal experiences, which included contacts with high-ranking personalities in the countries he visited; these officials used Ibn Battuta as an emissary to other dignitaries and as a representative of foreign courts, as he used them to further his own travel plans.

The Tunisian Ibn Khaldun (1332–1406) was one of the great social scientists of all time. His original interpretations of historical phenomena from a sociological perspective won him the title “father of sociology.” Ibn Khaldun's masterpiece, *al-Muqaddimah* (*Introduction*), is filled with brilliant observations on the writing of history, economics, politics, and education—the nature of human history itself. It is the lengthy introductory discourse, rather than the history itself, that has earned him a place among the greatest thinkers of all time. His treatment of historical method has been judged brilliantly insightful along with his original and unique explanatory concept of *asabiyyah*, or group solidarity, in the formation of civilization.

Islamic Spain also produced outstanding poetry and two poetic forms in particular, *muwashshah* and *zawal*, which are based on refrain and are meant to be sung. The subjects include pleasures and sorrows of the days, love, friendship,

revelry, flora and fauna, and above all the land itself, al-Andalus. These poetic forms significantly influenced European romance vernacular lyrics. Among the foremost of Moorish poets were Ibn Zaydun (d. 1071), Ibn Guzman (ca. 1078–1160), Ibn Hazm, and al-Tutili (d. 1126).

### THE PERSIAN AND CENTRAL ASIAN INFLUENCE

During the Abbasid Caliphate a great Persian literature emerged, some of it in Arabic. Of the large number of Persian authors in this period, the most significant were Firdawsi (ca. 935–ca. 1020 or 1026), Awhad ad-Din Ali (known as Anvari; ca. 1126–ca. 1189), al-Biruni (973–1048), Omar Khayyam (ca. 1048–ca. 1131), Jalal ad-Din ar-Rumi (ca. 1207–73), Saadi (ca. 1213–92), and Amir Khusrau Dihlavi (1253–1325).

In the early era of Persian Islamic literature the greatest achievement was a long poem of Firdawsi. The poem was begun by an earlier obscure poet, ad-Da'iqi (d. ca. 976–81), and after his death Firdawsi finished his work, which contains more than 60,000 couplets. The most important aspect of his nationalist epic was that Firdawsi deliberately tried to use Persian words and avoid the Arabic vocabulary. The subject of *Shahnameh* is the history of Iran, its heroes and glory, from legendary times to the Sassanian kings. In content it is not an Islamic work, as it documents the history of warfare between the Iraj (Persians) and the Tur (Turks) from the Pahlavi historical sources of the early kings.

Anvari was the most accomplished writer of panegyrics, or formal eulogies, using the *qasida* form of poetry. His eulogy “Tears of Khorasan” mourns the glorious past of the Seljuk Turks. With an encyclopedic mind and bilingual in Arabic and Persian, Anvari was also skilled in music, philosophy, and the natural sciences. Besides excelling in the art of the *qasida* poetry, he used the genres *ghazal*, *robai*, and *masnavi* with virtuosity.

The most original scholar of medieval Islam, al-Biruni, was conversant in Hebrew, Turkish, Sanskrit, Persian, and Syriac in addition to Arabic. He, too, had an encyclopedic mind and accompanied Sultan Mahmud of Ghazna (r. 997–1030) to India, where he learned Sanskrit and studied Indian sciences and literature. His most famous works are *al-Athar al-baqiya* (Chronology of Ancient Nations) and *Tarikh al-Hind* (A History of India); these works are penetrating, with detailed descriptions, and are remarkable for their objectivity. Al-Biruni also wrote books on topics of scientific interest, including astrology, mathematics, and astronomy.

Another scientist and mathematician, Omar Khayyam, became famous in the West for his *Rubaiyat* quatrains, a series of independent epigrammatic stanzas conveying a philosophy of skepticism—defiant yet compassionate and not totally hopeless. Each quatrain is an independent poem but

is related to the others by the recurrence of common themes. Omar Khayyam's authorship of the *Rubaiyat* has been questioned. Some critics have suggested that his quatrains may have been written as pithy summaries of his lectures on science and philosophy, but it is really impossible to ascertain which of the hundreds of quatrains attributed to him are his own. In the East he is still known more as an astronomer and a mathematician than as a writer.

Farid od-Din Attar (ca. 1142–ca. 1220), born in Neyshabur, was a Sufi master who wrote much concerning the spiritual quest for God. His masterpiece, *Mantiq al-tayr* (The Parliament of Bird), is of humanity's spiritual and mystic journey toward union with God. The main plot is well structured but is interspersed with random subsidiary tales.

Jalal al-Din, widely known as Rumi, was the best-known writer of mystical poetry in the *masnavi* style and founder of the Mevlevi order of Sufis (the twirling or dancing dervishes). His finest work is known simply as the *Masnavi-i manawi* (Spiritual Couplets). In about 27,000 verse couplets Rumi provides an exposition of the basic ideas of Sufism, or Islamic mysticism, using fables, stories, and reflections cast in the highly poetic language of *ghazal* odes and *rubais* quatrains. Many Sufis (Islamic mystics) regard the *Masnavi* as second in importance only to the Koran. Rumi was also the author of love lyrics that surpass in beauty even the tales in his *Masnavi*.

Nezami (ca. 1141–1203 or 1217), Persian poet of the romantic epic, was born in Azerbaijan. Nezami, though not a Sufi, was a pious and tolerant Muslim. A man of wide learning, Nezami is famous for five epic poems, written in a highly allusive style abounding in metonymy (substituting an attribute for the thing itself). The most popular one in the Muslim world is the epic romance *Majnun layla* (Layla and Majnun), a Bedouin love story. Nezami established the *masnavi* as a form for long and continuous narrative, thereby setting a pattern that had a long-lasting influence.

A poet and popular moralist, Saadi was one of the greatest figures in classical Persian literature. Born in Shiraz and orphaned at an early age, he took to a wandering life, visiting central Asia, Syria, Egypt, and India and making a pilgrimage to Mecca. He was also taken prisoner during one of the Crusades. Shortly after returning to Shiraz, he dedicated to the local ruler his collected poems, *Bustan* (The Orchard), consisting of dissertations on justice, good government, earthly and mystic love, humility, contentment, and other themes. In sum, *Bustan* consists of stories illustrating the virtues that Muslims are supposed to possess. Saadi's other masterpiece, *Gulistan* (The Rose Garden), is a collection of gnomic anecdotes written in rhyming prose with verse passages; the work consists mainly of prose interspersed with short poems and contains advice, aphorisms, and humorous reflections. Saadi

was also a prolific writer of occasional verse—panegyrics, elegies, and particularly *ghazals*.

Amir Khusrau Dihlavi was one of India's most significant Persian-language poets and wrote panegyrics of the sultans of Delhi. His best work, *Khamsa* (Pentology), heavily influenced by ancient Persian literary tradition, is a collection of five long idylls in *masnavi* form and deals with broad themes of Islamic literature.

By the time of Amir Khusrau's death in 1325, the Abbasid Caliphate had disintegrated. The golden age of Islamic literature gave way to regional literatures of Persia, central Asia, India, and North Africa. During the first century of the period a number of great works were produced; among them were the *Sirat Antar ibn shaddad* (*The Romance of Antar*), the *ghazals* of Hafez (1325 or 1326–89 or 90), and *Alf laylah wa laylah* (*The Thousand and One Nights*). Islamic literature was not confined to the highly sophisticated, erudite, and witty *adab* literature of the court or the profoundly mystical works of the Sufis; there also arose a wide body of popular literature collected mostly from anonymous sources.

The *Romance of Antar* is a widely popular anonymous work in Arabic literature, attributed to many authors, including al-Asmai (ca. 740–828), a philologist. It is a work of pure romance, idealizing the Arab chivalry of the pre-Islamic era. The protagonist is a pre-Islamic poet, Antarah, who glorifies the Arab past of tribal wars and heroic deeds through his poetry and exploits. Most probably written and compiled in the 13th century, this work was the first attempt at constructing a national epic of the Arabs and their desert paternity.

The most prominent poet of this time was Hafez. Born in Shiraz of poor parentage, Hafez is considered the greatest lyric poet of Islamic Iran and the foremost writer of *ghazal*, the form he perfected. His pseudonym suggests that he had learned the Koran by heart. His works consist almost entirely of about 500 *ghazals*, or short lyrics, on the conventional themes of love and wine. The poems project at once the sweetness of the joys of this world and its shortcomings. However,

they have traditionally been interpreted as mystical Sufi allegories, but many critics argue that Hafez was not a true Sufi and that the “beloved” of the love poems stands for a human beauty or a princely patron rather than God. If there is anything divine, it must be found in the very human dimension of it. Hafez's *Divan* (collected works) is a symbolic rather than an allegorical expression of human condition, caught between yearning for God and limits of this world.

The most popular work of Islamic literature during this period, *The Thousand and One Nights*, is only partly Arab in origin, and the romances woven into it are from all cultures and civilizations of the Islamic world, mainly from Indian sources but translated into Persian as *Hazar afsana* (A Thousand Tales) and then into Arabic. Many of the tales come from India and were later expanded to include tales and anecdotes from Harun ar-Rashid's (r. 786–809) court in Baghdad. The collection was further expanded during the Mamluk Period in Egypt to include stories of rogues, tricksters, and tramps, mainly from the lower strata of society. Individual stories, such as the Sindbad cycle and the Aladdin narratives, were also added. Although it is a frame tale, much like *Kalila wa Dumna*, snatches of verse are interspersed into the prose narrative, as in many types of Arabic literature, without much relevance. There was no standard text of the work until the 15th century. The work is written mostly in simple Arabic with significant traces of the colloquial Egyptian Arabic, contrasting starkly with the complicated idiom and style of the acknowledged masters of verse prose of *adab* literature in classical Arabic.

#### “Why the Bat Flies by Night” (undated)

A bush rat called Oyot was a great friend of Emiong, the bat; they always fed together, but the bat was jealous of the bush rat. When the bat cooked the food it was always very good, and the bush rat said, “How is it that when you make the soup it is so tasty?”

The bat replied, “I always boil myself in the water, and my flesh is so sweet that the soup is good.”

He then told the bush rat that he would show him how it was done; so he got a pot of warm water, which he told

(continued)

*(continues)*

the bush rat was boiling water, and jumped into it, and very shortly afterwards came out again. When the soup was brought it was as strong and good as usual, as the bat had prepared it beforehand.

The bush rat then went home and told his wife that he was going to make good soup like the bat's. He therefore told her to boil some water, which she did. Then, when his wife was not looking, he jumped into the pot and was very soon dead.

When his wife looked into the pot and saw the dead body of her husband boiling, she was very angry and reported the matter to the king, who gave orders that the bat should be made a prisoner. Every one turned out to catch the bat, but as he expected trouble he flew away into the bush and hid himself. All day long the people tried to catch him, so he had to change his habits and only came out to feed when it was dark, and that is why you never see a bat in the daytime.

~ "Elephant and Tortoise" (undated) ~

Two powers, Elephant and Rain, had a dispute. Elephant said, "If you say that you nourish me, in what way is it that you do so?" Rain answered, "If you say that I do not nourish you, when I go away, will you not die?" And Rain then departed.

Elephant said, "Vulture! cast lots to make rain for me."

Vulture said, "I will not cast lots."

Then Elephant said to Crow, "Cast lots! who answered, "Give the things with which I may cast lots." Crow cast lots and rain fell. It rained at the lagoons, but they dried up, and only one lagoon remained.

Elephant went a-hunting. There was, however, Tortoise, to whom Elephant said, "Tortoise, remain at the water!" Thus Tortoise was left behind when Elephant went a-hunting.

There came Giraffe, and said to Tortoise, "Give me water!" Tortoise answered, "The water belongs to Elephant."

There came Zebra, who said to Tortoise, "Give me water!" Tortoise answered, "The water belongs to Elephant."

There came Gemsbok and said to Tortoise, "Give me water!" Tortoise answered, "The water belongs to Elephant."

There came Wildebeest, and said, "Give me water!" Tortoise said, "The water belongs to Elephant."

There came Roodebok, and said to Tortoise, "Give me water!" Tortoise answered, "The water belongs to Elephant."

There came Springbok, and said to Tortoise, "Give me water!" Tortoise said, "The water belongs to Elephant."

There came Jackal, and said to Tortoise, "Give me water!" Tortoise said, "The water belongs to Elephant."

There came Lion, and said, "Little Tortoise, give me water!" When little Tortoise was about to say something, Lion got hold of him and beat him; Lion drank of the water, and since then the animals drink water.

When Elephant came back from the hunting, he said, "Little Tortoise, is there water?" Tortoise answered, "The animals have drunk the water." Elephant asked, "Little Tortoise, shall I chew you or swallow you down?" Little Tortoise said, "Swallow me, if you please!" and Elephant swallowed him whole.

After Elephant had swallowed Little Tortoise, and he had entered his body, he tore off his liver, heart, and kidneys. Elephant said, "Little Tortoise, you kill me."

So Elephant died; but little Tortoise came out of his dead body, and went wherever he liked.

~ “*The Myth of Quetzalcoatl*” (undated) ~

In Tollan dwelt Quetzalcoatl. And in Tollan all the arts and crafts that we know of were first practised, for Quetzalcoatl taught them to the people there. He taught them the smelting of silver and the clearing and setting of precious stones; he taught the craft of building with stones; he taught them how to make statues, and paint signs in books, and keep count of the moons and suns. All crafts except the craft of war Quetzalcoatl taught the people of Tollan. And they made sacrifice to him with bread, and flowers, and perfumes, and not as other peoples made sacrifice to the other gods—by tearing the hearts out of the opened breasts of men and women.

He lived in a house that was made of silver. Four chambers that house had: the chamber to the east was of gold, the chamber to the west was set with stones of precious green—emeralds and turquoises and nephrite stones—the chamber to the south was set with coloured sea-shells, and the chamber to the north was set with jasper. The house was thatched with the feathers of bright-plumaged birds. All the birds of rich plumage and sweet song were gathered in that place. In the fields the maize grew so big that a man could not carry more than one stalk in his arms; pumpkins were great in their round as a man is high; cotton grew in the fields red and yellow, blue, and black, and white, and men did not have to dye it. All who lived where Quetzalcoatl was had everything to make them prosperous and happy.

There was a time when they did not have maize, when they lived upon roots and on what they gained in the chase. Maize there was, but it was hidden within a mountain, and no one could come to where it was. Different gods had tried to rend the mountain apart that they might come to where the maize was; but this could not be done. Then Quetzalcoatl took the form of a black ant; with a red ant to guide him he went within the mountain Tonacatepetl, and he came to where the maize was: he took the grain, and laboriously he bore it back to men. Then men planted fields with maize; they had crops for the first time; they built cities, and they lived settled lives, and Quetzalcoatl showed them all the crafts that they could learn from him. They honoured

him who dwelt in the shining house. And Quetzalcoatl had many servants; some of them were dwarfs, and all were swift of foot.

Then it came to pass that Tezcatlipoca, he who can go into all places, he who wanders over the earth stirring up strife and war amongst men, descended upon Tollan by means of spider-webs. And from the mountain he came down on a blast of wind of such coldness that it killed all the flowers in Quetzalcoatl’s bright garden. And Quetzalcoatl, feeling that coldness, said to his servants, “One has come who will drive me hence; perhaps it were better that I went before he drives me, and drank from a fountain in the Land of the Sun, whence I may return, young as a boy.” So he said, and his servants saw him burn down his house of silver with its green precious stones and its thatch of bright plumage, and its door-posts of white and red shells. And they saw him call upon his birds of sweet song and rich plumage, and they heard him bidding them to fly into the land of Anahuac.

Then Tezcatlipoca, that god and that sorcerer, went to where Quetzalcoatl stood, and took him into the ball-court that the two might play a game together. All the people of the city stood round to watch that game. The ball had to be cast through a ring that was high upon the wall. Quetzalcoatl took up the ball to cast it. As he did Tezcatlipoca changed himself into a jaguar and sprang upon him. Then Quetzalcoatl fled. And Tezcatlipoca chased him, driving him through the streets of the city, and out into the highways of the country.

His dwarfs fled after him and joined themselves to him. With them he crossed the mountains and came to a hill on which a great tree grew. Under it he rested. As he rested he looked into a mirror and he said, “I am grown to be an old man.” Then he threw the mirror down and took up stones and cast them at the tree. He went on, and his dwarfs made music for him, playing on flutes as they went before him. Once again he became weary, and he rested on a stone by the wayside; there, looking back towards Tollan, he wept, and his tears pitted the stone on which he sat, and his hands left their imprints upon it where he grasped the stone. The stone is there to

(continued)

*(continues)*

this day with the pits and the imprints upon it. He rose up, and once again he went on his way. And men from Tollan met him, and he instructed them in crafts that he had not shown them before.

But he did not give them the treasure of jewels that his dwarfs and humpbacked servants carried for him. He flung this treasure into the fountain Cozcaapan; there it stays to this day—Quetzalcoatl's treasure. On his way he passed over a Fire-mountain and over a mountain of snow. On the mountain of snow his dwarfs and humpbacked servants all died from the cold. Bitterly he bewailed them in a song he made in that place.

Then Quetzalcoatl went down the other side of the mountain, and he came to the sea-shore. He made a raft of snakes, and on that raft he sailed out on the

sea. Or so some say, telling Quetzalcoatl's story. And those who tell this say that he came to the land of Tlappallan in the Country of the Sun, and there he drank of the Water of Immortality. They say that he will one day return from that land young as a boy. But others say that when he reached the sea-shore he divested himself of his robe with its bright feathers, of his snake-skin mask of the colour of turquoise, and that, leaving these vestments upon the shore, he cast himself into a fire and was consumed to ashes. And they say that Quetzalcoatl's ashes changed into bright-coloured and sweet-singing birds, and that his heart went up into the sky and became the Morning Star. After he had been dead for eight days that star became visible to men, and thereafter Quetzalcoatl was named the Lord of the Dawn.

### Asia and the Pacific

#### ~ "Harisarman" (undated) ~

There was a certain Brahman in a certain village, named Harisarman. He was poor and foolish and in evil case for want of employment, and he had very many children, that he might reap the fruit of his misdeeds in a former life.

He wandered about begging with his family, and at last he reached a certain city, and entered the service of a rich householder called Sthuladatta. His sons became keepers of Sthuladatta's cows and other property, and his wife a servant to him, and he himself lived near his house, performing the duty of an attendant. One day there was a feast on account of the marriage of the daughter of Sthuladatta, largely attended by many friends of the bridegroom, and merry-makers. Harisarman hoped that he would be able to fill himself up to the throat with ghee and flesh and other dainties, and get the same for his family, in the house of his patron. While he was anxiously expecting to be fed, no one thought of him.

Then he was distressed at getting nothing to eat, and he said to his wife at night, "It is owing to my poverty

and stupidity that I am treated with such disrespect here; so I will pretend by means of an artifice to possess a knowledge of magic, so that I may become an object of respect to this Sthuladatta; so, when you get an opportunity, tell him that I possess magical knowledge." He said this to her, and after turning the matter over in his mind, while people were asleep he took away from the house of Sthuladatta a horse on which his master's son-in-law rode. He placed it in concealment at some distance, and in the morning the friends of the bridegroom could not find the horse, though they searched in every direction. Then, while Sthuladatta was distressed at the evil omen, and searching, for the thieves who had carried off the horse, the wife of Harisarman came and said to him, "My husband is a wise man, skilled in astrology and magical sciences; he can get the horse back for you; why do you not ask him?" When Sthuladatta heard that, he called Harisarman, who said, "Yesterday I was forgotten, but to-day, now the horse is stolen, I am called to mind," and Sthuladatta then propitiated the Brahman with these words—"I forgot you, forgive

me”—and asked him to tell him who had taken away their horse. Then Harisarman drew all kinds of pretended diagrams, and said: “The horse has been placed by thieves on the boundary line south from this place. It is concealed there, and before it is carried off to a distance, as it will be at close of day, go quickly and bring it.” When they heard that, many men ran and brought the horse quickly, praising the discernment of Harisarman. Then Harisarman was honoured by all men as a sage, and dwelt there in happiness, honoured by Sthuladatta.

Now, as days went on, much treasure, both of gold and jewels, had been stolen by a thief from the palace of the king. As the thief was not known, the king quickly summoned Harisarman on account of his reputation for knowledge of magic. And he, when summoned, tried to gain time, and said, “I will tell you to-morrow,” and then he was placed in a chamber by the king, and carefully guarded. And he was sad because he had pretended to have knowledge. Now in that palace there was a maid named Jihva (which means Tongue), who, with the assistance of her brother, had stolen that treasure from the interior of the palace. She, being alarmed at Harisarman’s knowledge, went at night and applied her ear to the door of that chamber in order to find out what he was about. And Harisarman, who was alone inside, was at that very moment blaming his own tongue, that had made a vain assumption of knowledge. He said: “O Tongue, what is this that you have done through your greediness? Wicked one, you will soon receive punishment in full.” When Jihva heard this, she thought, in her terror, that she had been discovered by this wise man, and she managed to get in where he was, and falling at his feet, she said to the supposed wizard:

“Brahman, here I am, that Jihva whom you have discovered to be the thief of the treasure, and after I took it I buried it in the earth in a garden behind the palace, under a pomegranate tree. So spare me, and receive the small quantity of gold which is in my possession.”

When Harisarman heard that, he said to her proudly:

“Depart, I know all this; I know the past, present and future; but I will not denounce you, being a miserable creature that has implored my protection. But whatever

gold is in your possession you must give back to me.” When he said this to the maid, she consented, and departed quickly. But Harisarman reflected in his astonishment: “Fate brings about, as if in sport, things impossible, for when calamity was so near, who would have thought chance would have brought us success? While I was blaming my jihva, the thief Jihva suddenly flung herself at my feet. Secret crimes manifest themselves by means of fear.” Thus thinking, he passed the night happily in the chamber. And in the morning he brought the king, by some skilful parade of pretended knowledge into the garden, and led him up to the treasure, which was buried under the pomegranate tree, and said that the thief had escaped with a part of it. Then the king was pleased, and gave him the revenue of many villages.

But the minister, named Devajnanin, whispered in the king’s ear: “How can a man possess such knowledge unattainable by men, without having studied the books of magic; you may be certain that this is a specimen of the way he makes a dishonest livelihood, by having a secret intelligence with thieves. It will be much better to test him by some new artifice.” Then the king of his own accord brought a covered pitcher into which he had thrown a frog, and said to Harisarman, “Brahman, if you can guess what there is in this pitcher, I will do you great honour to-day.” When the Brahman Harisarman heard that, he thought that his last hour had come, and he called to mind the pet name of “Froggie” which his father had given him in his childhood in sport, and, impelled by luck, he called to himself by his pet name, lamenting his hard fate, and suddenly called out: “This is a fine pitcher for you, Froggie; it will soon become the swift destroyer of your helpless self.” The people there, when they heard him say that, raised a shout of applause, because his speech chimed in so well with the object presented to him, and murmured, “Ah! a great sage, he knows even about the frog!” Then the king, thinking that this was all due to knowledge of divination, was highly delighted, and gave Harisarman the revenue of more villages, with gold, an umbrella, and state carriages of all kinds. So Harisarman prospered in the world.

~ “How Gunther Won Brunhild,” excerpt from  
the Nibelungenlied (ca. 1200) ~

Meanwhile their bark had come so near the castle that the king saw many a comely maiden standing at the casements. . . . He asked his comrade Siegfried: “Hast thou no knowledge of these maidens, who yonder are gazing downward towards us on the flood? . . .”

At this Sir Siegfried spake: “I pray you, spy secretly among the high-born maids and tell me then whom ye would choose, and ye had the power.”

“That will I,” spake Gunther, the bold and valiant knight. “In yonder window do I see one stand in snow-white weeds. She is fashioned so fair that mine eyes would choose her for her comeliness. Had I power, she should become my wife.”

“Right well thine eyes have chosen for thee. It is the noble Brunhild, the comely maid, for whom thy heart doth strive and eke thy mind and mood.” All her bearing seemed to Gunther good. . . .

Thus the brave knights and good rode to the castle. Six and eighty towers they saw within, three broad palaces, and one hall well wrought of costly marble, green as grass, wherein Brunhild herself sate with her courtiers. The castle was unlocked and the gates flung wide. . . .

Then the tidings were told to Lady Brunhild, that unknown warriors were come in lordly raiment, sailing on the flood. The fair and worthy maid gan ask concerning this. “Pray let me hear,” spake the queen, “who be these unknown knights, who stand so lordly in my castle, and for whose sake the heroes have journeyed hither?”

Then spake one of the courtiers: “My lady, I can well say that never have I set eyes on any of them, but one like Siegfried doth stand among them. Him ye should give fair greetings. . . . The second of their fellowship is so worthy of praise that he were easily a mighty king over broad and princely lands, and he had the power and might possess them. . . .”

Then spake the queen: “. . . If the mighty Siegfried be come unto this land through love of mine, he doth risk his life. I fear him not so sore, that I should become his wife.” . . .

“Be ye welcome, Siegfried, here in this our land! What doth your journey mean? That I fain would know.”

“Gramercy, my Lady Brunhild, that ye have deigned to greet me, most generous queen, in the presence of this noble knight who standeth here before me, for he is my liege lord. This honor I must needs forswear. . . . For thy sake are we come hither. Fain would he woo thee, however he fare. . . . He is hight Gunther and is a lordly king. An’ he win thy love, he doth crave naught more. . . .”

She spake: “Is he thy liege and thou his man, dare he assay the games which I mete out and gain the mastery, then I’ll become his wife; but should I win, ’t will cost you all your lives.” . . .

“He must hurl the stone and after spring and cast the spear with me. . . .” spake the lovely maid.

Siegfried, the bold, went to the king and bade him tell the queen all that he had in mind. . . . “I’ll guard you well against her with my arts.”

Then spake King Gunther: “Most noble queen, now mete out whatso ye list, and were it more, that would I all endure for your sweet sake. I’ll gladly lose my head, and ye become not my wife.” . . .

Meanwhile Siegfried, the stately man, or ever any marked it, had hied him to the ship, where he found his magic cloak concealed. Into it he quickly slipped and so was seen of none. He hurried back and there he found a great press of knights, where the queen dealt out her lofty games. . . . The ring had been marked out, where the games should be, afore many valiant warriors, who were to view them there. . . .

Then was come Brunhild, armed as though she would battle for all royal lands. . . .

Then was brought forth for the lady a spear, sharp, heavy, and large, the which she cast all time, stout and unwieldy, mickle and broad, which on its edges cut most fearfully. Of the spear’s great weight hear wonders told. . . . The noble Gunther gan be sore afraid. Within his heart he thought: “What doth this mean? How could the devil from hell himself escape alive?”

Were I safe and sound in Burgundy, long might she live here free of any love of mine." . . .

Upon her fair white arm the maid turned back her sleeves; with her hands she grasped the shield and poised the spear on high. . . . Gunther and Siegfried feared Brunhild's hate, and had Siegfried not come to Gunther's aid, she would have bereft the king of life. Secretly Siegfried went and touched his hand; with great fear Gunther marked his wiles. "Who hath touched me?" thought the valiant man. Then he gazed around on every side, but saw none standing there.

"'Tis I, Siegfried, the dear friend of thine. Thou must not fear the queen. Give me the shield from off thy hand and let me bear it and mark aright what thou dost hear me say. Make thou the motions, I will do the deeds." . . .

Then with might and main the noble maiden hurled the spear at a shield, mickle, new, and broad, which the son of Siegelind bore upon his arm. The sparks sprang from the steel, as if the wind did blow. The edge of the mighty spear broke fully through the shield, so that men saw the fire flame forth from the armor rings. The stalwart men both staggered at the blow; but for the Cloak of Darkness they had lain there dead. From the mouth of Siegfried, the brave, gushed forth the blood. Quickly the good knight sprang back again and snatched the spear that she had driven through his shield. Stout Siegfried's

hand now sent it back again. He thought: "I will not pierce the comely maid." So he reversed the point and cast it at her armor with the butt, that it rang out loudly from his mighty hand. . . . With all her strength she could not stand before the blow. In faith King Gunther never could have done the deed.

Brunhild, the fair, how quickly up she sprang! "Gunther, noble knight, I cry you mercy for the shot." She weened that he had done it with his strength. . . . The noble maid and good raised high the stone and hurled it mightily far from her hand. . . . The stone had fallen twelve fathoms hence, but with her leap the comely maid out-sprang the throw. Then went Sir Siegfried to where lay the stone. Gunther poised it, while the hero made the throw. Siegfried . . . threw the stone still further and made a broader jump. Through his fair arts he had strength enow to bear King Gunther with him as he sprang. The leap was made, the stone lay on the ground; men saw none other save Gunther, the knight, alone. . . . Brunhild, the fair, waxed red with wrath. To her courtiers she spake a deal too loud, when she spied the hero safe and sound at the border of the ring: "Come nearer quickly, ye kinsmen and liegemen of mine, ye must now be subject to Gunther, the king."

#### THE FIRST ASSEMBLY

Al Harith, son of Hammam, related: When I mounted the hump of exile, and misery removed me from my fellows, the shocks of the time cast me to San'a of Yemen. And I entered it with wallets empty, manifest in my need; I had not a meal; I found not in my sack a mouthful. Then began I to traverse its ways like one crazed, and to roam in its depths as roams the thirsting bird. And wherever ranged my glances, wherever ran my goings at morn or even, I sought some generous man

before whom I might fray the tissue of my countenance, to whom I might be open concerning my need; or one well bred, whose aspect might dispel my pain, whose anecdote might relieve my thirsting. Until the close of my circuit brought me, and the overture of courtesy guided me, to a wide place of concourse, in which was a throng and a wailing. Then I entered the thicket of the crowd to explore what was drawing forth tears. And I saw in the middle of the ring a person slender of make; upon him was the equipment of pilgrimage, and he had the voice of lamentation. And he was studding cadences

(continued)

*(continues)*

with the jewels of his wording, and striking hearings  
with the reproofs of his admonition.

And now the medley of the crowds had surrounded  
him, as the halo surrounds the moon, or the shell the  
fruit. So I crept toward him, that I might catch of his  
profitable sayings, and gather up of his gems. And I  
heard him say, as he coursed along in his career, and the  
throat of his improvisation made utterance:

O thou reckless in petulance, trailing the garment of  
vanity! O thou headstrong in follies, turning aside to  
idle tales! How long wilt thou persevere in thine error,  
and eat sweetly of the pasture of thy wrong? How far  
wilt thou be extreme in thy pride, and not abstain from  
thy wantonness? Thou provokest by thy rebellion the  
Master of thy forelock; in the foulness of thy behaving  
thou goest boldly against the Knower of thy secret.  
Thou hidest thyself from thy neighbor, but thou art  
in the sight of thy Watcher; thou concealest from thy  
slave, but no hidden thing is hidden from thy Ruler.  
Thinkest thou that thy state will profit thee when  
thy departure draweth near? or that thy wealth will  
deliver thee when thy deeds destroy thee? or that thy  
repentance will suffice for thee when thy foot slippeth?  
or that thy kindred will lean to thee in the day that thy  
judgment-place gathereth thee? How is it thou hast not  
walked in the high-road of guidance, and hastened the  
treatment of thy disease, and blunted the edge of thine  
iniquity, and restrained thyself—thy chief enemy? Is  
not death thy doom? What then is thy preparation? Is  
not gray hair thy warning? What then is thy excuse?  
And in the grave's niche thy sleeping-place? What dost  
thou say? And to God thy going? and who shall be thy  
defender? Oft hath the time awakened thee, but thou  
hast set thyself to slumber; and admonition hath drawn  
thee, but thou hast strained against it; and warnings  
have been manifest to thee, but thou hast made thyself  
blind; and truth hath been established to thee, but thou  
hast disputed it; and death hath bid thee remember,  
but thou hast sought to forget; and it hath been in thy  
power to impart of good, but thou hast not imparted.  
Thou preferrest money which thou mayest hoard before  
piety which thou mayest keep in mind: thou chooseth a  
castle thou mayest rear rather than bounty thou mayest  
confer. Thou inclinest from the guide from whom thou

mightest get guidance, to the pelf thou mayest gain as  
a gift; thou letteth the love of the raiment thou covetest  
overcome the recompense thou mightest earn. The  
rubies of gifts cling to thy heart more than the seasons  
of prayer; and the heightening of dowries is preferred  
with thee to continuance in almsgivings. The dishes of  
many meats are more desired to thee than the leaves of  
doctrines: the jesting of comrades is more cheerful to  
thee than the reading of the Qur'an. Thou commandest  
to righteousness, but violatest its sanctuary: thou  
forbiddest from deceit, but refrainest not thyself: thou  
turnest men from oppression, and then thou drawest  
near to it; thou fearest mankind, but God is more  
worthy that thou shouldst fear him. Then he recited:

Woe to him who seeks the world, and turns to it his  
careering: And recovers not from his greediness for it,  
and the excess of his love. Oh, if he were wise, but a drop  
of what he seeks would content him.

Then he laid his dust, and let his spittle subside; and put  
this bottle on his arm, and his staff under his armpit.  
And when the company gazed on his uprising, and saw  
that he equipped himself to move away from the midst,  
each of them put his hand into his bosom, and filled for  
him a bucket from his stream: and said, "Use this for  
thy spending, or divide it among thy friends." And he  
received it with half-closed eyes, and turned away from  
them, giving thanks; and began to take leave of whoever  
would escort him, that his road might be hidden from  
them; and to dismiss whoever would follow him, that  
his dwelling might be unknown. Said Al Harith, son of  
Hamman: Now I went after him, concealing from him  
my person; and followed on his track from where he  
could not see me; until he came to a cave, and slipped  
into it suddenly. So I waited for him 'till he put off his  
sandals and washed his feet, and then I ran in upon  
him; and found him sitting opposite an attendant, at  
some white bread and a roast kid, and over against them  
was a jar of date-wine. And I said to him, "Sirrah, was  
that thy story, and is this thy reality?" But he puffed  
the puff of heat and went near to burst with rage; and  
ceased not to stare at me 'till I thought he would leap  
upon me. But when his fire was allayed, and his flame  
hid itself, he recited:

I don the black robe to seek my meal, and I fix my  
hook in the hardest prey: And of my preaching I make  
a noose, and steal with it against the chaser and the

chased. Fortune has forced me to make way even to the lion of the thicket by the subtlety of my beguiling. Yet do I not fear its change, nor does my loin quiver at it: Nor does a covetous mind lead me to water at any well that will soil my honor. Now if Fortune were just in its decree it would not empower the worthless with authority.

Then he said to me, "Come and eat; or, if thou wilt, rise and tell." But I turned to his attendant, and said, "I

conjure thee, by him through whom harm is deprecated, that thou tell me who is this." He said, "This is Abu Zayd, of Seruj, the light of foreigners, the crown of the learned." Then I turned back to whence I came, and was extreme in wonder at what I saw.

## ► metallurgy

---

### INTRODUCTION

By the Middle Ages almost every culture on earth possessed some form of metalworking, except for those in Australasia. Some tribal peoples in the Americas and in southern Africa, however, also never developed or received metalworking technology. Among basic technologies only stoneworking and agriculture were more widely distributed.

Metalworking began in prehistoric times with native metals, that is, metals that occur naturally in a relatively pure state. This condition is especially common in the case of gold and silver. Such metals were worked by hammering with either wooden or stone implements. Native gold and silver generally were worked into ornaments and other items used to signify prestige, often with amazing craftsmanship even in very early times. This stage of development seems to have happened very late in the Americas, not long before the beginning of the Middle Ages. The next stage of development was the ability to melt and cast copper from ore. This may have been first accomplished accidentally when copper-bearing rocks were used in the construction of kilns for firing ceramics and some pure metal melted out. Eventually it was learned that copper could be combined with other metals like tin to produce harder and more useful alloys, such as bronze. Bronze implements are so useful that they fostered an expansion of wealth and a new organization of society. Bronze working became one of the key factors in the development of

the first urban cultures in the Old World. In the New World, however, bronze existed, but metal products never acquired a practical purpose.

One of the most important developments in metallurgical technology was the use of iron. Native iron had long been used for ceremonial and prestige objects because of its rarity and because of its seemingly miraculous origin as fallen from the sky (most of it coming from meteorites). The ability to work iron ore in bloomery furnaces had been invented by the Hittites toward the end of the second millennium B.C.E. This process eventually spread to the entire world, except Australasia and the Americas. Perhaps the highest-quality steel was used in the manufacture of swords produced in central Asia and in Japan: the so-called Damascus sword and the world-famous samurai sword.

Metallurgy drove technological change and itself changed rapidly during the medieval period, often by necessity or serendipity. Metalsmithing requires the burning of tremendous amounts of fuel. In some areas this resulted in serious deforestation. In Oman, for instance, deforestation meant the end of an important metalworking industry for several centuries during the Middle Ages and led to permanent ecological damage. In Europe, on the other hand, the same pressures resulted in improved forest-management techniques and eventually the switch to the use of coal as a fuel in the place of charcoal from wood (perhaps because coal occurred in abundance near the surface of the ground, especially in England, and had been used as a cooking and heat-

ing fuel since Roman times). Once gunpowder was developed in medieval China (and soon imported to the West), Chinese and European soldiers both found a ready means to exploit the new substance, by using bronze bell-casting technology to create the first cannons.

Perhaps the most important medieval metallurgical technology was the blast furnace. This technology had been developed in China in antiquity and continued in use throughout the Middle Ages. It was invented independently in Europe in the 12th century. In both cases the bellows were run by complex water-powered machines. The iron production of blast furnaces was measured in tons per year rather than the few pounds of iron produced by a traditional bloomery furnace. Moreover, the iron produced was molten and could be easily cast. The improvement and development of blast furnace technology in Europe was continuous and rapid. It led to the growth of the bourgeois middle class and ultimately to the Industrial Revolution. But no such transformation, either technological or social, took place in China. This difference in the development of the two cultures is an important problem for the field of historical study today.

## AFRICA

BY KIRK H. BEETZ

By the beginning of the medieval era Africa had a long, ancient tradition of metallurgy. The only cultures that may not have smelted, refined, or forged may have been hunter-gatherers and pastoralists in the Kalahari Desert and southern Africa. Still, copper and iron were important parts of the lives of these peoples, who in their early recorded history would meet with outside traders who brought metal tools. They would trade mostly for ostrich feathers as well as for animal skins.

There were places in Africa where metal was not mined but where metalworkers flourished anyway. Iron and copper would be imported as ingots (a solid mass of metal), which were refined, if necessary, and then forged. There were very productive copper, iron, and gold mines in western Africa, in north-central Africa, in Nubia and Ethiopia in northeastern Africa, and in southeastern Africa, and archaeologists have made significant strides in identifying their furnaces and describing how the furnaces were used.

There is much disagreement among archaeologists about when and how Africans began working with metal. Some believe that Africans south of the Sahara learned how to work with metal from outsiders such as Carthaginians or Berbers, but archaeological evidence for this is scant. Others believe metalworking began independently in sub-Saharan Africa, perhaps several times in different places. Africans may have learned to work with copper first, possibly doing no more

than hammering naturally occurring copper nuggets, eventually learning to identify and work with copper ore and later using their knowledge of copper to help them recognize and work with iron ore.

At the start of medieval times the principal metalworking sites in Africa seem to have been in two places: the land of the mysterious Nok in western Africa and in northeastern Africa, where there is ample evidence of advanced metalworking in Nubia and Axum. In these areas one particular type of furnace for smelting ore predominated. This furnace consisted of a large hole dug at an angle in the ground. Around the surface of the hole was a bowl-shaped circle of clay. This circle varied from 3 feet to 6 feet in height. In western Africa and somewhat later in central Africa builders of the furnaces shifted from clay layered in circles to dried clay bricks and at an undetermined time in the middle of the medieval era to clay bricks that had been fired, probably by placing them directly into fires. The sides of the wall would be pierced with tuyeres—openings through which air could be forced into the furnace. Many furnaces for smelting and for refining had small holes in their floors apart from the main hole, and archaeologists speculate that religious or magical objects were placed in these holes to help guarantee that the smelting or refining went well.

These furnaces were filled with wood that was burned to make charcoal. Then the charcoal was supplemented by more wood and allowed to burn until it was very hot, at which time ore was placed inside and the top perhaps covered. Eventually metalworkers learned to use water to help cool the smelted metal, but this may not have occurred until late in the medieval era. In general, furnaces were allowed to cool on their own, perhaps for several days. When they were fully cooled, the furnaces were broken open, often with most of their walls knocked to the ground, and the smelted metal would be removed, usually mixed with ashes. It is possible that this resulted in the manufacturing of steel, which combined iron with carbon from ashes.

Sites in the grasslands south of the Sahara and in the central forests of Africa have ditches that were dug by making a furnace, breaking it open, then making a furnace next to the old one, and so on, apparently over many generations. The people responsible for these furnaces were probably nomadic pastoralists, who returned to the same locations to smelt their ore, perhaps because the spots had religious significance. Among those cultures in western Africa in which traditional smelting practices survived long enough to be recorded by outside observers, pieces of clay from the wall of a previously used furnace would be incorporated into the wall of a new furnace as a way of transmitting some of the spiritual power of ancient furnaces into new ones. Perhaps influenced by the

techniques of the ancient kingdom of Kush (900 B.C.E.–300 C.E.) in Nubia, the furnaces of the medieval Nubian kingdoms and of Ethiopia seem to have been more permanent, built for repeated use by leaving openings at the bottoms for extraction of the smelted metal.

The use of tuyeres may have been universal in Africa. These usually took the form of cones with the narrow end facing inside the furnace. There were typically three or four of these cones in a furnace and two bellows inserted into each tuyere. While one bellows was blowing air into the furnace, the other could reinflate, allowing for oxygen to be constantly blown into the fire to help it maintain a consistent temperature. This suggests the possibility of a mix of skilled and unskilled labor. The skilled metallurgists would build the furnaces and supervise their use, but unskilled workers could be taught to work the bellows.

For medieval Africans metallurgy usually had three steps: smelting, refining, and forging. The metal left after smelting seems to have been too adulterated with contaminants such as dirt and wood to have been useful. Medieval African metalworkers had a few choices of what to do with the metal they extracted through smelting. One was to take what was probably often a lump of metal and anneal it, that is, hammer it into some kind of shape for shipping elsewhere, perhaps in trade, where it would be further refined. They could take the slag, the refuse of the ore after smelting, and resmelt it to extract more metal because the basic smelting process would leave much metal still in the slag. This may have been done in Nubia. The third choice was to refine the metal, something that would have been done even after resmelting slag or annealing unrefined metal.

Typically, medieval African metalworkers built furnaces for refining metal on slopes. In central Africa down into Angola, members of the Kongo and Mbundu cultures often used termite mounds for slopes. Refining furnaces might be made of layers of clay or of clay bricks. They had tuyeres through which bellows blew air. The slope allowed refined molten metal to pour out a hole at the bottom of the furnace. The metal poured into open clay molds for ingots with the molds often lined with ashes. The ingots were in various patterns, such as H-shaped and crosses, and they seem to have been made in standardized sizes and weights. Ingots from western Africa have been found as far away as southeastern Africa, indicating that they were widely traded. Some ingots seem not to have been made in molds but instead to have been hammered into shape.

Blacksmiths were thought to be spiritually powerful. In some cultures village leaders would frequently consult the village's blacksmith on matters of public policy. Blacksmiths would sometimes be consulted by people who sought magi-

cal aid or help with a spiritual problem. In central Africa and southwestern Africa some blacksmiths became powerful enough to have their own armies. These were itinerant blacksmiths who were mostly concerned with keeping the narrow paths among small communities open so that they could travel safely, but some of these blacksmiths used their armies and spiritual authority to become kings.

The craft of smithing itself was often hereditary, with one family having a monopoly in a village. Smiths would pass on secret spiritual knowledge to their children that set their families apart from others. Archaeologists speculate that this may have served to help smiths remember their methods. Each technique, from hammering out a hoe to drawing out wire, would have a ritual to be followed, and in this way smiths could manufacture goods with tried-and-true methods without knowing exactly why they worked.

Smithing required hammers, punches, and adzes as well as a furnace or hearth and an anvil. The last of these items was seldom elaborate. Even in the present-day, traditional African blacksmiths use stones for anvils, perhaps no bigger than a person's foot. The furnace of a blacksmith would have required only one bellows—just enough to heat burning charcoal to a temperature high enough to soften metal. During the medieval era most tools produced by smiths were made of iron, while copper, bronze, silver, and gold were used for jewelry and coins.

Whether working in a city or a small village, blacksmiths tended to have a large set of tools. Hammers seem to have been used by all, and a typical tool kit would have hammers of different sizes, from big ones used to pound large ingots into the general form of the object to be made to small hammers used to create minute details or to smooth the surface of an object. Chisels were used to emboss objects and perhaps to work in fine details. Punches were used to make holes in sheets of metal. Adzes were used to chip at objects, perhaps to flatten a side. Wire was used for jewelry, for binding plates of iron together for suits of armor, and for binding metal to wood. The start of the process of making wire was probably like that for making nails. An ingot was heated and then worked with a hammer to form a rod. Holes of different sizes would have been punched through an iron plate. To make sure the holes were the correct width, the blacksmith would slip needles of various widths through them. Then the rod was heated to near melting, inserted into a large hole, and pulled through by tongs. The now narrower rod would be heated again and pulled through a smaller hole. This process continued until the resulting wire was of the desired width.

Smithing tended to be a home industry, except in parts of northeastern Africa such as Axum, where there may have been foundries where several furnaces and several black-

smiths may have gathered together to mass-produce goods. This may have been the continuation of a tradition begun in the city of Meroë in Kush in ancient times or may have been influenced by practices in the Byzantine Empire. From what archaeological discoveries have so far revealed, elsewhere most smiths worked indoors, either in their homes or in a building within their family's compound, or they worked outside next to their homes in small-scale family businesses. In western Africa and central Africa the women usually took care of the sale and trading of products manufactured by the men.

## THE AMERICAS

BY PENNY C. MORRILL

The story of metallurgy in Latin America had its beginnings in 1500 B.C.E., along the north coast of Peru, where renewal and innovation remained constant over many centuries. The remarkable work of Moche goldsmiths, discovered in the royal tombs of Sipán, is a triumph of artistic skill and imagination. Produced in 300 C.E., the intricate works of art reveal a well-developed level of technology that encouraged experimentation.

In Moche ceramics royal priests are represented in sumptuous ritual dress. The discoveries in the Sipán tombs indicate that these priests were buried in many layers of the same opulent costumes and jewelry they had worn in ritual performances. Such splendor could have been possible only in a hierarchical society governed by a small powerful, elite able to garner and control vast material wealth and employ a large contingent of artisans.

Gold and silver beads found at the Sipán site are conical, trapezoidal, or peanut shaped, and some end in spheres. They are representations of human, owl, or feline heads. One necklace of 10 beads, each composed of numerous layers to form the shape of an anthropomorphic spider atop its web, is a technological wonder. The base of each bead is a half sphere, produced from a gold sheet on a doming block, with additional chasing. A frame fits onto the open side of the dome and holds in place the gold wires that make up the diagonal lines of the spider web. The connecting lines of the web form ever-smaller circles into the center beneath the spider's body, which was also formed on a block. Gold-wire spider legs attach to the body. Fitted over the body and legs is the top of the spider, on which appears a human face in repoussé. This technique required the goldsmith to hammer the design into the back of the gold sheet. To form the gold wire used in these spider beads, Moche goldsmiths cut thin strips from gold sheets and then hammered, twisted, and rolled them into rods. These were pulled through a series of holes of decreas-

ing diameter until the proper size had been achieved, with little or no waste of the metal.

Another marvel from the tombs at Sipán is the octopus pectoral. This large-scale chest ornament measures just over 35 inches across, is made up of eight large curved tentacles cut from gold sheets, and is adorned with almost 100 gold and shell beads. The small gold beads that were soldered to the tentacles were produced either from two hollow hemispheres soldered together or by the lost-wax method. In the latter technique a ceramic bead was covered with a thin layer of wax and then placed in an outer mold made up of clay and pulverized charcoal. The artisan melted gold in a heat-resistant ceramic crucible and poured it through a hole in the mold. The molten metal replaced the wax, forming a gold bead around the ceramic core, which remained inside the bead.

*Gold pendant; Mixtec culture, Mexico, 1100–1520* (Los Angeles County Museum of Art, The Phil Berg Collection, Photograph © 2006 Museum Associates/LACMA [M.71.73.249a])

The goldsmiths of Sipán were masters at combining gold or copper with shell and stone, as exemplified by a massive owl headdress. The owl at the center of the headdress is three-dimensional, its eyes inlaid with white shell and turquoise. Goldsmiths attached bangles to the owl's large gold wings with gold wire, an ensemble that must have created impressive sounds and reflected light as the priest walked in procession.

The explosion of creativity that took place after 500 C.E. throughout Central America, in Costa Rica, and in Panama was mostly influenced by developments in Colombia. Gold and copper were abundant in Panama, where gold indicated status, both in life and death. Panamanian metalsmiths worked in *tumbaga*, an alloy with a high percentage of copper mixed with gold. These artisans embossed gold plaques with representations of fantastic creatures. Human and animal figural pendants were also formed in lost wax, as was the openwork, or false filigree, that ornamented these works.

In Costa Rica gold casting began around 500, with influences from Panama and Colombia. Costa Rican goldsmiths were adept at depletion gilding, a technique that produced a seamless surface layer of gold. A good example of this kind of work, a frog pendant from Chaparrón, was first formed of *tumbaga*. The goldsmith removed the surface copper by heating the piece in an open hearth until the copper oxidized. He then used a plant-based acid solution to dissolve the black oxidized copper from the surface, leaving behind a thin layer of almost pure gold that could be burnished to a high finish.

After 500 in the Caribbean lowlands of Colombia, Zenú caciques, or leaders of chiefdoms, had become powerful and resourceful and were commissioning gold adornments to indicate their status. Near important sources of raw gold, the Cauca and Nechí rivers, Zenú metalsmiths mastered gold casting and depletion gilding. The artisans imitated the appearance of plumage on the figure of a bird by using false filigree and cast-wire swirls and spirals. The Zenú also embellished wooden idols with sheets of gold. Twenty-four of these idols were discovered in a temple in the ceremonial center at Finzenú. A significant development among the Zenú was that a portion of the gold production was meant for trade, for Zenú pieces have been discovered at some distance.

In the Cordillera Oriental mountain range of Colombia, the Tairona and Muisca people had very different approaches to metalsmithing. For the Muisca (after 800), votive objects in gold with copper alloy were cast in the lost-wax technique, but with a difference. These artisans used a stone matrix, with several designs carved in high relief on one stone. The carving was impressed into the clay, which when dry was coated with beeswax on the outer surface. The wax was impressed with the stone relief, thus creating a negative and positive

imprint in the wax. Several objects could be produced from the one wax model, imprinted with different designs from the single stone.

In contrast to the Muisca, the Tairona goldsmiths created elaborate clay core images that were destroyed at the time the mold was broken open and the gold object removed. The Tairona were less interested in producing multiples and more focused on a refined finished piece. These pendants are highly symbolic, very unlike the simpler votive figures of the Muisca.

In the northern coastal region of Peru, the Sicán (after 900) had access to copper and arsenic-bearing ore deposits. They could acquire gold and silver from the northern highlands. The Sicán metalsmiths worked in high-carat gold alloys, silver, arsenical bronze, silver alloyed with copper, and *tumbaga*. They added small amounts of arsenic to improve the hardness and malleability of copper, giving the metal a silvery appearance.

These artisans were particularly adept at producing gold sheets and enhancing their designs with repoussé, chasing, and joining. In one Sicán tomb, archaeologists found thousands of depletion-gilded *tumbaga* squares that had originally been sown onto a costume, creating a resplendent display. The Sicán metalsmiths also did surface depletion of silver from gold. Masks and ceremonial headdresses are indicative of the sophistication reached by these artisans, in terms of alloying, combining metals and stones, and of their technical expertise. Movement and articulation became part of the design of the piece. One headdress, measuring 3 feet high by 2 feet wide, included gold bangles, some with turquoise inlay, portrait heads of deities cut from silvery-colored gold alloy sheets, feline heads of gold alloy, and the mask itself, which was made up of several sheets of gold and *tumbaga*.

The Chimú, at their capital of Chan Chan on Peru's north coast, developed (after 1000) a distinctively elegant and aesthetic approach to gold ornament and jewelry. Meant for ostentatious display for the Chimú nobility, most pieces were produced from gold sheets. Reflective of this preference is a pair of ear spools, each comprising more than 100 tiny gold pieces, soldered or stapled into a profuse and extravagant pattern. Chimú goldsmiths also mastered the technique of granulation. They cut out small pieces from a gold sheet, placing them on a heated charcoal block. During the melting process, surface tension caused the gold pieces to become spheres. To adhere the tiny beads to a gold surface, the Chimú used copper-salt reduction or reaction soldering. In this technique the granules were placed on an organic glue that had been mixed with a finely ground copper salt, like malachite. With heat, the glue burned off and the copper salt was reduced to metallic copper in a liquid state. At the points where the granules

came into contact with the metallic copper, they became soldered to the surface.

Western Mexico seems to have had a trading relationship with the coastal people of Peru and Ecuador. Copper artifacts dating as early as 600 reveal that western Mexican metalsmiths had acquired the ability to work in lost-wax casting and with various alloys. Around 1200 the techniques of metallurgy spread to the Oaxaca, Maya, and Huastec regions, a development that may have been the result of several points of influence.

The earliest finely crafted work in gold in Mesoamerica was taken from the sacred cenote (well) at Chichén Itzá and dates to around 1000 to 1200. The gold masks and large discs worked in repoussé provide evidence for the mythic status accorded Toltec goldsmiths by the Aztec. The gold discs, approximately 6 to 8 inches in diameter, represent themes that are specific to Chichén Itzá, with aspects borrowed from central Mexico (Tula) and the Maya region. A depiction of a human face emerging from an eagle's beak before a kneeling figure resembles a vision serpent. Another disc represents a figure descending from a serpent's mouth at the dramatic moment of a heart sacrifice.

In the past these works were thought to have been produced in Panama. It seems more credible that the Toltec-Itzá were trading with the Panamanians for gold. The artisans of Chichén Itzá would have learned goldsmithing techniques from the Panamanians. This interaction between these two regions had been taking place over many centuries, as indicated by Olmecoid jade figurines discovered in Costa Rica. While influence from western Mexico is evident, it is more likely that the Toltec-Itzá were precursors of the Mixtec goldsmiths in Oaxaca, where gold was plentiful.

## ASIA AND THE PACIFIC

BY KIRK H. BEETZ

As far as archaeologists have determined, during the medieval era the people of Oceania—the lands of the Polynesians and the Australians—did not practice any form of metallurgy. Among the peoples of central Asia and Siberia metal objects came from people of the Near East, from whom pastoralists of central Asia and Mongolia learned to work metal and perhaps passed their knowledge on to Koreans. The Chinese had learned to manufacture bronze early in their history, perhaps from the ancient cultures of the Near East or perhaps on their own. In about 500 B.C.E. the Chinese learned to smelt iron ore and within about 100 years had mastered most of the techniques for working with iron. The speed of this development, which seems to have taken at least several hundred years in the Near East, has led many archaeologists to con-

clude the Chinese learned how to work iron from people of India or the Near East. During medieval times metallurgists from the Sassanian Empire (226–651) fled the Arab invasion of their homeland and settled in China, bringing with them advanced techniques for making alloys and for decorating metal objects. The Koreans were heavily influenced by Chinese metallurgists, and most of their medieval practices were identical to those of China. Japan followed a unique path in its development of metallurgy. For example, the Japanese had an iron age before they had a bronze age because they depended on foreign supplies of metal, and they imported iron from Korea before importing copper and tin, which are both used in making bronze.

Medieval Indian documents on metallurgy do not seem to have survived, and the archaeological history is spotty. Relics from the 500 years before medieval times, however, show that the skills of Indian metallurgists were already extraordinary and included one or more techniques for making steel that would not rust and an ability to cast steel objects weighing tons. Most of the metallurgy of southern Asia seems to have followed the practices of India, with the exception of northern Vietnam, which was dominated by China. The metallurgical practices of Indonesia are not well known. The peoples of Java and Sumatra manufactured their own metal weapons and tools.

The extensive religious literature of medieval India includes explanations of the duties of Hindu castes such as blacksmiths. From this literature and archaeological remains, some aspects of their metallurgical practices can be determined. The Indians exploited their rich deposits of ore; good ore high in metal content was probably selected by eye. Iron, copper, and other metals were smelted in furnaces equipped with bellows. The metal was either made liquid and poured into molds to make ingots or came out of the furnaces as misshapen masses still mixed with slag. The slag would have been refined by reheating in a furnace, worked free of the contaminants, or reshaped by hammering.

The most famous Indian metal was *wootz* steel. This was made by melting low-carbon iron with a measured amount of carbon in a crucible, which was sealed and heated to about 2,200 degrees Fahrenheit. The crucible was then shaken, and it made a distinctive sound when carbon and iron had formed steel. The crucible was allowed to cool for days, resulting in an alloy of iron with about 1.5 percent carbon. This *wootz* steel was highly valued for its flexibility and strength and was exported to the Near East, central Asia, and the Far East.

The principal tools of blacksmiths were hammers and tongs. They also used anvils and worked close to the furnace in which they heated the metal. They heated the metal until it was white-hot and then, using tongs, withdrew it from the furnace. Next they hammered, twisted, and hammered the

*Bronze water pot; Japan, Kamakura Period, 13th century* (Freer Gallery of Art, Smithsonian Institution, Purchase, F1965-26a-c)

metal again, cut it to desired lengths, reheated it, again hammered and twisted, then quenched it in water and repeated the process. In this manner they made mostly iron tools such as spades, saws, hammers, tongs, plowshares, and sickles. They also made needles for sewing, scissors for cutting cloth or nails, razors for shaving, machetes for hacking through brush, and surgical instruments. Household goods such as cooking utensils were made of various metals such as iron, copper, zinc, lead, and meaning tin.

Specialists among smiths were those who worked with gold and silver. Gold beaters spent their time beating golden ingots into thin sheets. Goldsmiths used touchstones to test their metal. A touchstone was basalt or jasper, which were hard, black stones. Gold was rubbed against a touchstone to see whether it left a streak the color of pure gold, adulterated gold, or a fraudulent piece of metal; the same was done for silver. Some dishonest goldsmiths made imitation touchstones that would make their fake goods seem to be made of gold. Indian governments usually had well-trained agents who regulated the goldsmiths and tested the goldsmith's scales, touchstones, and products. The smiths used small crucibles to melt their precious metals into liquid form, and they were masters at making alloys by mixing metals.

Exactly how Indian techniques spread is not clear. Routes through northeastern India were probably used by Indian metallurgists to migrate to China. In Southeast Asia metallurgical techniques probably traveled by the migration of metallurgists, most notably to Funan (a kingdom in the Mekong Delta) prior to the medieval era and to Indonesia with Hindu and Buddhist clergy throughout the medieval times. It is unlikely, but not known for certain, that blacksmiths existed in the Khmer Empire (802–1432) in the density that they did in India, although some must have worked in the villages near the great religious complexes built by the Khmer, manufacturing and repairing tools.

People in both India and China cast metal. The techniques they used were ancient, using either clay models or the lost-wax technique. By 1000 B.C.E. the Chinese were using extraordinarily complex molds and making them so that they could be mixed and matched; these included molds for bottoms, for central vessels, and for tops, such as round mouths. This meant that at that early date the Chinese could mass-produce bronze or copper objects for everyday use. The lost-wax technique involved making a wax figure, then adding wax columns around which clay was pressed. When heated, the wax melted out the openings left by the wax columns. These were stopped up, and molten metal was poured in an opening that had been left unstopped. After cooling, the clay was broken open, leaving a unique object. The bumps or ridges left by the molds were filed down. The rules for making objects with the lost-wax method were so precise among Indians that many objects seem nearly identical, their makers having sought to copy a masterwork rather than deviate from what tradition required of them. The Chinese so excelled at casting metal that objects cast using clay molds and those using the lost-wax technique sometimes showed no sign of seams or wax bumps and so required no filing.

The medieval Chinese had a sophisticated bellows system that could simultaneously suck in air from outside while blowing it into a furnace, allowing Chinese smelters to maintain consistent temperatures while ore was heated. They added phosphorus to their mix in the furnace, which enabled iron to melt at lower temperatures than would otherwise have been needed. This meant that their iron ore became fully liquid, which resulted in bountiful amounts of cast iron. The furnaces were fairly small and made of heat-resistant clay. Coal was used to provide the heat.

Steelmaking was a tricky business. Too much carbon mixed with iron made for a hard but fragile product that fragmented easily. Too little carbon made for soft steel that was easy for a blacksmith to work but unsuited for any tool that needed to be resistant to hard blows. This was wrought iron, with a carbon content of about 0.06 percent. To be strong and

not brittle, steel required a carbon content greater than 0.06 percent but less than 1.8 percent; the lower the percentage, the softer the steel. In the 400s C.E. Chinese metallurgists melted iron with a high carbon content and placed bars of wrought iron into the liquid; it seems to have been a trial-and-error process of development before the metallurgists learned the best proportions of wrought iron bars to carbon-rich iron liquid that resulted in tough steel. Chinese blacksmiths developed a process of hammering out bars of hard steel, welding soft steel to them, hammering them into rough shape, and repeating the process many times, quenching the steel in water after each period of hammering. The result was a steel object that was hard yet flexible.

This process made its way into Japan in the 600s, most likely via Korean metalworkers whose skills were in demand in Japan. At the time Japan depended on imports from Korea to meet its need for metal. Copper was discovered in Japan during the medieval era, although historians disagree with one another by about a thousand years over when exactly the discovery was made. In any case, Japan had to import copper and iron to meet its needs during most of the medieval era; as the era waned, however, the Japanese were increasingly using iron smelted from sand mined from their rivers. This iron was considered particularly fine and was desired for making swords. The medieval Japanese used furnaces similar to those of China, and they made a very high grade of steel.

In medieval Japan steel was thought to carry within it supernatural power; each step in the process of making steel was part of religious ritual. Sword smiths wore ceremonial clothing and surrounded their workplaces with ropes of rice straw, just as shrines and sacred objects would be. What set Japanese smiths apart from others was their constant effort to innovate in how they worked with metal. Master smiths developed their own secret formulas for mixing alloys, working different grades of steel together to make tools or weapons, and annealing and quenching. One of the secrets of their steel's high quality was the annealing process. They not only welded soft steel to hard steel, as had the Chinese, but they also flattened out the welded steel and folded it, quenched it first in water and then in oil, reheated it, welded again, and then hammered, folded, and quenched it, eventually no longer adding weldings but continuing to fold and hammer, quench, heat, and fold and hammer again. Even an ordinary sword had more than 4 million total layers. Many swords had the added dimension of a casing of soft steel out of which the cutting edge of the layered blade protruded. Making the best Japanese steel objects was very labor intensive, and during the 1400s the demand for the export of swords to China resulted in a reduction of the quality of Japanese smithing

as smiths spent less time on each sword in order to produce more to meet demand.

## EUROPE

BY MARCOS MARTINÓN-TORRES AND THILO REHREN

The decline of the Roman Empire and the related weakening of the central authority that began in the third century led to a regional fragmentation of the metallurgical industry. Although miners and smelters continued to serve local needs, they generally worked at a small scale, leaving little room for technological innovation. This decline affected particularly silver, lead, copper, and tin; iron and steel were still necessary for axes, knives, spades, and plowshares. Not until the ninth century, when the political situation became relatively more stable, did the metallurgical innovations associated with the Middle Ages start to appear.

A few books of the period illustrate the metallurgical knowledge of the time. The most important is *De diversis artibus* (On Divers Arts), written by Theophilus (d. ca. 1125), a Benedictine monk interested in many crafts. The book provides detailed instructions on building furnaces and technical descriptions of processes such as copper smelting and refining, silver cupellation (refining in a cup), manufacturing gold foils, refining by amalgamation, brass making, tin soldering, bell casting, and iron welding. Textual information gathered from the archaeological remains of mines, workshops, and metal objects provide clues regarding the technology, skill, and trade of the metallurgist.

However, little was written about iron and steel, the main metals produced and used throughout the Middle Ages. Archaeological evidence shows that the direct or bloomery process was used ubiquitously to produce lumps of soft iron (blooms), which were then carburized (combined with carbon) if steel was needed. Suitable iron ores were available almost everywhere: bog ores in the wetter climates of northern Europe and siderite, hematite, and other rock ores as well as lateritic surface formations in drier regions. The diversity of ores and cultural traditions led to regionally different furnace types, but the ubiquity of iron ores meant that most demand was met by local or regional production. The high demand for charcoal in iron smelting resulted in exploitation of surrounding woodlands, and woodland management, primarily coppicing (cutting back to encourage regrowth) and rotating, became necessary to sustain production.

The heart of medieval nonferrous metallurgy was in areas of central Europe that were rich in ores, timber for charcoal fuel, and streams for transport and hydraulic power. Particularly productive areas were the Black Forest, the Harz mountain range, Saxony, Bohemia, Silesia, and Hungary. These

regions were progressively colonized by Flemish, German, and French settlers, who became the most renowned metallurgists of their time. Beginning around the ninth century the rich mines of Hungary were smelted by captives under the rule of Charlemagne. The discovery of rich silver ores in Freiberg, Saxony, in the 12th century led to a “silver rush” and the subsequent development of a full metallurgical town with some 30,000 inhabitants. From mountains in the Harz range, including Rammelsberg and Mansfeld, ores were exploited for silver, copper, zinc, and lead; however, Stora Kopparberg in Sweden became a serious competitor in the 14th century.

Important metallurgical centers also developed outside central Europe. In England, for example, tin production in Cornwall rose steadily, reaching an average of 700 tons a year in the 14th century, and the silver mines of Devon were leased by wealthy Florentine investors. Lead production was also very important in England, reaching levels comparable to those of central Europe. In 1316 lead ores containing silver were discovered in Languedoc. Other important silver and copper ores were exploited in the Alps. Zinc ores in the Meuse Valley and elsewhere were utilized for the production of brass, an alloy of copper and zinc that was increasingly used for household implements as well as civil and ecclesiastical

furnishings. This led to a steady rise in the demand for copper. Other important metals in the period were pewter, an alloy of lead and tin used by the middle classes for tableware and jewelry, and caldarium, a heavily leaded and impure copper obtained as a by-product of silver extraction by liquation and used for cauldrons and other large domestic vessels.

Casting church bells posed important technical challenges because the molds were much larger than those used for any common object, and the high-tin bronzes employed resulted in objects that had a very fine sound but were extremely heavy and fragile. The first large bronze bells were cast in the eighth century, and in the following centuries they became widespread in western European churches. The experience of itinerant bell founders became crucial when, following the invention of gunpowder, the first bronze cannons and cannonballs were cast.

The need to produce arms and armor prompted both ornamental and practical improvements in metal manufacturing. Techniques for gilding shields and helmets and improved methods of metal inlay in general were introduced from the East. Since the seventh century Western metallurgists had developed a peculiar technique of pattern welding, forging together strips of steel and soft iron to create very sharp and durable swords and other weapons. Their products were in demand even in Arab countries but did not reach the quality of the damascene blades made from central Asian crucible steel. Bronze firearms and cannons came into use from the mid-14th century in Germany, but within a few decades they were replaced by cast iron.

Mints and alchemical laboratories were important focal points for developments in analytical chemistry used in metallurgy. Both the need to meet a legal standard for coin composition and the practical experiments in transmuting metal triggered significant improvements in refining and analyzing chemically inert metals and the discovery of mineral acids.

One of the most important technological innovations affecting medieval metallurgy was the use of waterwheels to power bellows and hammers. In most cases this advance was sponsored by the initiative of monastic orders. Waterwheels used for bellows are first recorded in the 11th and 12th centuries in the Alps, Silesia, and France, and there is evidence for their use in Germany beginning in the 13th century.

The impact of water-driven bellows was particularly noticeable in the iron and steel industry, where larger furnaces could operate at higher temperatures. As a result, metal extraction became more efficient, and production from previously unsuitable ores increased significantly. However, the larger furnaces consumed fuel at a much higher rate, further increasing the pressure on the available woodlands. The new process first produced high-carbon pig iron, which was then

*Knight on horseback, the earliest hollow-cast pewter figure known in England and one of the earliest examples of a mass-produced medieval metal toy; Britain, ca. 1300* (© Museum of London)

decarburized in a fining hearth to produce malleable wrought iron similar in quality to the earlier bloomery iron. This technology not only increased production but also gave smelters better control over the carbon content of the iron. Consequently, some smelters could produce carbon-free wrought iron, low-carbon steel, or high-carbon cast iron, depending on the intended application. However, archaeological remains throughout Europe show very significant regional variations in metalworking technologies, depending on local traditions and environments, demand and production scales, and technical knowledge. For example, steel was produced both by decarburization of cast iron and by carburization of bloomery iron in a process called cementation.

Among the improved furnaces are the Catalan forge, used in parts of Spain and France; the Osemund furnace, used in Germany and Scandinavia; and above all the Stückofen, used in central Europe, the Alps, and eastern France. The Stückofen reached 13 feet in height and yielded pieces of wrought iron weighing about 815 pounds in 1430 and 1,320 pounds by the end of the 15th century. The output of the improved furnaces was 40 to 50 tons a year, about three times that of more rudimentary furnaces. Mechanical hammers powered by waterwheels and weighing up to 3,525 pounds were used to forge the iron.

The use of fossil coal rather than vegetal charcoal as a fuel, first introduced in the 12th century, came as a partial solution to the insidious deforestation, and it was widely employed in forges in England, France, the Low Countries, and Italy. Being much stronger than charcoal, mineral coal also could be used in larger furnaces. Ultimately, the availability of waterpower and coal led to the development of blast furnaces, much larger and more efficient than the older bloomery furnaces. Still, even though bigger furnaces were in use in the 13th century, they did not function on a large scale until the 15th century, and charcoal remained the main fuel for smelting until the advent of the Industrial Revolution. Traditional bloomery smelting remained the typical iron-production technology throughout the medieval period.

The huge scale of medieval metallurgical industries and their impact on the European economy were primary factors behind the development of new middle classes, such as the merchants and bourgeoisie, and increasing labor specializations, such as charcoal burners, miners, smelters, iron founders, and bell founders. Miners' and metallurgists' guilds gained increasing control of their trades through negotiations with emperors, kings, and civil and ecclesiastical patrons and lords, who typically owned the natural resources and kept an important share of the profits. The monetary system also developed in this period, and metal prices were adjusted by the law of demand and supply.

From the second half of the 14th century, the Black Death (1348–50) and the Hundred Years' War (1337–1453) resulted in a shortage of labor and a general decline in the production of metals. Widespread deforestation added to this crisis in the industry. Despite legislation intended to prevent it, charcoal and metal prices increased sharply as workers left smelting industries in favor of the farms.

Around 1450 the industry began showing signs of a recovery. However, the richest ore deposits in the Harz mountains, Saxony, Bohemia, Hungary, Alsace, Sweden, and Cornwall had been exhausted, and poorer and deeper deposits had to be exploited. A major development was the invention of liquation to extract silver from copper ores, significantly increasing the supply of silver in central Europe and changing the economic landscape for many copper and lead producers. Larger technological investments became necessary for draining mines and assaying ore samples to guide subsequent exploitations. Because smaller operations could not face these economic and technical challenges, centralization and capitalization became necessary. Larger smelting installations were created, with external investors financing the maintenance of the more efficient technologies and mechanical power. Capital and labor were thus progressively separated as mining and metallurgy entrepreneurs emerged to provide the funds without being involved in the practical exploitation of ores and metals.

Nonferrous metals were traded across the continent on a large scale from markets such as Nuremberg and Venice, leading to the rise of merchant families, among them, the Fuggers and the Turzos. At the same time learned metallurgists such as Lazarus Ercker (1530–94) and Georg Agricola (1494–1555) started to bridge the divide between metallurgical practice and intellectual education, thus paving the way for more efficient metallurgical engineering and a more empirical understanding of nature that would contribute to the rise of modern science.

By the end of the Middle Ages, German metallurgists were increasingly renowned and sought internationally as the experts of their time. German specialists and their metallurgical tools such as crucibles are documented in France, Scandinavia, England, and later in the New World colonies. The prosperity of European metallurgy lasted only until 1530, when the stream of precious metals from America and a crisis in credit led to another upheaval of the industry.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

The products of metalworkers in the medieval Islamic world were famous throughout Asia and Europe. Damascus steel swords were legendary for their suppleness and toughness.

Inlaid objects were coveted for their brilliance and beauty. The achievements of the Islamic world's metalworkers came from a synthesis of foreign and local knowledge as well as materials and from a passion for excellence revealed in the graceful outlines even of everyday dishes for ordinary people.

Most of what survives is brass. One reason for this is that objects made of gold or silver were commonly melted down so that their metal could be reshaped to suit the latest style fashions, and they were often melted down for the minting of coins. The other reason is that brass objects were so well made and so beautifully decorated that they were in high demand not only throughout the Islamic world but also in Europe. Brass itself was not so valuable as to make it worth someone's while to melt it down, but brass objects were manufactured in enormous quantities, making brass a metal that archaeologists have found almost everywhere in the Islamic world.

People in the Arabian Peninsula had been smelting copper since about 300 B.C.E. By the 500s C.E. their smelting techniques were fairly complex. Metallurgists set up their furnaces at the locations of copper mines, even living with their families at the sites of their work. One site in Oman was organized by household, with each house corresponding to smelting pits and furnaces that may have been used exclusively by members of the family of the household. Most sites do not show such correspondences. Arabian metallurgy may have reached its height in skill and productivity in the mid 800s to the late 900s. In the mid 900s mining and smelting sites were abandoned, perhaps because nearly all the surrounding trees had been felled to provide wood for the fires the smelters needed. Some archaeologists have speculated that the felling of trees in Oman for smelting resulted in an ecological catastrophe in which fruitful land became desert because of the loss of trees. Mining and smelting restarted in the mid 1100s but on a much simpler basis.

Typically, copper ore was placed on stone slabs and then hammered, probably with large stones. The crushed ore was placed in pits lined with clay, surrounded at their edges by stone, and containing burning charcoal. The resulting mixture of copper and slag was then placed in a furnace. Furnaces were typically built on slopes, sometimes with leveled platforms in front of them where metalworkers stood. Furnaces were 4 to 5 feet tall and about 18 inches wide. Their shafts were lined with mortared stone. The previously roasted ore was poured into the furnace from the top. Bellows attached to pipes were used to pump air into the furnaces to keep their fires hot. When mining and smelting revived in the 1100s, furnaces were just shallow concave circular pits in level ground, lined with stone.

When Arabs conquered the Near East and North Africa, they tended to follow the practices of Byzantine and Sassanian

*Canteen; brass with silver inlay, Syria or northern Iraq, 13th century* (Freer Gallery of Art, Smithsonian Institution, Purchase, F1941-10)

metallurgists. The status of metalworkers varied according to region. In western North Africa, metalworkers were classified the same as butchers—as people without shame. Thus metal shops in cities tended to be located in the worst parts of town. Metalsmiths in North Africa often were Jews, some of whom had migrated south of the Sahara, bringing their skills and knowledge to Mali and other African cultures. On the other hand, the skills of metalworkers in Syria and Iran were admired, and they frequently were rewarded with important government posts.

The two metal products for which Islamic medieval metalsmiths are nowadays most famous both have the description of “damascened,” which can be confusing. Inlaid metal objects were called *damascened* because European traders first encountered them in Damascus. Linguists are not entirely in agreement as to why a certain type of high-quality steel also came to be called *damascened*, but it is likely that the name was attached to Damascus swords, which were made of Damascus steel. This steel was probably called *Damascus* because European traders first bought the swords in Damascus.

Copper was mined not only in Arabia but also in the regions of modern-day Pakistan and Afghanistan, and it may have been imported into the Islamic world from sub-Saharan

Africa and India. Metallurgists combined the copper with tin, which was usually imported, and zinc to make bronze and brass, respectively. The finest brass of the medieval world may have been manufactured in Lahore and other locations in modern-day Pakistan. Finding a good way to mix zinc and copper to create brass was a challenge in medieval times. Often, brass was an inconsistent mixture of copper and zinc, with the two metals bonded together in a process of annealing and hammering. In the region of present-day Pakistan, metalworkers figured out how to melt copper and zinc together into liquids in a process archaeologists are still learning about. Perhaps the metalworkers used crucibles similar to ones used in India. The resulting alloy was over 33 percent zinc and required no annealing to make it brass; it emerged from furnaces so well mixed that metalworkers could cool it in thin sheets without the need for hammering.

This brass had many functions. It was used to make scientific instruments and is best known as the metal used to make the plates in astrolabes and other astronomical instruments, but it was used for scales and surgical instruments as well. The brass became part of everyday life in the Islamic world, turned into simple plates, cooking utensils, lamps, and other common objects. The metallurgists became so adept at making the alloy that they could vary the percentage of zinc in it to create different effects in the finished product. For instance, they would increase the percentage of zinc to make a brass that when polished had a brilliant sheen that resembled gold. This meant that people who could not afford gold still could have objects in their homes that had the luster and beauty of gold.

Inlaying metal objects was a craft in itself, apart from smithing. Smiths and casters would make objects that would then be given to inlayers. Both casting and smithing techniques resembled those of India and the Byzantine Empire, with India's techniques slowly becoming dominant from Islamic India to Egypt. There were two ways that medieval metalworkers of the Islamic world inlaid objects. Both were borrowed from India and China but were brought to their height in Iran. The first was introduced to the Islamic world through eastern Iran, which produced fine inlaid objects throughout the medieval era. A sharp-edged steel tool was used to gouge images into the object's surface. Sometimes acid was used to deepen the scratches. Then wire or metal sheets were applied to the scratches, usually wire for copper and silver and sheets for gold. This was a laborious process begun by pressing the wire or sheets into the scratches and then using awls and punches to fix the inlay into the object's surface. When this process was completed, the object was reheated to perhaps 1,400 degrees Fahrenheit to fix the inlay in place, after which the object would be polished. Although

most inlaid objects were brass, some were iron, steel, bronze, copper, silver, or gold. Precious and semiprecious stones were sometimes fixed in the object's surface.

The other form of inlay was faster and less expensive but yielded a less satisfactory product. This involved roughening the surface of a metal object so that it was covered by shallow incised lines and pits. These incisions and pits would hold inlaid metal no matter what pattern was used, so an image could be drawn on the surface to be followed by inlaid metal, or the metal inlay could just be applied freehand to form patterns or images. The inlay was mostly sheets of very thin metal that were pressed or tapped into place using punches and hammers. The principal drawback to this technique was that the inlay tended to peel off the surface over time. It became a common form of inlay in the Islamic world during the last few centuries of the medieval era.

Damascus steel swords were recognizable by the wavy patterns on their blades. These patterns probably resulted from a refining process that produced carbon nanotubes (microscopic tubes, with a diameter measured in nanometers) that swirled during the annealing process. The steel came from India. Modern-day archaeologists and metallurgists have long debated how the steel acquired its toughness and flexibility and have proposed several possibilities. In general, they agree that Damascus swords were the best weapons in the medieval Islamic world, perhaps equaled or surpassed by some swords in China but truly surpassed by swords made in Japan. Iron from some Indian mines contained trace amounts of vanadium, at about 0.003 percent. It is possible that the vanadium helped the carbon nanotubes remain smoothly mixed in the iron rather than clustering in brittle clumps, and it may have prevented the carbon from becoming graphite, which would have deprived the steel of its toughness.

Steelworkers moved from Iran through much of the eastern Islamic world. The Mongol invasions of the 1200s caused some to flee their homes in Syria and migrate to North Africa and al-Andalus. The finest manufacturers of steel products seem to have been Yemen and Syria, but the details of how they turned Indian iron into Damascus steel do not seem to have been recorded, perhaps because working with steel tended to be a hereditary occupation with its techniques passed on as secrets from one generation to the next, thus ensuring the future prosperity of the family. Steel was occasionally cast to make objects, but it seems to have usually been worked by smiths. The process for making Damascus steel resembled processes used in China and Japan. The steel from India, now known as "wootz steel," was heated, hammered, quenched in water or other liquids, heated, hammered, and quenched again until it had the desired shape. In the case of a sword or knife, this was a narrow bar. This process seems to

have created layers of vanadium that developed during cooling. This process yielded a very sharp, durable edge.

Some smiths seem to have welded wrought iron to the steel. Wrought iron is iron with .06 percent or less carbon. It is soft, flexible, and relatively easy to shape. The wrought iron would be welded to the steel bar in a furnace, then the bar would be folded on itself, hammered, quenched, reheated, folded, hammered, quenched and so on. The wrought iron could make the blade more flexible. In any case, the flat sides of the blade would have iridescent swirls caused by the carbon nanotubes. Smiths in Afghanistan and perhaps elsewhere became so adept at working with Damascus steel that they could choose special patterns of swirls by how they heated and quenched the steel.

## ► migration and population movements

### INTRODUCTION

In the Old World the concept of the Middle Ages as a distinct period in history was conditioned by a series of migrations that fundamentally changed the demographic, cultural, and political shape of Eurasia and Africa. The most important of these migrations, the one that brought about the collapse of the Western Roman Empire and initiated the Middle Ages in their narrowest and original sense as post-Roman European culture, was the out-migration of Hunic and Turkic peoples from inner Asia. This process, which was not completed until the 13th century, had even more far-reaching effects than the fall of Rome. It changed the entire political and cultural geography of Eurasia.

The Huns and Turks lived as nomads tending herds of horses and other domestic animals in the vast area of steppes between Europe, India, and China. They had no settled homes or country and followed their herds, wandering hundreds or thousands of miles a year and living in tents and wagons. Accustomed to the life of the steppe, the peoples of inner Asia produced the finest cavalrymen in the world. The steppe tribes usually had little trouble attacking and overcoming more settled populations when they wished. In the Middle Ages the steppe tribes gained a tremendous advantage through adopting the stirrup. It made their way of life virtually living in the saddle far easier and made them still more effective as cavalry fighters. The history of the stirrup is not well understood. There is evidence that a loop for the rider's big toes was used in India in ancient times. Other evidence suggests a true stirrup may have been invented in China. However, it was used in the Kushan Empire in inner Asia by the second century C.E. and spread quickly from there to the nearby nomad populations.

Why the medieval migration took place is far from clear, but Hunic raids against China were heavily repulsed as early as the first century. By the early fourth century Huns were in the Ukraine, and in 392 they had conquered the Kushan Empire on the southern fringe of inner Asia, but the decisive wave of migration was to the west. The Huns initially displaced Iranian-speaking Sarmatians and Alans from the steppes of the Ukraine and Caucasus. Turned back from Gupta India also, they brought more pressure to bear on the Germanic tribes in the West, both the nomadic Visigoths in the Ukraine and eventually those in the German homeland between the Vistula and Rhine and all the way to the borders of the Roman Empire. This caused a flood of displaced Germanic peoples into the empire that broke up the Western Roman Empire. Attila unified a state among the Huns and Germanic peoples in Europe and raided the empire himself as far as Orléans (in present-day France) and Rome.

Turks followed hard on the heels of the Huns out of inner Asia and entered in large numbers into the Islamic Empire, especially as mercenaries, though without losing their tribal identities. The Seljuk and then the Ottoman Turks came to rule the center of the Islamic world. The Ottomans, in particular, expanded their rule into Europe, conquering the Byzantine Empire and capturing Constantinople in 1453 and eventually advancing to the gates of Vienna (in present-day Austria). Other steppe nomads, the Magyars, who spoke a Finno-Ugric language, invaded Europe in the ninth and 10th centuries and contributed to the chaos of the period.

The last great wave of out-migrations from inner Asia was the Mongols under Genghis Khan. He and his successors conquered an empire that endured throughout the later Middle Ages and stretched from China to include all of inner Asia, Iran, the Near East as far as Baghdad, Russia, and much of India. Mongol forces had won victories in the region of today's Poland and conquered modern-day Hungary and were preparing to attack western Europe. Except for the death of the Great Khan Ögedei and a recall to Mongolia to elect his successor, the planned campaign to reach the Atlantic may well have succeeded. In the 14th century Tamerlane, a Mongol nobleman (leading a mainly Turkish army), conquered northern India, and his successors in the Mogul Dynasty later overran nearly the entire subcontinent.

The nomadic horse-breeding tribes of Arabia also had an out-migration that helped to condition the formation of the medieval world. Their rapid conquests in the mid-seventh century from inner Asia and northern India through the entire Near East and across north Africa to Spain spread Islam as one of the great world religions and Arabic as one of the world's most common languages. They entirely absorbed the

Sassanian Empire and took half the territory of the Byzantine, or Eastern Roman, Empire.

The cultures of Africa and of Polynesia also took on new characters during the medieval period as the result of migration. Bantu-speaking peoples spread over southern Africa from their homeland somewhere in the Congo basin, completing their movements by 400 C.E. They supplanted or absorbed existing cultures and spread agriculture, pastoralism, and ironworking into areas where many of the previous inhabitants had been hunter-gatherers. Also in about 400 a new wave of Polynesian migration moved out across the Pacific, reaching Hawaii and New Zealand. A few may have ventured as far as the coast of North America; that, at least, is one explanation offered for the presence of domestic chickens in the pre-Columbian Americas.

In North America, Athabascans and farming tribes from the Great Basin moved south throughout the Middle Ages, displacing many tribes, including the people who eventually settled in the basin of Mexico and became the Aztec. Many tribes have legends of extensive wanderings in the past, but the era in which this occurred cannot always be easily determined. Most migrations in the Americas during the Middle Ages were on a very small scale of population and often quite slow.

## AFRICA

BY CHARLES W. ABBOTT

Migration and population movements characterize Africa as far back as our knowledge extends. Generalizing about medieval times is a challenge because written records are scarce and patchy during most of the period. Only the regions of Egypt and the Nile Valley corridor have abundant written records dating back to 500. These same regions have been studied most intensively by archaeologists as well. Arabic language documents begin to mention Sudanic states such as Ghana sometime around the year 800. Except for the Swahili coast, we have almost no written information about the southern half of Africa until the coming of the Portuguese. Written history being nearly blank, our knowledge about much of central and southern Africa is based largely on linguistic and archaeological evidence.

It is tempting for us to focus on empires, large states, big events, and well-known ethnic groups, but by doing so we impose our own biases on events. The glory of major states often meant suffering for their neighbors, and in speaking of Bantu peoples, or Berbers, or Nilotics we may imagine uniformity when Africans who lived through these times saw variety, identifying with close kin groups and experiencing conflict with those just like themselves.

## A HISTORY OF MOBILITY

The African setting provides some peculiarities relative to Eurasia, distinctions that set the context for a discussion of population movements. There were few economically valuable “hearth areas” in sub-Saharan Africa comparable to the Fertile Crescent. The Fertile Crescent hosted sophisticated urban civilizations for thousands of years, as did China’s great river valleys. In those areas individual communities might suffer war and conquest, but the urban fabric endured or was quickly restored. Even in Europe many cities date back to Roman times. In contrast, Africa seems to have always been a thinly populated continent with few urban hearths that endured permanently. Large-scale irrigation south of the Sahara was unknown outside a few favored settings such as the Niger River’s inland delta (in present-day Mali), and rains were uncertain.

In *States and Power in Africa*, Jeffrey Herbst summarizes the issue: Land was abundant; it was people to work the land who were scarce. Much of the land had low productivity and was prone to drought or soil exhaustion—it wasn’t great land, but there was plenty of it. In most places the ox-drawn plow was rare or nonexistent; instead, people worked the land with hand tools. Low productivity, poor soils, and variable rains combined to make it hard to maintain large numbers of people in one place (to inhabit a city permanently, for example). African states often based their power not on control of valuable agricultural territories but on control of long-distance trade routes. With land abundant relative to people, property rights in people were well defined. Much of the labor market was not a system for wage labor; it was instead a market for slaves. Throughout Africa family ties were conceptualized and described in extremely elaborate terms. Kinship provided a key method for mobilizing labor, maintaining cooperation, sharing risk, and protecting oneself from outsiders.

In such circumstances people were relatively free to flee bad conditions or to move toward good ones. Cities might hold large populations for a time, but such settlements periodically appeared to outlive their usefulness. We can discuss migration in terms of “push-and-pull factors.” Push factors drive people away; they are conditions such as drought, sickness, and war. Pull factors draw people closer; they are conditions such as peace, abundant resources, and just rule. Africans were sensitive to these factors, and often they moved quickly in response to them rather than stay put. Pull factors might aggregate people in one place, but often push factors dispersed them again.

Despite migrations, linguistic evidence indicates that most communities remained small. From our present-day perspective, sub-Saharan Africa is home to about 12 percent

of the world’s population but hosts roughly 29 percent of the world’s 6,912 living languages enumerated by *Ethnologue*, an encyclopedia that catalogs known living languages. Such linguistic fragmentation implies a corresponding political fragmentation—the tendency for many people to live their lives within small communities, indifferent to empires or bigger states. Large empires tended to rise and then fall, but it was the kin group and the local community that mattered.

We can distinguish between pastoralists and cultivators. Pastoralists specialized in caring for and herding large animals; cultivators specialized in planting, weeding, and harvesting crops. In Africa these specialties were sometimes performed by separate groups that belonged to different cultural and political communities. Relations between pastoralists and cultivators were often good—the two groups had complementary livelihoods and a strong incentive to trade with one another (milk for grains or pasturage in crop stubble for the manure left by herds). With respect to population movements, pastoralists are of special interest because they found it easier to migrate over long distances in short periods of time; cultivators moved more slowly.

If pastoralists were prone to move long distances quickly, some (but not all) cultivators were prone to move shorter distances. Scholars often distinguish between “shifting cultivation,” in which farmers actually relocate their dwellings as they exhaust local soils, and “bush fallow,” in which fields are abandoned for long periods to restore fertility, while farmers continue to reside in a permanent settlement. Shifting cultivation facilitates mobility—households relocate periodically in any case, and they may continue to move in the same direction indefinitely. If a farm hamlet moves 2 miles every two years, it can move 100 miles in a hundred years, or 1,000 miles in a thousand years.

## POPULATION DYNAMICS

As the medieval age dawned in Africa, most Africans lived in small, close-knit communities. Farming peoples lived in dispersed households or small villages; hunter-gatherers and pastoralists were more mobile and often lived in temporary encampments. Pastoralists might associate themselves in small bands that split up and regrouped periodically during the year as they moved with their herds to find good pasture. Egypt was the most populous place in all of Africa. It was largely a Christian land, and its people still spoke Coptic (ancient Egyptian) not Arabic. The Sahara may have been smaller than it is in modern times, and its fringes may have been wetter.

By 400 a process called the Bantu expansion had drawn to a close. It left most of Africa south of about 5 degrees north latitude inhabited by peoples who spoke languages in

the Bantu family. The peoples associated with the Bantu expansion made iron tools, practiced farming, and knew cattle husbandry. The expansion apparently was not the result of simple migration; it probably resulted from a combination of migration, intermarriage, and the spread of technology and culture over several thousand years. The recently arrived Bantu speakers were not alone in their region of Africa, since preexisting communities speaking languages in the Khoisan language family remained in southwest Africa, and Pygmoid peoples who continued to practice foraging remained in isolated pockets. The expansion is of great significance to us because in the absence of written records, linguists detect more recent migrations by subsequent disturbances of a largely Bantu linguistic landscape.

### EGYPT, THE NILE CORRIDOR, AND THE HORN OF AFRICA

The human record (historical, linguistic, and archaeological) leaves an impression of the development of shifting states and centers of power as the medieval era progressed. One visible change was the Islamization and sometimes Arabization that proceeded from the Middle East after Arab armies conquered Egypt in the years 639 to 642. Arabs did not replace the previous inhabitants of Egypt and did not move into Egypt in large numbers. Instead, over time, the Egyptian language (Coptic) became relegated to a local and household language; Arabic became a language of higher status and was mandated for most public purposes. After 650 peoples as far distant from Arabia as Morocco, Mauretania, and Sudan slowly became progressively Arabized, a process that continues in Africa up to the present-day. Other communities became Muslim without being Arabized—Berbers of the Maghreb and Sahara and Somalis of the Horn of Africa became Muslims without becoming Arabs. Thus our understanding of migration requires careful analysis. One language community can replace another through war and the flight or domination of the vanquished. Alternatively, a group can remain in the same place and undergo linguistic conversion.

The Nile Valley and its corridor had historically served as a “bridge” for migrations between Egypt and the rest of Africa. Nubia (the area of the Nile Valley between the first and sixth cataracts) was the home of ancient kingdoms such as Kush and Meroë, and it remained Christian for hundreds of years after the Arab conquest of Egypt. Nubia’s forces were finally defeated militarily by Egypt under the Mamluks after 1260; this opened the upper Nile to Arab invaders and camel-herding pastoralists. One eventual result was the isolation of highland Ethiopia, which had become Christian around the year 500. Following the fall of Nubia, Ethiopia became an island of Christianity surrounded by Muslim peoples

(Arabs, Somalis, and the peoples previously called Galla and now known as Oromo who moved out of Somalia, harassing the Ethiopian highland peoples). The Nile corridor became a pathway between the Muslim Middle East and the states of the Sudanic zone. After the conversion of Sudanic Africa to Islam, the Nile became one pathway for the pilgrimage to Mecca as well.

### SUDANIC STATES

As the Middle Ages progressed, we find clear and abundant evidence of large imperial states in the Sudanic zone, that is the band of savanna between the Sahara and the equatorial forests. Ancient Ghana, then ancient Mali (neither should be confused with the modern-day African countries of the same names), and later Songhai were three of the largest such states. These states served the trans-Saharan trade, as did the later-arising Hausa city-states (such as Kano, Katsina, and Zaria), Kanem-Bornu, and Darfur.

Sudanic states influenced population movements in four ways. First, they structured space in a particular way, providing law and order (if not equality and democracy) for the relatively large numbers of people who were governed by them in their core territories. The concentrations of people within the core territories represented agglomerations of market demand, agricultural and craft skills, political power, and military might.

Second, such states were foci for long-distance trade, and they attracted foreign experts of all kinds. Foreign merchants journeyed across the Sahara for trade, and by the 800s these trans-Saharan merchants were usually Muslims. The Sudanic states were thus incorporated into an Islamic system, facilitating the migration of specialist scribes and clerics. Sudanic states had market niches for specialists of various sorts, such as healers, court historians, teachers, and military advisers. In this sense, we are reminded that there are various types of migration. We may think first of all of the migration of peoples en masse, but also noteworthy is the migration of specialists.

Third, the Sudanic states tended to have predictable impacts on their neighbors. They were politically well organized and militarily powerful, and they thrived in part by enslaving their neighbors. The Sahara was almost empty, but nearby and to the south of the Sudanic states were various peoples who became prone to enslavement; often they were from numerically small and politically unorganized groups who were unevenly matched against Sudanic armored cavalry. The capture and enslavement of neighboring peoples itself produced migration (in this case forced migration); slaves were forcibly transported hundreds of miles from their place of origin so that escape through flight was nearly impossible. Some enslaved persons were sold across the Sahara to North Africa;

some toiled in open-pit salt mines within the Sahara. Some, such as eunuchs, attendants, or soldiers, became court slaves of inestimable value to kings or elites. As the Sudanic states' harried neighbors struggled to defend themselves, they often evolved into tributary states, protecting themselves from raids by paying tribute with slaves that they themselves went and captured from farther away.

Such tributary status was facilitated by conversion to Islam. Islamic thought and culture distinguished between *dar al-Islam*, lands under Muslim rule where peace should prevail, and *dar al-Harb*, lands under non-Muslim rule where war and raiding for plunder was legitimate. Slave raiding affected not only those persons captured but entire societies as well. Those persons who were not captured often migrated away from open landscapes favorable to horses, retreating into settings unfavorable for cavalry, such as dense forests, rugged terrain, or swamps. In this way each Sudanic state concentrated power in its core territory south of the desert, but it emptied out some lands on its fringe as vulnerable neighbors fled from its predations.

Fourth, as the Sudanic zone became Islamized, Sudanic cities became nodes on the path of the hajj, the pilgrimage to Mecca. The hajj was physically demanding—most routes followed one of several paths north across the Sahara, while eventually an eastern course developed that ran past Lake Chad through Darfur, traversing semiarid lands but skipping nearly all of the Sahara proper. Even if Sudanic peoples made the hajj, it provided a means for the transmission of information, technology, ideas, and news about the wider world. The hajj linked Sudanic Africa to the medieval Middle Eastern empires that were for hundreds of years the largest and most sophisticated states outside China.

## FORESTS AND SOUTHERN REGIONS

The Sudanic states exemplify state formation on a larger scale, and their impacts on population movement were considerable. In the forests to the south we see similar dynamics on a much smaller scale. We see differences as well, because several factors contributing to the vitality of the Sudanic states and their impact on population movements were absent in the forest. To begin with, Sudanic states were termini for trade routes across the desert to North Africa, channeling the North African demand for such products as gold, ivory, and slaves. In addition, the Sudanic zone was free of disease-bearing tsetse flies that sickened and killed camels, horses, and cattle, and the use of cavalry favored the expansion of large states. This advantage of cavalry faded out in the forest zone, where horses and camels quickly sickened and where dense vegetation checked their maneuverability and favored defense measures and the ambush of invaders.

South of the Sudanic belt proper lay a transitional zone—what in Nigeria is called the middle belt, and farther west in present-day Ghana was the land of the Mossi states. In this zone a variety of small monarchical states imitative of the large Sudanic empires arose. Farther south lay the true forest, with a closed canopy of trees and tsetse flies deadly to horses and cattle, where the texture of life was different: more rain and food crops of yam rather than grains. Portions of the western forest generated states and kingdoms of their own, such as Benin, Asante, and Ife. These states, especially in gold-producing portions of the forest, were linked by trade to the Sudanic states. Besides gold, other valuable commodities were slaves, ivory, and kola nuts.

The trade networks in many places represented an ethnic diaspora—they depended on the strategically scattered presence of coethnics who had left their home areas and settled elsewhere as strangers to do business. In present-day Nigeria many of the traders were Hausa-speaking Muslims; in modern-day Ivory Coast they were often Dyula.

Some places in the forest belt of western Africa, such as Iboland (southeast Nigeria), were honeycombs of autonomous local societies where most persons never traveled or migrated at all. The average person would have found it unsafe to leave his own cluster of villages—the area was a patchwork of village republics, each of which lived in a state of armed truce if not open warfare with its neighbors. The people of this area were “stateless,” meaning that they had no government above the level of a cluster of villages. In regions such as Iboland wealthy individuals joined politico-religious associations that enabled them to move unmolested between communities. In Iboland the Aro were one such group; they were not an ethnic group but rather a trading network with links to their sacred oracle at Arochuku.

A still different pattern yet holds among peoples of the Guinea Coast, such as the Biafada and Kru. They traveled along the Atlantic coast in large canoes, fishing, harvesting kola nuts, transporting trade goods back and forth along the coast, and sailing up coastal rivers to exchange with Mande traders who were linked to the trans-Saharan trade. After the Middle Ages Mande groups from inland successfully fought their way down the coast.

The central African rain forest that comprises much of the Congo basin made for relatively inhospitable territory. The area was thinly populated, and polities were quite small. Pygmoid peoples continued to dwell there as hunter-gatherers, even after the Bantu expansion. We might note that in major portions of central and southern Africa there was no local source of gold, no links to North Africa and the greater Muslim world, no horses, no camels, and no mounted warrior knights. The growth of states, with their internal security

## WHERE DID THE PEOPLE OF GREAT ZIMBABWE COME FROM?

The ruins of the city of Great Zimbabwe, once capital of an empire, have mystified and entranced people for hundreds of years. It was situated on the Zimbabwe plateau at the confluence of trade routes for gold, animal hides, feathers, and gems, and its people became rich and prospered. Historians generally agree that the people of Great Zimbabwe were Shona, people from woodlands hundreds of miles to the west who in the 1000s gradually expanded eastward all the way to the coast, where the city of Sofala flourished as a center for exporting gold and importing goods from across the seas. They expanded their range to the north to the Zambezi River.

The origins of the Shona are uncertain. They may have been of the Bantu language group, part of the centuries-long migration of Bantus from western Africa eastward and southward. They would have been just one of several waves of southward migration as Bantu farmers moved into central African rain forest only to abandon its poor soil and tsetse flies and only to be replaced by new migrants, while they themselves discovered that the open woodlands south of the rain forest also had poor soil and the tsetse fly. If this was so, their migration eastward may have been a matter of trying to survive by searching for richer and healthier lands.

On the other hand, the people of Great Zimbabwe brought with them a cattle-herding tradition. The capital city and its many satellite settlements had corrals for keeping cattle. This suggests either Khoi ancestry from South Africa or a different Bantu lineage coming from the Bantu descendants who migrated southward along the eastern coastal plain. Both had cattle-herding traditions. The Khoi were rarely farmers, but the people of Great Zimbabwe were. After the migrations of the Bantu cattle herders followed Bantus who were farmers. Both groups of Bantus could have spread westward into the heartland of the Shona to become the Shona, yet this does not entirely rule out the Khoi or other pastoral cultures of the interior. Those people who migrated south through the interior of Africa often settled among and intermarried with people who were already there. The Shona could have been a culture formed out of the mixing of cultures, forming their own tradition of mixed farming and herding.

and external predation, was on an altogether smaller scale. Enslaved persons were more likely to be retained locally or to be used as porters for loading trade goods.

In central Africa portions of the Congo River supported seasonal and permanent migration via canoe for harvesting fish; the surplus could be traded to peoples who lived far from good fishing. Farther to the east and south the area between the Zambezi and Limpopo rivers had resources of copper, gold, and ivory; it was also close enough to the trading towns of the Swahili coast to be integrated into the Indian Ocean trade system. It was this area that produced the community of Great Zimbabwe.

### PASTORALIST MIGRATIONS

One major example of pastoralist migration is that of the Fulani people, also known as the Fulbe. They are striking in appearance because of their tendency to be tall and light skinned, and all evidence indicates that they are indigenous to the Senegal River valley. Specializing in cow-based pastoralism, they have expanded their pastoral range century by century, moving into and over the Fouta Djallon highlands and thence ever eastward through the Sudanic zone. Becoming Islamized over time but often retaining an identity separate from their sedentary neighbors, the Fulani have always been

a minority relative to their settled neighbors; when inhabiting cities, they have rarely become farmers but often clerics, rulers, and judges. By 1500 they had reached the Hausa cities of northern Nigeria.

If the Fulani provide an example of a pastoral ethnic group remaining largely coherent in its migration, the general contours of a contrasting example appears in East Africa, where cow-based pastoralists moved south from the upper Nile valley into the interlacustrine (situated between lakes) region of East Africa. Waves of these groups moved into the Great Lakes area and farther south after about 1300; they appear to have spoken Nilotic or in some cases Kushitic languages. They interacted with the preexisting Bantu people of the area in a number of ways: disrupting, displacing, conquering, and being assimilated by them.

One key factor driving this migration was probably population pressure—not from people but from their cattle. Based on ethnographic knowledge of similar groups in historical times, we know that many ethnic groups viewed cattle as a status symbol and a durable store of wealth to be owned but rarely killed. In addition, many pastoralist groups had a segmentary lineage system that promoted external aggression to preclude internal conflict. A final element is an age-grade system and manhood ceremonies in

which young men were required to demonstrate their martial prowess. When these are combined, the result is societies of land-hungry cattle herders who are eager to find fresh new pasture before they start fighting among themselves. The vanguard of such a people is young men itching for a fight that they consider desirable and inevitable. Some of this is conjecture, though similar movements are documented in historic times. The primary evidence is archaeological, anthropological, and linguistic.

Aside from land-based migration and population movements, two seaborne movements bear mentioning. The first is that centered on the Swahili coast of East Africa, where seaborne traders traversed the coast, traveling as far as the Persian Gulf and India to establish Swahili cities. The Swahili cities were settled by a fusion of Arab and local African population. These cities served as trade links between the interior of East Africa and the Indian Ocean trading system, but they did not exercise much influence on the interior of East Africa, remaining relatively small, outward-looking cities.

Toward the end of the medieval period Portuguese mariners rounded the bulge of Africa for the first time. When they did so, they ended the isolation of the Atlantic coast of western Africa; from then on it would not be an isolated periphery of the continent, but one of Africa's links to the wider world. As maritime trade began to link Africa to the rest of the world, trading systems started to reorient themselves away from the Sudanic zone and the Sahara. Isolated coastal fishing villages on the Atlantic coast were fated to grow slowly into more substantial mercantile settlements. Some of their earliest new residents would be mixed race Portuguese-Africans and the growing number of Africans who moved to the coast in pursuit of trade.

## THE AMERICAS

BY LAWRENCE WALDRON

By the beginning of the Common Era most of the major migrations of indigenous American peoples had already taken place. From the first great Siberian crossing over the Bering Strait to the colonization of the Caribbean islands, these migrations had led to the emergence of hundreds of ethnicities. However, these groups seldom stayed put in the ecological niches to which they had first adapted. In the case of hunting-and-gathering societies, some American peoples would remain mobile well past the dawn of the Common Era, even into modern times. The development of agriculture by ancient Native Americans did not guarantee that nations would remain sedentary, since farming often could not match the diversity or quantity of food sources provided by the natural

environment. Additionally, climate changes, ecological collapses, warfare, religion, and long-distance trade all contributed to the dispersal of populations.

Several millennia after their first arrival, the original American groups were joined by newer waves of people making separate crossings from Asia. The ancestors of the modern Navaho and Inuit arrived in Alaska in the ninth millennium B.C.E. and 5,000 years later, respectively, adding to the thrust of internal American migrations. The former group, the Athabascans, would continue to migrate south, displacing other groups, well into the age of the Anasazi (ca. 900–ca. 1300 C.E.). Thus, numerous migrations within the Americas, coupled with the arrivals of new groups from Asia, caused many ethnicities to relocate from earlier homelands, sometimes more than once.

## NORTH AMERICA

Of the Americas, the most internal mobility was exhibited in North America, with its extremely wide range of populations, including many loosely organized groups of hunter-gatherers. The continent's hunter-gatherer migrations followed a seasonal cycle, as bands of Native Americans followed bison, which were themselves seeking out the greatest concentrations of edible grasses. Thus, groups from Saskatchewan to Texas behaved much like particles in a convection current, leaving one grazing expanse on either the north or south end of bison territory to follow the animals deep into the Great Plains or the Great Basin, then returning to their original territories the following year. With respect to these movement patterns, the archaeological record is sometimes difficult to read because groups occasionally used such different tools in the different parts of their migrations that they appear to be different peoples by the evidence left behind. Spear and arrow tips changed in shape and size as people moved from areas with more diverse game to areas where bison was the only source of meat. Nomadic groups also used different natural materials to make their tools, vessels, and clothing as they moved from one ecological environment to another. From remains in graves and trash heaps (called middens), archaeologists often can identify the times of arrival or dispersal of very large groups who used stone, clay, or bone implements. On the other hand, tracing the movements of groups who used biodegradable tools, weapons, and containers is much more problematic. In the case of the American Southwest a record of the great population movements has been preserved by the relatively dry and undisturbed desert environment, but in the wetter woodlands elsewhere in the United States and Canada, water activity, bacteria, and other agents have destroyed much of the evidence of early peoples.

Of course, not all groups in pre-Columbian North America were constantly mobile. The area that is now the United States in fact produced several different models of human settlement, some of which defy easy classification. Agrarian groups living along the Mississippi River and farther east are known to have mixed a settled, agriculture-based lifestyle with regular hunting and gathering. From the Adena, Hopewell, and Cahokia peoples to the ancestors of the Iroquois ethnicities, eastern Native Americans practiced a kind of occasional migration in and out of territory where they owned permanent homes, attended ceremonial observances, and raised children. Even after the introduction of maize as an essential staple sometime in the fourth or fifth century, Eastern Woodland peoples continued to migrate to the forests to obtain meat, fish, and other foods during some part of their yearly cycle.

Along the Pacific Coast from California to Alaska, fishing and foraging for nuts and fruit provided rich stores of nourishment to local residents. In fact, the wealth of this environment may have been the very reason that some groups remained mobile. New groups sometimes arrived from inland to compete for coastal resources, perhaps even waging war on and displacing the people already living there. In general, the abundant rich fisheries along coasts and rivers seemed to deter many Native Americans from settling down into agriculture, as the natural environment was able to provide for all the needs of the expert fisher-forager. The migration patterns of groups who practiced this lifestyle were far more conservative than those of their bison-hunting contemporaries deep inland but certainly more mobile than those of their neighbors just to the east, who were among North America's first maize farmers.

The farming lifestyle could be a fragile one, since changes in rainfall, frost, and snow could easily ruin crops. In fact, climate change had dramatic effects on the western United States and was one of the main forces driving rapid changes in lifestyle and settlement patterns. In the 13th century a drought brought on by the Little Ice Age seems to have caused several agrarian groups in the Great Basin area to abandon their sedentary lives and again become mobile. With masterly adaptability, many Native American groups simply moved farther south in search of better hunting, grazing, and gathering, as well as better vegetable-fiber sources for their clothing. However, every movement southward caused these migrating groups to come into direct competition or conflict with groups already there. War, intermarriage, and further migrations could all be results of these cultural collisions.

Historians have presumed that some of the Great Basin farmers migrated into the American Southwest, but even in this relatively dry region, one of the best in North America

for preserving artifacts, some migrations have proved very difficult to track. Many different groups arriving in a given area can greatly complicate the archaeological record. Also, the fact of a migration may be evident to archaeologists from the sudden appearance or cessation in the production of certain cultural artifacts, but the routes by which that culture left one territory and arrived in another might remain undiscovered. A lack of large numbers of skeletons might likewise assure scientists that a people did not die in one spot from disease or warfare but either moved to a certain unknown location or dispersed in various directions.

With a sudden cessation of artifacts and a lack of any apparent route of out-migration, the Anasazi of the Colorado Plateau are one of those peoples whose departure from their territory is of a nature undetermined by historians. The Anasazi were a powerful first-millennium culture spread out over the Four Corners region, with trade contacts as far away as Mexico and the Pacific Northwest. The disappearance of these enigmatic cliff-dwelling people seems to have coincided with the southerly migrations into their territory of several new linguistic groups, including the Athabascan-speaking Navajo. Not far behind the southbound Navajo and Apache were groups of Great Basin farmers, including the Ute, Paiute, and Shoshone, all fleeing the drought farther north. The term *Anasazi* is in fact a Navajo word meaning "ancient enemies," such that many archaeologists have drawn conjectures regarding the coincidence of Navajo arrival and Anasazi cessation.

The rapid decline and disappearance of the Anasazi in the early second millennium have remained a matter of great interest for archaeologists and anthropologists. They do not appear to have wholly died out from epidemic or warfare, although signs of war have been found in some Anasazi settlements. One possibility is that after being swamped by waves of northern newcomers who cut off their trade routes and access to natural resources, they may have simply abandoned their increasingly beleaguered towns and cliff dwellings and dispersed throughout the Southwest. They would have then reverted to small-scale agriculture and also may have intermarried with other peoples. Thus, the combination of migration and cultural shift would have caused them to essentially become a different people. The Hopi have always referred to the Anasazi as the *Hisatsinom*, meaning "ancestors," which suggests that some of the Pueblo Indians of the present day are descendants of the dispersed Anasazi.

## CENTRAL AMERICA

During the great population movements from the Great Basin to the Colorado Plateau and beyond, a humble group of hunter-gatherers left the Southwest and migrated even far-

ther south through the Mexican desert. On their journey they encountered many strange and beautiful ruins, the likes of which they may have beheld only at the southernmost Anasazi sites. These Mexican cities, known today as Teotihuacán and Tula, stood in ruins, their inhabitants having disappeared centuries earlier; they may have gone south as well. Perhaps inspired by the magnificent empty ruins, the wandering band of southwesterners finally arrived in central Mexico. There, they were repeatedly forced to move farther by rival groups until they finally settled in a swamp in the Basin of Mexico sometime in the 14th century. They would in time manage to drain the swamp, reclaim the land, and build the most magnificent city in central Mexico, the capital site of Tenochtitlán. In view of their mythic home in the American Southwest, a place they called Aztlan, they became known as the Aztec.

While the abandonment of the cities encountered by the Aztec on their way south is a matter of speculation, with archaeological work continuing at both Teotihuacán and Tula, the fate of the Teotihuacanos and Toltec is partially known. The inhabitants of Teotihuacán seemed to have exerted great cultural and possibly military influence on the Classic Maya as far south as Tikal, in Guatemala. The kings of Teotihuacán may have moved their capital south into the Mayan region or else demanded a sort of asylum there from their subordinate Maya regents after being expelled by the subjects of Teotihuacán. Such overthrows were known to happen in Mesoamerica following droughts, military defeats, and natural disasters, all believed to be punishment from patron deities.

The dissolution of Tula, like that of Teotihuacán, is couched in myth. Mexican and Mayan histories tend to agree that the city of Tula was abandoned sometime in the mid-12th century. In these accounts the Toltec king Topiltzin Quetzalcoatl had been expelled two centuries earlier by a local rival and had arrived at the Mayan city of Chichén in 987. Taking power there, he set up a dynasty that would give way to another northern invasion by an obscure people called the Itzá in the 13th century. Thus, over a period of four centuries the city now called Chichén Itzá lived through a succession of Maya, Toltec, and Itzá rulers, all of whom had migrated there from other parts of Mesoamerica.

Against the overall southward trajectory of American peoples from Idaho to Yucatán, only one major group seems to have moved northward—the Maya. Expanding, in fact, in all directions, the Maya seem to have emerged already fully formed as a nation out of Mesoamerican prehistoric time to become the most diverse, most powerful culture in the region's Common Era history. The influence of the Maya stretched far beyond their known migratory routes, although some of the migrations themselves were quite expansive. Evidence of Mayan contact has been found as far north as the

Mississippi Delta, as far south as the Andes, and as far east as the Caribbean islands, but these travels do not seem to have been conducted with the intent to settle. The Maya were an agrarian culture with a royal tradition of leadership that derived its authority from both military and religious power.

The only major migrations conducted by the Maya seem to have been the Late Classic (ca. 650–ca. 900) movements out of the Petén, the Mayan homeland in highland Guatemala, onto the flat plains of the Yucatán Peninsula, where they founded many great cities, including Uxmal, Rio Bec, and Palenque. As did many of the cultures that preceded and followed them, the Maya eventually abandoned their great cities after various environmental and military upheavals. Sometime between the 10th and 12th centuries they dispersed throughout the Central American rain forests. By the first landing of Europeans the Maya were too scattered to be summarily conquered. At that time they spoke more than 30 dialects and lived in small agrarian settlements from Nicaragua to Mexico.

## SOUTH AMERICA

Like the earlier Maya kingdoms to the north, the Inca of the 15th century were known to have covered vast areas, not in search of new homes but in attempts to expand the boundaries, influence, and wealth of their centralized kingdoms. Thus, their population movements had trade and annexation rather than settlement as their impetus. In fact, the Inca often migrated to conquer, and Incan conquests typically were followed by unusual forced migrations: The royal children of conquered kingdoms and chiefdoms would be transported back to the Inca capital of Cuzco, where they would be educated in Incan customs, sciences, and history. This sequestering of conquered territories' heirs had several intended functions. The royal children were at once hostages and future representatives of the Cuzco administration while being inculcated into Inca loyalty. Upon being returned to their native territories in other parts of Peru, Bolivia, and Ecuador, they would govern on behalf of the Inca.

The Inca were not the first South Americans to control large areas through the annexation of adjacent territories, as the Nazca, Moche, and other cultures earlier in the Common Era had established tribute empires. Some of the peoples of these civilizations migrated up and down the continent's Pacific coast in the process of conquering smaller groups and maintaining power. Many Andean peoples also undertook religious pilgrimages to holy sites, called *huacas*. The routes between these *huacas* frequently were clearly marked. Sacred stones, ruins, rivers, mountains, and other natural features could inspire visits from pilgrims who lived hundreds, even thousands of miles away.

In the case of the Nazca, such devotional ambulation may have inspired the design of the famous Nazca lines, gigantic geoglyphs (a symbolic figure sketched in the earth) visible only to flying birds and modern aircraft. Some of the geoglyphs were simple geometric shapes, but many delineated the figures of various rain forest and marine creatures; both groups of species were associated with environments far wetter than the pampas that were home to the Nazca. The Nazca fashioned their geoglyphs by removing thin layers of topsoil, revealing differently colored earth just beneath. This color difference was enough to create clear lines on the vast, flat landscape, and with the use of basic surveying techniques, both straight and curved lines could be drawn with precision.

The fact that the Nazca lines resolve into pictures only from far above has inspired many outlandish speculations about archaic balloons and even alien spacecraft. Few scholars debate the origins of the figures, however, since the creatures depicted in the geoglyphs are very similar in style to Nazca and earlier Paracas textile patterns. Also, in Andean textile craftwork, the artist often cannot see the image she or he is making; weavers must maintain their concentration in visualizing the intended design, which in some weaving techniques appears only near the very end of the process. Thus, visualization was an important aspect of Nazca artistic and religious thought, such that Nazca pilgrims may have envisioned spiders, whales, or monkeys with fair facility as they walked the courses of the geoglyphs. While the origins of the geoglyphs are little disputed, their exact function remains a topic of scientific and popular speculation.

## THE CARIBBEAN

By the beginning of the Common Era the Caribbean had seen no fewer than three waves of American Indian settlers, spanning some 5,000 years. Paleo-Indians had been followed by several groups of Arawakan-speaking settlers, each migrating out of the Orinoco Delta to the islands of the Lesser Antilles. Arawaks leaving South America may have been responding to pressures from groups within the continent encroaching on their former territories in the Amazon basin and through Colombia and Venezuela. Thus, migrations to the Caribbean islands may have actually begun far up the Orinoco, in Colombia's Andean piedmont.

Into the first millennium colliding waves of South American Indians began to develop an artistic, social, and religious syncretism in Trinidad that would later culminate in the unified chiefdoms of Puerto Rico, Hispaniola, and Cuba. By the second millennium the Greater Antilles were united under a few great caciques, or chiefs, in a loose Taíno confederation. Yet indigenous migration did not end with this consolidation of Arawak power, and in fact one last great wave of In-

dian settlers would arrive—the Caribs. Departing the South American mainland from along the coasts of Guiana and Venezuela, these adept seamen navigated the waves in large dugout canoes. When the Caribs arrived in the Lesser Antilles sometime in the latter half of the first millennium, they quickly began to take over Arawak territories. The Arawaks were driven further into the larger islands, most of which were in the northwest. Pressures from the northward thrust of successive Carib groups may have lent urgency to efforts to consolidate Taíno power in the Greater Antilles. The Taíno nations were still resisting Carib encroachment by the time of Columbus.

Ultimately, the Spanish were the ones to stay the Carib expansion into the Greater Antilles. The skilled and cunning Carib warrior parties had proved too difficult for even the great Taíno caciques to handle. When Taínos told Christopher Columbus that the encroaching Caribs ate human flesh, they may have been inveigling the European strangers, who bore frightening and novel weapons, into helping them fight their Carib enemies. From that time, the Arawak word for “Carib” quickly evolved into the word *cannibal*, carrying a dark connotation for Spaniards. This term, frightening for many, also became a convenient label for Native Americans whom Europeans sought to eliminate in the competition for colonial territories and resources.

## ASIA AND THE PACIFIC

BY KENNETH HALL

During the medieval era there were four major migrations of peoples in the regions of Asia and the Pacific, each of which would have substantial regional consequences. A second wave of Polynesian migration occurred in the Pacific basin from initial settlements in Samoa, Fiji, and Tonga as Polynesians crossed the Pacific to settle in Hawaii and Easter Island beginning around 400 and the islands of New Zealand beginning around 1000. On the Asian mainland Burmese, Thai, Lao, and other populations from the mountainous foothills of the Himalayas in modern-day southern China entered Southeast Asia and migrated south, where they were foundational to the emergence of the present-day states of Myanmar, Thailand, and Laos. The major migrations of consequence in southern Asia, in contrast to movements of nomads and pastoralists, were those of the Huns into what is now Afghanistan and northwestern Pakistan during the era of the Gupta monarchs (320–550) in India and the later migrations of Turkish peoples from central Asia into southern Asia from the sixth through the 11th centuries. Both the Hun and the Turkish migrations from central Asia also had consequence to the neighboring eastern European and Middle Eastern regions.

## PACIFIC BASIN MIGRATIONS

The widely scattered islands of the Pacific basin, stretching from New Guinea eastward across the Pacific Ocean, were populated by seagoing people with initial roots in Southeast Asia. Having migrated from mainland Southeast Asia sometime before 10,000 B.C.E., some Polynesian maritime sojourners left New Guinea around 1500 B.C.E. and settled in the Solomon Island chain and then the Banks, Vanuatu, and Samoan archipelagos.

In roughly 400 C.E. Samoa, Fiji, and Tonga had special roles as the strategic points for the next wave of Polynesian voyages of migration, as these are mentioned in local traditions as the points of origin. These Polynesians navigated the Pacific in double-outrigger canoes. Their boats consisted of two hulls connected with lashed crossbeams and covered with a central platform. Although it was referred to as a canoe, the vessel was driven by wind and used sails made of natural-fiber matting. The two hulls gave the craft stability and resiliency in the open ocean and the capacity to transport people and supplies over long distances. A medium-size boat 50 to 60 feet long could carry two dozen people and their belongings, including plants and animals, such as chickens, pigs, and goats, to introduce on the new islands they settled. Over time settlers from diverse points and mixtures of cultures and languages arrived. Local legends emphasize their movements, their heroic voyages of discovery, their observations of such natural signs as the stars and ocean currents, and their mixed cultural heritage to become a unique Polynesian island culture rather than the transplant of an Asia-derived heritage. The name *Polynesian* came to represent the shared cultural heritage of the islands and does not imply a geographic or political unity. Polynesian cultural traditions also distinguish Polynesians from neighboring populations in the Pacific island regions of Micronesia and Melanesia, who derived from different Southeast Asian points of origin in the ancient era.

Current knowledge of the initial voyages of migration to and settlement in Hawaii comes from a mix of oral tradition and archaeological discovery. Scholars debate whether the original Polynesian voyagers arrived from the Marquesas Islands, Tahiti, or both, from about 500 to 600. One theory attributes the Marquesas as the original source and argues that the Tahitian settlers did not arrive until 1300 as a second-wave migration. In both the “one-migration” and “two-migration” theories, there was not a single settlement voyage but a continuous series of migratory voyages that populated the Hawaiian Islands. Local folk tradition attributes the initial voyages to the legendary Hawai’i Loa, the chief of a band of voyaging fishermen who discovered the island of Hawaii,

which was named after the chief, and then the island of Maui, which was named for his son. The initial band of voyagers returned to their home island and then made a return voyage with Hawai’i Loa’s wife and children, for whom the other Hawaiian Islands were named. They mixed with the other male voyagers to originate the Hawaiian race.

Known by its native population as Aotearoa (“land of the long white cloud”), New Zealand was the last Pacific island region settled by migrating Polynesians known as Maori between the mid-12th and the 14th centuries. The Maori traveled there by boat from islands, possibly the Society Islands, in eastern Polynesia. This is considered the Hawaiki, or “homeland,” in local legend. These voyages of settlement were led by the legendary Whatonga and his grandfather Tai. They followed an initial 10th-century contact by traveling in double-outrigger canoes (*waka hourua*) led by the adventurer Kupe from Hawaiki. According to Maori legend, he found what he named Aotearoa uninhabited by “people of land” (*tangata whenua*). The discoveries of archaeologists confirm the potential truth in these legends, since the earliest evidence of settlement is an early 10th-century Maori settlement in the Bay of Islands and gardening at Urimatao, on Motura Island, but then an absence of settlement until later. Sometime later Te Awa populations arrived and settled the Dargaville area on the North Island’s western coast, from which they moved farther to the south, where they built other fortified villages (*pa*) at Rawhiti and Manawaora. The final migrating voyagers, called the Ngare Raumatī, landed in the Bay of Islands area in the later 14th century, where they intermarried with the earlier settlers. By the time the first Europeans arrived in the late 16th century about 5 percent of the Maori population lived on the South Island, while most Maori lived on the tropical North Island’s northern coastline.

## TIBETO-BURMAN, THAI, AND LAO MIGRATIONS FROM SOUTHERN CHINA

In response to the migrations of other ethnic groups from the central Asian steppes into the southern China region, during the medieval era populations migrated from the Himalaya foothills into the hills and lowlands of Southeast Asia. Among these were the Burmese, who by the second millennium had become the dominant ethnicity in Myanmar; the Thai, including one group who occupied the fertile rice plain of the Chao Phraya River in modern-day Thailand in the 11th century and who are still known by the Thai name today, and others who migrated into the hill regions of Myanmar’s north, where they became known as Shans and Karens; and the Lao, who migrated into the hill regions east of the Mekong River between Thailand and Vietnam.

The waves of migration resulted from the nomadic hunting and gathering and shifting cultivation lifestyles, internal rivalries, and inability to establish unity among the various cultures. These migrating populations were originally residents of the hills and valleys of Sichuan, Guizhou, and Yunnan, where people of similar ethnicity remain today. According to the oral traditions of the earliest migrants, which were recorded in the Shan chronicles sometime after 1500, the major movements of populations began in the sixth century, when the Shans moved from southern Yunnan into Myanmar. There they established many city-states, which linked their diverse villages, each ruled by a local chief, and collectively took the name “Great Thai” (*Thai long* or *Thai*). Later waves of migrating Thai who entered Thailand and Laos were pejoratively referenced as “Little Thai” (*Thai noi*).

The Shan chronicles assert that the earliest migrants were skilled farmers who settled in areas where the soil quality was good and water plentiful and initiated long-term irrigated cultivation. By the 14th century the Shans had a highland “kingdom” led by two brothers who, around 1350, led a network of 99 allied chiefs on a series of military expeditions against their lowland Thai and Lao neighbors to the east and their Burmese lowland neighbors downstream to the south and west. These Shan raids also extended into the Assam region of modern India, where some Shan warriors and their kinsmen settled and became settled farmers in the Brahmaputra River system.

According to Burmese inscriptional and chronicle records, in the ninth century ethnic Burmese migrated into the upper Irrawaddy River valley from Yunnan. As they moved south, they encountered Mon ethnic groups, who were long-time settled farmers near the downstream Irrawaddy and Salween rivers and practiced the Buddhist and Hindu religions. Gradually the Burmese absorbed these Mon populations and their Indianized civilization into their Bagan polity. This reached its height in the mid-11th century under King Anawrahta (r. 1044–77), who patronized the reformed Theravada Buddhist tradition that was based in Sri Lanka. From that time Burmese kings apportioned a manpower and tax-collection system to princes, officials, and members of the extended royal family, who “ate” the resources of their provinces. The state council (Hlutdaw), dominated by four chief ministers, claimed to exercise administrative and judicial authority directly on the king’s behalf. The king retained control over state finances, which were managed by his inner council of four “inner ministers,” who also controlled the royal palace. At the death of the monarch, rivalries between the Hlutdaw and the “inner council” of the king resulted in factional alliances that involved military officers, royal princes, and regional nobles and officials.

In the 11th century a new wave of Thai populations migrated from southern China into today’s Thailand. Initially they were subject to the authority of Khmer monarchs based in Angkor, in present-day Cambodia. According to Thai legend, the earliest Thai highland state was called Nan Chao, or Nanzhao, said to have existed since 738 in the upstream borderlands between China and Thailand. The Thai chief Rama Khamheng (r. ca. 1275–1317) freed the Thai from Angkor’s authority to begin the Sukothai Buddhist monarchy in the Chao Phraya River basin. In part the new Thai state was a result of a 1253 Mongol China military expedition into Myanmar around 1253, which set in motion a new wave of migrations. Among these were groups of Thai hill cultures who migrated south from the Nan Chao region to settle and became the population base for the new Thai Sukhothai monarchy, which governed a now-settled Thai wet-rice agricultural society. During this period another Thai monarchy known as Lanna formed at Changmai in the northwestern upstream mountainous region of modern Thailand. At various times it ruled over parts of northern Myanmar, Laos, Yunnan, and northern Vietnam. A Lao kingdom known as Lang Sang also formed, based in the mountains adjacent to the Mekong River on the eastern borders of the Angkor Cambodian realm and the western borders of Vietnam.

In 1438 Ayudhya replaced Sukhothai as the dominant regional Thai power and, annexing the previous Angkor-dominated Mun River basin agricultural lands to the east of the Chao Phraya River basin, claimed to be the rightful heirs to Angkor’s political authority. King Trailok (r. 1431–88) was the architect of a Thai system of government that would last for the next 400 years. Trailok issued the Law of the Three Seals in 1466, a law code divided into civil, military, and provincial components, which created a realm-wide hierarchy based on assignments of numerical rank to everyone in the kingdom. This inclusive hierarchy grouped the Thai region into functional or territorial units for administrative and military purposes. The realm was partitioned into civil (Mahatthai) and military (Kalahom) divisions. The Mahatthai controlled the ministries of the capital, the palace, agriculture or lands, and the treasury (Phrakhlang), each with subdivisions and provincial units. The Kalahom was divided among four generals. All Thai were attached to a specific department of the government to which they owed compulsory labor service.

### HUN MIGRATIONS FROM CENTRAL ASIA

Migrating pastoral populations called Xiongu by the Chinese, Chionites by the Greeks, and Hunas by Indians moved from the central Asian steppes into northern Iran and modern-day Afghanistan in the fourth century. They used that base to launch a series of fifth- and sixth-century attacks against the

settled agrarian societies of the Roman West, Iran, and Gupta India. The most famous of the Hun leaders in western records was Attila (r. 434–53), who led the western Hun hordes then based in eastern Europe to victories against Rome.

In Asia several waves of eastern Hun warriors were defeated by the Persian Sassanid empire in the early fourth century, but in 392 another horde seized the regions known as Bactria and Gandhara on the northwestern border of India, absorbing the remnants of the Kushana and other Indo-Greek states that were successors to the conquests of Alexander the Great (r. 336–323 B.C.E.). They launched regular attacks against Gupta India's northwestern frontier from the mid-fifth to the mid-sixth century. The Gupta kings successfully blocked their armies from entering the Gangetic Plain, but the continuing effort drained the Gupta realm's resources and led to the end of the dynasty around 550.

The original language of the Huns has been lost; they absorbed the languages of the regions they conquered or settled. Most scholars believe that the original Hun language differed from the Mongolian or Turkish languages. According to the Chinese Buddhist pilgrims who report their encounters with the Huns on their travels to India during the sixth century, they had no script and instead used tally sticks to communicate. Remaining coins, however, which imitated those of the Kushana and Sassanids, demonstrate that the eastern Huns used the Bactria script of their predecessors. Their language was a mixture of the Greek and Persian languages, and it used a Greek alphabet. The Chinese pilgrims as well as the Chinese dynastic records indicate that the Huns followed several of their predecessors' cultural practices, including cremation of their dead, the use of the straight sword and compound bow, and the strange custom of artificially elongating their skulls upward, which is depicted in their coinage portraits. Chinese pilgrim accounts note that most Huns practiced the Zoroastrian religion, which included the worship of heaven and fire. Archaeological remains along the Silk Road caravan network between India and China demonstrate that some Huns also were patrons of the Buddhist religious tradition.

Like the later Mongol nomadic hordes, Hun warriors were expert horsemen. Each kept several small, tough horses. In battle they would make quick cavalry charges, shooting arrows at their enemy, and then retreat to mount a new horse. Using his string of horses, a Hun warrior could continue charging indefinitely. Their opponents feared them so much that they paid them not to attack. Hun warriors lived most of their lives in tents. The tributary payments by their neighbors, the use and sales of war captive slaves, and collections of ransoms on war prisoners subsidized their comfortable lifestyle. Huns also traded in horses and furs, which they exchanged for grain, weapons, and luxuries such as Chinese

silk. Until the time of the Mongols, most Eurasian populations thought the Huns the symbol of ferocious barbarian cruelty and deceit.

India's Gupta rulers had to defend their territories against waves of Hun migrants, known in Sanskrit as Sveta-Huna, "White Huns." Their migrations are thought to have been set in motion by China's Han rulers (202 B.C.E.–220 C.E.), who drove the nomadic steppe populations the Chinese knew as Xiong Nu from their borderlands in the first century. Subsequent Hun migrations pushed all the way to the doors of Rome. White Huns from the 400s repeatedly attempted to invade India. From their base in Afghanistan they attacked India in 455 and again in 464, but they were defeated each time by Gupta forces led by the Gupta king Skanda Gupta (r. ca. 455–67). However, between 465 and 470 the Huns took control of most of modern-day Pakistan, where they set up a *tegin*, a tribal state led by Mehar Gul ("Sunflower"), who ruled from his capital at Sakala. Their success against a Gupta military alliance allowed them to enter northern India around 500, but when they were decisively defeated by Gupta forces in 528, their remaining forces retreated into Kashmir. The remaining Huns in Pakistan and northern India gradually assimilated into the local populations. In 565 western Turks defeated the Huns and replaced them as the rulers of the regions of on India's western frontier until the mid-seventh century, when waves of migrating Turkish Muslim warriors replaced them as the rulers of India's northwestern frontier.

Persian writers knew these White Huns as Heithalites or Epthalites ("big power"), who by the sixth century had a tribal empire on the northern and eastern peripheries of Iran. In China they were variously known as Yanda, Ye-tai, or Xiong Nu. Between 507 and 531, under a ruler the Chinese called Ye-dai-yi-li-tuo, they sent 13 emissaries to the Northern Wei Dynasty (439–534). According to the Chinese dynastic records, the White Hun realm at that time consisted of 30 "states" that stretched across central Asia to Iran. In 558 they paid tribute to the Northern Zhou Dynasty (557–89) and in the 610s to the Sui Dynasty (589–618) but then disappeared, falling to migrating Turkish forces.

The White Hun migrations based in modern-day Afghanistan and Pakistan became the dominant ethnicity and heirs to Afghan and Pakistani civilizations and that of neighboring Rajputana in northwestern India. These include the modern Afghan-Pathan peoples and most of the Rajput and Jat clans of the Punjab and Sind. Perhaps the greatest legacy of the Huns was their militant clan system, which continues to be the basis of regional social hierarchy and political authority throughout their former regions. In India the Rajput name resulted from the attempts by Indian Hindu scribes to represent the Rajputs as a militant caste group of *ksatriya*, re-

ferring to warrior and ruler stature. *Rajput* was the composite of *raja* (“king”) and *putra* (“son”), the king’s son, or a member of a ruling family or clan.

### TRKISH MIGRATIONS FROM CENTRAL ASIA

Turkish populations spread across central Asia between the sixth and 11th centuries. In central Asia they displaced remnants of the White Huns and Iranian populations. Their ancestors are thought to be the Xiong Nu of Mongolia or from the Siberian regions farther north. The first record of their existence appears in sixth-century Chinese sources, which call them Tujue. Their earliest surviving records are Turkic-language inscriptions of the early eighth century. Linguistically, from the medieval era the Uralic-Altai central Asians divide along Turkish and Mongolian lines. In the west the Turkish languages accommodated Arabic and Persian, while in the east the linguistic patterns derive from the Mongolian language.

The first Turkish state was the sixth-century Gokturk (*gok* for “blue” or “celestial”), which gave its name to the states and populations that followed. The early Turks were led by the head of a clan. The earliest Chinese dynastic records report that the Turks were excellent metalworkers who provided Turkish warriors with high-quality weaponry. Turkish warriors wore armor that was covered by quilted cloth garments, felt, fur coats, and leather. Their armor consisted of metal plates that were laced together in rows. Metal helmets were riveted together; the warriors’ lower legs and arms were protected with metal armor, and they wore boots that extended over the knee. They used a shield that was strapped across the arm to allow the use of bows and arrows in horseback combat. While the bow was the main means of combat, warriors also used a sword that was initially straight and single-edged, although curved swords later became popular.

By the eighth century Turkish populations included the Karluks, Uyghurs, Kyrgyz, Oghuz, and Turkomans, who controlled tribal clan states that stretched across central Asia to Iran. In the west their contact with Muslim populations led some of them to adopt the Islamic religion by the end of the first millennium, while others continued to practice the regional religious traditions of their predecessors in central Asia, including Buddhism and Zoroastrianism. By the 13th century Turkish soldiers in the army of the Abbasid caliphs were the rulers of the Muslim Middle East.

In central Asia the Kyrgyz and Uyghurs continuously warred with each other and the Chinese empire. The Kyrgyz eventually settled in the region now known as Kyrgyzstan. After their 13th-century submission to the Mongol conquests of Genghis Khan (r. 1206–27) the Tatar Turks conquered and settled the lands of the Volga Bulgars (remnants of a central

Asian population that had migrated into modern-day Bulgaria in the seventh and eighth centuries) in what is today Tatarstan. Turks in the western part of central Asia who had embraced Islam formed the Ghaznavid, Saljuq, and Khwarazmian dynasties in the years previous to the Mongol conquests. Remnants of a Turko-Mongol people, after the breakup of the Mongol Golden Horde in the late 15th century, settled in present-day Kazakhstan and Uzbekistan.

By the end of the 10th century Turks were in power in northern India thanks to the aggression of Mahmud of Ghazna (r. 997–1030), whose base of power was in Afghanistan. In 1008 his troops defeated an alliance of Rajputs in India, and they followed with periodic raids into India to plunder Indian temples. Rather than staying to rule, he retreated to his Ghaznavid power base, leaving behind a network of Hindu, Jain, and Buddhist vassal states in the modern Punjab region. The year 1008 is significant in Indian history as the date of the initial penetration of Muslim authority into India. Later armies of Turkish and Afghan warriors would stay to form what became known as the Delhi Sultanate (1206–1526).

Like the Huns, the early Turks left a continuing legacy of a clan-network system, known as the *ghuzz*, that allied diverse groups. The initial written records of the Turks, the eighth-century Orkhon inscriptions from the Yenisey River valley in today’s eastern Turkistan, document the “nine clans” that were then allied in a Turkish tribal confederacy. These Orkhon records, which are attributed to the Orkhon Uighur Khanate (Qaghanate; 745–840), are inscribed on gravestones, stele, and obelisks that describe the important events in the life of the buried Turkish warrior and highlight the distinguished enemies killed by the deceased. The two largest monuments, erected in 732 and 735, honor the Turkish prince Kul (d. 731) and his brother, the “emperor” Bilge (r. 716–34) of Mongolia.

These inscriptions contain references that allow the reconstruction of the local belief system characteristic of the Turkish clans, although they are primarily epic tales of battles waged by the Turks against their neighbors and their efforts to maintain the unity of the “nine clans.” There is disagreement among scholars as to whether the inscriptions record commitment to a monotheistic faith derived from the Zoroastrianism that was patronized by their Hun predecessors and focused on a heavenly divine, as would have been appropriate to their centralizing ambition, or whether the inscriptions instead are indicators of worship dependent on traditional local shamanism, consistent with the reality of the fragmentary nature of their clan alliance.

The Orkhon inscriptions use the eclectic Uighur language, which is a mixture of Persian, Russian, and Turkish and which also was used in other contemporary historical paper documents recovered from this region. Together they

demonstrate a high level of literacy among these Uighur Turks during the medieval era. Among the recovered documents are numerous religious texts, including those of the Buddhist, Manichean, and Christian religions that were translations from Sanskrit, Chinese, Persian, and other languages. The main purpose of these religious documents was their transmission from an original source to eastern Turkistan, Mongolia, and China. There were also legal documents that record the sales and purchases, loans of money and property, borrowing of cattle, rental of property, and orders and references of authorities concerning the economic activities of landlords and farmers. In the 12th and 13th centuries the Mongols adopted the Uighur script and took Uighur clerks, administrative officials, and the local khans' children as educators to the Mongol courts, including the Mongol Yuan Dynasty in China (1279–1368).

In the post-Gupta age of the seventh century Buddhism was losing its support in India and had not yet been accepted by China's rulers. Thus, this eastern Turkistan region became a temporary hub for Buddhism, with hundreds of Buddhist monasteries and thousands of resident monks. Buddhist scholars came to central Asia to purchase religious books, participate in Buddhist rituals, and engage in theological discussions. As a consequence of this demand, the old method of book copying became overly expensive and was too time-consuming to satisfy demand. In response, at Turpan, a Silk Road caravan center east of Uighur on the western edge of modern China, book printing by xylography, or woodblock printing, was invented. Uighur became a vital source of paper from the bark of a mulberry tree, which was treated with flower, fruit, and tree sap, and it was a producer and recipient of these earliest printed religious texts. Its climate allowed the preservation of these and other paper records, which provide a vital window into the affairs of central Asia during the medieval era.

## EUROPE

BY BAILEY YOUNG

Three great epochs of migrations and population movements occurred during Europe's medieval millennium (ca. 500–ca. 1500 C.E.). The first two took place during the earlier centuries, which have traditionally been seen as marked by invasions of barbarian peoples trying to move into the more civilized centers to plunder or at least share in the wealth. The third, which took place during the centuries when medieval civilization was itself at its height—the High Middle Ages—was, on the contrary, characterized by migrations of peoples from the centers outward, to claim new lands to settle and civilize rather than to invade and plunder. Recent research

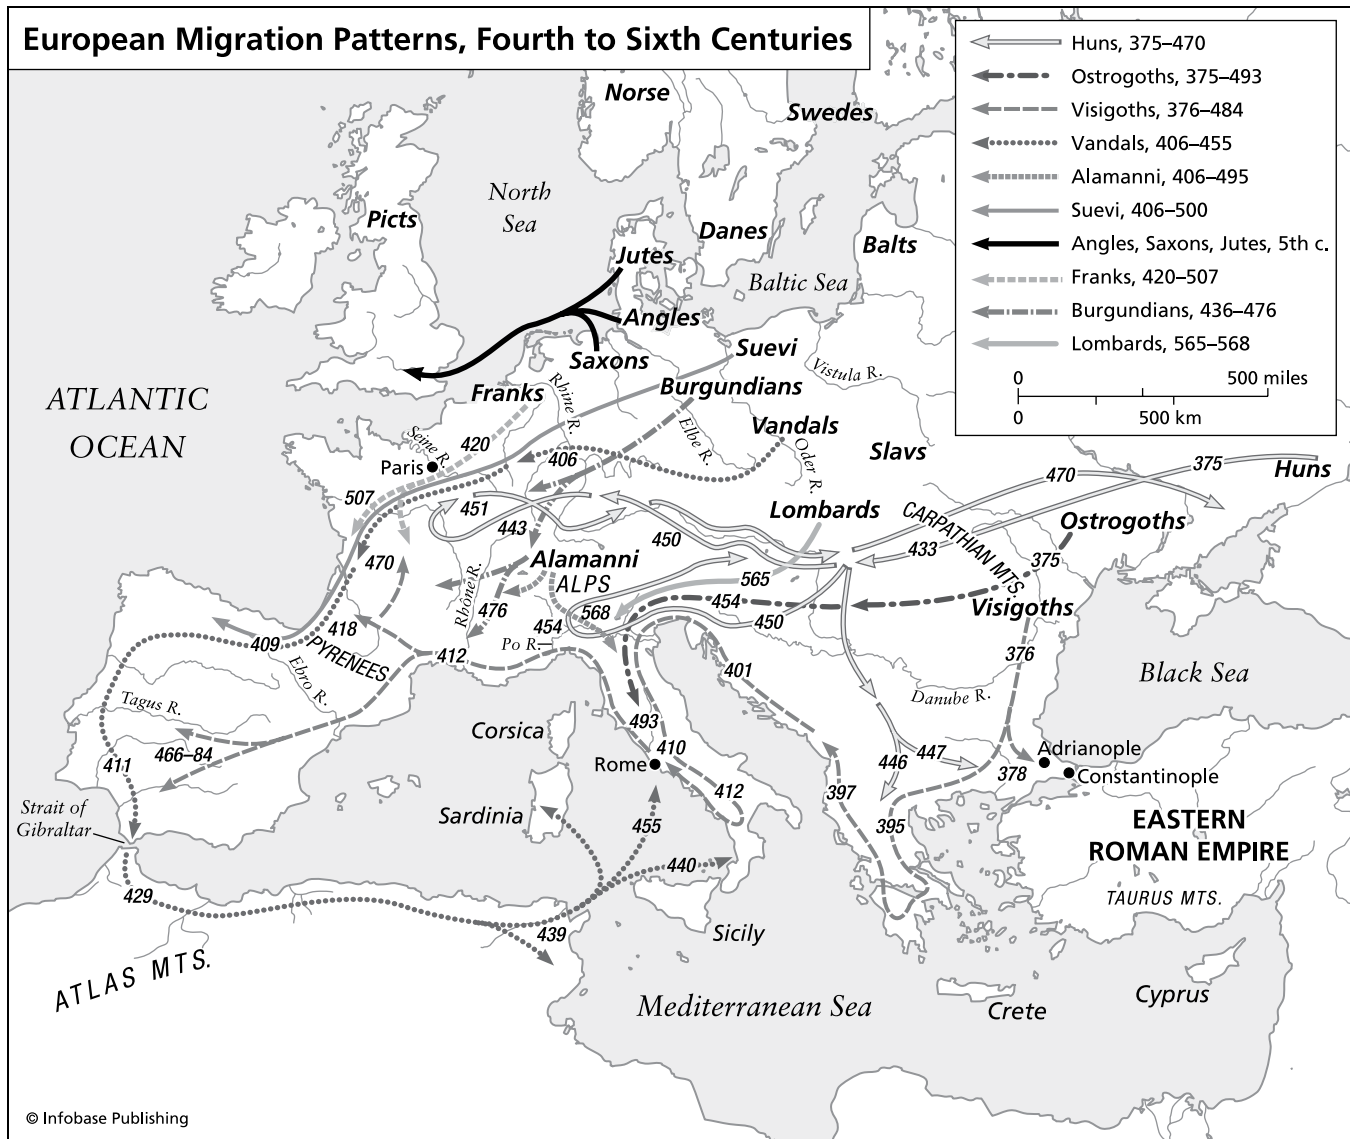

shows that the reality in each of these epochs was much more complex than the traditional views indicate, with elements both of violent invasion and of more peaceful settlement and cultural adaptation in all epochs.

### INVASION AND ASSIMILATION

In the traditional interpretation, as developed by the great 18th-century historian Edward Gibbon, barbarian invasions are understood to have been one of the main causes of the fall of the Roman Empire, which brought on the Middle Ages. Indeed, so much movement of peoples then took place that this time is called the “Migration Period” in several different European languages. The story of this period begins dramatically in the 370s, when a central Asian people called the Huns, skillful mounted warriors feared for their ferocity, swept westward across southern Russia and the Balkans, spreading terror among the Germanic peoples living there. Some of them, the Visigoths, crossed the Danube River into the Roman Empire, seeking refuge, but when they were mistreated by the Roman authorities, they decided to fight.

In 378, at the battle of Adrianople, the Visigoths defeated a major Roman army and killed the Eastern Roman emperor; afterward they began 40 years of restless wandering about the empire in search of a place to settle in safety. Although they became notorious for sacking the city of Rome itself in 410, the Visigoths were eventually offered the chance to change their status from dangerous enemy to valued ally and partner, as they were no longer the only barbarians within the gates. The Huns by then had taken control of the old province of Pannonia (modern-day Hungary) and were using it as a base from which to stage devastating raids on Roman territory, afterward allowing themselves to be bribed by the emperor into retreating—for a time. Under their great chief Attila, the Huns became ever richer and more powerful through such means. Meanwhile, in 406 a confederation of other tribes (mostly Germanic but including central Asians, too, such as the Alans) crossed the Rhine River and broke into the Western Roman Empire; for a century, then, invasions, the sacking of cities, and population movements over great distances were indeed the order of the day.

During this period one of the Germanic peoples, the Vandals, not only passed quickly through Gaul (present-day France) into Spain but also proceeded into North Africa; by 439 they had seized control of the richest lands there, with King Genseric ruling from the great city of Carthage (modern-day Tunis) and learning how to attack the Romans from the sea. Other Germanic groups did not move so far. The Burgundians were content to seize control of the Middle Rhine valley; farther north, the Franks, who had always lived around the Lower Rhine, slowly pressed to the south

Early medieval Europe was heavily affected by the movements of such peoples as the Huns, Visigoths, Franks, Burgundians, and Lombards.

and west, settling the largely deserted countryside and imposing their language where Celtic or Latin dialects had been spoken. Their eastern neighbors, the Saxons, and southern Scandinavians, such as the Angles, rather adventurously took to sea and by about 450 were seizing the eastern parts of the former Roman province of Britain, so that the land took on their name (*England*, literally being the “land of the Angles”). Far to the west the Celtic Irish, then called Scoti, also took to sea to plunder and, in more limited numbers, to migrate and settle in coastal areas. Thus, the Scoti who settled the isles and coasts of northwest Britain (then called Pictland) eventually bequeathed it the name of Scotland.

Scholars have long debated how much of this moving about involved massive and lasting population shifts and

how much involved the adoption of new cultural fashions by indigenous peoples. Specific cases have been the best sources of perspective. After long wandering about after their sack of Rome, the Visigoths found themselves in the rich Roman province of Aquitaine (modern-day southwest France) in 418 when the emperor offered them a deal—in Latin, a *foedus*. They could stay in Aquitaine as legal residents, to claim a regular one-third share of its wealth, live under their own laws and customs, and be ruled by their own king; in return they would swear to be loyal allies of the empire and be on call to fight its enemies. Accepting the deal, they were sent right over into Spain to chase out the Vandals, and they did. (It was not their problem that the Vandals moved on to Africa.) When Attila the Hun invaded

Gaul in 451, the Visigoths loyally joined the Roman general Aetius to stop him.

By this time deals were being made with other barbarian peoples as well. One of the Frankish warlords in the north, Childeric, ruling from the Roman town of Tournai, seems to have helped the Romans defeat Saxons and other invaders. After Childeric's death, his son Clovis (r. 481–511) decided that he would rather rule everybody, Franks and Romans alike, and his warlike career established a kingdom that became the basis of France. Clovis even defeated the Visigoths and drove them out, over the mountains into Spain. Although they had ruled Aquitaine for a century, they left so little trace there that archaeologists cannot even identify a "Visigothic grave" from that time. In addition, certain questions remain: Did not the Franks of Clovis spread all over the land that came to bear their name (France)? Are not the thousands of graves archaeologists have found with "Frankish" weapons and jewelry proof of this? The answers have proved far from clear, largely because indigenous peoples can adopt whatever customs and dress are in favor with new elites in power, just as invading or migrating peoples can adopt cultural features from them. Thus the Franks, originally Germanic speakers, came to be the French, speaking a Romance language. Indeed, modern historians continue to debate how much of what happened in those distant days was due to significant migrations of whole peoples—as opposed to movements of smaller elite groups who would soon mix with indigenous peoples—and how much was due to cultural adaptation and the forging of new senses of group identity.

All scholars would agree that the early Middle Ages were a time of great instability, when new movements of peoples were set in motion by new threats and opportunities. In the 530s the Byzantine emperor in Constantinople, Justinian, decided to send his armies west to retake lands that had come to be ruled by barbarian groups. In two years the Vandals of North Africa were defeated, to abruptly disappear from history without a trace. Italy had been ruled for 40 years by another group of Goths who had originally migrated in with Byzantine approval. After 20 years of savage wars, they, too, disappeared from history, but their place was soon taken by another Germanic people called the Lombards, then living over the Alps, in present-day Austria. The Lombards had been feeling pressure from the east, from the Avars, a new group of mounted central Asian warriors who had replaced the long-vanished Huns. Deciding they would rather fight the Byzantines for Italy than risk facing the Avars, the whole people in 568 crossed the Alps and seized the plains of the Po Valley, which have borne their name (Lombardy) ever since. The Byzantines held on to the seacoasts, for the longest time to the south, around Bari, set-

ting in place a cultural contrast between these regions that a visitor to Italy still feels today.

By about 600 a western European core area had emerged, and the migrations seemed to have subsided. In all the lands from Rome to the borders of Scotland, from the Rhine to the Atlantic, power was intensely localized, as the heirs of indigenous peoples and of migrants from outside strove to forge new cultural identities as Franks or Lombards, as Irish or Anglo-Saxons. Only memories of Roman grandeur and a Christian faith based on Latin liturgy and scriptures gave these peoples a vague sense of common culture. This sense was sharpened by hostility to those peoples on the outside who did not share in that culture, such as the Avars, considered dangerous, to the east and the Slavic peoples who were likewise pagan and were considered primitive. In the late 700s a mighty figure would arise to unite most of these lands for the first time, creating an "empire" with a sense of Christian identity. This was Charlemagne, who before dying in 813 waged war upon bloody war to extend his power northeast into Saxony, forcing the people there to become Christian; he so smashed the Avars that they, too, vanished from history. Yet for all his success, Charlemagne's last years were troubled by the stirrings of what was to become the second great early medieval epoch of invasions and migrations, bearing in on the core area of western Europe. To the south, a dynamic and destabilizing force of unprecedented proportions—at least from Charlemagne's point of view—proved to be Islam.

Bursting out of Arabia in the 630s, Islamic armies swept over North Africa, conquered most of Spain, and by the 730s were raiding far to the north in France. Their defeat near Tours in 732 by Charlemagne's grandfather stopped their advance in the west; in the 770s Charlemagne led his armies into northeast Spain, thus beginning the Christian reconquest, which would take more than 700 years to finish. During the centuries up to 1100 the Muslims were most often the aggressors, but their usual interest was not land to settle and control but loot—including slaves—with which to return home.

From 800 to 1000 the danger of the frequent Islamic raids from the south was matched by that of attacks by other warlike outsiders from the north and the east. The Magyars were a migrant people from the Asian steppes who in 895 seized the same mid-Danubian plains earlier occupied by Huns and Avars. At first, like these earlier peoples, they used the region as a base from which to raid and plunder, riding their powerful horses to attack deep in Italy and Germany. After a defeat by the German ruler Otto I in 955, however, they settled down to develop a society based on agriculture, and, significantly, converted to western Christianity. In 1000 their ruler was baptized with the name Stephen, accepting the Latin rites of the Roman Catholic Church. From the

north the Scandinavian warriors known as Vikings attacked in their famous longships, marvelous clinker-built vessels sturdy enough to withstand the cold stormy seas but so light and shallow of draft that they could penetrate far up the river systems of western Europe. They often came in war bands of a few score men to raid and carry plunder home, but migration and settlement was also an important part of the Viking story. The Swedes traveled thousands of miles along the river systems of Russia, setting up trading stations that would grow to become the region's first significant towns, such as Kiev, on the Dneiper River (in modern-day Ukraine). In 989 their chief Rurik was baptized into the rites of the Byzantine (Greek Orthodox) Church and took the name Vladimir, a sign that the Scandinavian migrants were assimilating into the Slavic majority.

Western Scandinavians launched some major invasions and migrations. Throughout the 800s Danish and Norwegian (Norse) Vikings attacked France and the British Isles in increasing numbers and with much success. By 911 their control of the English Channel coast was so strong that the Frankish king forged a treaty recognizing their leader Hrolf as duke, and the region itself came to be called Normandy (land of the Northmen). The trading settlements established by the Vikings in Ireland, like Dublin, grew into the first towns on that hitherto rural island, and they assimilated into the Celtic population. In England their invasions were much more massive and destructive, as they wiped out the Anglo-Saxon kingdoms on the eastern side of the island and replaced them with new ones of their own. Extensive excavations at York have revealed many details of life during the days of the Viking kingdom there. Although Alfred, king of Wessex, was able to stop their drive westward in 878 and lay the basis for a reconquest of the Danelaw (the region ruled by Danish law) in the 900s, renewed invasions from Denmark brought all of England under the rule of the Danish king Canute (r. 1016–35). But by then the Vikings, like the Magyars, were settling down and assimilating into the culture of the western European core area by adopting Christianity. In 966 the Danish king Harald Bluetooth, Canute's grandfather, was baptized and built a church beside the pagan burial mound of his father Gorm, which can still be seen today.

Norway was converted largely through the efforts of the saintly king Olaf (1016–29). From Norway's shores, too, came perhaps the most daring migration venture of the era: the settlement of Iceland, an empty North Atlantic island discovered about 860, which was accomplished by 930. The Norwegians' descendants still live there today. Early Iceland had no king; in the year 1000 the settlers met together and decided to adopt Christianity.

## OUTWARD EXPANSION

By 1100 the basic pattern from the previous centuries, with western Europe being under pressure from outside forces, was reversing in favor of a new dynamic of outward expansion. This trend had a very visible political and military aspect, aptly symbolized in 1100 by the establishment of the Latin Kingdom of Jerusalem, as ruled by knights from the old Frankish core area who had led the First Crusade. In Spain, too, the once poor and weak Christian kingdoms of Castile and Leon, in the northwest, had begun to turn the tide against the dominant Muslim powers and were reclaiming lands for Christendom. By the end of the Middle Ages, the core Christian area of Europe had doubled from Charlemagne's day; the modern historian Robert Bartlett has shown how this can be understood as the result of the energetic efforts of knights, peasants, merchants, and churchmen alike, as driven by a complex mixture of religious (or ideological) and economic motives. Migration, settlement, conversion to Christianity, political domination, development, and trade were all inextricably bound together in degrees that differed considerably from place to place.

The crusaders who seized control of Palestine around 1100 were able to hold on to this land so far from home for as long as they did (almost 200 years) only because European ships (mostly from Italian cities like Venice and Genoa) controlled the sea and could bring human reinforcements and material supplies. But these Frangi, as the native Arabic speakers called the Franks, were never more than a small military elite dominating a society made up largely of peasants and townspeople who were not all Muslims—many were Jews or Eastern Christians—but were all foreign to them. The Franks were never numerous enough to affect the sociocultural matrix durably, and powerful Muslim states like Egypt surrounded them; in 1292, in fact, an Egyptian ruler expelled them. A contrast is provided by southern Italy and Sicily, which were dominated in 1000 by the Byzantine Greeks and Muslims, respectively. In the later 1000s bands of Norman knights (descended from the converted Vikings of Normandy) invaded the area and captured its strongholds, one by one. The pope, whose prestige as the spiritual leader of Christendom was growing, approved their cause. The combination of military might and religious valorization, as helped by closer contact with Europe's economic dynamism and by the political skills developed by the Norman rulers, was enough to bring about the annexation of these areas to Europe; still, residents of these areas never fully embraced European culture.

The expansion of Christian Europe was most thorough and culturally transformative in the three exotic "frontier" areas Bartlett discusses: the "Celtic fringe" lands to the

northwest, the Iberian lands being recovered from Islam, and the vast Slavic lands of Europe east of the Elbe River. Ireland may seem an unlikely frontier—after all, Saint Patrick had brought Christianity there before 500 C.E.—but when the Norman king of England Henry II claimed the right to rule there in 1170, sending knights to seize lands and build castles to hold them, he had the support of the pope, who deemed the Irish form of Christianity corrupt and in need of reform. Within a few years Dublin had become the stronghold of Anglo-Norman rule, as surrounded by an area about 50 miles wide, called the Pale, held by barons loyal to the English king. An enterprising baron seized another area in Ulster, to the northeast, that also became a center of foreign power. Irish chieftains continued to rule the western parts of the island, which remained Celtic in language and culture until modern times, but the English king and the Anglo-Norman barons encouraged English peasants and townspeople to immigrate into the areas they controlled. This was thus a kind of migration different from any seen before, a deliberate “colonization” meant to change the culture to fit an approved pattern, as directed by the politically dominant group for its own benefit. It was successful. The actual population influx was limited in scale, but by the end of the Middle Ages, English was well on the way to replacing Irish as the dominant language, and English political control was destined to extend across the whole island.

### **INFLUENCE OF CHRISTIANITY**

Actual migration and fundamental change in the character of the population were much more significant in the other two frontier areas, as was religious change. The Christian reconquest of the Iberian Peninsula involved much more than military victories and a change in political power. After the capture of Toledo, in 1085, the kingdoms of Castile and Leon more than doubled in size; after a decisive victory in 1212, all of Spain except the mountainous kingdom of Granada, in the far south, was soon conquered. Although the Christian rulers at first promised the Muslim and Jewish populations that they could stay and practice their religions, they also actively encouraged resettlement by Christians from the north, especially peasants who could convert underpopulated and war-devastated regions into productive farmland and sheep ranches. Some of these immigrants came from France, since French knights had assisted in the wars and French peasants had been developing useful land clearance and development skills in their homeland. The overall European population was growing in the core area at an unprecedented rate, as a result of improved food productivity deriving from technological progress and the increases in farmland, so the opportunities on the Spanish frontier were attractive.

By 1300 the balance of the Spanish population was shifting, as were royal policies and popular attitudes. Arabic could no longer be used in court cases, and the remaining Muslims were under increasing pressure to convert, as the church took an ever-harder stance against non-Catholics. Granada finally surrendered to the Catholic majesties Ferdinand and Isabella in 1492, and in 1504 the Muslim population was faced with the choice of converting or leaving; many migrated to North Africa. The Jewish population, once the richest, best integrated, and perhaps the largest in Europe, was faced with the same choice. Some converted, but tens of thousands of Sephardic Jews scattered throughout the Muslim-ruled Mediterranean lands or migrated to the Low Countries, one part of Christian Europe with a more tolerant attitude. Spain was now officially and uniformly Catholic, and the Inquisition was set in place to ensure that it stayed that way.

In Europe east of the Elbe River, invasion, plunder, conquest, migration, colonization, development, and profound cultural change through forced or voluntary conversion to Christianity were played out on the largest scale seen throughout the later Middle Ages. After Charlemagne’s death a warlike frontier developed between the now Christian Saxons and the pagan Slavic tribes—including the Wends, Prussians, Poles, and Balts—beyond the Elbe. The success of the First Crusade inspired some German knights in 1198 to found a new crusading order dedicated to conquering and converting these heathens. The pope approved, and in 1232 the Holy Roman Emperor granted all of East Prussia to these Teutonic Knights. Some of the Slavic leaders had by this time converted on their own, founding new Christian states like the Kingdom of Poland. In any case, adopting Christianity also meant adopting the cultural features (writing, the Latin liturgy) and socioeconomic institutions (manorial estates supporting feudal lords, towns run by privileged merchant guilds engaged in brisk trade) of the core area of western Christendom.

### **EASTERN IMMIGRATION**

As Bartlett shows, Germanic lords and bishops and Slavic princes alike actively sought to encourage the immigration of a skilled labor force from the west, offering many inducements. Peasants who cleared new land were promised ownership rights without servile duties; craftsmen and merchants who settled in new towns were granted charters of self-government. The immigrants came from German-speaking areas, like Flanders and the Rhineland, in such numbers and over such a long period that by the end of the Middle Ages some lands (such as the Wendish homeland and Prussia) had become German rather than Slavic. Even in the Slavic polities, such as Poland, Bohemia, and Lithuania, towns were often dominated by wealthy German-speaking minorities. The

organized and collective character of much of this migration merits special attention.

Peasant families did not usually set off on their own, like pioneers in 19th-century America; rather, for example, an eastern lord with land to develop would make contracts with an entrepreneur, perhaps himself a peasant who had come from Flanders with an earlier group, to find takers for so many farms by such a date. Still, most of this settlement was not so closely tied to a strong central government as tended to be the case in Ireland and Spain. Teutonic Knights, bishops, kings, noble lords great and small, and even chartered towns and their guilds would encourage new settlers in accord with the changing needs of the moment.

Some of the eastward movement of populations involved Jewish communities, largely because this High Medieval migration period also saw the rise of anti-Semitism in the western core areas. Jews in the Rhineland were massacred during the First Crusade; around 1300 the rulers of both England and France expelled all Jews from their kingdoms; and in some places in the mid-14th century they were blamed for the Black Death, or bubonic plague. Lords in the east, eager to acquire the skills for which the Jews were known, notably with respect to trade and money, were often more welcoming. The Jewish migrants eastward were culturally Germanic, or Ashkenazi. Thus, by the end of the Middle Ages the elements that would thenceforth long characterize the eastern European cultural matrix—a volatile mixture of Germanic, Slavic, and Jewish communities—were in place.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

### HEGIRA

The word *hegira* is often translated into English as “flight,” as in “to flee” from something, probably because it is associated with Muhammad’s flight from Mecca in the fall of 622 to escape a plot to murder him. Its closest English translation is actually “migration,” as in the movement of people from one place to another. There were two notable hegiras during Muhammad’s lifetime: one to Axum in Africa, across the Red Sea, and one from Mecca to Medina. When capitalized, *Hegira* customarily refers to the movement of Muhammad’s followers from Mecca to Medina.

The migration to Axum is sometimes called the first *Hegira* to signify its importance to the Islamic faith. In Arabia in Muhammad’s era, family relationships were more important than law or government, and governments often were no more than agreements among families about how public policy should be run. In the 610s Muhammad’s teachings were

creating problems for the leaders of the major clans of Mecca, especially his assertion that all gods save Allah were merely idols, a doctrine that they found very insulting. Further, his insistence that all human beings were spiritually equal was seen as an incitement to rebellion. Muhammad and most of his chief followers were protected from harm by their families, and for the time being their enemies did not threaten them. Those of Muhammad’s followers who were poor, without a family, or slaves were not protected, and by 615 Muhammad’s enemies had begun murdering them. Therefore, Muhammad sent these men and women out of Mecca, across the Red Sea to Axum, a trading empire in northeastern Africa.

The people of Axum were descendants of mixed African ethnic groups and Sabean ethnic groups from Yemen. Sending followers to Axum may have been a gamble on Muhammad’s part because the king of Axum probably had no reason to regard Muhammad as a friend. However, Muhammad’s followers seem to have gotten along well with Christians, and Axum was a Christian kingdom. When Muhammad’s followers reached Axum, they petitioned the king for sanctuary, and he gave it to them. Emissaries from Mecca asked the king to return the refugees, claiming that they had fled illegally and that some were slaves. The laws of Axum apparently allowed people to plead their cases before the king, and the refugees did so. The king rejected the arguments of the Meccan emissaries and gave the refugees permanent residence status in Axum. Muslim scholars of medieval times interpreted this act as a sign that the king accepted the truth of Muhammad’s teachings. Some of the refugees settled in Axum; others eventually rejoined Muhammad. Those who settled formed their own community, and with the aid of other Muslims, in the eighth century they drove the Axumites out of the Axumites’ lowlands into the Ethiopian highlands, where the Ethiopian Empire was established.

In 622 the leaders of Mecca decided to take direct action against Muhammad by assassinating him and his father-in-law, Abu Bakr (ca. 573–634). When the assassins entered Muhammad’s residence at night, they found someone else in his bed because Muhammad had known about the threat on his life. He and his followers had left for the town of Yathrib, where he had admirers. Thereafter the town was called Medina, meaning “the city.” Muhammad’s followers were called the *muhajirun*, meaning “emigrants,” and those who welcomed them in Medina were called the *ansar*, meaning “helpers.” This migration, the *Hegira*, was marked by the Islamic world as the moment their faith began to expand, and consequently it is year 1 in the Islamic calendar. In Medina, Muhammad gained a measure of temporal power, which he used to drive out two of the leading Jewish clans and to execute all of the men and sell all of the women and children

into slavery for their hostility toward him. From Medina he waged war against his enemies in Mecca.

## NEAR EAST

To appreciate the next stage in Islamic migrations, it is important to understand what Muslims meant by the term  *jihad* . The complete idea actually was  *jihad fi sabil Allah* , meaning “striving in the path of God.” Although the most memorable way of acting upon this idea was to wage war against infidels,  *jihad*  actually took two forms, both inspired by the Koran.  *Jihad*  could be an attack on pagans or a defense against attacks on Muslims. Medieval scholars often cited passages in the Hadith, accounts of the life and sayings of Muhammad, which show Muslims waging war on others, arguing that the passages justified attacks against nonbelievers. These ideas formed the basis for the concepts of  *dar al-harb* , meaning “the abode of war,” and  *dar al-Islam* , meaning “the abode of Islam.” Where Islam dominated was  *dar al-Islam* , but everywhere else was  *dar al-harb* . People in  *dar al-harb*  were outsiders who were to be brought into  *dar al-Islam*  either by persuasion or by force.

By the time of his death Muhammad had brought much of Arabia under his rule. After his death his followers debated whether his revelations were for Arabs only or for the entire world. This issue was not yet resolved when Muslims decided to take military action against the major powers of the Near East, the Sassanian and Byzantine empires. The Sassanian Empire had seized control of much of Yemen in the late sixth century, and it had taken control of the northeastern Arabian kingdom of Lakhmid in 602. In 631 the Sassanian Empire accepted Muslim authority in its Yemen territory. In 627 the Byzantine Empire took control of formerly Sassanian lands around the Tigris and Euphrates rivers and formed alliances with peoples in northwestern Arabia. Both empires had expended many lives of soldiers and much of their wealth in their recent war, enabling the great expansion of the Islamic world out of Arabia and into the rest of the Near East and into North Africa. About 1 million Arabian Muslims spread in the lands of 40 million to 60 million people, migrating into Egypt, into the eastern Mediterranean coast, and across the Near East into Iran.

The Muslims were a small minority trying to govern a vast territory filled with people of many different religions and cultures. As would often be the case with Islamic armies, many soldiers chose to settle in the lands they had conquered. The Islamic community had not yet decided whether Islam was only for Arabs or for the world at large. Muslims were concerned about maintaining the purity of their bloodlines because family and clans were still the basis for their social organization and a clear relationship to a particular family

was still the way for people to claim social privileges. As a result, Muslims built garrison towns, such as Basra and al-Kufa in Iraq.

In 636 a Muslim army destroyed a Sassanian settlement south of modern-day Basra and established a camp there. In 639 Basra was made a garrison city for the troops who conquered Khuzistan (639–42). Thereafter Basra served as a base of operations for invasions of Iran. Al-Kufa was founded in 637 or 38 near the city of Hira and served as a base of operations for the invasions of Iran. Al-Kufa attracted several clans from Arabia, and by 642 it had taken on a life of its own. Both Basra and al-Kufa became important intellectual centers, with Basra contributing much to medieval Islamic legal scholarship; both cities became embroiled in the theological disputes among Shiites and Sunnis. These cities represented a pattern that was followed elsewhere. Both began as encampments for Muslim soldiers. Basra was established where most of the local population had been killed or driven away, whereas al-Kufa was established near a still-functioning city. Al-Kufa served as a place where Arabs could live apart from local peoples and be protected from attacks by non-Muslims, who constituted perhaps 95 percent of the population in the late seventh century. The prosperity of each city may have attracted local peoples to the Islamic faith—to get ahead in Islamic society and to escape the  *jizya* , special taxes paid by Christians, Jews, Zoroastrians, and other “people of the book” (non-Muslims who had received divine revelations from God). Such cities as Basra and al-Kufa also contributed to the urban culture of Islam because the early gathering of Muslims in garrison towns helped orient their culture toward cities.

## NORTH AFRICA

Egypt may have been the biggest prize of the early Islamic conquests. It was a rich source of grain, art, and science. Those populations who resisted the Muslim invaders were put to the sword, but once the change of regimes from the Byzantine Empire to the Islamic Empire was assured, the earliest Muslim migrants behaved with tolerance toward Christians and Jews. During the medieval era Egypt remained a majority Christian land. The building of garrison towns was more of a conscious act in Egypt than had been the case with Basra and al-Kufa, which grew out of temporary military necessity. Such places as al-Fustat were intended to be bastions of the Arab elite.

In September 641 an Arab army under the command of Amr ibn al-Aas (d. 663) conquered the Egyptian city of Alexandria. Because of its long history of commercial, political, and intellectual achievement, Alexandria seemed to be the logical place for the capital, but Umar I, “the Great”

(r. 634–44), the second Rashidun caliph, wanted Egypt to have its capital on the east side of the Nile, making it more accessible from Arabia than was Alexandria. Earlier Amr ibn al-As had camped on the eastern side of the Nile. When a bird laid an egg in his tent, he interpreted the event as a sign that the tent was on holy ground. He marked the spot, and after seizing control of most of Egypt, he returned and pitched his tent on the spot, and his lieutenants planted their tents around his, resulting in the place being called Misr al-Fustat, meaning “town of the tents.” A mosque eventually replaced the tent of Amr ibn al-As, and using local labor, the Arabs built a walled city, mostly out of stone taken from ancient Egyptian monuments. The idea was to create a place where Arabs could live apart from the local people and maintain their Arabian bloodlines without intermarriage. The people of Egypt were allowed to live as they wished as long as they acknowledged Muslim superiority and paid their taxes.

This situation resulted in severe problems for the immigrants from Arabia to al-Fustat because they had little experience in running such a complex economy and government as those of Egypt therefore, they allowed Christian and Jewish government officials who had served the Byzantine Empire into al-Fustat to run the government. Not spreading out more into the lands of Egypt may have made the governing elite especially vulnerable, and in 969 the Fatimid Shia sect from the Maghreb, where Tunisia is today, invaded and seized control of Egypt, beginning a migration to Egypt from the rest of North Africa. Al-Fustat became one of the great cities of the medieval world, attracting from throughout the Islamic world migrants who came to attend its schools, to become merchants, to serve in its government, or to take advantage of its commercial opportunities for craftsmen.

In 670 or 71 Kairouan was founded as a site for a garrison in the Maghreb, in a forest, and it was used as a defensive position against Berbers and for launching attacks against Berbers and others in North Africa. Initially a settlement for Arabs, it became a way station for migrations of Arabs westward and for migrations of Western peoples eastward. From Kairouan the faith of Islam spread among local peoples. In 910, with the support of Berber soldiers, the Fatimids captured Kairouan and later spread their power to Egypt, drawing with them the Berbers, who spread their presence across North Africa. At this time the people of the region were primarily settled agriculturalists. Kairouan fell out of control of the Fatimid Dynasty in Egypt, and the political structure of the Maghreb fragmented into small, independent principalities. In the 11th century the Banu Hilal and other nomadic Arabian tribes migrated into the Maghreb, overturning the agricultural order, replacing it with pastoralism.

## SAHEL

The Sahel was a region stretching west to east along the southern edge of the Sahara. During the medieval era it was the site of the empires of Ghana, Mali, and Songhai as well as of numerous small kingdoms and chiefdoms. Exactly how much migration there was from North Africa across the desert to the Sahel is much debated among historians.

In the 12th century the Almoravid Berbers arose. The word *Almoravid* was derived from *al-Murabitun*, meaning “people of the monastery,” and oral tradition holds that their leaders had spiritually prepared themselves in a monastic retreat. Their exact movements are unclear, but they may have traveled first to Senegal and from there tried to conquer the lands of the Sahel, invading Ghana in 1156, fatally weakening the empire but not conquering it. The Almoravid Berbers ended up scattered thinly across much of western Africa. By the 13th century Mali was a seat of great Muslim scholarship, and its schools attracted students from throughout the Islamic world. In general, migrants from North Africa and beyond had to live apart from the local population. Visitors and migrants from the rest of the Islamic world were primarily Arabs and Berbers as well as Jews whose skills in such crafts as metalworking were welcome.

The advance of Islam in medieval western Africa and central Africa may have been more successful by peaceful means than by invasions. As a matter of faith, Muslims were expected to be able to read the Koran; in western Africa and central Africa they were literate people among people who were mostly nonliterate. Being able to write was considered an almost supernatural power among the cultures south of the Sahel. Thus, in many communities Muslims were welcomed as spiritual guides and as healers. For the Muslims who took up residence in villages, winning conversions was as simple as telling barren women who came to them for help that they would be able to become pregnant only if they became Muslim. Those medieval African societies regarded family and especially children as vital to their sense of self-worth as well as their positions in society, so such advice carried much weight.

## AL-ANDALUS

The history of Muslim Spain, known in the Islamic world as al-Andalus, has been the source of much romantic fiction as well as romantic histories. The conquest of the Iberian Peninsula, where Portugal and Spain are today, was not a simple matter of warfare. Many Christians and Jews seem to have welcomed Muslims, who brought stability and order to a land in turmoil. The initial advance of the Islamic world into the Iberian Peninsula seems to have been almost an accident. In 711 Tariq ibn Ziyad (d. ca. 720) led a small force of Berbers

and Arabs into Iberia near or through Gibraltar. Accounts differ as to why: They were pirates raiding the coast; they were on a reconnaissance mission sent by Count Julian, ruler of Sabta on the coast across from the Iberian Peninsula; they were raiders sponsored by Julian; they were sent by Julian to reclaim one of his daughters, who had been kidnapped by Visigoths, who ruled Iberia at the time. Any of these scenarios could be true because Muslims of the era did all of these activities in one place or another. What is known is that in 711 at Guadalete, the small band of Muslims defeated a Visigoth army and then plunged northward toward Seville. By 716 almost all the peninsula was under direct Islamic rule, with only a couple of exceptions, where Christian rulers acknowledged Islamic sovereignty over them.

The conquerors of Iberia were followed by settlers, not only Muslims but also Christians, Jews, and even pagans from North Africa. They were attracted by the rich opportunities al-Andalus provided. As elsewhere in the Islamic world, Muslims set about building an urban culture with a high demand for craftspeople. Muslim governments transformed much of the land with irrigation projects, bringing wild lands under cultivation, thereby making al-Andalus one of the most productive agricultural lands in the Mediterranean world. The Muslims began as a minority, but they won many converts among Christians and Jews, although some of the Christian converts readily converted back to Christianity if their homes fell under the control of Christian lords. The Muslim armies tended to be composed of outsiders. Turks, Italians, and especially Slavs were brought to al-Andalus as slaves or came to serve as mercenaries. All settled on the land and eventually married into the local population. By 1035 al-Andalus was divided into 24 different independent states. Five of these were eastern states dominated by Slavs; eight were central and southern states dominated by Berbers.

In the late 11th century King Alfonso VI of León (r. 1065–1109) and Castile (r. 1072–1109) began conquering Islamic lands. The ruler of Seville asked the Murabituns of North Africa for assistance. The Murabituns were then a rising power, mostly tribesmen who had migrated north from south of the Sahara. It seems that most people of al-Andalus saw the Murabituns as foreigners and much more alien than the Christian states with which they shared the Iberian Peninsula. This situation contributed to the confusion of armies on both sides having Christians and Muslims fighting alongside each other. By 1102 the Murabituns controlled almost all of al-Andalus, and they brought with them an influx of sub-Saharan Africans as well as North Africans.

The Muwahhiduns were highland Berbers who had migrated into North Africa's lowlands and then in the 1140s into al-Andalus. The Muwahhidun court persecuted Chris-

tians and Jews, causing Christians to migrate to the Christian kingdoms north of al-Andalus. Jews may have migrated to elsewhere in the Islamic world. Beginning in about 1216 the northern Christian kingdoms began advancing south, often expelling Muslim farmers and encouraging Christians to take over their farms. The displaced Muslims migrated either to Muslim states to the south or to North Africa, where they received a mixed welcome, with many becoming valued members of communities and others being persecuted or killed. The armies of the Christian kings were mixes of Muslims and Christians, as were the armies of the Muslim rulers, but eventually most Muslims and Jews chose to flee persecution and scattered across North Africa.

### EAST AFRICA

Before the time of Muhammad there had long existed trade routes by sea connecting Indonesia, China, India, Sri Lanka, Arabia, and East Africa. It was long thought by many historians that Muslims established trading cities along East Africa's coast, organizing trade between the interior of Africa and the international sea routes; however, modern-day archaeological digs have demonstrated that the great East African seaports began as settlements by local people, often to take advantage of ocean fishing rather than trade. By the time of Muhammad these cities, which stretched from Ethiopia to just north of the southern tip of Africa, were already important ports of call. The first outsiders to take up residence in these cities were probably Indonesians, who also settled much of Madagascar. The Indonesians were followed by Indians, Arabs, Egyptians, and occasionally Chinese. Thus, when the Arab traders began arriving in port with their new faith, they were already familiar visitors, and some had already settled in East African cities to run export-import businesses.

During medieval times many Muslims married local people, forming the Swahili culture and helping to develop the international trading language of Swahili. Most rulers of the East African city-states became Muslims, and they built mosques of coral. It is hard to say how deeply the faith of Islam penetrated the local population. In the 12th century most people in the cities and surrounding areas were still animists, with at least some believing that almost anything had spiritual qualities. By the mid-15th century this situation seems to have changed, with at least a few cities having adopted Islamic law and many of the most prosperous residents practicing the Islamic faith. There may not have been a mass migration from the Islamic world to the East African cities, but there was likely a steady but small migration of Muslims from North Africa and the Near East who sought to experience adventure, to accumulate wealth, to preach, or to solidify trading partnerships through intermarriage.

## EASTWARD BY SEA

The adoption of Islam by the Arab merchants who plied the waters along the southern coast of Asia seems to have occurred quickly, and these merchants spread their faith where they traveled. They established colonies on the coast of India, took up residence as merchants in Sri Lanka, and established colonies on the Malay Peninsula, in China, and in Indonesia. Muslim merchants sailed to trading posts along the west coast of India and followed sea-lanes south of Sri Lanka, between Malaysia and Sumatra, then north to Southeast Asia, and then to ports in China. They had colonies in Beijing, near Shanghai, and at Guangzhou. They carried with them Muslim missionaries who managed to convert some Sumatrans in the late 13th century and much of southern Malaysia and part of Java in the 15th century. In China they lived in special towns that the Chinese set aside for them. In these towns lived immigrants from many lands, most of whom worked in shipping. The Muslims were allowed to enforce their own laws, except in disputes involving people outside their own faith, when Chinese judges would impose Chinese law to settle matters.

## CENTRAL ASIA

During their first great expansion of territory during the 660s in central Asia, Muslims came up against tough, warlike peoples who tended to be lumped together under the term *Turks*. In 652 the Muslim army advanced into Balkh in Sughd and then to the fabled city of Samarqand, a key way station on the ancient Silk Road. In 713 they subdued some nomadic tribes and pressed against the western edge of Tang China's dominion, soon ending China's domination of the trade routes through central Asia. Two momentous events arose from the invasions of central Asia. One was the conversion to Islam of many Turkish cultures and the eventual rise of the Seljuk Turks, who would eventually dominate much of the Near East. The other was the attack of the Mongols during the 13th century, triggering a massive internal migration in the Islamic world.

Seljuk soldiers served in armies through much of the Near East, beginning the spread of their people and culture. Eventually they formed their own army, and in 1038 their leader, Tughrul Beg (ca. 990–1063), proclaimed himself the champion of both Sunni Islam and the Abbasid caliph in Baghdad. This proclamation was an important symbolic act because the champion of the faith was often the military ruler of Islam. Although the caliph was Sunni, Baghdad was under control of Shiites. The Seljuk army drove out the Shia army, and the caliph declared Tughrul Beg sultan—officially the military ruler. In 1040 the Seljuk Turks invaded Iran, eventu-

ally overthrowing the Ghaznavid Dynasty. In 1071 a Seljuk army defeated a Byzantine army and forced most of Anatolia to acknowledge Seljuk authority, although the land remained Christian.

The Seljuks formed a vigorous culture out of Turks, Arabs, and Iranians. In 1220 the Mongol armies of Genghis Khan (ca. 1162–1227) attacked central Asia. They drove deep into the Near East. Cities and towns that resisted the Mongols were put to the sword—every child and grownup. After a pause following Genghis Khan's death, an army of his grandson Hülegü (ca. 1217–65) sacked Baghdad and killed the caliph, ending the Abbasid Caliphate in 1258. Hundreds of thousands, perhaps millions, of people fled the invasions of the Mongols, either before the arrival of the Mongol armies or after the armies devastated the land. The economy of central Asia and the northern and eastern Near East was ruined. Refugees included not only Muslims but also Christians, Jews, and some of those Turks who still followed their old religions. Egypt, which in a desperate battle in 1260 managed barely to stave off the Mongol invasion, became the destination for many refugees. Others fled into Europe. They brought with them some of the finest craftspeople of the age, contributing to a flowering of arts, crafts, and economy in the empire of the Mamluks.

## INDIA

By 713 the Arab armies had conquered the land of Sind, to and just beyond the Indus River, seizing the valley that may have been the birthplace of Indian civilization. Then there was a poignant pause of about 300 years, during which the kingdoms of northern India and the Islamic empires to the northwest existed mostly in peace. During that period Buddhists, who had once been numerous in Sind, almost disappeared there, not from persecution but from peaceful conversion to Islam. In what is now Afghanistan, Hindus and pagans clung longer to their faiths. In the lands ruled by Hindus, Islam made headway through the preaching of Muslim missionaries. Islam had an appeal similar to the appeal that Buddhism had had several hundred years earlier. Buddhism did not recognize caste distinctions. The Muslims offered Indians a faith in which all people were equal before God. Neither king nor general was spiritually superior to any commoner. Discrimination on the basis of caste did not exist; all were allowed to worship equally in mosques, and all were allowed to know all of the sacred texts. In the Hindu caste system access to holy books was denied to low-caste members.

Thus, when Muslim armies invaded the lands east of the Indus River, there were already communities of Muslims in northern India. The invasions changed attitudes markedly, from acceptance of Muslims to outright hatred and a deter-

mined resistance to Islam among many of India's cultures that persisted throughout Islam's domination of the land. Islam was a minority religion throughout medieval times.

The invasions began mostly as raids. Historians have characterized the raiders as adventurers, bandits, and thugs, based on the writings of Muslim chroniclers who exult over acts of cruelty and slaughter. The raiders themselves seem to have wanted to be characterized as Islamic heroes, carrying doom to the infidels of India. The raiders were composed of Turks, central Asian nomads, Iranians, and others from the Near East. Outright invasion probably began with Mahmud of Ghazna (r. 997–1030), who earned the nickname "Hammer of the Infidels." By 1018 his armies had conquered Kashmir and Punjab and as far south as the city of Kalinjar. The Ghurids came from the mountains of Afghanistan and supplanted the Ghaznavids in about 1092. They went on to conquer east into Bengal and south to the Narmada River. The major migrations during this era were not so much Muslims moving eastward as hundreds of thousands of slaves moving westward, bringing with them such Indian skills as steel making and intermixing with the populations of the Near East. Muslim chroniclers record entire cities burned to the ground and over 50,000 civilians slain at a time. Having devastated local economies, the Muslim rulers sustained themselves by attacking and looting cities and temple complexes to the south.

Many of the soldiers of the Islamic armies settled in India, often recreating cities or establishing new ones. After the

Wars against the Mongols, the Mamluks ruled most of Islamic India from the 13th century to the 16th century, becoming known as India's slave kings because of their origins as military slaves. The amount of territory they ruled was fluid and depended on the abilities of each individual sultan. Nearly all of India fell under Muslim rule, either under the slave kings, who ruled from Delhi, or under the sultans of Madura, who controlled the far south of India. Most of the Islamic migrants to India were Turks, and they gradually adapted to local Indian culture, becoming more acceptable to local people by admitting Indian converts into their governments as well as by adopting some local customs of behavior.

~ *Extract from the Annals of Saint Bertin*  
(*ninth century*) ~

843 A.D. Pirates of the Northmen's race came to Nantes, killed the bishop and many of the clergy and laymen, both men and women, and pillaged the city. Thence they set out to plunder the lands of lower Aquitaine. At length they arrived at a certain island [the isle of Rhé, near La Rochelle, north of the mouth of the Garonne], and carried materials thither from the mainland to build themselves houses; and they settled there for the winter, as if that were to be their permanent dwelling-place.

844. The Northmen ascended the Garonne as far as Toulouse and pillaged the lands along both banks with

impunity. Some, after leaving this region went into Galicia [in northern Spain] and perished, part of them by the attacks of the crossbowmen who had come to resist them, part by being overwhelmed by a storm at sea. But others of them went farther into Spain and engaged in long and desperate combats with the Saracens; defeated in the end, they withdrew.

845. The Northmen with a hundred ships entered the Seine on the twentieth of March and, after ravaging first one bank and then the other, came without meeting any resistance to Paris. Charles [the Bald] resolved to hold out against them; but seeing the

(*continued*)

(continues)

impossibility of gaining a victory, he made with them a certain agreement and by a gift of 7,000 livres he bought them off from advancing farther and persuaded them to return. Euric, king of the Northmen, advanced, with six hundred vessels, along the course of the River Elbe to attack Louis of Germany. The Saxons prepared to meet him, gave battle, and with the aid of our Lord Jesus Christ won the victory. The Northmen returned down the Seine and coming to the ocean pillaged, destroyed, and burned all the regions along the coast.

846. The Danish pirates landed in Frisia. They were able to force from the people whatever contributions they wished and, being victors in battle, they remained masters of almost the entire province.

847. The Northmen made their appearance in the part of Gaul inhabited by the Britons and won three victories. Noménoé [a chief of the Britons], although defeated, at length succeeded in buying them off with presents and getting them out of his country.

853-854. The Danish pirates, making their way into the country eastward from the city of Nantes, arrived without opposition, November Eighth, before Tours. This they burned, together with the church of St. Martin and the neighboring places. But that incursion had been foreseen with certainty and the body of St. Martin had been removed to Cormery, a monastery of that church, and from there to the city of Orleans. The pirates went on to the château of Blois and burned it, proposing then to proceed to Orleans and destroy that city in the same fashion. But Agius, bishop of Orleans, and Burchard,

bishop of Chartres, had gathered soldiers and ships to meet them; so they abandoned their design and returned to the lower Loire, though the following year [855] they ascended it anew to the city of Angers.

855. They left their ships behind and undertook to go overland to the city of Poitiers; but the Aquitanians came to meet them and defeated them, so that not more than 300 escaped.

856. On the eighteenth of April, the Danish pirates came to the city of Orleans, pillaged it, and went away without meeting opposition. Other Danish pirates came into the Seine about the middle of August and, after plundering and ruining the towns on the two banks of the river, and even the monasteries and villages farther back, came to a well located place near the Seine called Jeufosse, and, there quietly passed the winter.

859. The Danish pirates having made a long sea-voyage (for they had sailed between Spain and Africa) entered the Rhone, where they pillaged many cities and monasteries and established themselves on the island called Camargue. . . . They devastated everything before them as far as the city of Valence. Then, after ravaging all these regions, they returned to the island where they had fixed their habitation. Thence they went on toward Italy, capturing and plundering Pisa and other cities.

### *The Islamic World*

#### ≈ *Ibn al-Athir: "On the Tatars" (1220-21)* ≈

For some years I continued averse from mentioning this event, deeming it so horrible that I shrank from recording it and ever withdrawing one foot as I advanced the other. To whom, indeed, can it be easy to write the announcement of the death-blow of Islam and the Muslims, or who is he on whom the remembrance thereof can weigh lightly? O would that my mother had

not born me or that I had died and become a forgotten thing ere this befell! Yet, withal a number of my friends urged me to set it down in writing, and I hesitated long, but at last came to the conclusion that to omit this matter could serve no useful purpose.

I say, therefore, that this thing involves the description of the greatest catastrophe and the most dire calamity

(of the like of which days and nights are innocent) which befell all men generally, and the Muslims in particular; so that, should one say that the world, since God Almighty created Adam until now, has not been afflicted with the like thereof, he would but speak the truth. For indeed history does not contain anything which approaches or comes near unto it. For of the most grievous calamities recorded was what Nebuchadnezzar inflicted on the children of Israel by his slaughter of them and his destruction of Jerusalem; and what was Jerusalem in comparison to the countries which these accursed miscreants destroyed, each city of which was double the size of Jerusalem? Or what were the children of Israel compared to those whom these slew? For verily those whom they massacred in a single city exceeded all the children of Israel. Nay, it is unlikely that mankind will see the like of this calamity, until the world comes to an end and perishes, except the final outbreak of Gog and Magog.

For even Antichrist will spare such as follow him, though he destroy those who oppose him, but these Tatars spared none, slaying women and men and children, ripping open pregnant women and killing unborn babes. Verily to God do we belong, and unto Him do we return, and there is no strength and no power save in God, the High, the Almighty, in face of this catastrophe, whereof the sparks flew far and wide, and the hurt was universal; and which passed over the lands like clouds driven by the wind. For these were a people who emerged from the confines of China, and attacked the cities of Turkestan, like Kashghar and Balasaghun, and thence advanced on the cities of Transoxiana, such as Samarqand, Bukhara and the like, taking possession of them, and treating their inhabitants in such wise as we shall mention; and of them one division then passed on into Khurasan, until they had made an end of taking possession, and destroying, and slaying, and plundering, and thence passing on to Ray, Hamadan and the Highlands, and the cities contained therein, even to the limits of Iraq, whence they marched on the towns of Adharbayjan and Arraniyya, destroying them and slaying most of their inhabitants, of whom none escaped save a small remnant; and all this in less than a year; this is a thing whereof the like has not been heard. And when they had

finished with Adharbayjan and Arraniyya, they passed on to Darband-i-Shirwan, and occupied its cities, none of which escaped save the fortress wherein was their King; wherefore they passed by it to the countries of the Lan and the Lakiz and the various nationalities which dwell in that region, and plundered, slew, and destroyed them to the full. And thence they made their way to the lands of Qipchaq, who are the most numerous of the Turks, and slew all such as withstood them, while the survivors fled to the fords and mountain-tops, and abandoned their country, which these Tatars overran. All this they did in the briefest space of time, remaining only for so long as their march required and no more.

Another division, distinct from that mentioned above, marched on Ghazna and its dependencies, and those parts of India, Sistan and Kirman which border thereon, and wrought therein deeds like unto the other, nay, yet more grievous. Now this is a thing the like of which ear has not heard; for Alexander, concerning whom historians agree that he conquered the world, did not do so with such swiftness, but only in the space of about ten years; neither did he slay, but was satisfied that men should be subject to him. But these Tatars conquered most of the habitable globe, and the best, the most flourishing and most populous part thereof, and that whereof the inhabitants were the most advanced in character and conduct, in about a year; nor did any country escape their devastations which did not fearfully expect them and dread their arrival.

Moreover they need no commissariat, nor the conveyance of supplies, for they have with them sheep, cows, horses, and the like quadrupeds, the flesh of which they eat, naught else. As for their beasts which they ride, these dig into the earth with their hoofs and eat the roots of plants, knowing naught of barley. And so, when they alight anywhere, they have need of nothing from without. As for their religion, they worship the sun when it rises, and regard nothing as unlawful, for they eat all beasts, even dogs, pigs, and the like; nor do they recognise the marriage-tie, for several men are in marital relations with one woman, and if a child is born, it knows not who is its father.

Therefore Islam and the Muslims have been afflicted during this period with calamities wherewith no people

*(continued)*

*(continues)*

hath been visited. These Tatars (may God confound them!) came from the East, and wrought deeds which horrify all who hear of them, and which you shall, please God, see set forth in full detail in their proper connection. And of these was the invasion of Syria by the Franks (may God curse them!) out of the West, and their attack on Egypt, and occupation of the port of Damietta therein, so that Egypt and Syria were like to be conquered by them, but for the grace of God and the help which He vouchsafed us against them, as we have mentioned under the year 614 [1217–18]. Of these, moreover, was that the sword was drawn between those who escaped from these two foes, and strife was rampant, as we have also mentioned: and verily unto

God do we belong and unto Him do we return! We ask God to vouchsafe victory to Islam and the Muslims, for there is none other to aid, help, or defend the True Faith. But if God intends evil to any people, naught can avert it, nor have they any ruler save Him. As for these Tatars, their achievements were only rendered possible by the absence of any effective obstacle; and the cause of this absence was that Muhammad Khwarazmshah had overrun the lands, slaying and destroying their Kings, so that he remained alone ruling over all these countries; wherefore, when he was defeated by the Tatars, none was left in the lands to check those or protect these, that so God might accomplish a thing which was to be done.

### ► military

#### INTRODUCTION

In the wake of the professionalism of the Roman army, the Middle Ages in Europe and the Mediterranean saw the return of the heroic warrior. The Germanic and Arabic tribal

peoples that overwhelmed the empire possessed an ethos of duels and vendettas carried out by single warriors fighting against each other for honor. Close-order drill and the submersion of the warrior into the mass of mere soldiers were foreign to this mentality.

The Islamic states that succeeded Rome on the southern and eastern shores of the Mediterranean and expanded far into central and southern Asia quickly copied the professional organization, tactics, and logistics of their main opponent, the surviving Eastern Roman Empire, or Byzantine Empire. In the West, however, the heroic ideal lived on in the knight. The feudal aristocracy of western Europe saw themselves as heroic knightly warriors devoted to ideals of personal honor. In war they would rather capture an enemy than kill him, so that his armor (a very valuable commodity) could be taken and a ransom collected. They trained for single combat, and a major focus of their careers was the tournament, a sort of stylized display of single combat in which the combatants essentially gambled their armor on the outcome of their fights. While knights devoted their whole lives to warfare, they remained, as it were, professional amateurs.

Knights did make highly effective heavy cavalry, but they found themselves at a disadvantage when fighting professional Byzantine or Islamic armies. The knightly heroic form of warfare came to an end when it became evident that they could not withstand more flexible professional peasant armies, as evidenced by the difficulties knights encountered

against levies of Welsh archers in the Hundred Years' War and the popular peasant armies of the Swiss and of the Czechs in the Hussite wars.

The Aztec also engaged in heroic warfare. Although Aztec warriors began as professional mercenary soldiers, once they formed an empire in central Mexico, they developed an entirely heroic style of fighting. They faced no serious external military threat, so their warrior honor was satisfied by annually declaring war on their own subject peoples and sending warriors out to fight them. They gained honor not by killing the "enemy" but by wounding them and bringing them back as captives to the Aztec capital Tenochtitlán for ritual sacrifice.

Notable military professionalism developed in the Middle Ages among the Inca. Their method of waging war depended on putting overwhelming numbers of soldiers into the field and keeping them supplied as a force through an excellent logistical system. A similar development of military professionalism with an emphasis on force size and logistics enabled the growth of the Kongo Empire in central Africa at the end of the Middle Ages. But the triumph of medieval military professionalism came from a most unexpected source, the steppe tribe of the Mongols. Their leader Genghis Khan was a military genius on the order of Alexander the Great or Napoleon. He forged a group of talented professional command and staff officers around himself that was able to achieve strategic and logistical miracles (especially in the conquest of the Khwarezmian Empire in inner Asia and Iran) and absorb and adapt the superior military technology of China. Once the influence of Genghis Khan's personal magnetism ended, the Mongol Empire (the largest in history) fell apart, and its military arts stagnated.

The transformation of warfare in later eras depended on a new development introduced into warfare in the Middle Ages: gunpowder. The substance itself probably was invented in China about 1100 by alchemical experiment. It was only slowly adapted to warfare. It was spread to Europe and the Islamic world by the success of the Mongol conquests. At first it was used in the form of grenades (explosives thrown by catapults) and as a sort of flamethrower shooting out of brass tubes mounted on the end of sticks. The effect of these early weapons was more psychological than actual. Eventually the flamethrowing tubes began to be loaded with broken glass or pebbles, which evolved into both small arms and cannon. These arms used existing technologies: the bronze-casting technologies used to make bells and the spherical stone balls already favored as projectiles in trebuchets.

Cannon became effective in siege warfare in China in the 14th century and in Europe in the 15th century. It made all existing fortifications obsolete, since the thin, high cur-

tain walls could be breeched quickly by cannon fire. Small arms, however, proved ineffective because of their slow rate of fire. They were first used practically by the Hussite peasant army in Bohemia and finally were properly integrated into a tactical system with pikemen and cavalry by the Spanish, as demonstrated in the battle of Cerignola (1503) at the very end of the Middle Ages, resulting in a mass slaughter of knights attacking harquebusiers (soldiers manning matchlock guns) in fieldworks.

## AFRICA

BY JUSTIN CORFIELD

The tribal customs that involved people serving in the armies of medieval Africa varied, with few parts of Africa able to maintain large standing armies. As a result, those places where large armies were able to be maintained quickly emerged as powerful kingdoms; many of them, however, did not last for more than a few centuries, possibly because of a failure to be able to continue to pay for the costs of running a large army as much from internal factionalism and outside pressures.

From the 430s until the 530s the Vandals emerged as a major military power in northern Africa, managing to take most of modern-day coastal Morocco, Algeria, and Tunisia from the declining Roman Empire. They raised their armies essentially by heavy expansion, rewarding their supporters by looting and pillaging cities, and their name remains synonymous with wanton destruction or desecration. Their soldiers were mainly mounted on horses without horse armor used by the late Romans and Byzantines at that time, enabling them to raid enemy settlements and evade pursuit. In battle it also gave them greater maneuverability. This method of fighting and the process of enlarging their land holdings allowed the Vandals to maintain large numbers of soldiers as long as they were successful militarily and continued to expand. This meant that when the Vandals started to suffer military reverses, such as attacks by the Byzantines in the 530s, the Vandal forces rapidly collapsed, as they had not relied on raising soldiers from the populations of areas they had occupied.

From the early seventh century there seems to have been extensive fighting in the Nile states of Maqurrah, Nabotia, and Alwah, with Maqurrah conquering Nabotia. The power vacuum that resulted led to the creation of a number of small states on the southern frontiers of Egypt; farther south it was not long before the Bantu kingdom of Zanj in modern-day Kenya had taken over the southern part of Somalia. This proliferation of states accelerated with the decline of the Axumite empire when the queen of the kingdom, Esato (or "Judith"), destroyed the countryside around Axum in 976. The fall of Axum also led Maqurrah and Alwah to grow in power. Both

became wealthy through trade with the Arabian Peninsula. It seems likely that Arab weapons were traded, which allowed both Maqurrah and Alwah to increase in power.

In western Africa the kingdom known as Wagadou and later as the Ghana Empire, located in modern-day Mali, rose in power through the use of its military strength. This seems to have been because the gold reserves that the kingdom had built up could be used to raise armies from the people within the empire to maintain a small standing army whose mobility on horseback made them impossible to challenge. The Almoravids from northwestern Africa raised large numbers of horsemen and attacked isolated settlements, and in 1076 they sacked the Ghanian capital of Kumbi. This seems to have been because the Almoravids were able to maintain a larger army for a longer time than their opponents, and they used the tactic of surprise on their rivals in Ghana.

The sacking of Kumbi led to a rapid decline in the Ghana Empire, and it broke up into a large number of smaller states; the most important three were Susu, Mali, and Songhai. The

Susu were the first to emerge as a strong military power, led by King Sumanguru, who commanded an attack on Kumbi in 1203 and the temporary conquest of Mali in 1224. However, the victory of the Susu was short-lived, and in 1235 King Sundiata of Mali managed to expand his lands to cover some of the area previously controlled by the Susu and the Songhai. The kingdom of Mali reached its height under the emperor Mansa Musa, who reigned from 1307 until 1332. Much is made of his pilgrimage to Mecca, when he took some 60,000 servants and soldiers and 12 tons of gold. While the emperor Mansa Musa was away, he left General Sagmandia in charge, and the general took the opportunity to attack the Songhai capital at Gao, thus allowing Mali to expand its lands much farther than ever before.

By the mid-ninth century the kingdom of Kanem near Lake Chad had become so wealthy through the trans-Saharan caravan trade that it also could maintain its own armies for longer periods than its neighbors. By this time the Axumite empire was declining in importance and the Zagwe Dynasty from central Ethiopia was starting to become more powerful. This was achieved largely by deploying garrisons throughout northern Ethiopia to protect isolated settlements from the depredations of the Mamluks of Egypt. With the Mamluks and their allies powerful at sea, the Zagwe Dynasty gradually withdrew from its coastal settlements, which in turn caused Ethiopia to become more isolated. Because Mamluk attacks were usually made with cavalry charges, Ethiopian military fortifications incorporated higher walls with narrower and smaller entrances to forts and monasteries that included at least two levels of defenses, thereby forcing attackers to dismount in order to pass through the first line of defense, making them more vulnerable to the defenders.

Although the civilization of Great Zimbabwe also dates from the mid-ninth century and undoubtedly had a large army to maintain its state structures, nothing is known for certain about the training and tactics used; however, it is probable that they did employ methods similar to those in other parts of southern Africa during the early modern period. Young, unmarried men served in a permanent standing army; after giving up this role to marriage, they could still be called up as reservists at any later stage. Training would be undertaken with a view to fighting other tribes as well as hunting for food or sport. In terms of tactics, the vast majority of the fighting was hand to hand; the army that was better trained and larger had the advantage. Most groups in southern Africa were unable to maintain large standing armies. The grain supplies at Great Zimbabwe thus were established, as some archaeologists have argued, to provision just such a force at times of emergency and for far longer periods than their opponents.

*Archer figure; inland Niger Delta region, Mali, 13th to 15th centuries* (National Museum of African Art, Smithsonian Institution, Photograph by Franko Khoury, Museum purchase, 86-12-1)

The rise in power of Mali seems to have encouraged a number of Hausa states in western Africa to use imported weaponry and tactics in their own war of colonial expansion. This was also done by the kingdom of Kongo in modern-day Democratic Republic of the Congo and Angola. This trend toward importing weapons became noticeable during the last decades of the 15th century when Portuguese traders had started to arrive in western Africa and Kongo, bringing with them the technology for the use of musketry and cannons. Similarly, in East Africa, contact with Arab traders allowed people in and around modern-day Zanzibar to import Turkish weaponry.

As a result of this imported technology, from the 1430s until the 1490s there was a dramatic change in the power balance throughout much of Africa. The city of Timbuktu was sacked by the Tuareg in 1431, Ewuare the Great of Benin (fl. 1440–80) massively expanded his kingdom, the Songhai under Sonni 'Ali sacked Timbuktu in 1468, and the Mossi continued their lightning cavalry attacks on the Sonni, leading to the battle of Kobi in 1483 when the Mossi were finally defeated. During the 1480s contact between the Portuguese and the kingdom of Kongo allowed the latter to gain new technology, leading to the creation of one of the first “secondary empires” in Africa.

## THE AMERICAS

BY J. J. GEORGE

The best information regarding military systems in the period from 500 to 1500 correlates with the largest and most organized societies of the time: the 15th- and 16th-century Aztec and Inca civilizations as well as the city of Teotihuacán, which had an institutionalized military by at least 500. Like other developed social institutions, military institutions are intended to organize values, attitudes, and interests in the service of social needs. An organized military implies a sophisticated authority structure often attributed to advanced societies and is thus linked to the origin of civilization. Regardless of whether the military is necessary for the transition to state organization and civilized life, it is very close to the core of civilizations as they have developed. The Americas was no exception.

After 500 Teotihuacán, centered 40 miles northeast of contemporary Mexico City, began to decline. Teotihuacán introduced the use of quilted-cotton body armor, which the Aztec later adopted. Other innovations used by the military of Teotihuacán was the atlatl (spear-thrower), thrusting spear, and rectangular shield, all of which were standardized and thus indicative of mass recruitment and an organizational capability usually reserved for advanced societies.

Murals at Teotihuacán also depict warriors as eagle and jaguar deities, suggesting individual ritualized battle as part of a growing war cult and of sacrificial practices meant to indulge the gods, a practice especially common among the Toltec and later the Aztec.

Teotihuacán fell by 750, and in the ensuing power vacuum, regional centers emerged in central Mexico, many in fortified hilltops, including Xochicalco, Cacaxtla, and Teotenango. Tula (800–1150), or Tollan, the center of the Toltec, emerged as a major city and regional power, of which militarism was a major feature. Military prominence is reflected in carvings of giant warriors, the prominent positions of the military orders of eagles and jaguars, and the introduction of new weaponry. The Toltec introduced a short, curved wooden sword, about 18 inches long, with inset stone blades. Armed with the atlatl, quilted-cotton armor, and a shield, the Toltec warrior was effective both as a projectilist and hand-to-hand combatant. Toltec weaponry appears to have been standardized, suggesting state control, formal units, military societies, and a chain of command. Legends told by the Aztec and recorded by the Spanish further reveal Toltec military prowess, though some of these are exaggerations by the Aztec to ennoble themselves by adopting the Toltec legacy as part of their own ancestry.

The Aztec, or more specifically the Aztec-Mexica, were originally a pugnacious, wandering people from the north. Their legends describe them leaving Tollan around 1250 and entering the Mexico basin around 1325 to settle a swampy, virtually uninhabitable island in the middle of Lake Texcoco. This island became their great capital city of Tenochtitlán and then Mexico City after the Spanish arrived in 1521.

Their reputation as soldiers served them well. Initially they hired themselves as mercenaries to local polities in need of extra punch. By the mid-15th century they had organized themselves and were a legitimate civic enterprise with a confident military institution. Aztec armies were extremely well managed and supplied. The army was typically divided into commands of 8,000 men, who could march up to 12 miles a day carrying rations for an eight-day campaign. All males, regardless of their place in the rigid social hierarchy, were born as potential warriors and had a chance to rise to high warrior status by attending the military schools (*calpulli*) in their city districts. The men were warriors, not soldiers in the traditional sense, expected to fight because of a place in society and not because of pay or obligation.

The typical warrior was a novice fresh from training and one of a group organized to learn how to take captives. A unique feature of the Aztec war machine was that its goal was not to kill enemies but to take them hostage to realize ritual sacrificial requirements. Warriors were graded according to

Warrior figure; ceramic with slip and paint, Remojadas culture, Mexico, 600–900 (Los Angeles County Museum of Art, Gift of Constance McCormick Fearing, Photograph © 2006 Museum Associates/LACMA [M.86.311.41])

the number of captives taken, and the most senior warriors, those who had taken seven or more captives, were distinguished by magnificent eagle and jaguar warrior costumes.

The matched duel was the preferred mode of combat, with warriors searching the battlefield for an enemy of equal or just-higher rank. Bringing an opponent down by a blow to the leg was ideal, wounding him enough to enable the Aztec warrior to wrestle the enemy to the ground, bind him by rope, and take him to the rear of the battlefield. The preferred Aztec weapon was the wooden club or sword studded with obsidian flakes. They also used the bow and arrow, spear, and atlatl and later adopted the thrusting spear with a longer-bladed surface (*tepoztalli*) and the bladed wooden broadsword (*macuahuitl*). Warriors carried small round shields and wore quilted-cotton body armor, similar to that of Teotihuacán and sufficient to retard arrows. The Spanish adopted cotton armor once they realized their steel breastplates were not only morbidly hot but also superfluous.

In the Mayan areas of Central America combat was largely a noble's enterprise, which translated into small forces with no chain of command, little or no standardized weaponry, and no drilled formation combat. Rather than large-scale battles, raids seem to have been the typical form of engagement. Raids legitimated kings and their right to rule. Further, preferring not to conquer and control cities or centers, which necessitated too much manpower, the Maya

conducted raids to gain tributaries and control dependent laborers. Defeat meant the loss of wealth, territory, and labor and thus a loss of power.

Warfare is a general characteristic of prestate complex societies similar to many Mayan polities. Competition over prime agricultural land, labor, and access to prestige goods may have motivated conflict in these societies. Mayan polities, however, often did not have the political strength, manpower, or organizational and logistical sophistication to conquer and control other polities and may have opted to weaken competitors or form alliances. To repel these protomilitaristic advances, many later Mayan sites developed fortifications. The Mayan lowlands are littered with fortifications and fortresses. The weaponry of the time—spears, spear-throwers, rocks, slings, and obsidian-bladed clubs—was limited in range, and height was a primary tactical advantage. Thus, securing the chief temple in most Mesoamerican centers was of prime tactical advantage. Defensive moats were known as early as the Late Formative Period (ca. 300 B.C.E.–ca. 250 C.E.) at Tikal and Becan, and defensive walls were known at El Mirador and Calakmul. Further indication of military organization among the Maya is seen in lintels at Piedras Negras (sixth to ninth centuries) showing numerous soldiers in standard uniforms kneeling in ranks before an officer. At Chichén Itzá in the Mexican Yucatán, the Toltec invasion in the late eighth or early ninth century brought with it weapons, cotton armor, and the Toltec short sword, a combination that allowed Chichén Itzá to maintain a small regional empire for more than 300 years.

The advanced, organized, state-controlled military enterprise of the Aztec or Teotihuacán was unknown in North America, and conflicts there are better categorized as chiefly warfare and raiding. Evidence of defensive fortification from many sites throughout the Southwest, Midwest, and Southeast indicate that warfare was common. Many sites in the Southwest were located and built defensively. Communities were spaced by large no-man's lands yet were located to effect line-of-sight communication between them. This community-building strategy was intended to minimize conflict or, in the event of conflict, to enable neighbors to communicate. Most Mogollon villages dated between 200 and 600 are located on hilltops. In the Anasazi region of southwestern Colorado and northern New Mexico, small hamlets with palisades were established, and some larger sites are located on mesa tops. Among the Mississippian cultures of the Southeast and Midwest some form of a military cult was thought to be extant, as seen in figural images displaying idealized warriors dressed as bird deities—not unlike the Aztec and Teotihuacán eagle and jaguar warriors—bearing clubs and holding severed heads. With warfare endemic, towns became fortified by palisades, bastions, and moats.

In South America the best evidence comes from the Inca, which flourished magnificently, though briefly, from 1434 until the Spanish arrival in 1532. For the Inca, diplomacy, reward, and enculturation were essential ingredients of empire building, though the military had its role. When military action was necessary, the Inca relied on a large, well-disciplined army with a well-organized supply system; strategy and logistics, not training, tactics, or technology, were primary reasons for Inca military success. Late in Inca times the army may have become a professionalized standing army, but initially it comprised units of peasant conscripts on rotational labor duty, using their own weapons and led by their own lords. The emperor was commander in chief and, at least in the initial stages of the empire, acted as field commander. A hierarchy of soldiers was beneath him, the highest of which were usually royal kin. The Inca were said to be able to raise an army of 100,000. Accordingly, favorite tactics included the use of overwhelming force and counterattack.

Logistical efficiency was paramount, given the nature of the physical empire—stretching over 3,400 miles from Quito, Ecuador, to Santiago, Chile, through deserts and jungles and over and around the Andean mountain range. The ability to maintain control relied on a sense of order; to maintain order the Inca had many strategies, including forced displacement of populations, construction of provincial centers from the ground up to facilitate administration, as well as subjugation through military control. Although fortified strongholds were not abundant in most of the Inca region, structures appropriate for military use were found all over. *Kallankas*, large rectangular buildings that sometimes served as barracks, were the most appropriate construction. At Vilcaswaman, one such *kallanka* was said to house 30,000 soldiers. The Inca also built storehouses across the region to feed, clothe, and maintain army units on long-distance campaigns. Finally, the far northern and southern frontiers of the Incan lands saw a heavy concentration of fortified sites, reflecting an intense concern for military security at the frontier.

## ASIA AND THE PACIFIC

BY NAM C. KIM

China's medieval period starts in the fifth century during a time marked by conflict and instability. The nature of medieval warfare stemmed from developments in the Warring States Period (ca. 475 B.C.E.– 221 B.C.E.), including large standing armies along with the advent of cavalry forces and crossbow weaponry. From then on, the scale of battles grew as the result of the sponsorship of state-level polities. Battles fought by competing dynasties had armies numbering in the tens of thousands as well as naval fleets. Mobilization and

transport requirements were important considerations. In addition to infantry, armies consisted of skilled horse archers, who provided the tactical advantages of speed and mobility. Wheeled vehicles drawn by animals also were deployed as mobile fortifications.

Deploying naval forces involved tactical use of inland waterways. Boats were used both for transportation and as mobile firing platforms. Powered by sails and oarsmen, vessels carried crossbowmen, and some had trebuchets (engines of war with a sling for hurling objects or projectiles). By the time of the Sui Dynasty at the close of the sixth century, mixed land and naval forces numbering in the hundreds of thousands were being sent into battles. Military power depended on farming communities from which governments could draw taxed resources, in the form of food, fabric, and *corvée* (unpaid) labor. *Corvée* labor was necessary for building and maintaining fortifications and canals, and all male commoners could be called to military service.

Armored cavalry often played a decisive role on the battlefield, particularly during the early Tang Dynasty at the start of the seventh century. Superior mobility allowed cavalry units to scout terrain, outmaneuver enemy forces, break enemy lines, and raid supply convoys. Military units consisting of hundreds of locally recruited men were based in prefectures (districts). Tang soldiers, known as the *fubing*, were expected to support themselves through farming during peacetime and served lifelong military commitments.

In the 13th century Mongol forces overthrew the Western Xia and Jin dynasties of China, establishing the Yuan Dynasty. Mongol military tactics featured steppe cavalrymen, armed with the composite bow, shock weaponry, and light armor. Mongol forces were highly mobile on open battlefields, and horses were equipped with saddles and stirrups, allowing soldiers to carry equipment and fight from the saddle. The Mongols also used siege warfare, with trebuchets, to overtake Chinese fortifications. There is evidence suggesting that the Mongols encountered and acquired gunpowder from the Chinese at this time and that the Mongols in turn may have introduced the innovation into other parts of Asia, such as India.

Although the origin of gunpowder remains the subject of debate, Chinese armies began using explosive projectiles during the Song Dynasty of the 10th through 13th centuries. Gunpowder-based weaponry remained rare early on. Over the next few centuries, gunpowder devices evolved into delivery of explosive grenades by catapult and mortar tubes, gradually culminating in the use of firearms. During the Ming Dynasty (1368–1644), Chinese military forces were increasingly using firearm and cannon technologies. In addition, naval forces were also employing cannons.

Mainland Southeast Asian warfare during the first millennium shared similarities with Chinese warfare. Northern parts of Vietnam were under Chinese rule until the 10th century, at which time the Vietnamese fought against imperial control and reestablished indigenous rule. The battle of Bach Dang River in 938 illustrates military tactics of the time. Chinese forces from the north were mobilized southward into the region by warships along the seacoast. Using the high tide as cover, the Vietnamese planted large barrier poles, sharpened and iron tipped, into the riverbed while using smaller boats to bait the Chinese ships to give chase. As the Chinese sailed upriver in pursuit, the tide fell, and they were trapped in the river by the poles. Three centuries later the Vietnamese used a similar tactic at the same location to repel Mongol invaders.

Champa is the generic name referring to small coastal kingdoms ruling over central Vietnam during the first millennium. These kingdoms became unified into a regional power during the early second millennium. Not much is known about military tactics, though historical and archaeological evidence suggests periods of warfare, which include the Vietnamese military incursions into Champa territory between the 10th and 15th centuries. During this time the Chams erected large, fortified citadels with earthen ramparts and outer moats.

Inscriptions describe the founding of the Khmer Empire in the ninth century through pacification of the Cambodian countryside in the lower Mekong River basin. Angkor Wat was built in the 12th century and served as the imperial capital of the Khmer Empire, which dominated much of Southeast Asia for six centuries. Angkor Wat's outer wall is approximately 5 yards in height and is surrounded by a large moat. During the Angkor Period (802–1431), the region was marked by internal and external warfare, including wars with the Champa Kingdom. The Khmer Empire pursued military expansion, possibly to finance state activities by capturing and incorporating labor in neighboring territories.

Japan's medieval period generally spans the 12th century to the 19th centuries. During this time powerful regional families and warlords (shoguns) ruled the country, with an emperor serving as a figurehead. Before this era much of Japan's military order was influenced by Chinese civilization. The decline of Chinese influence during the 10th century led to Japanese civil war and the emergence of various military clans.

Military recruitment became largely privatized, even for government troops. The emperor's court was left intact and without a state-run army, only to perform ceremonial functions, while the powerful *bushi* class raised and trained private armies of samurai warriors. At the beginning of the medieval period the emperor still retained the right to sanction mili-

tary mobilization. However, this power gradually lessened as power shifted into the hands of the shogun *bushi* class that often led private military campaigns against each other.

Before gunpowder Japanese military weapons were already widely used during the first millennium B.C.E. Prominent weaponry included the horse and longbow, usually made from wood or bamboo. After the fifth century C.E. lamellar armor (armor composed of small plates laced together) became common, and mounted archers emerged, as horses were imported into the islands. For the most part, horse-riding archers defined the military tactics of early medieval Japan. Swords were also widely distributed and used during the Heian Period (737–1185) at the close of the first millennium.

By the 11th century samurai combat marked most battles. Over the next few centuries, sword dimensions changed, including length, blade curvature, and use of hand guards. Premedieval and medieval soldiers also used self-standing wooden shields and lamellar body armor, usually made from iron or rawhide. As the medieval period progressed, military forces used mixtures of light and heavy cavalry with light and heavy infantry. The Portuguese introduced firearms into Japan during the 16th century, and though culturally rejected at first, firearms would eventually become incorporated into military tactics very late in the medieval period.

Medieval Japanese warfare also saw the use of fortifications in the form of ditches, palisade walls (fenced enclosures), and towers. Extensive fortifications were relatively rare until the 14th and 15th centuries. Before that time field fortifications characterized by ditches and earthen ramparts were largely basic and temporary.

On the Indian Subcontinent during the fifth century, the Gupta Empire ruled over most of modern-day India and Pakistan. Known as the golden age of India, the Gupta Period spans approximately the years 320 to 600. Military tactics featured infantry archers with longbows and metal arrow points. The long range of bows offered an efficient means of defense against horse archers. Archers were used in conjunction with infantry, who were equipped with swords, javelins, and shields. Gupta military forces also used elephants, armored cavalry, and siege engines, such as catapults.

In the Middle Ages of India armies generally consisted of feudal levies. Indian kings lacked standing armies, and village chiefs probably were responsible for raising horses and soldiers when called upon by the king, with mercenary forces being used as well. Armies combined the use of infantry and mounted soldiers. For instance, the Pala Empire, which controlled northern and eastern India from the eighth century to the 12th century, used a combination of infantry, cavalry, elephants, and chariots. Weaponry ranged from shock weapons, such as swords, clubs, axes, and hammers, to projectile

weapons, such as discuses, bows, javelins, and slings. Fortifications were relatively similar to earlier times, although there was an increased use of hilltop fortifications. Defensive works usually incorporated walls, defended gates, bastions, and moats. Many cities were fortified, and siege warfare consisted of blockades and direct assaults.

The Three Kingdoms Period (300–668) of the Korean peninsula featured the rival polities of Koguryo, Paekche, and Silla. Historical and archaeological evidence indicates warfare between the three kingdoms and with outside powers in China and Japan. Given the peninsula's geographic proximity to China, much of the available military technologies on the peninsula were relatively similar. For example, the Koguryo military featured use of cavalry mixed with infantry. Infantry soldiers wore padded armor and helmets, while higher-ranking officers were equipped with armor of lamellar iron. Shock weapons included bronze and iron swords, spearheads, and axes, while longer-range weapons included bows with metallic points.

Human colonization of many of the South Pacific islands commenced during the first millennium B.C.E. and continued during the first millennium and early second millennium C.E. According to oral histories, warfare was widespread within these Oceanic and Polynesian societies prior to 18th-century European contact, especially as populations grew. In general, warfare was a means to consolidate resources, people, agriculturally productive territory, and political power. Native histories describe battles waged by ruling classes of chiefly leaders who fought wars of conquest and succession. Complementing the historical record, warfare is indicated by archaeological evidence, which includes fortifications, weaponry, war temples, and refuges.

For example, the Maori of New Zealand first settled the island during the 11th century, and their communities eventually developed into large, hierarchical villages. Maori societies constructed heavily fortified settlements known as *pa*, typically consisting of a hilltop fortress marked by palisades, ditches, and embankments. Over 4,000 such forts have been found. Hawaiian societies did not construct fortifications, although there is evidence for the use of refuges, such as walled-up lava tubes. For Marquesan societies, warfare ranged from simple raiding to conquest of land. Some Marquesan settlements were also marked by defensibility, with ditched fortifications and strongholds.

Very broadly speaking, Polynesian warfare included both long-distance weapons, such as slings and spears, as well as shock weapons, such as lances, wooden daggers, and clubs. Maori warriors, known as *toa*, used spears and clubs with embedded shell, bone, or stone for lethal edges. These societies also used war canoe fleets, propelled by sails or paddles,

for transporting troops over longer distances. For instance, the Tongans used war canoes to invade and conquer Samoa.

## EUROPE

BY BRADLEY A. SKEEN

The art of war, the understanding and application of strategy, was largely static during the Middle Ages, although there were incremental changes in some areas, such as the design of armor and the naval architecture of warships. Western European armies of knights evolved from the war bands of the ancient Germanic kings. The Byzantine Empire maintained a professional army that was based on that of the older Roman Empire. Warfare changed dramatically, however, in the 15th century as new technology such as gunpowder became prominent and popular armies began to emerge.

The Byzantine army was reformed by the emperor Maurice (r. 582–602), who transformed the Roman army of late antiquity into its medieval form. All officers were directly appointed and could be removed at will by the emperor. The army was distributed throughout the empire. Each theme (a Byzantine government administrative unit) had its own force of as many as 10,000 men. If this force was unable to deal with an invasion, forces from neighboring themes would come to its aid. This deployment dedicated the Byzantine state to a defensive posture. Beset on all sides by enemies who vastly outnumbered them, the Byzantines did not think in terms of grand offensives that would solve their military problems once and for all.

Byzantine soldiers were long-service professional volunteers. They were highly disciplined and trained; thus, they were far more effective than any other soldiers in the Middle Ages. Soldiers came especially from the mountainous regions of central Asia Minor (modern-day Turkey). Such recruits had the natural advantages of highland soldiers. Because their family farms were principally concerned with raising cattle, sheep or goats in mountain pastures rather than only the cereal crops that dominated agriculture in most areas, they were taller and more physically capable, owing to a diet more heavily based on meat and milk products rather than the wheat gruel that was the staple of most peasants. Also because of diet, the infant mortality rate was low; thus, mountain farmers tended to have more children than their land could support, creating a steady supply of young recruits. They were experienced in riding and hunting even before entering the army. These same features would characterize other outstanding groups of soldiers throughout the Middle Ages, such as the Welsh and Swiss.

The tactical model of the Byzantine army was descended from the warriors of the Germanic tribes that had made up

## CROSSBOWS

One of the major weapons of war in late medieval Europe was the crossbow. It had been developed in China during the Han Dynasty (202 B.C.E.–220 C.E.), being used in war as early as 353 B.C.E.; indeed, some representations of crossbows have been found among the so-called Terracotta Army of Qin Shi Huang (r. 221–210 B.C.E.), the first emperor of China. Anna Comnena, daughter of the Byzantine emperor Alexius I Comnenus (r. 1081–1118), called the crossbow “a weapon of the barbarians absolutely unknown to the Greeks,” but soon it was being adopted by the Byzantines and first used in Europe soon after the First Crusade of 1099.

The effectiveness of the crossbow and the fact that it was first used against the Byzantines by the Turks led Pope Urban II (ca. 1035–99) to ban its use against other Christians, but within 100 years it was being used throughout Europe. Workshops in London, Genoa, Paris, and Prague mass-produced the crossbows, and, initially at any rate, it was to be used against non-Christians only. Conrad III, duke of Swabia and Holy Roman Emperor from 1138 until 1152, forbade anybody to use the crossbow in his lands, despite the fact that there were already many crossbowmen in Bohemia. The king of England, Richard I, “the Lion-hearted” (r. 1189–99), used a crossbow and was himself killed by a bolt from a crossbow. In 1238 the emperor Frederick II of the Holy Roman Empire (r. 1212–50) started using a cavalry unit of Hungarian mercenaries armed with crossbows as skirmishers.

Pope Gregory IX (before 1170–1241) used mounted crossbowmen from Provence, in southern France, to defend his lands against the Lombard League (an alliance of cities in northern Italy) in the following year, and Louis IX of France (r. 1226–70) also used the crossbowmen to great effect at the battle of Mansura, in February 1250, during the Seventh Crusade. Gradually they proved to be less effective against the English longbowmen, as seen at the battle of Crécy in 1346, though they continued to be used by the Spanish during their expeditions to the Americas from 1492.

the forces of the later Roman Empire rather than the classical Roman legions. The cavalry was the most important arm of service. The heavy cavalry, or cataphracts, could charge with the lance, but its main weapon was the bow. Troopers and their horses both wore full suits of mail armor (that is,

a leather suit with small overlapping metal plates sewn on). More lightly armed cavalry wore only a mail cuirass (armor covering the body from the neck to the waist) and carried a shield; they fought with a lance or sword. The heavy infantry wore light armor and carried a shield and battle-ax. Light infantry fought with bows.

In his military manual the *Tactica* (Tactics), the emperor Leo VI (r. 886–912) describes the specific tactics useful against each of the diverse enemies the Byzantines faced. Fighting Western forces in Italy, the massed charge of fully armored knights was something the Byzantine forces could not withstand. They nevertheless considered the Europeans to be their easiest opponents. Byzantines thought European commanders incompetent; blinded by “chivalry” to military necessity; willing to accept battle whenever it was offered, even if on unfavorable terms; and incapable of maintaining outposts or reconnaissance. After a few weeks of maneuvering, the inferior logistic system of the European armies would break down and cause them to start to break up even without battle, and many of the soldiers would desert with no prospect of finding glory in battle. The charge of the knights could be dealt with by the Byzantine army simply by retreating, pretending to have been broken; not realizing that this was a trick, the knights would scatter to begin a pursuit and then could be effectively counterattacked when the Byzantines stopped their feigned retreat.

The nomadic steppe tribes that lived north of the Black Sea specialized in raids and ambushes. If they could be forced to fight, their forces could be destroyed by the charge of Byzantine heavy cavalry. They could not sustain contact with Byzantine infantry either, since their bows had a shorter range. The Slavic tribes in the Balkans were easy to overcome in pitched battle, because they had no cavalry and could not withstand a charge of Byzantine cataphracts. They were, however, expert at laying ambushes in their native mountains.

The Arab armies were the most difficult for the Byzantines to fight. By Leo’s time the Arabs had essentially copied the Byzantine military system, though their forces were far less disciplined, especially the infantry. The problem the Arabs posed came from their frequent raids into Anatolia. A raiding Arab force was to be shadowed by local Byzantine units until an overwhelming superiority of heavy cavalry could be concentrated from nearby themes for a counterattack.

Byzantine cities were surrounded by thick curtain walls; those around the capital of Constantinople were of sufficient thickness to resist cannon fire. The Byzantines were able to deploy “Greek fire,” a sort of primitive flamethrower originally designed for naval operations. Although it was no doubt devastating in its immediate area of use, the effect of this burning-liquid weapon was mostly psychological, since no

other medieval army possessed the secret of its manufacture or composition and it seemed nearly miraculous to inexperienced enemies.

The basis of the medieval army in western Europe was the mounted knight. His equipment consisted of horse, sword, lance, and armor. Originally, knights wore mail similar to that of Byzantine cataphracts, but over time this changed to the lighter and more flexible chain mail (made of tiny interlocked rings of iron) and, finally, to plate armor that covered the entire body and that of the mount as well. Contrary to popular conceptions, plate armor was not a heavy burden that made movement awkward; because its weight was suspended from different parts of the body, it allowed more flexibility and swifter motion than older types of armor.

Knights generally owed military service to the king because of their landholding. The idea of feudalism, that land was granted by the king in return for military service, is an idealization largely reflecting the royal ideology of the later Middle Ages, after Roman law began to be revived. Every free citizen of the kingdom was liable for military service, but the burden fell especially on landholders who were wealthy enough to supply their own equipment. The king and nobles would also employ cavalry and infantry as mercenaries, though these units had far inferior equipment. The kings could and did call up militias from towns and provinces when needed, the burden of service again falling on small landowners who could provide their own equipment as infantry. Knights considered that warfare was not a mere profession but a way of life. Their training for combat was constant throughout their lives but focused on the practical needs of individual fighting: fencing, riding, and archery rather than the study of strategy, tactics, or military history.

Medieval Italian armies, responsible not to the emperor but to individual city-states, consisted of infantry raised from civic militias. These armies were supplemented by mercenaries. The employment of mercenaries in Italy—the *condottiere*—was common and continuous enough that mercenary captains became important figures with their own private armies for hire, a trend that would spread throughout Europe after the end of the Middle Ages.

The king's or great noble's army consisted of a small group of mounted knights maintained as a permanent force, supplemented by mercenary men-at-arms; it included the forces maintained by any noblemen the king could call upon for service and militias called hurriedly into service from the area near the field of battle. Such a force would rarely number as many as 20,000 soldiers. It was summoned into existence as late as possible and dismissed as early as possible because of the lack of disposable wealth to pay and support it. There was no professional military life that could educate and train

soldiers in strategy rather than in fighting, develop doctrine, or preserve institutional memory.

There was no organized drill or discipline; knights did not practice close order drill on horseback in massed formations in that way that Byzantine cavalry did. Even knights did not consider that they needed any military training beyond the skills of single combat: The massed charge of the knights as a body of heavy cavalry was not something practiced in peacetime. This lack of professionalism limited the effectiveness of medieval European armies. The French army, for instance, was so inflexible and amateurish that the English kings, during the Hundred Years' War, could on three separate occasions use small forces of Welsh longbowmen (competent with their weapon from civilian lives spent hunting in the Welsh mountains) and annihilate a larger army of French knights willing to use traditional, though defeated, tactics and charge headlong into fortified positions of archers at Crécy (1346), Poitiers (1356), and Agincourt (1415).

Another well-known feature of medieval military life was the castle. The system of having castles dispersed throughout the countryside developed during the Viking Period (espe-

Chain mail shirt of riveted iron rings; Britain, 13th century (© Museum of London)

cially 850–1000), when places of safety were needed in the face of raids by Vikings, Magyars, Arabs, and other raiders. It was perpetuated afterward because the class of nobles in charge of the castles managed to retain their hold on power against the relatively weak centralizing powers of kings and emperors. Castles were forts made of thin, high, curtain walls built of stone blocks. They were virtually impregnable because of the lack of knowledge of siege warfare techniques among the knightly nobility (although this knowledge improved after extensive contact with Islamic soldiers during the Crusades). Even in the later Middle Ages, when the effectiveness of siege engines such as the trebuchet (a kind of giant sling operated by a falling counterweight that could hurl projectiles weighing up to 300 pounds) increased, this was largely on the initiative of civilian contractors who designed and operated the machinery.

Naval warfare remained unchanged in the Mediterranean from ancient times to the 16th century; it consisted of galleys (ships propelled by several banks of rowers) either ramming each other or coming alongside to allow marines to board an enemy ship. Fighting was then essentially a land battle on the decks. The Byzantines, however, were able to gain considerable advantage with Greek fire, a burning liquid that could be forced out under pressure against target several meters away (its precise chemical composition is still not well understood). The stormy conditions of the North Atlantic made the use of galleys impossible, and throughout the Middle Ages larger and larger sailing vessels were built. Lacking practical naval cannon, the main means of ship-to-ship fighting remained grappling the enemy vessel and boarding it with marines. The advantage went to the ship with the higher deck, so ships were progressively built larger and with higher and higher “castles” (platforms) at the front and back of the ship, from which marines could leap or rappel down to the enemy vessel.

Gunpowder artillery, borrowed by Europeans from the Islamic world, was first used at the siege of Metz in 1324. Fortifications in both cities and castles consisted of curtain walls: thin, high courses of stone. Cannon could knock a breach in these walls after a few hours of bombardment. Consequently, every military fortification in Europe had to be rebuilt to withstand cannon fire, a process that carried tremendous economic and social costs and that would not be completed until the 17th century.

Gunpowder small arms did not become important during the Middle Ages because the slow rate of fire made individual gunners too vulnerable to attacks by cavalry. An exception to this was the military of the Hussites. Between 1419 and 1430 the followers of the religious leader Jan Hus (who was executed at the Council of Constance in 1415) staged a revolt

in Bohemia. The Hussites produced the first popular army in Europe, drawn from a mass movement of peasants. Freed from aristocratic tradition, the Hussites were highly innovative in their tactics. Their armies traveled in armored wagons that, when they were attacked by a force of mounted knights, would form a circle in the manner familiar from Hollywood westerns. When mounted knights charged this wagon fortress (*Wagenburg*), they were met with concentrated small-arms fire from ports in the sides of the wagons. Once this defense broke the attacking formation, the Hussites’ own cavalry would charge to attack the retreating enemy.

Another answer to the knightly cavalry charge was the Swiss pike square. This tactical system organized infantry into small formations in which each man was armed with a long pike. When the pikes were leveled, their points formed a barrier onto which charging cavalry would be impaled. In the mid 1470s the Swiss won a series of victories against Charles of Burgundy. This early conflict also had the nationalist character of a peasant army resisting a feudal overlord. The Swiss style of fighting proved so effective that they soon found themselves in demand as mercenaries throughout Europe. As the pike square became widely imitated and small firearms became easier to use, the era of the mounted knight ended with the Middle Ages around 1500.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

The Arabian world into which Islam was first introduced was still in the heroic age of fighting: that is, war was a matter of individual heroics, and battles were fought by warriors pairing off against each other, each fighting for personal glory and the honor of his clan. An example of how this worked was the battle of Badr in March 624. Muhammad led a core group of about 300 followers as well as an additional 950 allies on the raid of a Meccan caravan of about 1,000 camels carrying goods. The fighting began with each side sending three champions to fight in gap between their assembled forces. These champions paired off and fought in epic style, with two of Muhammad’s champions slaying their opponents and one of the Meccan champions almost winning his match before the two victorious champions of Muhammad’s army attacked and killed him. This preamble to the main battle was reminiscent of the heroic Bronze Age Greeks as related in Homer’s *Iliad* and the customs of Bronze Age European Celts. The battle of the champions was followed by volleys of arrows from both sides and then a charge of infantry. The principal weapon of infantry was the sword.

Also reminiscent of ancient military practices was the outfitting of warriors. Each was responsible for his own gear,

including bows and arrows, swords and other side arms, and armor. An Arab army of the 600s and 700s was composed of men sporting a motley of colors and garb, with each wearing what he could afford and what local custom demanded. Many warriors wore no more than cloth because they were too poor to buy armor, and only the richest of men could equip themselves from head to toe in armor. Armor consisted of a shield and, if the warrior could afford it, a helmet; if he could afford more, he also wore a coat of chain mail. Bows and arrows were the essential weapons of Arabian warriors, with swords also playing an important role. Knives, maces, spears, and lances often were used.

Some heroes who could afford armor or at least helmets chose to forgo both armor and helmets in order to display their bravado and daring. The grandson of Muhammad, Husayn ibn Ali, whose martyrdom is still celebrated by Shiite Muslims, was said not to have worn any armor when he was slain in battle in 680. Accounts of Islam's earliest battles often tell of such heroic men winning admiration with outsized deeds. Even those who perished won honor if they acquitted themselves with courage. In this, the early Arabian armies resembled the armies led by Alexander the Great (356–323 B.C.E.) 900 years earlier.

Cavalry was rare in Arabia. For one battle, Muhammad's army had only two horses; for others, the army had no horses at all. Camels were seldom used in battle, but they were used to transport goods and were sometimes ridden by warriors to the site of battle. The warriors would dismount and fight on foot or would mount horses if they could. Horses were seldom ridden on the way to battle; they were too valuable to risk tiring them by weighing them down during travel. Horses gave armies strategic advantages. For instance, at the battle of Uhud in March 625, a near victory for the forces of Muhammad turned into a rout of his army when Meccan cavalry charged his troops. It ended with significant troop losses, along with the wounding of Muhammad and the death of his uncle Hamza.

Despite horses' value in battle, there were not enough of them in Arabia to equip large cavalry forces. Accounts of battles indicate that about 200 cavalry was the most any one side managed to muster. Thus, infantry was the mainstay of early Islamic armies. In this, Muslims had special strength. Arabians often joined the armies of the Sassanian and Byzantine empires, serving as mercenaries in the infantry. These well-trained, battle-hardened veterans often returned to their cities. When Muslims gained control of most of Arabia, these veterans formed highly disciplined fighting units in which group cooperation was more important than individual heroics. Further, they were thoroughly versed in the tactics and predilections of the Sassanian and Byzantine armies. At the

moment the Islamic world attacked the empires of the Near East, both empires were exhausted of manpower and wealth after prolonged wars against each other. Moreover, neither empire at first took the Muslim armies seriously, because Arabs had been raiding their neighbors in the Near East from the time of Sumerian kingdoms and had either gone home with their booty or had been absorbed into the societies they had raided. Still, the Muslims were different, because they intended not only to stay but to impose their way of life on their conquered lands as well.

Accounts of the Islamic armies of the medieval era often depict the Muslim soldiers as raving, terrifying fanatics, riding madly into their enemies. Actually, their fighting styles tended to be more prosaic. Their massed infantry showered arrows on their enemies. If the enemy was getting the best of the exchanges of volleys of arrows, the infantry charged,

trying to quickly close the gap between themselves and their enemies. Their cavalry seldom could overwhelm the massed infantry of their opponents, but charging with lances, they could disrupt enemy archers, buying their infantry time. Truly terrifying to their enemies were neither charges nor volleys of arrows, but instead a trait that Muslim soldiers consistently displayed—they rarely stopped fighting. A soldier minus his legs, missing an arm, his belly sliced open or featuring other plainly fatal injuries continued to try to cut down his enemies. Even when the main Muslim army was in retreat, their injured men continued to try to attack the advancing enemy in any way they could, even if only by biting.

By the 700s the Islamic world had learned how to use Greek fire, which the Arabs called *naft*. This was a liquid concoction that could be sprayed under pressure on enemies and lighted on fire. The Byzantines had long used it to terrify their enemies, and their ships often sprayed it onto enemy ships. But medieval Muslims seem rarely to have used *naft* to good effect. Indeed, the building of warships and the manning of the warships was left primarily to Christians who lived within the Islamic world.

The employment of so-called infidels (unbelievers in the Islamic faith) in Islamic armies became a necessity in the late 600s. During the 600s and 700s the Muslims may have numbered no more than 1 million, with almost every able-bodied man under arms at one time or another. They conquered a territory containing as many as 60 million people. Perhaps this is why the Islamic military built fortified cities in Egypt and Syria and why the Muslim governments in those cities often left local peoples to their old customs and religions as long as they did not rebel. Wholesale slaughter of rebellious conquered peoples was a way of terrorizing the rest into submission.

Muslim regimes were usually great builders, and among their construction projects were fortresses and fortifications for cities. Many of their best fortifications they seized from the Byzantine Empire, whose masterpiece of defensive construction may have been the city of Antioch, then in Syria and now in southern Turkey and known as Antakya. Muslim architects learned from the impressive stone fortifications of the Byzantine Empire, building walls so high that the inner space of the fortification was in darkness during the day. From numerous towers arrows and *naft* could be poured on besiegers. The purposes of fortifications were twofold: One was as defense against invaders and bandits. The other was as defense against other Muslims. By the 900s even hunting lodges for caliphs and sultans looked like castles, because Muslims had taken to warring among themselves.

The internecine warfare motivated caliphs and sultans to create elite military units that were especially loyal to them.

The most successful of these were the Mamluks and the Janissaries. By the 800s the Islamic world's military had undergone a significant change. Horses had become much more common, and the wealth of the Islamic governments enabled them to purchase as well as breed them in large numbers. During the century battlefield tactics shifted from emphasizing infantry to emphasizing cavalry based on the practices of the Sassanian Empire. Swift moving archers on horses, using the recently introduced iron stirrup, became the centerpieces of Muslim armies. The cavalrymen and infantrymen were recruited from the fringes of the Islamic Near East and included Armenians, Bulgars, Turks, and Berbers.

The Abbasid caliph Abu Ishaq al-Mutasim ibn Harun (r. 833–42) created the Mamluks, and he used them in gaining the caliphate. The word *mamluk* means “one who is owned” and refers to the slave-soldiers who served the caliphs and sultans and who became an elite military caste. The Mamluks were purchased at about age 10 to 12—old enough to have survived the childhood diseases that killed many children of younger ages, yet young enough to be molded by tough, relentless training. Originally, Mamluks were slave boys from many cultures but preferably not Islamic ones, because it was against Islamic law to sell free Muslims into slavery. Eventually, boys from the “Turks” came to be preferred. (The Islamic world called any nomadic people from central Asia “Turks.”) The Turkish boys were valued because by age 10 they were already thoroughly knowledgeable in riding and caring for horses. Mamluks were used throughout the Near East and North Africa. They were trained in the skills of fighting from horseback, in working together as units, and in the Islamic faith, and they were taught to value loyalty to their *ustadh* (“master”), who they came to regard as their father, and to each other. Although they were officially slaves, Mamluks could become important government officials, and, in fact, they ruled Egypt from 1250 to 1517.

With the rise of the Ottoman Turks came the institution of the Janissaries, founded in the 1300s. The Turks divided their army into two distinct forces. One was the cavalry, led by *sipahis*, meaning “cavalry officers.” The cavalry was supplanted in importance by the other important force, the infantry. The core of the infantry consisted of the Janissary regiments. The Ottomans imposed a special tax on Christians; this tax was paid by surrendering Christian children to become slaves. Like the Mamluks, the Janissaries were trained in the skills of war and the ways of Islam and were taught to be loyal to one another. They lived in barracks, each of which had a large cauldron from which soup was served to its regiment. The cauldron and its soup represented the unity and esprit de corps of the regiment. This cauldron was carried into battle, and it was shameful to allow the cauldron

to fall into enemy hands; Janissaries fought to the death to protect their cauldron.

~ Guy, a Knight: Letter from the Sixth Crusade (1249) ~

**FROM DAMIETTA, 1249.**

To his dear halfbrother and wellbeloved friend, master B. of Chartres, student at Paris, Guy, a knight of the household of the viscount of Melun, greeting and a ready will to do his pleasure.

Because we know that you are uneasy about the state of the Holy Land and our lord, the king of France, and that you are interested in the general welfare of the church as well as the fate of many relatives and friends who are fighting for Christ under the king's orders, therefore, we think we ought to give you exact information as to the events of which a report has doubtless already reached you.

After a council held for that purpose, we departed from Cyprus for the East. The plan was to attack Alexandria, but after a few days a sudden tempest drove us over a wide expanse of the sea. Many of our vessels were driven apart and scattered. The sultan of Cairo and other Saracen princes, informed by spies that we intended to attack Alexandria, had assembled an infinite multitude of armed men from Cairo, Babylon, Damietta and Alexandria, and awaited us in order to put us, while exhausted, to the sword. One night we were borne over the waves by a violent tempest. Toward morning the sky cleared, the storm abated, and our scattered vessels came together safely. An experienced pilot who knew all the coast in this part of the sea and many idioms, and who was a faithful guide, was sent to the masthead, in order that he might tell us if he saw land and knew where we were. After he had carefully and sorrowfully examined all the surrounding country, he cried out terrified, "God help us, God help us, who alone is able; we are before Damietta."

Indeed all of us could see the land. Other pilots on other vessels had already made the same observation, and they began to approach each other. Our lord, the king, assured of our position, with undaunted spirit, endeavored to reanimate and console his men. . . .

In the meantime our assembled vessels approached the land. The inhabitants of Damietta and of the neighboring shores could view our fleet of 1,500 vessels, without counting those still at a distance and which numbered 150. In our times no one, we believe, had ever seen such a numerous fleet of vessels. The inhabitants of Damietta, astonished and frightened beyond expression, sent four good galleys, with well-skilled sailors, to examine and ascertain who we were and what we wanted. The latter having approached near enough to distinguish our vessels, hesitated, stopped, and, as if certain of what they had to report, made ready to return to their own party; but our galleys with the fast boats got behind them and hemmed them in, so that they were compelled, in spite of their unwillingness, to approach our ships.

Our men, seeing the firmness of the king and his immovable resolution, prepared, according to his orders, for a naval combat. The king commanded to seize these mariners and all whom they met, and ordered us afterward to land and take possession of the country. We then, by means of our mangonels which hurled from a distance five or six stones at once, began to discharge at them firedarts, stones, and bottles filled with lime, made to be shot from a bow, or small sticks like arrows. The darts pierced the mariners and their vessels, the stones crushed them, the lime flying out of the broken bottles blinded them. Accordingly, three hostile galleys were soon sunk. We

*(continued)*

(continues)

saved, however, a few enemies. The fourth galley got away very much damaged. By exquisite tortures we extracted the truth from the sailors who fell alive into our hands, and learned that the citizens of Damietta had left the city and awaited us at Alexandria. The enemies who succeeded in escaping and whose galley was put to flight, some mortally wounded, uttering frightful cries, went to tell the multitude of Saracens who were waiting on the shore, that the sea was covered with a fleet which was drawing near, that the king of France was coming in hostile guise with an infinite number of barons, that the Christians were 10,000 to one, and that they caused fire, stones, and clouds of dust to rain down. . . .

In consequence of this speech, fear and distrust seized the enemy. All of our men, assured of the truth, conceived the greatest hopes. In emulation of one another they leaped from their vessels into the barks; the water was too shallow along the shore, the barks and the small vessels could not reach the land. Several warriors, by the express order of the king, cast themselves into the sea. The water was up to their waists. Immediately began a very cruel combat. The first crusaders were promptly followed by others and the whole force of infidels was scattered. We lost only a single man by the enemy's fire. . . . The Saracens giving way, retired into their city, fleeing shamefully and with great loss. Great numbers of them were mutilated or mortally wounded.

We would have followed them closely, but our chiefs, fearing an ambush, held us back. . . . We rested until the next day, When, with the aid and under the guidance of slaves who knew the country and the roads, we got possession of what remained to be captured of the land and shore. But during the night the Saracens, who had discovered that the captives had escaped, had killed those who remained. They thus made of them glorious martyrs in of Christ, to their own damnation.

In the darkness of the following night and on Sunday morning, as they lacked weapons and troops, the Saracens seeing the multitude of the Christians

who were landing, their courage and firmness, and the sudden desolation of their own city, lacking leaders, superiors and persons to incite them, as well as destitute of strength and weapons for fighting, departed, taking their women and children and carrying off everything movable. They fled from the other side of the city by little gates which they had made long before. . . . The king, no longer fearing an ambush, entered the city before three o'clock without hindrance and without shedding blood. . . .

I must not forget to say that the Saracens, after having determined to flee, hurled at us a great quantity of Greek fire, which was very injurious to us, because it was carried by a wind which blew from the city. But this wind, suddenly changing, carried the fire back upon Damietta, where it burned several persons and fortresses. It would have consumed more property, if the slaves who had been left had not extinguished it by a process which they knew, and by the will of God, who did not wish that we should take possession of a city which had been burnt to the ground.

The king, having then entered the city in the midst of cries of joy, went immediately into the temple of the Saracens to pray and thank God, whom he regarded as the author of what had taken place. . . .

By the divine goodness, the Christian army, like a pond which is greatly swollen by the torrents pouring in, was added to each day by some soldiers from the lands of lord Villehardouin and some Templars and Hospitalers, besides pilgrims newly arrived, so that we were, by God's grace, largely reinforced. The Templars and Hospitalers did not want to believe in such a triumph. In fact, nothing that had happened was credible. All seemed miraculous, especially the Greek fire which the wind carried back onto the heads of those who hurled it against us. A similar miracle formerly took place at Antioch. A few infidels were converted to Jesus Christ and up to the present time have remained with us.

*The Islamic World*

~ Ahmed Mohammed al Makkari: "Tarik ibn Ziyad's  
Address to His Soldiers," excerpt from *The Breath of Perfume* (711) ~

When Tarik had been informed of the approach of the enemy, he rose in the midst of his companions and, after having glorified God in the highest, he spoke to his soldiers thus:

"Oh my warriors, whither would you flee? Behind you is the sea, before you, the enemy. You have left now only the hope of your courage and your constancy. Remember that in this country you are more unfortunate than the orphan seated at the table of the avaricious master. Your enemy is before you, protected by an innumerable army; he has men in abundance, but you, as your only aid, have your own swords, and, as your only chance for life, such chance as you can snatch from the hands of your enemy. If the absolute want to which you are reduced is prolonged ever so little, if you delay to seize immediate success, your good fortune will vanish, and your enemies, whom your very presence has filled with fear, will take courage. Put far from you the disgrace from which you flee in dreams, and attack this monarch who has left his strongly fortified city to meet you. Here is a splendid opportunity to defeat him, if you will consent to expose yourselves freely to death. Do not believe that I desire to incite you to face dangers which I shall refuse to share with you. In the attack I myself will be in the fore, where the chance of life is always least.

"Remember that if you suffer a few moments in patience, you will afterward enjoy supreme delight. Do not imagine that your fate can be separated from mine, and rest assured that if you fall, I shall perish with you, or avenge you. You have heard that in this country

there are a large number of ravishingly beautiful Greek maidens, their graceful forms are draped in sumptuous gowns on which gleam pearls, coral, and purest gold, and they live in the palaces of royal kings. The Commander of True Believers, Alwalid, son of Abdalmelik, has chosen you for this attack from among all his Arab warriors; and he promises that you shall become his comrades and shall hold the rank of kings in this country. Such is his confidence in your intrepidity. The one fruit which he desires to obtain from your bravery is that the word of God shall be exalted in this country, and that the true religion shall be established here. The spoils will belong to yourselves.

"Remember that I place myself in the front of this glorious charge which I exhort you to make. At the moment when the two armies meet hand to hand, you will see me, never doubt it, seeking out this Roderick, tyrant of his people, challenging him to combat, if God is willing. If I perish after this, I will have had at least the satisfaction of delivering you, and you will easily find among you an experienced hero, to whom you can confidently give the task of directing you. But should I fall before I reach to Roderick, redouble your ardor, force yourselves to the attack and achieve the conquest of this country, in depriving him of life. With him dead, his soldiers will no longer defy you."

## ► mills and milling

### INTRODUCTION

The technology of mills and milling has been fundamental to civilization. Grains were first grown as crops in the ancient Near East, but even before then it is likely that people had learned to grind grain to make flour for baking. Millstones were a part of everyday life in most of the medieval world. Grain, nuts, and other foods were placed on stones, and other large stones were used to grind the food. This basic form of milling was practiced in the Americas; throughout Asia, including the Near East; Africa; and Oceania during the medieval era. It was convenient for families to be able to grind their own grain in their home, even though it was a labor-intensive process.

The term *hand mill* is not usually applied to the simple millstone and its grinder. Instead it applies to a kind of mill developed in ancient Rome that became common in much of the world. This device consisted of a heavy stationary stone set on the ground, with another stone that could be turned set on top of it. The upper stone was attached to a rotating post that had one or more horizontal rods sticking out of it. It is called a hand mill because the rods were pushed by human beings. In ancient Rome milling typically was done by slaves, but for many a bakery or family farm family members pushed the rods to turn the grinding stone. The preferred source of power was that of animals. In enclosed spaces this was gen-

erally a donkey. In large spaces, especially out of doors, the grinding stones could be very large and would be turned by oxen or mules. In many places the hand mill was preferred over other kinds of mills, because flowing water and steady winds were not always available.

The origins of watermills are obscure, perhaps because they usually were made of wood, and the wood of the earliest ones has decayed, leaving little for archaeologists to find. Watermills had three basic forms in medieval cultures. One is called the Norse mill or the Greek mill. The word *Norse* is used because the earliest of these mills so far discovered have been found in the far north of Europe, whereas the word *Greek* is used because it was through the Greeks of early Christian times that this kind of watermill was transmitted to other cultures. It consisted of a horizontal wheel with blades that were turned by water flowing against one side of the wheel, thus turning a shaft in the center of the wheel that turned a grinding stone on a floor above. Another watermill was the undershot wheel. This device had a vertical wheel with blades that was turned by water flowing under it. By far the most efficient watermill had an overshot wheel. This watermill had a vertical wheel with bucketlike blades that caught water at the top of the wheel, with gravity pulling down the blades. The biggest drawback to this kind of watermill was that it was much more expensive to make than the alternatives.

Windmills seem to have developed independently in northern Europe and in the Sassanian Empire. Both kinds of windmill were subject to variations in the wind. The one invented in the Middle East featured a horizontal wheel resembling that of the Greek mill. Horizontal rods thrust out of a horizontal wheel; attached to these rods were triangular sails that resembled those used on medieval ships in the eastern Mediterranean and the waterways south of Arabia. The wheel and rods were enclosed by a circular wall that had an opening by which the wind was directed onto sails, one at a time, causing the wheel to rotate. As with the Greek mill, on a floor above the wheel a shaft attached to the center of the rotating wheel turned a grinding stone. Shutters on the opening in the circular wall could be adjusted to control how much wind reached the sails, thus adjusting the turning speed of the wheel. This form of windmill spread through much of Asia.

Windmills with vertical sails were invented in northern Europe, becoming common only in the 1400s but spreading in use throughout Europe, North Africa, the Near East, and much of the rest of Asia. Its vertical wheel was often little more than a horizontal rod to which a circular fan of rods were attached, each having its own sail. At first these windmills had horizontal posts in their sides, and people pushed the posts to turn the building to have the sails face the wind. Before the end of the medieval era windmills were built with domes to

which the wheel was attached, and a miller could use a rod to push or pull the dome to have the sails face the wind.

## AFRICA

BY MICHAEL J. O'NEAL

A mill is any type of tool used to grind or cut materials into smaller pieces. One common type of mill is the gristmill, used to grind grain into flour. Similarly, a sawmill enables the operator to cut raw wood into lumber, and milling operations are used to grind wood fragments into fiber for papermaking. Additionally, milling operations often are used to grind ores into more usable form, and they can be used to grind minerals for use in various substances.

Mills can be powered in a number of ways. One is simple human power. Using a stone or similar tool a person can, for instance, grind grain. Sometimes a mortar and pestle are used for a similar purpose; a mortar is a bowl-like container that holds grain, and a pestle is a tool with a rounded end that grinds the grain in the mortar. Another source of power is animals. Horses, mules, and oxen have commonly been used to turn large millstones. A third source of power is water. The energy from the flowing water of a river or stream is harnessed to turn a waterwheel, which is attached by gears to a millstone or other type of milling tool. Water also can be stored in a reservoir located above the mill and then released to turn the waterwheel. Similar to the waterwheel is the windmill, which operates according to the same general principle but harnesses the energy of wind to operate the tool.

In medieval Africa milling technology relied primarily on human power. Waterwheels and windmills had been employed in the Roman Empire, and by the medieval period they were in wide use in northern Africa and throughout Europe. In China water mills were used for papermaking. Similarly, animal-powered mills were used in other parts of the world. But the archaeological record of medieval Africa shows little in the way of milling technology. At various sites throughout sub-Saharan Africa, including the savannas of western Africa, the Ethiopian highlands, and the Zimbabwe culture of southern Africa, archaeologists have excavated villages and living areas where they have found a relatively large number of hand-powered grinding stones. The relatively small size of these stones and their presence in living areas strongly suggest that milling tended to be a household rather than a community activity. One exception is Zimbabwe, where such stones generally have not been found in domestic quarters. Further, archaeologists commonly have discovered grinding stones at pastoralist and other sedentary sites rather than at sites inhabited by hunter-gatherers. This would be predicted, given that pastoralists and farmers process foodstuffs for

consumption while hunter-gatherers consume foodstuffs in their natural state. Finally, the disposition of these stones in domestic settings suggests that milling was primarily a female occupation.

Archaeologists are interested first in the composition of these stones. The most effective ones were made of an igneous rock such as basalt. The advantage of this type of rock is that its grains do not detach easily, so grit from the stone does not get into the material being ground. Such rock, though, was not always available, so grinding stones made of limestone, sandstone, and other types of rock have been found.

Archaeologists next are interested in the chemical makeup of these grinding stones. Chemical analysis has shown that such stones often contain traces of elements that would not have been found in the rock itself. These elements include arsenic, antimony, and bismuth, suggesting that the grinding stones were used in the manufacture of such products as dyes, medicines, and cosmetics. They also could have been used to grind together metals to form alloys. Additionally, many grinding stones are stained with ocher, an impure iron ore that leaves behind a red or yellow color. Ocher was used as a pigment, often for ceremonial purposes, suggesting the grinding stones were put to use in ceremonial rites.

Third, archaeologists are interested in the shape of the grinding stones. They have discovered two basic designs, both of which are similar to the mortar and pestle. A term that is often used to refer to the mortar is *quern*. This refers to the stationary stone on which the material to be ground is placed. The pestle often is called simply a hand stone. Sometimes the word *quern* is used to refer to both parts of the mechanism taken together. One type of quern is the saddle quern, so called because the hand stone is rocked forward and backward in a "saddle" to create a grinding motion. The other type is called the rotary quern. This type of quern, which produces more of a crushing motion, uses a hand stone that resembles a modern rolling pin. Using both hands, the operator rolls the "rolling pin" back and forth over the material to be ground. In both cases the stationary stone is not smooth and flat. Parallel grooves cut into the stone give the fine material a place to go as the grinding process continues on the remaining larger pieces. The grooves also provide edges on which the material being ground can break.

Fourth, archaeologists are interested in the types of materials that were ground using these stones. Ores and minerals were ground to produce a variety of products. The most common use for grinding stones, though, was to mill grains into flour used in bread making or in the preparation of other foods. While the specific type of grain varied depending on the area, a common type of grain was relatively soft millet. Sorghum also was a common crop that had to be ground, and

later maize was added to the menu. Additionally, these stones were used to grind vegetables, nuts, seeds, fruits, spices, meat, bark, or any other substance that had to be broken up into smaller pieces for consumption or combination with other substances.

Grinding stones may have served as status symbols. In many places in sub-Saharan Africa stones made from igneous rocks such as basalt had to have been imported, suggesting that their owners enjoyed higher social status. Additionally, some sites contain more than one grinding stone. A site in Zimbabwe, for example, consists of a single dwelling with numerous grinding stones (along with other objects, such as pots, iron objects, and statues), suggesting that the occupant was socially prominent.

## THE AMERICAS

BY MICHAEL J. O'NEAL

Mills were powered in a number of ways before the advent of electricity. The most common was simple human power. In cultures throughout the world, including the Americas, stones were used to mill grain. Generally these hand-powered mills were similar to a mortar and pestle—that is, a bowl or flat surface (the mortar) to hold the substance being milled, and a tool (the pestle) worked back and forth to grind the substance. A more technologically advanced option to mill greater quantities of material was the use of animals, including horses, mules, and oxen, to turn large millstones. Still more advanced societies powered mills with water, harnessing the energy from the flowing water of a river or stream to turn a waterwheel, which is attached by gears to a millstone or other type of milling tool. In some areas of the world mill operators stored water in reservoirs located above the mill, which they then released to turn the waterwheel. The windmill operates according to the same general principle but harnesses the energy of wind to operate the tool. Both waterwheels and windmills, though, require familiarity with the technology of the wheel, so they were not employed in the Americas until after contact with the Europeans.

The development of milling technology is inevitably an outgrowth of the needs of the people. The most common need is food, so in medieval North America hand mills for grinding grain and corn were commonly used. In general, there was no such thing as commercial production; milling was typically done by individual households. Among the Cherokee people, for instance, it was necessary to grind corn into a form that could be used for the baking of breads. A traditional way of doing this was first to boil corn in a pot and then to rinse the corn. The corn would be placed in a corn beater referred to as a *ka-no-na*. Typically, the beater

consisted of a hollowed-out stump or log into which the boiled corn was placed. The corn was beaten with a heavy pole until it attained the consistency of flour. This corn flour could then be used to make bread or combined with other ingredients, such as beans, to make soups.

Milling technologies were not highly developed in areas of the Americas where the land provided suitable food that could be consumed in its natural state. People in the far north relied primarily on products from the sea for their subsistence, in particular sea mammals; Eastern Woodlands Indians harvested the forests for game, fruits, and nuts; and Plains Indians relied on game animals. Further, extensive milling tends to be a characteristic of sedentary agricultural societies, so more nomadic cultures, such as the Plains Indians, devoted little attention to it. The milling of grains was much more important to the peoples of the southwestern United States and throughout much of Mesoamerica. These people relied on agriculture for their subsistence, so a daily task for many was grinding grains, corn, beans, and other foodstuffs.

A good example is provided by the peoples of the American Southwest, although their technologies would have been similar to those used farther south throughout Mesoamerica and South America. Here archaeologists have uncovered ample evidence of the production of milling stones. In one region of western Arizona and eastern California an area of some 300 acres was given over to the production of milling stones. Archaeologists have determined, on the basis of debris and discarded stones, that over the centuries hundreds of thousands of these stones must have been manufactured.

Typically this production took place on flat areas roughly 5 feet in diameter. The production of the *metate*, or lower milling stone—the stone on which the material to be milled was placed—consisted first of testing stones for their integrity; numerous examples of stones rejected because of fault lines have been found. Using hammerstones made of quartz, an appropriate rock was shaped so that it provided a convex (that is, slightly bowl-shaped) area. Hammerstones came in various sizes and weights; the larger ones were used to chip away the larger pieces of excess stone, and progressively smaller ones were used to chip away flakes of stone until the lower milling stone was complete. A similar process was used to produce the *mano*, or handheld pestle. While the pestles came in various sizes, a common size was that of a large loaf of bread. Once the two components were made, the process of milling grain was relatively simple. The grain was placed on the *metate*, and the *mano* was rolled back and forth over it. This action crushed the outer hulls of the grain, which was then filtered out, leaving behind the edible core.

Additionally, people in the American Southwest and farther south created gristmills out of wood. Similarly to Ameri-

can Indians farther north, they hollowed out a log or stump, but the grinding was done with a long, cylindrical pestle made of stone. Cottonwood logs usually were used for this process, largely because the cottonwood was easily hollowed out.

Among the Maya and Aztec of Mesoamerica maize was the most important food staple. The Mesoamericans developed sophisticated methods for cultivating maize, including terraced fields and slashed-and-burned fields. A primary goal of Mesoamericans was to convert the maize into flour that could be used to make light bread products similar to today's corn chips and tortillas. The process is referred to as wet milling, or *nixtimalization*. In many ways the process was like that used by native North Americans. The corn was boiled in an alkali solution, generally produced by the use of lime or wood ash. After the solution cooled, the hulls of the corn were washed away. The soft interior parts of the kernels were then ground on a three-legged stone called a *metlapil*. The householder ground the corn using a stone similar to a modern rolling pin. The result of wet milling was a dough called *masa*. What was extraordinary about this process was that it altered the nutritional value of the corn. *Nixtimalization* changes the protein makeup of corn, releasing the essential nutrient niacin. When mixed with beans and vegetables such as peppers, the result was a nutritionally balanced food. In areas that did not employ *nixtimalization*, the result was a dietary disease called pellagra. Thus, the milling process was intimately bound up with nutritional needs. Milling was by no means restricted to maize. The Aztec used similar tools to grind other grains, including amaranth, a coarse herb that was believed to have magical powers. Additionally, the cacao bean was ground to form chocolate, which became a staple in the diet.

A primitive form of animal-powered milling was used by the Mesoamericans in working ores containing precious metals. In this process gold and silver ores were mixed together on a stone floor. To purify the metals, substances such as salt and quicksilver (mercury) were added. The mixture was then "milled" by the action of horse and cattle hooves. These animals were brought into walk back and forth over the ores to crush them. Only old, poor-quality animals were used for this process, for the quicksilver was toxic to the animals, which soon died after extensive exposure to it. The process was not particularly efficient, but it was an effective form of animal-powered ore milling.

Among the Inca of South America milling technologies were not advanced. The Inca maintained a sophisticated agricultural system, but food continued to be ground by hand. Much like Americans to the north, the Inca relied on a flat milling stone on which grain and other substances were placed. The handheld stone was typically formed into a half-

moon shape, which could then be rocked back and forth over the lower stone. This type of hand milling was generally more efficient than the process employed in North America and Mesoamerica because it led to less wasted motion. However, the Inca made far less use of ground grain than did peoples farther north. Potatoes became a staple crop, and although maize was consumed, it was not as widely ground into flour. Accordingly, the Inca did not have much incentive to search for nonhuman sources of power for milling operations. Additionally, the absence of wheel technology hampered the development of more efficient milling not only in South America but throughout the Americas.

The people of the Andean region acquired more technologically sophisticated milling technologies only after the arrival of the Europeans. By the 1500s waterwheels had been introduced throughout much of western South America in such places as Peru, Bolivia, Lima, and the Andean highlands. All of these water-driven gristmills, however, were horizontal. That is, rather than erecting a vertical waterwheel attached to the millstone by a system of gears, the people in western South America laid the waterwheel horizontally so energy was transferred from flowing water directly to the millstone. This type of mill had the advantages of being cheaper to build and easier to operate than vertical waterwheel mills. The descendants of the Inca used these mills to grind wheat, barley, beans, and quinoa (a type of pigweed cultivated for its edible seeds). While the flour produced was coarse and contained many impurities, including tiny bits of the millstone itself, it was able to produce large quantities of nutritionally good food.

After the introduction of waterwheels the grinding of grain became much more efficient. However, the old ways of grinding grain using the wet milling technique persisted; in fact, they continue to be used by Andean peasants in the modern era. Wet milling by hand allows the householder to get rid of the outer husk of the grain without crushing the inside, the chief disadvantage of the horizontal waterwheel.

## ASIA AND THE PACIFIC

BY ILCIA SPREY

When humans first cultivated such crops as grain and rice, they processed the seeds by crushing them between small flat stones. In Southeast Asia milling through the medieval period usually meant using a wooden trough and a wooden stick or foot-powered lever that moved through the trough, breaking up the rice and producing very coarse flour. Over time the Chinese were the first in the region to develop mills, which were powered by humans or animals turning an axle connected to a grinding stone. These methods, which were an improvement over the earlier system, were highly inefficient

means to feed people, especially in Asia, where the population was growing rapidly. By the second century water mills, which offered a more sophisticated milling process, were introduced in China. Mills became an important symbol of political power in China and elsewhere as well as a source of conflict between local landowners, Buddhist monasteries, merchants, and the imperial authority in almost all regions of Asia.

By the first century, if not earlier, mills were widely used in China to process grain into flour. However, they were not employed in weaving or fabric production in China, Japan, India, or elsewhere in Asia or Southeast Asia until the early-modern period. Instead, weaving was done by hand in small rural workshops. Most villages and smaller towns in China built mills that were powered by human or animal labor to meet their immediate food needs. Beginning with the technological revolution and advances in science that took place under the early Song Dynasty (960–1279), those communities fortunate enough to be located on a river or a powerful stream with a regular flow of water built mills. In strategically located rural villages or along major roads people erected mills by combining the resources of the population or perhaps a local lord, who expected either a payment or a percentage of processed flour and financed the initial cost of construction. The rural mills were fairly basic and minimal in size, reflecting the small population they served, and they could at times be located in an area as small as a 10-foot square. Images and descriptions of urban mills, however, have survived in great numbers, and they allow a careful examination of the mills' mechanical structures.

Using the depictions found in Chinese paintings, historians have a sense of how water-powered flour mills were laid out and organized for efficient production, particularly for the grinding of grains such as millet, wheat, and rice into flour. A typical water mill might have at the side of the main structure a large, flat covered area where farmers would deposit the raw grain from sacks and baskets. Using a series of sieves, the grain was then winnowed and the chaff removed. Next, the separated grain was washed in river water, dried again, and brought into the central mill building, where it was ground between large circular-shaped horizontal milling stones. These grinding stones were powered by a wooden shaft that was moved by a series of cogs and gears, which were connected to a horizontal waterwheel driven by the passing river water.

Following the grinding, the flour that had been produced in this process would be put through a sifter (powered by a second horizontal waterwheel) to remove bits of chaff, stone, and any other materials that had been incorporated into it during the milling process. The sifted flour was set

out on a second flat, covered area on the far side of the main building to dry thoroughly in the sun and air; this procedure curtailed the growth of mold or mildew while the flour was stored. Last, the dried flour was bagged and carried by humans or loaded on carts and sold in marketplaces and to private customers, primarily in the local region. While small local mills might be operated by a single individual, the larger imperial and commercial mills, especially those servicing the imperial court, regularly employed upward of 100 men.

Control over all significant courses of revenue was important to the Song Dynasty, which needed the steady income to finance domestic and foreign policies. In the 960s the government established monopolies over both mills and over the associated wineshops that were often built in the shadows of the mills. Over time the use of mills expanded, and by 1080 the Song state administration took a dominant role in the processing of raw tea leaves into powder. Certain mills were licensed to grind the dry tea leaves into a fine powder that was then pressed into regularly shaped square cakes, which were easier to transport to long-distance markets than bags of powdered tea. The processing and sale of tea were guaranteed to produce revenue for the Song administration. Tea sales brought in an average of 400,000 strings of cash per year for the Song, each string consisting of 1,000 copper coins tied together by a cord through the coins' centers. To appreciate the significance of such a sum, consider that the average annual income of a local government official at that time was approximately 90 strings a year. The efforts by the state to maintain the monopoly on mills continued until 1079, by which time it was too costly for the state to continue to run the mills, and control over them was returned to private hands, often those of the local elite. Later dynasties were unable or uninterested in attempting to reestablish an imperial monopoly over the mills.

Since mills were established on lands controlled by Buddhist monasteries in China, Korea, and Japan, they helped the economies of both the local populations and the monasteries. The efficient organization and the circular motion of the mill's wheels and stones led Buddhist monks to see the mill's wheels as representative of the Buddhist wheel of fate (dharma), or the Buddhist concept of eternal balance between moral behavior that keeps evil in check and of harmony in a state and universe that is properly ordered and run.

While commercial mills were widely known in China, they had a much smaller presence in Japan. The technology that made large mills possible was brought into Japan from two sources—Japanese Buddhist monks who had learned the technology while traveling in China in the seventh century and Korea, where the Chinese-style of large-scale milling had

previously been adopted. The *Nihon-shoki* (The Chronicles of Japan) for the year 610 states that the king of Korea presented to the Japanese emperor Suiko the first mill in Japan. Another chronicle, *Nihongi* (Early History of Japan), states in the section for the year 670 that water mills were constructed in Japan but does not say where or for what use.

The style of mill introduced into Japan appears to have been the rotary quern. A quern is a grinding apparatus in which the lower circular stone is stationary and the upper circular stone is turned by means of a spindle put through a hole in its center. This spindle is hand-turned and keeps the two stones lined up. Grain was poured through this central hole to be ground between the two stones. As it was being ground, centrifugal forces moved the ground material outward to and over the edges of the lower stone, where it was collected. The rotary quern was an improvement over the hand-turned quern, since the upper stone was turned by various power sources, including animal and water power.

Japanese Buddhist monasteries quickly built these rotary querns on their lands and found them to be a significant source of revenue, as all those who were tenants of the monastery had to abandon the use of the much smaller hand-turned querns and were forced to pay to use the monastery-owned mills. Outside Buddhist-held lands, large-scale stone mills appeared in Japan more as a technological curiosity to show visitors and were never widely constructed or used. One such large stone mill from the seventh century survives at the temple of Kanzeon-ji in Fukuoka Prefecture on the island of Kyūshū. Its grinding stones show no evidence of use. The novelty factor of rotary querns is also demonstrated by the fact that in archaeological excavations pieces of this type of quern were found only in the remnants of a few wealthy households and never in those of middle- and lower-class farmers and peasants.

There are two other reasons why large-scale grain milling was not widely adopted in premodern Japan. First, rice and barley were the dominant grains in the Japanese diet of all social classes, and wheat was little used, so this kind of mill would get little use. Second, the Japanese preferred their food to be prepared fresh, and therefore in the majority of Japanese households rice for each meal was ground as needed in small hand-turned querns. Even the poorest households ground their rice on a primitive quern formed by placing the grain kernels on a large flat rock and rolling over them either another rock or a wooden roller.

Rotary mills for grinding grain did not catch on in Japan, but by the 14th century they were adopted there as a way to grind green tea into the fine powder used in the elaborate tea ceremony. This ceremony became an essential element of samurai culture by the end of the 16th cen-

tury, and this specialized quern, known as *chausu*, became highly prized and was often passed on in samurai families as an heirloom.

Prior to the introduction of the quern into India, people in that region ground grain by using a mortar and pestle. A stick or hand-size piece of stone with a rounded end was used to push the grain against the concave sides of a rounded stone vessel until unrefined flour was produced. This basic form of grinding remained the norm in the northeastern Ganges River basin until the modern era. Based on archaeological evidence from Sirkap (in modern-day Pakistan) in the northwestern portion of the subcontinent, grain-grinding querns came into the Indian Subcontinent from the Mediterranean region in the first century at the earliest. This quern was not moved by a spindle in the center of the top stone but instead by two handles on either side of the top stone, which was then turned in a counter-clockwise direction.

The first Indian improvement to this form of the quern was the transition from two handles to a single handle and from that to a vertical handle that worked like a crank. Remnants of these altered designs have been found at archaeological sites at the fifth-century Buddhist Kunala Monastery in Taxila (in modern-day Pakistan). This more efficient form of the hand-turned rotary quern provided a practical means of grinding grain for most Indian households and did not require animal power, since its grinding stones were fairly small in size (only 1–2 feet in diameter). The celebrated author of the first history of the Kashmir region and people, Kalhana (active middle of the 12th century), wrote that working these mills was the harshest and most miserable form of labor of his time.

The technology of this kind of mill was improved and adapted over time to other uses, and other sources of power were harnessed so that mills were not always dependent upon less-efficient human labor. There is evidence that between 700 and 1200 yoked oxen were first used to power larger stone mills. The animals walked in continuous circuits around the structure and could be prodded on by a single individual, who could also put in the grain to be processed as well as bag it. The greatest Indian improvement and alteration to the rotary quern borrowed from the Hellenistic world was the invention of the worm drive, a gear in the form of a screw. Used original in the Indian cotton gin, this mechanism consisted of two large screws whose turnings fit into one another, thereby threshing the material caught between them. This made it possible for sugar milling to begin perhaps as early as the tenth century. These mills also were used to extract oil from olives, which would then be used for lamps and cooking, depending on its quality.

## EUROPE

BY AMY HACKNEY BLACKWELL

The best-known type of mill is a device that uses stones or other hard items to grind objects into smaller pieces. The most common use of mills is to crush grains, such as wheat or corn, into a finer powder that can more easily be used in cooking. During the first millennium grinding grain into flour was nearly the only use of mills. Medieval mills gradually became more complex, employing waterpower or wind power and complex sets of gears to turn the stones. In the last centuries of the medieval period people began using mills for industrial processes, such as manufacturing cloth, processing metal, or sawing wood.

The most basic type of mill is a flat, smooth stone on which a person can place grain and then crush it by rolling or pounding another smooth, round stone on it. There are many varieties of this type of hand mill, many of which were employed by medieval Europeans. Some mills consisted of a bowl and an oblong object used for crushing or pounding the grain. The best-known mill of this type is the mortar and pestle, which people used to crush small amounts of grains, spices, or herbs. A mortar is a small, relatively deep bowl, and a pestle is heavy stick with a rounded end. Medieval mortars and pestles could be made of stone, ceramic, wood, or any other substance strong and heavy enough to stand up to hard use. A user would place the substance that needed grinding in the mortar and use the pestle to crush it against the sides of the bowl. This type of grinding is labor intensive and useful only for grinding small amounts of a substance. Alchemists and herbalists commonly used mortars and pestles to prepare drugs, and home cooks used them to crush spices.

For large grinding jobs, such as grinding a town's wheat crop, medieval Europeans used much larger mills. Water mills were common during the early medieval period. Windmills appeared in the late 12th century. Both types of mills worked on similar principles, using natural forces to power grinding surfaces.

The most common grinding surface was stone. Millstones were specially quarried and processed to create suitable grinding surfaces. Every mechanical mill had to have two millstones, one stationary and the other mobile. The moving stone, the runner stone, was attached to moving gears powered by whatever powered the mill, and it rotated against a stationary bed stone. Millers carved grooves into their millstones to cut grain kernels and to channel them out of the mill for collection. The millstones, the runner stone, and the bed stone had similar patterns of grooves. The miller would place the stones and adjust them to achieve the correct degree

of grind. When the stones ground against one another, the grooves created a kind of scissors action that cut the grain to pieces. These grooves had to be recut from time to time to keep their edges sharp.

One of the most common and powerful types of mill was the water mill, a mill powered by natural running water. The water mill was invented during the Roman period, probably around the second century B.C.E., but it was not commonly used until the start of the medieval period. Before this time slaves had done much of the milling work by hand, but during the fourth and fifth centuries slaves became less common, and the population as a whole dropped, making hand milling impractical. Water mills were much more efficient than hand mills; historians have calculated that an early medieval water mill could produce about two horsepower of grinding energy; in other words, one mill could grind as much grain in a day as 30 to 60 humans grinding by hand. Water mills became very common during the medieval period. Although there are no exact statistics, it is known that by 1086, when William the Conqueror (r. 1066–87) created the Domesday Book (a sort of census), there were 5,624 mills in England. Many towns had more than one mill, and the number of mills in a town was a good indication of a region's prosperity.

A water mill worked by using the force of running water to turn a wheel connected to an axle that turned the mill's machinery. The wheel that caught the water to power the mill could be either horizontal or vertical. The earliest water mills used horizontal wheels. These wheels turned their millstones directly, without the use of gears. These devices were fairly simple to construct, but their speeds could not be controlled. As the medieval period progressed, vertical wheels with wooden paddles became more common. These mills were constructed with gears that took the power from the vertically spinning wheels and used it to power horizontal millstones. These gears allowed millers to control the speed of their runner stones so that the stones always ground at an even tempo. Large vertical wheels could be very powerful. Some water mills on large rivers contained multiple runner stone and bed stone combinations, allowing a miller to grind a large amount of grain at once.

A water mill had to be situated next to a river or a stream with sufficient current and volume to turn the wheel. A mill needed a fairly precise amount of water to turn its wheels at the correct speed. The mill could not turn without enough water, and too much water would make the gears move too fast, possibly damaging the mill. To avoid these problems, millers built series of sluices, or gates, to control the flow of water, keeping the power consistent regardless of river levels. They might dam the river to create a pond next to the mill to

supply a reliable power source. The local people might take advantage of this pond to raise fish for food.

Not every location had consistent supplies of running water. In areas with strong, predictable winds, people used wind to power mills. A windmill contained a large, vertical wheel covered with sails or blades that caught the wind to make the wheel spin. The spinning wheel turned a horizontal shaft that was connected to a vertical shaft with gears. This vertical shaft turned the runner stone against the bed stone, producing the force needed to grind grain. Designs of windmills varied, but most of them had some means of moving the wheels as winds changed direction. Some windmills affixed their wheels to shafts that could rotate to face the wind on a given day. Others were built as large towers with rotating tops to which the wheels were affixed. These structures could be larger and hold wheels with longer blades, allowing them to catch more breezes than smaller mills. Most windmill blades were made of cloth sails. A miller could take down the sails or adjust them to fit the winds on a given day. A windmill could grind about 1,000 bushels of grain per week when winds were steady.

Windmills appeared in western Europe in the late 12th century and quickly grew in popularity. Windmills were cheaper to build than water mills but were not as powerful or reliable because they needed steady wind speeds of 15 to 25 miles per hour. Many windmills were built on top of hills, where they could catch the strongest breezes. They were common in England, France, and the Low Countries and on the islands of the Aegean and the Mediterranean. By 1400 there were about 10,000 windmills in England. During the late medieval period the islands of the Aegean became important milling centers for the various kingdoms that ruled mainland Greece during that time. Many Cycladic islands had far more windmills than were required for local grinding needs. The wind power of the Cyclades was so strong that it was practical for landowners to ship their harvested grain to the islands for grinding and then ship it back to the mainland as flour.

Animals could also power mills. Throughout Europe people employed horses, oxen, donkeys, and dogs to turn the gears of mills. The animals were hitched to a horizontal wheel and made to walk in a circle, turning the apparatus. In some places the animals were the only source of power for the mill. In other areas mills used animal power to supplement waterpower or wind power.

Lords and nobles generally owned the mills situated on their lands. They were required to keep their mills in good repair and to build new mills as needed to meet the needs of the local populace. The peasants who farmed their lands had to use the local mills to grind their grain and would pay over

to the lord a certain percentage of their flour. The miller had to grind the lord's grain for free, without taking his usual percentage. Millers were generally quite prosperous. All farmers had to take their grain to their local mill to have it ground into flour. The miller would keep a percentage of the ground flour as his payment for the grinding. Millers had a popular reputation for dishonesty, as is illustrated by the "Reeve's Tale" in Geoffrey Chaucer's *Canterbury Tales* (late 14th century). It was commonly believed that millers stole grain and flour from their customers, who had little recourse in the matter because they had no other options for grinding their wheat.

During the late medieval period people began using mills for purposes other than grinding grain. Two of the most common uses of water mills and windmills were for producing cloth and for sawing wood. Water mills called fulling mills used waterpower to pound woolen cloth, a process that made the cloth thicker and stronger. This work had previously been done by people who stomped on the cloth with their feet. Fulling mills appeared in France during the 11th century, spread to England in the 12th century, and were common in western Europe by the 13th century. The use of mechanical power made cloth manufacture much more efficient and led to the dramatic growth of the English cloth industry during the last centuries of the medieval period.

During the 13th century sawmills appeared in France. These mills used waterwheels to power saws to cut and plane logs into boards. Mills were also used by metal processors. Some blast furnaces that processed iron ore used waterwheels to power their bellows. During the 13th century mills began to be used to power grindstones to sharpen tools. By the end of the 15th century millers had begun using mills to process iron bars into nails.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

In the medieval Islamic world there may have been nothing more important to the survival of society than the milling of grain. Flour from milled grain produced bread, which was the essential food in cities and agricultural settlements. Rare was the meal anywhere in the Islamic world, from southern Asia to al-Andalus, at which bread was not served. When there was insufficient bread to feed the common folk or when bread cost more than most people could afford, civil resistance to government authority, riots, and outright armed rebellions might occur.

The principal grain to be milled was wheat, which was grown in most of the Islamic world. Millet, sorghum, and rice might also be ground in gristmills—mills that ground grain. Millet was the least nutritious of these but was an

important crop in sub-Saharan Africa and the Near East; sorghum was important in East Africa; rice was perhaps the most nutritious grain except for wheat and was essential to the diet in India, central Asia, parts of Africa, and al-Andalus, although it was more rarely ground into flour than wheat was.

When Muslim Arabs swept through the Near East and North Africa in the 600s and 700s, they absorbed into their empire several different cultures, each with its own tastes in flour and its own technologies for making it. By the 700s these cultures seem to have formed a preference for the finely ground flours typical of Byzantine cities. The technologies they absorbed included milling by hand, by water, and by wind. Milling done by hand was the most common form, using a millstone and a grinder, often a pestle. Even after Islam had established itself as primarily an urban culture, in rural areas and remote regions (such as the mountains of Afghanistan and in North Africa) the laborious process of placing grain in a hollowed, heavy stone and then crushing it with a stone pestle remained common throughout the medieval period.

Milling by hand was a family project. The grain was laid out in front of family members, who then picked through it to remove stones, hulls, and other contaminants. Even so, bits of stone might end up being ground into the flour. Women did the grinding, a process that was slow, since only a small amount of grain could be ground at one time. It was also very hard work, because a heavy stone had to be lifted and then ground into the grain against another stone. After the grain was ground into flour, it was run through a sieve, which caught remaining hulls and pieces of grain not yet ground fine enough for use.

The ancient Romans had improved on this grinding process with what is generally called the hand mill, even though it was not always powered by human hands. The hand mill that was common throughout the Islamic world consisted of a large stationary stone, usually circular, with a rotating post in its middle to which was attached another stone that revolved as the post revolved, grinding against the stationary stone. It could be turned by people pressing against poles sticking out of the rotating post, but by Islamic times, it was more often moved by animals harnessed to the poles. This was the most common kind of mill found in bakeries. It might be small enough to fit into a room of a shop or house, where it would be turned by a donkey. Or it could be much larger, requiring oxen to turn it; this kind would be found in the countryside. Even though the technologies for waterwheels and windmills were well known in the Islamic world, the hand mill was often preferred by peasants because it was

inexpensive to build and maintain and beasts of burden were usually available to turn it. Further, it did not depend on water or wind to power it and could be set up even where flowing water or consistent winds were unavailable.

Although the Islamic world's hydrological engineers were superior to those of Christian Europe, the Islamic world made far less use of the waterwheel than did Christian Europe, probably because of the shortage of fast-moving streams, except in al-Andalus. The most common type of waterwheel in the Islamic world was the horizontal wheel, the least efficient of the choices. The advantage of this wheel was that it could function well in slow-moving water. It consisted of a horizontal wheel of blades that caught the motion of moving water, either with one side walled off from the water so that it turned in only one direction or with a sluice or chute directing water against only one side of the wheel.

In the middle of the wheel was a vertical post going up through the mill's floor to the grinding room, where the post rotated, with a horizontal pole out of its side turning a stone wheel that ground against a large millstone with a hole in its middle for the post to pass through. Grain could be poured onto the millstone and would collect in troughs. The horizontal waterwheel achieved about 5 horsepower, which was a vast improvement over the horsepower available when grinding by hand or animal; it was cheap enough to build that even small communities could construct one. This horizontal waterwheel was already in use in the 600s.

The vertical waterwheel may have been independently invented in more than one place in Europe and Asia. The one used in the Islamic world was the *noria*, invented in India or the Sassanian Empire. It was originally powered by cattle, but by the 600s it had been adapted to water. This waterwheel is said to be "undershot," meaning that its blades caught the flow of water at the bottom of the wheel, where they rested in the stream. A horizontal post ran through the center of the waterwheel that was attached to two gears, one vertical and the other horizontal, which transferred its energy to the rotating post that rose up through the floor in the center of the stationary millstone to rotate another movable millstone that ground against the bottom one. The undershot waterwheel also was used to raise water from one level to another for irrigation. Although Christian Europe used the undershot wheel for several industries, such as woodcutting and pushing air into smelting furnaces, in the Islamic world it was seldom used for anything other than grinding grain and raising water.

The overshot waterwheel did not come into general use until the 1400s and remained rare in the Islamic world. This innovation was probably a European one. In the overshot wheel water flowed over the top of the wheel, usually guided

by a chute, where bucketlike blades filled with the flowing water and then were pulled down by gravity. It was the most expensive mill to build, requiring more gears and more maintenance, but it was much more efficient than the undershot wheel. When built beside a fast-moving stream, it often proved worth the expense, being twice as efficient in supplying power as the undershot wheel.

The windmill seems to have been invented in two different places in two significantly different forms. One was invented in the Sassanian Empire, probably in Sistan, in modern-day Afghanistan or Iran. It looked as though it had been inspired by the wind-driven prayer wheels of Tibet. It had a horizontal wheel like that of the horizontal waterwheel, but instead of blades, it had between six and 12 rods with three-cornered sails attached, similar to the sails on the boats of the Near East and North Africa in medieval times. Outside the circumference of the circle formed by the rods and their sails was a circular masonry wall with an opening that faced the prevailing wind. Wind would enter the opening and spin the wheel, which turned a rotating post in its center. The shaft went up through the mill's floor and through the bottom millstone, turning the upper stone to grind grain. This relatively efficient mechanism could spin too fast, scorching grain and endangering the miller. Therefore, the opening in the masonry circle had sliding shutters that could be adjusted to restrict how much air passed through, allowing millers to regulate the speed of the rotation of their millstones. After the Arab conquest of the Sassanian Empire, this form of windmill spread across the Islamic world and remained in widespread use throughout medieval times.

The vertical-wheel windmill was a latecomer to the Islamic world. Invented in northern Europe, probably in East Anglia in England, it offered much higher efficiency in adapting wind power to milling, because all its sails were catching the wind and moving with it all the time. The first of these mills had poles thrusting horizontally out of the sides of their outer walls, and people would form a team and push the poles to shift the entire building so that the wheel faced the wind. It was only in the late medieval era that this form of windmill made its way into use in the Islamic world, although when it did, it spread widely from Grenada to Turkey. In the 1400s a variation on this mill found its way from Europe into the Islamic world. This mill had its wheel attached to a dome that surmounted the building. A miller used a long pole to push or pull the dome to shift the wheel to face the wind. This innovation became very popular in the Islamic world, and some of these domed mills from late medieval times still exist in Turkey, North Africa, and Spain in the early 21st century.

The parts for all these mills were nearly always made of wood. Wood wore out faster than iron did, but iron parts were very expensive, requiring large smelting plants and blacksmiths who could fashion large fastenings for posts and gears. Two advantages of using wood rather than iron was that it was easier to fashion into parts and that wooden parts could be fabricated by the miller or by local farmers, without requiring specialized craftspeople. In cities the people who operated the mills in bakeries may have been men, but in the countryside millers seem universally to have been women.

## ► mining, quarrying, and salt making

### INTRODUCTION

During the medieval era people revealed what minerals they valued by how much effort and risk they put into finding them. This may be best illustrated by salt. Salt makes food tastier, but it also is an essential nutrient, without which people cannot live. Only small amounts of salt are needed to keep people alive, but when even small amounts are unavailable, people will sacrifice much to obtain it. During most of the medieval period people in western and central Africa had to trade for their salt. The salt came to them from two places: one was by sea, and the other was from the Sahara desert. Medieval Africans who lived south of the Sahara paid an equal amount by weight in gold for salt. This was not just from having plenty of gold; by then the gold miners had exhausted most surface sources of gold and would have put themselves at risk digging into the earth to follow veins of gold. By trading gold for salt, they were trading life for life. In China and India governments monopolized salt production and taxed the sales of salt even after they had sold the salt to merchants. In both regions, people paid the taxes because they had to have the salt; in both regions people deeply resented the government for taking advantage of them in this way.

There were three basic sources of salt: the sea, rock salt left from ancient oceans, and underground brine deposits such as those in China. Most salt in medieval times came from the sea, usually from a process of drying out trapped seawater. The effectiveness of this process varied considerably, because the salt content of water varied greatly, from about 1 percent in the Baltic Sea to about 9 percent in the Dead Sea. Rock salt was gathered from surface deposits, from digging mines, and in Africa from the use of water to cause salt to rise out of the ground. The brine deposits of China were so valued that the Chinese invented a new technology to get at them: deep bore-hole drilling. In the process, they discovered natural gas.

Stone seems to have been of value everywhere, and many medieval people had a sophisticated understanding of different kinds of stone and to what uses they could be put. For instance, medieval Australians preferred granite for their tools and weapons, but they used sandstone to sharpen their granite tools. Blocks of stone were used for construction in many cultures. The value cultures placed on stone for construction can be seen in their determination to free stone blocks from quarries. In the Americas and Oceania people often worked with only stone tools to free the stone blocks, requiring long and strenuous effort on their part. In Great Zimbabwe, Europe, and elsewhere fire was used. A stone surface would be heated, and then water would be splashed on it, the sudden cooling causing the stone to crack or shatter. In India and

Ethiopia metal chisels were used to free and shape stones in quarries. In both India and Ethiopia a special form of quarrying flourished in the early medieval era: Stonemasons quarried entire temples, churches, and monasteries out of stone.

Many metals could be found in surface deposits in ancient times, but most of these deposits were gone by medieval times. In some areas, such as Japan and China, it was possible to pan for gold in streams, and many a peasant did so in order to supplement his or her income. In North America huge deposits of copper made it readily accessible to simple digging throughout medieval times, but in other areas it became something to be sought after in tunnels, dug to follow the copper deposits through the earth. In South America miners of gold, silver, and copper worked in cramped, narrow tunnels scores of yards within mountainsides, using tools of deer horn—a perilous and grinding effort eased in the Inca Empire only by liberal sick-leave policies and by mining only during warm months.

In Europe and Asia miners risked cave-ins and floods. The ancient Romans had developed an effective system for eliminating water by using waterwheels on which people treaded, turning the wheels and the buckets attached to them to raise water up from one level to the next until it could be poured outside. In Japan hand pumps were used to raise water to the surface, where it was put to use sluicing ore downhill toward smelting furnaces. The risks were great in digging into the earth, and slaves were often forced to do the work, or local populations were drafted to work government mines. Still, it seems that almost everywhere metal was known to exist, individual entrepreneurs risked their lives to find metal, because metal could improve their lives enough to make risking their lives seem worthwhile.

## AFRICA

BY FLORDELIZ T. BUGARIN AND BRADLEY SKEEN

During the medieval period in Africa a wealth of different minerals shaped historical events, culture, and the everyday lives of various peoples. The mining, quarrying, and processing of these resources brought economic opportunities to various regions and affected local communities, trade routes, and political relations. Mineral abundance led to the development of market centers, the birth of new cities, and the appearance of groups of individuals with specialized skills. The production of valued commodities, such as salt, gold, iron, copper, and bronze, stimulated vast social and economic changes throughout Africa.

Salt is said to have been as priceless as gold during the medieval era. Some believe that salt was the monetary equivalent of gold and that it was exchanged measure for measure.

From oral traditions and written documents it is clear that it was a prized commodity that attracted many camel caravans of traders, stimulated the development of trade to all corners of Africa, and drew the attention of international communities. Numerous Arabic references attest to its importance as a form of currency and as a royal treasure. Because it was in high demand, salt linked traders from Timbuktu in western Africa to places as far away as Europe, Iran, and southern Africa. Lesser-known centers of production included Taghaza located north of Timbuktu, Awlil and Ijil in the western Sahara, and Kawar in Niger.

The earliest trade relations may have arisen because of the demand for salt. By the medieval period salt mining in the Sahara and the existence of a trans-Saharan salt trade route were well established. In the 12th century it was widely documented that salt was highly valued by many Africans and was collected from the sand dunes of the Sahara. The majority of these Saharan salt deposits were located at Taoudenni and Taghaza in northern Mali and at Tichitt in Mauritania.

Many techniques were used to process this mineral. Major quantities of salt came from rock deposits in places such as Ethiopia. Often it was collected from shallow mines, extracted from soil, or made by a process of evaporation. On estuaries, lagoons, and tidal flats people constructed shallow dams or directed seawater into nearby ponds. They extracted salt from these pools through solar evaporation. When solar evaporation was impossible owing to humidity, cloud cover, or rainfall, people boiled seawater. Ethnohistorical sources suggest that Africans living in the savanna regions produced salt from grasses that flourished in saline soils and stored salt in their stalks. People burned the blades, dissolved the ash, and continuously filtered and boiled the remains until they collected a sizable amount of salt. A comparable procedure involving dilution, filtration, and boiling was followed when salt was obtained from saline soils.

Methods of producing salt varied by geographical region. Since saline regions or salty conditions were unfavorable for crops, farmers usually relied on specialists to procure salt and traders to deliver supplies. Through trade and distribution, salt stimulated cultural and economic interaction. The need for salt played a major role in the development of cities. When Timbuktu was founded in Mali around 1100, it became a center for traders who wanted to trade salt from the mines in the Sahara for gold and slaves. By 1330 Timbuktu was part of the Mali Empire, and the leaders of this region were in control of the lucrative gold-salt trade routes.

Similarly to salt, gold was a major commodity in a wide-ranging network of exchanges. Gold was produced in five major areas during the medieval period and transported to many markets throughout Africa. Production centers included an-

cient Ghana, Mali, and Asante in western Africa; Axum on the northern Ethiopian plateau; and Zimbabwe in southeastern Africa. Gold traveling on northward trade routes largely came from sources within forested zones.

Researchers conducting metallurgical tests support the claim that the gold used to make Almoravid coins originated from western Africa. Many believe that western Africa after the 11th century became the primary source of gold for a global market, with most of the gold collected from the Senegal and Niger rivers or in the Lobi and Akan fields in Ghana. From there gold traveled to centers of trade such as Jenne-jeno and other posts that dotted the Sahel. The mining and quarrying of gold often involved small teams, and although production was low during these times in comparison to later periods, it had a powerful impact on trade. Just like salt and other valued goods, gold perpetuated established trade routes and solidified Africa's role in an international arena.

Gold mining was the primary factor in the rise of Great Zimbabwe and its satellite communities in modern-day Zimbabwe. The Zimbabwe plateau is rich in both alluvial gold (nuggets washed down into streambeds) and veins of gold occurring in quartz deposits within the granite substrate of the plateau; the former was collected simply by gleaning through the gravel beds of the streams and the latter by cutting shallow mine shafts into the bedrock. During the development of Great Zimbabwe into southern Africa's largest city between approximately 1250 and 1450, at least 330,600 kilograms of gold were extracted from the surrounding country, and more than 370 miles of mine shafts were excavated. The city grew up in something of a gold rush, and probably a large proportion of its population was engaged in gold mining or the mining of iron and copper ores, which also were abundant in the area. Those engaged in mining seem to have lived in camps at the extraction sites (perhaps their families remained in the city itself), while smelting and other forms of processing were done at Great Zimbabwe.

Iron, copper, and brass also were mined and traded during the medieval era. Records, oral traditions, and archaeological data indicate that these commodities traveled from one trade center to the next. Oral traditions explain the importance of copper and its alloys as luxury goods, markers of status, and highly valued commodities by populations living in forested environments. Archaeological evidence at places such as Igbo-Ukwu suggests that the metal used in many copper-based alloy items came from African sources. Large amounts of metal artifacts found at archaeological sites indicate that raw materials were reworked into a variety of tools and crafts.

Throughout most of sub-Saharan Africa metal extraction was carried out in a highly dispersed and low-intensity

manner. Individual blacksmiths would oversee the production of perhaps 20 pounds of iron per year, from mining to finished products. A smith and perhaps a dozen apprentices and assistants would begin by surveying their local area for iron deposits. These had to be near the surface, since no sophisticated mining techniques existed. If iron ores were not plainly visible, deposits could be detected from such signs as small particles of iron contained in the balls of soil and animal waste collected by dung beetles, since these insects dug their own network of shallow tunnels. The same group of smiths would then mine the iron, smelt it in a furnace, and work it into tools or weapons at the master smith's forge. Each worker received a share of the final profit based on his skills and contributions to the effort. In areas where iron was available in alluvial deposits on the surface of streambeds, the work of collection was delegated to the female family members of the smith.

Stone was not an important building material throughout most of Africa. Medieval Ethiopia, however, produced some of the world's most amazing examples of stonework. This was possible because of a tradition of craftsmanship, both in quarrying and working stone, that persisted through the many political and economic upheavals that brought constant change to Ethiopia throughout the Middle Ages. The kings of Axum in the fifth and sixth centuries erected a series of stone stelae to mark their tombs. The largest of these was one piece of granite 108 feet long, the largest single piece of stone ever quarried (including in modern times). Although it collapsed and broke during the process of erection, about 100 stelae between 50 and 80 feet long were put in place successfully.

Ethiopian skill in working stone continued after the collapse of the kingdom of Axum in the ninth century and reached another high point under the Ethiopian emperor Gebre Mesqel Lalibela (r. 1189–1229). He converted his birthplace of Roha into a highly imaginative copy of the city of Jerusalem and renamed it Lalibela after himself. His foundations included 11 churches carved out of solid rock. These were large, multistory buildings that had the appearance of ordinary monumental churches, but they were not built of joined stone blocks in the usual manner. Trenches were cut down into the rock as far as 40 feet deep to relieve the facades of the structures, and then individual rooms were carved out of the rock in situ. Elaborate architectural details were carved into the interior and exterior of the structures to depict artistically many of those elements created by joining stone blocks together.

Quarrying was nowhere more important in medieval sub-Saharan Africa than in the civilization of Great Zimbabwe. One spur to the building of the largest stone structures in southern Africa was the abundant supply of

granite. In the Zimbabwe plateau thin layers of granite continuously flaked off any exposed outcrops of bedrock. These large, flat pieces of granite could be broken up very easily into the kind of building stones used in the structures at Great Zimbabwe and other towns. When the natural supply of rock waned, a new layer of granite could be flaked off the outcroppings by building a bonfire over the desired area and then dousing it with water, producing cracking from the change in volume caused by the sudden change in temperature. This work was probably carried out by labor gangs drawn from the common population of Great Zimbabwe. The plateau also yielded excellent natural clay that was one of the many materials used in the construction of common dwellings.

The mining, quarrying, and production of mineral resources brought many changes to Africa during the medieval period. Camel caravans flourished, new communities arose, and economic relationships changed over time. To support trade, numerous techniques were used to acquire and manufacture raw sources. Once collected, these goods would mark social and economic differences and impact the lives of various communities.

## THE AMERICAS

BY KEITH JORDAN

On Isle Royale and the Keweenaw Peninsula of modern-day Michigan and on the eastern shore of Lake Superior in Ontario, Native Americans continued to mine copper during the medieval period as they had for thousands of years previously. Although native North Americans did not cast or smelt copper, they produced tools and ornaments out of pure copper by cold-hammering and heating (annealing) the material. Lake Superior copper provided the source for copper objects found in the graves of Mississippian chiefs in the Midwest. Other sources of the copper used to create those burial ornaments were farther south, in the Appalachians of Georgia and the Carolinas. As yet, however, no archaeological evidence of mining comparable to the Lake Superior workings has been discovered in the southeastern United States.

By the time the Europeans arrived, indigenous peoples had dug hundreds of mines in the Lake Superior region, and between 5.6 million and 2 billion pounds of copper had been removed. Like all other mining in the pre-Columbian New World, this work was conducted using very simple tools. Large stone hammers weighing 5 to 40 pounds each were used to break up the bedrock, with kindling fires built against the bedrock helping to shatter it. Some of these hammers may have been fitted with wooden handles or swung on cords,

while many were simply held in the digger's hand. The Native American miners dug trenches following veins of copper and excavated pits up to 50 feet deep to reach metal deposits beneath the surface. High-water tables and rain flooded the pits, and the builders were forced to dig additional trenches for drainage or simply to bail out the water with buckets made of birch bark or wood. Wooden scoops resembling canoe paddles served to remove the broken pieces of copper. Some pits were lined with logs or stones to reduce the risk of cave-ins.

The harsh climate precluded any work on the mines during the winter months. In addition to the natural obstacles, early Native Americans considered copper sacred and Lake Superior the home of powerful and dangerous spirits; thus ritual precautions probably were taken to protect the miners from supernatural injury.

In the southwestern United States, Anasazi, or Ancestral Pueblo (ca. 900–ca. 1300), peoples and their neighbors mined for turquoise, both for local use in jewelry and ritual objects and for trade with peoples to the south in Mesoamerica. Native American turquoise mines built before European contact have been discovered in New Mexico, Colorado, Utah, Arizona, Nevada, and California. One of the most important is located near Cerillos, New Mexico, and may have been controlled by the powerful Anasazi site of Chaco from 950 to 1100. Chemical analysis matching finds of turquoise to their geological source demonstrates that Cerillos turquoise was traded as far south as the Mayan site of Chichén Itzá. The mining was carried out using basically the same technology as other pre-Columbian American quarrying: using large stones, stone tools, and fire to fracture bedrock and detach pieces of stone for removal. Very similar technology produced the quarried sandstone blocks that went by the millions into the construction of buildings at Chaco and other Anasazi settlements.

## MINING INCA GOLD

The Incas mined not only gold but silver, copper, and tin as well. They panned for platinum in streams in Ecuador. As the Inca Empire expanded, traders were sent into newly conquered provinces to look for sites that might be suited to the mining of gold or silver. The gold of the empire came in three fundamental forms: nuggets, small grains that had to be separated from dirt by washing, and bits of gold that were mixed with minerals and often embedded in rock. Sources for gold, silver, and copper were scattered through most of the empire, but tin tended to be found primarily in the south.

The mountains in which ores were found were worshiped, and the Inca would pray to the mountains to give up their ores. Ore itself was sacred, and ore deposits would be given offerings. Miners would gather at holy places and dance in religious ceremonies to please the mountains. The stone in which metals were found was worshiped, and the metal was treated as sacred.

Mining sites could be large or small. Near Chuquiabo (in present-day Bolivia) was a site of several mines in the walls of a river gorge. Just climbing the walls to the mine openings would have been daring, but the miners had to enter narrow tunnels, too narrow for more than one miner and not high enough for the miner to stand erect. Miners had no illumination and had to crawl from 25 to more than 100 yards in the dark to find the end of the tunnel and there carve into a vein of gold that the tunnel followed erratically. They used tools made from deer antlers.

The imperial government owned all the gold and silver that was mined in the empire. At important mines such as those near Chuquiabo (a name that means “farm of gold”), the government posted guards, who watched carefully as dirt was carried out of mines and taken down to the river to be washed to extract gold. The dirt was heaped on smooth stones, and water was splashed on it until the dirt washed away, leaving the heavy grains of gold behind.

The Maya of the Classic Period (ca. 200–ca. 900) quarried the limestone used to construct their cities from the limestone formations under their territories in Guatemala and Yucatán. Regional geology often determined building materials: at Copán in western Honduras, Mayan builders used volcanic stone, or tuff, for construction and sculptured monuments. The primary tools used to quarry any stone were other stones: small rounded stones employed as handheld hammerstones, and chisels made of flint, perhaps driven with wooden mallets. Because both limestone and the tuff used at Copán are soft when encountered in the ground but harden on exposure to air, the job of quarrying may have been easier than the work of the sculptors who later carved the blocks. Mayan quarry workers made their tasks easier by their knowledge of local geology. They directed their percussive attacks to natural cleavage planes in the limestone to easily detach blocks of the right sizes and shapes for royal monuments. Besides its use as a building stone, limestone was burned to create the powder needed for making mortar and stucco. Natural deposits of crumbled, powdery limestone, or marl, produced such material almost ready made.

The Maya manufactured salt by boiling seawater or allowing it to evaporate in ceramic vessels. Not surprisingly the major centers for salt production for the Maya during the Postclassic Period (ca. 1000–ca. 1550) were located along the Caribbean coasts of Yucatan and Belize. The city of Chichén Itzá in Yucatán may have controlled salt production and trading from the early part of that period to about 1200. Traders hauled the processed salt in canoes to coastal ports for redistribution.

Theoretically at least, all metal deposits in the Inca Empire belonged to the ruler himself. In practice they were mined by local peoples as part of their *mita*, or tax in labor to the Incan state, under the watchful eyes of Incan overseers. The richest sources of metals—gold, silver, copper, and tin—were mines located in the Andes in present-day southern Bolivia and northern Argentina and Chile. Incan mines, cut like their counterparts in North America using stone hammers, were narrow tunnels cut into mountainsides and rock faces, wide enough to admit only one worker at a time. They were comparatively shallow in depth and up to 20 feet long. Because of the cold temperatures at many of these mountain mines, digging could go on only during the summer months; to avoid problems of cold, heat, and limited lighting, the laborers worked only between noon and sundown. Many of the Incan mines were taken over by the Spanish conquistadors after 1532. The colonial authorities did not limit the work hours of the indigenous miners as the Inca had done, and many of the weakened workers succumbed to European diseases.

## ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Mining, quarrying, and salt making were ancient practices that were fundamental parts of the societies and economies of Asian and Pacific peoples. In medieval Australia the emphasis was on fairly simple quarrying. Australians searched river beds for stones to use in their axes and other tools, and they knew of outcrops of granite where fragments of stone would fall to the ground. In such places they would gather stones to use. Sometimes they used their stone tools to chip out pieces of stone from the granite outcrops. Many medieval Australians had no sources of stone in their own territories, which meant they had to venture into the territories of others who had such sources. This required getting permission, with the understanding that a reciprocal favor was expected for the future.

Others in the Pacific quarried stone in more spectacular ways, and Easter Island has the most famous results of what seems to have been an ancient tradition among Polynesians. For instance, Easter Islanders built *ahu*, which were ceremonial platforms on which they set giant, enigmatic statues to face the ocean. Similar platforms have been found among other island cultures such as those in the Marquesas Islands. The *ahu* were built of stone quarried from extinct volcanoes. For the *moai*, the giant statues, the Easter Islanders quarried the buff-colored bodies from Rano Raraku, a volcano near the eastern end of the island, and they quarried the ruddy stone for the topknots of the statues from Puna Pau, a volcano near the western end of the island.

The quarrying was done with stone chisels. The bodies of the statues were enormous, sometimes weighing hundreds of tons, and it probably took about a year to carve one out of the quarries of Rano Raraku. Quarriers always carved all

Jade phoenix ornament; China, Liao Dynasty, 10th or 11th century (© The Trustees of the British Museum)

around the statue until only its spine was still attached to the volcano. Although the people of Easter Island eventually wiped out almost all the forest with which it had once been covered, during the period when the statues were built, ending in about 1650, enough trees were still available for large tree trunks to be installed atop the lip of the crater of Rano Raraku. Two trunks were anchored in the ground, and thick ropes were strapped around them. It would have taken teams of people to work the ropes, slowly pulling up one side of the statue. One theory for how the statues were moved across the islands suggests that the process of moving the statues out of the quarry turned them on their bellies, which are rounded. On a sledge of wood, the statues would rock forward and back on their rounded bellies, perhaps accounting for the folklore of the islanders that says the statues walked from the quarries to their *ahu*, because the rocking would have resembled a steady gait.

The Easter Islanders were master stonemasons who quarried stones for construction. Originally, their homes had stone walls topped by thatch. The best examples have carefully dressed stones that fit neatly, like the best of Incan stonework, but the islanders apparently developed their techniques for doing this independently of outsiders. When the island was denuded of almost all its trees, the islanders dug their homes into the ground, using dressed stones to line the interiors of those caves.

Moving westward from Oceania to Southeast Asia, archaeology is of less help than on Easter Island. For instance, medieval Indonesians certainly worked with bronze and iron, but their mining practices remain obscure. Not so to the north, in Japan, where archaeologists are continuing to unlock the mysteries of Japanese stonework and mining. For most of the medieval era Japan was dependent on imports for most of its needs for metal. Japan brought in most of its iron from Korea. In fact, unlike China and Korea, Japan had its iron age before its bronze age, because Korean iron became readily available before bronze from China did.

For iron tools and copper money Japan was long dependent on its neighbors. When Japan sent tribute to the Chinese emperor, the Chinese emperor by tradition sent gifts more valuable than the tribute back to the Japanese emperor. The essential aspect of the tribute was Chinese copper coins, the only currency in Japan for centuries, only being fully supplanted by Japanese-made coins in the 1500s.

During the medieval era sources for copper, silver, and gold were found on the island of Sado and in some territories on Honshu and Kyushu. Japan was divided into fiefdoms ruled by daimyo, who were warlords. It was up to each daimyo to exploit the metal deposits on his land, and many did not invest much in mining. Thus, even though late-medieval Ja-

*Bronze figure of the seated Buddha; Danesar Khera, central India; Gupta Period; fifth century. Bronze figures such as this one, made from copper mixed with tin and other alloys, indicate India's early sophistication in mining and casting. (© The Trustees of the British Museum)*

pan had discovered enough copper deposits to meet its needs, it still suffered from shortages of the metal.

Copper, silver, and gold each could at first be found in surface deposits, but these deposits were quickly played out. Gold could be panned from mountain rivers, and many farmers added to their incomes by panning for the gold, an activity that remained vigorous long after the end of medieval times. Perhaps it was through such panning and the effort to separate sand from grains of gold that iron was discovered in the sand of the beds of Japan's rivers. This was a momentous discovery, because it meant that Japan at last had a source other than Korea for some of the iron used in tools and weapons. The dredging of the sandy bottoms of rivers became a small industry, and the iron smelted from the sand became the iron preferred in the making of steel for Japanese swords.

Much of Japan's mining of metal depended on digging into the ground. This was tough, dangerous work. Mines were narrow tunnels with barely enough room for one person to walk through them. Cave-ins were common, because of poorly shored-up ceilings as well as from Japan's frequent earthquakes. Further, the mines often flooded. In following

the ore into the earth, mines often went deep below the surface. Ore was placed in buckets to be hauled upward by rope or in inclined conveyors operated by pulleys. Hand-operated pumps often moved water out of the mines to the surface, where the water was used to sluice the ore downhill to a nearby furnace, where it was smelted. Mines often were run by the local daimyo, but some small ones were operated by an independent entrepreneur who paid the daimyo with a share of what he mined.

Wood was the primary building material in medieval Japan, and it never ceased to be abundant because of a tradition of replanting land where trees had been harvested. Thus, stone was rarely used for other than the lower floors of fortresses, defensive walls, and special buildings such as palaces or temples. The upper floors of fortresses were almost inevitably made of wood. Thus the quarrying of stone was probably not a big industry, and for big building projects it was usually done by commoners drafted into service for the purpose.

On the other hand, salt was an important industry. In Japan it came mostly from the sea. People would form pools that filled during high tide and then dried during low tide, leaving behind a residue that included salt. Another technique involved laying mats over holes; during high tides water would filter through the mats, leaving behind grains of salt that could be swept up after the tide receded and the sun dried the mats.

Similar techniques were used in China, where as much as 75 percent of its salt may have come from the ocean. Some salt came from pans that were filled with seawater and then allowed to dry. In various areas of China there were salt pools and salt marshes and, in the southwest, salt wells. The lives of salt makers were bad. They were poorly paid, and because China occasionally suffered a shortage of copper coinage, they were often paid in food insufficient to feed a family. Some escaped by becoming bandits. Others joined the army, the only legal way out of their misery, because otherwise the law required them to make salt all their lives.

In ancient times underground deposits of brine were discovered in western China, and the deep-borehole technique for extracting the brine was developed. The drill bit was very heavy and was suspended from a long cable. The cable was hemp wrapped in cowhide, and it was both strong and flexible. Bamboo pipes accompanied the bits, to drain away water. In this way natural gas was discovered, and bamboo pipes were used to vent the gas, which was ignited to heat cauldrons for drying the salt. Salt was heavily taxed, inflating its cost tenfold. At times the imperial government backed the value of its banknotes with salt.

Just as salt production was owned by the imperial government, so were all metals and mines during medieval times.

Miners had lives little better than those of salt makers. They were underpaid, overworked, and not allowed escape except into military service. China had a chronic problem with its gold and silver mines: Miners tended to sneak some of what they found out of the mines for their own enrichment. Their foremen, mine managers, and government officials in charge of mining operations all stole the precious metals. Perhaps one third of the gold and silver mined never made it to the imperial government. Chinese miners had many tools available to them, including picks and wheelbarrows. Coal was used for heating in China by the 1200s and was mined much as metals were mined. By the medieval era China's surface deposits of copper had been played out; although it had huge deposits of copper ore, the ore was very poor, only about 0.4 percent copper (compare with the 6 percent in ore in the Congo).

Somewhat less is known about mining in medieval India than in medieval China, despite a strong interest among archaeologists to find mines that were legendary in medieval times. India was the only source of diamonds in the medieval world. Its mines also produced sapphires, rubies, emeralds, lapis-lazuli, topazes, and crystal. Further, its mines produced perhaps the best iron in the world. Some of its mines produced iron that was made into wootz steel, valued through most of Asia and all the way to Europe. The iron contained about 0.003 percent vanadium, which alloyed with the iron when making steel, making the steel extra tough and flexible. Gold, silver, copper, mercury, and lead also were mined in India. Quarries produced marble, granite, and sandstone for building.

Miners used heavy iron axes to split stone out of the walls of mines or quarries. Mining was usually a monopoly of the state, with profits going to the government. Salt production was also a government monopoly. The most common process for making salt involved the use of pans in which seawater evaporated, with the resulting salt being taken inland. Other significant sources of salt were salt mines. The government sold salt to merchants and then taxed the merchants and buyers on transactions of salt, greatly inflating its price and causing resentment among many buyers.

## EUROPE

BY THILO REHREN AND MARCOS MARTINÓN-TORRES

The end of the dominance of the Roman Empire over Europe north of the Alps resulted in dramatic changes in the organization of society and profoundly affected the lives of the ordinary people. The framework of long-distance trade—a globalized economy with specialized producers providing commodities for the entire empire—broke down, but so did the urban way of life, with its large building projects of tem-

ples and administrative centers, and the army, with its insatiable demand for metals and other raw materials. Instead, a plethora of smaller political units developed, with most of the population engaged in rural life and agrarian economies. The metal demand that persisted, mostly iron for tools and implements, was easily produced from the near-ubiquitous surface deposits of bog ore, while nonferrous metals such as copper, silver, and lead were relatively simple to acquire from recycled Roman relics. With the rebound of greater political organization, most notably in the Carolingian Empire (751–987) and its successors, came a renewed thirst for fresh commodities, requiring a resurgence of mining that persisted through the late medieval period and all later periods.

Mining covers the extraction of mineral resources from the ground; as such it is, together with agriculture, the original primary production on which all human material culture is based. Depending on the nature of the minerals extracted, mining comprises several activities, each with its own traditions and techniques. Most mined minerals are used to produce bricks for building purposes and are extracted by quarrying stones and clay. Mining of ore is the extraction of rocks and minerals that are smelted to produce metals. Medieval salt mining was of particular importance in the moderate climates north of the Alps, where harvesting sea salt through evaporation of seawater was not normally possible. Although mineral coal was occasionally used where it outcrops at the surface, it did not play a major role in medieval mining and metallurgy.

Quarrying provides building stones from suitable geological formations. In the Middle Ages most building stones were banded sedimentary or volcanic rocks, such as limestone and sandstone, which were relatively easily broken into near-rectangular blocks. Slate, split into thin sheets, was used for roofing and cladding. Quarrying was predominantly done in open-pit operations, using wedges and simple cutting tools to liberate the rocks from their banks. Large building programs, such as the medieval cathedrals, often maintained large quarries of their own to ensure constant and consistent supplies of stones. Regions with little or no suitable rock formations exposed at the surface, such as the low-lying parts of northeastern France, the Netherlands, northern Germany, and most of the countries south and east of the Baltic, relied on bricks fired from clay for use in stone buildings and in some timber-frame buildings. Clay quarrying leaves few traces in the landscape, and limited fuel supplies for the kilns meant that good-quality bricks were relatively expensive. Because overland transportation of bulk materials was limited, most quarries, stone or clay, usually served only their immediate regions, resulting in regionally characteristic building materials. The cost of transporting stone was so high that some-

times the location of suitable stone determined the site of the building. However, some transportation took place; for example, the famous limestone used in southeast Britain came from Normandy.

In mining for metallurgy, ownership of the ore minerals depended on the metal. The metals used for coinage, gold and silver, always belonged to the Crown. Base metals such as copper, lead, and tin were owned by the landowner under British common law or by the Crown in Germanic countries; the owner of a mine owed one-tenth of its production to the landowner or the Crown and enjoyed certain tax and legal privileges in return. Most iron ores, nonmetallic minerals, and rocks were exempt from those mining regulations.

Metal mining takes two main forms: open-pit extraction and underground mining through shafts and adits, or horizontal passages. Throughout the Middle Ages open-pit extraction was the dominant method for acquiring iron ore, typically bog iron formations and tin stone concentrated in placer deposits—that is, gravel and sand beds downstream from tin-bearing rocks. Much of surface mining for iron ore was done by individuals or small groups for their own needs, smelting the metal in small bloomery furnaces with little capital investment, legal control, or regulation. Even where iron ore was covered by mining law, bog ore was free for the landowner to exploit. Hushing—uncovering mineral veins by a heavy discharge of water from an artificial reservoir—often was used to prospect for lead veins, which were then worked through pits and simple shafts from the surface; as the depths of mines increased, underground mining became more economical.

Significant developments in underground mining began in the early Middle Ages, when much of it took the shape of disparate near-surface warrens following the ore seams and veins from the surface into the rock, with little regard for long-term sustainability, overall water drainage, and labor regulation. A major hiatus in mining occurred with the Black Death (ca. 1347–ca. 1353), which killed an estimated 25 million people, around one-third of the population of Europe. Many mines were given up and flooded, making it difficult to reopen them later. In addition, many rich ores near the surface had been exhausted. The time after the Black Death was characterized by increased mechanization to compensate for the lack of manual labor and to facilitate extraction of larger quantities of poor ores. Both required much capital investment and extended organizational structures, both of which were provided by the largest landowners: the church and the Crown, which had strong economic and political interests to stimulate production. The Cistercian order of monks was particularly active in mining and metallurgy, from Cumbria to southern Germany.

Mining in the Hapsburg Empire benefited from regal protection and support, and much of the imperial expansion was financed by profits from the mining industry. In 1347 King Magnus Eriksson of Sweden visited the mine in Falun, then the world's largest copper producer, and issued the Charter of Privileges; in 1360 he set out detailed mining regulations to improve regal control over production. Some time later the Schwaz district of Tirol (in present-day Austria) assumed a leading role in silver and copper production and eventually became the second-largest city in the empire, after Vienna. Mining towns in Schwaz and throughout central Europe were given their own relatively liberal social and economic regulations, primarily to attract people to settle the less-arable mountain lands.

Toward the end of the Middle Ages, the importance of the Schwaz district was documented by the *Schwazer Bergbuch* (The Schwaz Mining Book, 1556), the earliest book to describe mining regulations and laws and to illustrate mining practices and technical inventions. In the same year Georg Agricola published his famous *De re metallica* (On the Nature of Metals), a systematic compendium on mining and metallurgy, including geological and technical aspects; the book veered from the purely descriptive approach and thus appealed to the more inquisitive minds of Renaissance and early-modern readers. By the time those two volumes were published, capitalist companies—such as those of the Fugger and Turzo families, with their continent-wide trade networks—dominated much of the European mining industry and trade in metals, providing the finances to set up or modernize mines and to market their products.

Two methods dominated underground mining throughout the Middle Ages: fire setting and mining with iron tools. By setting an open fire against a rock face, hard rock could be weakened as a result of its expanding and contracting as it was first heated and then cooled. Fire setting produces adits and galleries with characteristic rounded cross sections, often reaching diameters in excess of 30 feet; it was used for mining massive ore bodies, such as the tin-rich stocks in Saxony and the Bohemian Erzgebirge. For more-limited ore bodies, such as veins and seams, iron tools (notably the hammer and pick) were used to produce adits and galleries with rectangular or coffin-shaped cross sections. Typically, progress in hard-rock mining was measured in inches per week. The exhaustion of superficial ore bodies and the increased depth of mines required added effort to remove water, ensure sufficient ventilation to facilitate fire setting, and maintain acceptable working conditions. Draining a large mine often required building an adit at the lowest possible level specifically to allow water to flow into the valley; all productive mines above the large mine had to pay one-tenth of their ore

to the large-mine owner, in addition to the one-tenth they paid to the Crown. Explosives such as gunpowder, although known during the Middle Ages, were not used in mining until the early 17th century.

An elaborate system of specialized labor maximized production and effective use of power. The ore was sorted underground according to grade, and each grade was hauled separately, with the rich ore kept in locked wooden boxes. Barren material and host rock were used to refill old galleries, and ore was extracted very selectively. Large mines were worked continuously in shifts all year, and experienced miners were sought after and often free to move from one region to another. For example, one of the administrators of the Spanish mine of Guadalcanal wrote to the government in 1551 to ask for 200 or more German miners.

As a result of changing geological, technological, and economic conditions, the same mine could be used in different centuries to extract different metals. The Rammelsberg near Goslar, for instance, was a copper mine during the early medieval period; became a lead and silver mine in the revival after the Black Death, when the rich copper ore was exhausted but advances in smelting technology made it possible to profitably extract silver from the lead ore initially left underground; and finally became a zinc mine in the 19th century, based on the sphalerite-rich ore left behind by all earlier miners.

Salt was vital as a component of people's diets and as a food preservative. This, combined with the scarcity of salt in particular in areas away from the shores, meant that salt commanded high prices. Underground salt mining can be traced in the Dürrenberg region of Austria to prehistoric times and again from about 1200 until 1989. Medieval salt miners built solution chambers directly into the rock underground, where salt-rich solutions formed. Salt was extracted from the brines by evaporation in large salt pans—riveted metal pans suspended above wood-fueled fires. The forming salt was scraped from the thickening solution and pressed into cone-shaped forms; after drying, the cones were ready for trade, either whole or smashed to grains and packed in barrels. The same procedure was used where natural salt springs were exploited, such as in Soest in Westphalia, where the earliest known salt production dates to the sixth century, and in Lüneburg in northern Germany, which produced much of the salt used by the fishing industry in the Baltic and North Sea.

## THE ISLAMIC WORLD

BY TOM STREISSGUTH

The Arab conquest that began in the seventh century brought a new religious, social, and economic order to the Middle East, Iran, and northern Africa. From their homeland in the

Arabian Peninsula the armies of Islam conquered a vast area, overthrowing long-established realms such as the Persian Empire and the Middle Eastern territories of the Eastern Roman (Byzantine) Empire. The Arabs seized important gold mines in Nubia that had supplied ore for the bezants (coins) of the Byzantine Empire. They conquered mines in Ethiopia, home to the declining Christian realm of Axum, and began mining alluvial deposits in the Nile River valley. A new gold coin, the dinar, was minted by the Umayyad Caliphate (661–750) of Damascus. Modeled on the bezant, the dinar carried quotations of the Koran in place of imperial portraits and Byzantine emblems.

Gold and silver ore were the lifeblood of the caliphate, providing a stimulus to urban craft industries and a medium of exchange for merchants and long-distance traders. Silver coins called dirhams were exchanged with Europeans, who melted these coins down to mint their own denomination, the silver denarius. Silver was in such high demand in both Europe and the Middle East as a basic metal for coinage that a severe shortage of the metal developed in the later Middle Ages. The Islamic realms of the Middle East also were an important source of gemstones, including sapphires from the Arabian Peninsula and Iran, emeralds from Egypt, and turquoise from Iran.

Gold bullion was fashioned from the ore dug from underground or hillside mines or filtered out from river deposits. It became a key item of barter as well as a medium for paying tribute and taxes. During the medieval period hundreds of mines were worked in the Arabian Peninsula, some of which dated to antiquity and several of which are still in production. Among these mines were Bahran, Biram, and al-Nuqrah, deposits under the control of the Quraysh society

to which Muhammad (ca. 570–632), the founder of Islam, belonged. Historians have estimated that the al-Hamdah and Mahd al-Dhahab mines, two of the largest in the Islamic realm, each produced more than 1 million ounces of gold in the Middle Ages.

Although gold and silver enriched the Hejaz region of the western Arabian Peninsula and the early Islamic caliphate, conditions were extremely harsh for the mine laborers, many of whom were war captives or slaves and condemned to spend their lives working in quarries or underground mine shafts. Workers were housed in large barracks located near the mine; they worked with picks, axes, and shovels to excavate and collect ore-bearing rock and sand. In most places technology was limited, preventing the construction of deep mine shafts, which require strong reinforcement as well as a method of pumping water and moving large amounts of rock and soil. Miners simply followed veins of ore with pickaxes and cleared surrounding rock with shovels.

Mine owners set up smelters near the mining sites to separate the metals from ore and convert them to a usable form. Smelters needed high temperatures to operate and had to be fueled by an abundant source of wood. Much of the Arabian Peninsula is treeless, so conditions often precluded the profitable exploitation of smaller deposits.

The mines were under the direct control of the caliph and his local governors, who would consign the operation to a private owner in exchange for a regular levy on the profits of mining, known as the *khums*. Muhammad and his successors granted the use of mines to private individuals, who had the right to the mine's production over a limited period of time in exchange for a payment. This was similar to the European feudal system of usufruct, which granted the use of loaned property for the purpose of profitable gain.

Copper mines existed in Oman, at the southern limit of the Arabian Peninsula, and a wide variety of valuable minerals were produced in Iran. Baku, on the western coast of the Caspian Sea, was the site of oil seeps that brought petroleum to the surface. Shallow pits were dug to allow the oil to collect; by the 16th century these pits were reaching 100 feet in depth. The oil was collected and used for heating, lighting, and the flammable liquid known as Greek fire that was used in warfare. On the nearby Apsheron Peninsula oil condensate and natural gas escaped through fissures in the ground and in many places ignited into a constant flame.

Morocco produced silver, and the caliphate of Spain exploited mercury mines. These were worked by separate gangs of laborers to quarry the rock, carry fuel for heating it, sift the ore, and fashion tools and utensils. The life expectancy of workers in constant contact with this highly poisonous substance must have been quite short.

Brass basin inlaid with silver and gold; Cairo, Egypt, or Damascus, Syria, ca. 1320–41 (© The Trustees of the British Museum)

Northern Africa was the site of extensive trading for the gold produced in the sub-Saharan regions of western Africa, including rich alluvial deposits located in the watersheds of the Niger and Senegal rivers. In the eighth century the Arabs of northern Africa launched a military campaign across the desert intending to seize control of these sources, but they were thrown back with heavy losses. From that time forward the Islamic states of northern Africa traded or bartered for their gold. They set up regular staging posts for the use of the long camel caravans that carried trading goods north and south across the Sahara. Gold was mined in Bambuk, just south of the upper Senegal River, and traded through the cities of Djenné and Timbuktu in what is now Mali. On the East Africa coast the trading cities of Sofala and Kilwa did a brisk business in gold brought from the African interior.

The demand for gold and other precious metals rose steadily through the medieval period as great empires rose and rival caliphates vied for power in northern Africa and the Middle East. Gold mints were established in Kairouan (in what is now Tunisia) and Al-Fustat (later called Cairo), the first Islamic capital of Egypt. Throughout Islamic Africa gold coins replaced the iron bars and cowrie shells that had provided the principal medium of exchange in the pre-Islamic period. Gold demand increased in the 11th century as the Fatimid Caliphate (909–1171) sought to finance war against the Umayyads and the Abbasids, who reigned from their capital of Baghdad.

Gold was frequently traded for slaves and for salt, which for many Africans was just as precious a commodity as gold. Salt was an essential part of the diet and a useful medium for the preservation of food. In some places it was used as a form of currency. Salt was mined or collected in Palestine, Mesopotamia, Egypt, and the Arabian Peninsula, where it existed in large quantities. Throughout northern Africa salt mines were carefully guarded and their locations kept secret.

There were many different methods of salt production. Along the coast seawater was trapped and collected in pools, and salt crystals were collected as they formed on the stagnant surface. Salt also was collected by dissolving salt-loaded soil with water and collecting the crystals in a filter or screen. Sandy soils frequently held layers of salt underneath the surface, and in some rock formations salt could be excavated from mine shafts. Salt was commonly cut into slabs and transported by camels or by slaves for merchants, who bartered the commodity for ivory, gold, slaves, and other goods from the sub-Saharan region. Salt mining formed the economic foundation for many Saharan communities, which existed in a harsh climate that had few

other resources and was ill-suited to the growing of crops or animal husbandry.

Iran was home to extensive deposits of copper, lead, iron, and cobalt. Neyshabur was the location of rich veins of turquoise that had been mined since ancient times and traded with the Middle East, central Asia, Afghanistan, and India. Turquoise had been an important trade and barter item since the time of the Persian Empire. Persian turquoise made its way north to central Asia, east to Afghanistan and India, northwest to the Caucasus region, and as far away as Siberia.

The medieval Persians mined precious gemstones, salt, lime, marble, and gypsum. Copper deposits existed at Khorasan, Kerman, and Azerbaijan along the coast of the Caspian Sea. Coal was mined in the mountains near Tehran. Orpiment, a highly toxic substance used to make poisons and artist's pigment, was mined at Afshar and Orumiyeh. Cobalt, mined at Kamsar, was used to tint glass, jewelry, and porcelain a deep blue color. There also was a large alum mine at Tarom and at other sites in the Middle East, which was the principal source of this mineral for Europeans throughout the medieval period. Alum was used in the textile industries as a medium to fix dyes in wool and other fabrics.

The conquest of the Byzantine Empire by the Ottoman Turks in the middle of the 15th century disrupted trade in gold, precious gems, and valuable minerals through the Middle East. The hazards of overland trade through western Asia's Islamic states prompted Europeans to send expeditions across the oceans in search of gold, spices, and other valuables. When knowledge of the Saharan caravan routes came to the Portuguese, a new era of exploration and exploitation opened along the western African coast, and the gold deposits of sub-Saharan Africa began moving into the treasuries of European monarchs. The result, eventually, was an important shift in the balance of economic and military power between the Islamic world and Christian Europe.

## Asia and the Pacific

~ Marco Polo: Excerpt from *The Glories of Kinsay*  
*[Hangchow] (ca. 1300)* ~

**TREATING OF THE GREAT YEARLY REVENUE  
 THAT THE GREAT KAAN HATH FROM KINSAY**

Now I will tell you about the great revenue which the Great Kaan draweth every year from the said city of Kinsav and its territory, forming a ninth part of the whole countrv of Manzi.

First there is the salt, which brings in a great revenue. For it produces every year, in round numbers, fourscore tomans of gold; and the toman is worth 70,000 saggio of gold, so that the total value of the fourscore tomans will be five millions and six hundred thousand saggio of gold, each saggio being worth more than a gold florin or ducat; in sooth, a vast sum of money! (This province, you see, adjoins the ocean, on the shores of which are many lagoons or salt marshes, in which the sea-water dries up during the summer time; and thence they extract such a quantity of salt as suffices for the supply of five of the kingdoms of Manzi besides this one.)

Having told you of the revenue from salt, I will now tell you of that which accrues to the Great Kaan from the duties on merchandize and other matters.

You must know that in this city and its dependencies they make great quantities of sugar, as indeed they do in the other eight divisions of this country; so that I believe the whole of the rest of the world together does not produce such a quantity, at least, if that be true which many people have told me; and the sugar alone again produces an enormous revenue. However, I will not repeat the duties on every article separately, but tell

you how they go in the lump. Well, all spicery pays three and a third per cent on the value; and all merchandize likewise pays three and a third per cent. But sea-borne goods from India and other distant countries pay ten per cent. The rice-wine also makes a great return, and coals, of which there is a great quantity; and so do the twelve guilds of craftsmen that I told you of, with their 12,000 stations apiece, for every article they make pays duty. And the silk which is produced in such abundance makes an immense return. But why should I make a long story of it? The silk, you must know, pays ten per cent, and many other articles also pay ten per cent.

And you must know that Messer Marco Polo, who relates all this, was several times sent by the Great Kaan to inspect the amount of his customs and revenue from this ninth part of Manzi, and he found it to be, exclusive of the salt revenue which we have mentioned already, 210 tomans of gold, equivalent to 14,700,000 saggio of gold; one of the most enormous revenues that ever was heard of. And if the sovereign has such a revenue from one ninth part of the country, you may judge what he must have from the whole of it! However, to speak the truth, this part is the greatest and most productive; and because of the great revenue that the Great Kaan derives from it, it is his favourite province, and he takes all the more care to watch it well, and to keep the people contented.

## Europe

~ Extract from "*Accounts of Tin Mining in Cornwall*"  
 from *The Stannary Charter (1198)* ~

**THE STANNARY CHARTER, 1198**

Know that the sheriff of Devon and Cornwall has received by the hand of William de Wrotham, the command of the Lord Archbishop of Canterbury in these words:

Hubert, by the grace of God, Archbishop of Canterbury, Primate of all England, Legate of the Apostolic See, to the sheriff of Devon and Cornwall, greeting. We order you, on behalf of the Lord King, that in place of Geoffrey Fitz-Peter you entrust to William de Wrotham

(continued)

*(continues)*

all the stannaries of the Lord King in your bailiwick and all that belongs to those stannaries. And you shall see to it that he has tin miners with that freedom which they should have, and which they have been accustomed to have, and you will see that he has all those lawful men whom the same William will name for you. You shall see that they expedite this matter, that they bring aid and counsel for the keeping of the king's stamps, and all the products of those stannaries, and see to the disposal of the profit from the same. Forbid all men free admission to your bailiwick lest, without permission of the same William, they carry away any tin either by land or sea. You will also give him much help in expediting the present business of the Lord King, that it may prosper, and that your Lord King may not suffer loss through neglect on your part.

Witness, Stephen of Turnham, at Westminster, on the twentieth day of November. . . .

And we give notice that on the nineteenth day of January in the ninth year of the reign of King Richard, at Exeter in the county of Devon, we inquired upon the oath of . . . wise and prudent men, about the true weights of the tin of Devon, and we inquired about such quantity as was the just and ancient weight of the city of Exeter, by which in ancient times, now and always, it has been customary to weigh the second smelting of tin, and what it always ought to be, and we found that the just and ancient weight of the first smelting formerly, now and always, was eight times the weight of the second smelting, and it ought to be nine times the weight according to the weight of the city of Exeter for this reason, namely, that from any thousand weight weighed by the greater weight thirty denarii are given to the Lord King, according to ancient custom for the ferm of the stannaries of Devon and for the expense of conveyance to market towns, and because the tin at the second smelting was less, and according to their oath it was measured and determined by such measure in our presence in the stannaries and towns of Devon. . . .

All miners and buyers of black tin, and first smelters of tin and merchants of tin of the first smelting have just and ancient customs and liberties established in Devon and Cornwall. Likewise just and ancient weights of the

first and second smelting of tin, determined by the oath of the above-mentioned jurors, and marked with the stamp of the Lord King, shall be kept.

Also all men have the common right of buying tin by just, ancient, and free customs, as they are accustomed to have and ought to have, by the mark from any thousand weight of the second smelting. And in the towns and market towns wherein the chief warden of the stannaries shall have appointed a time for a second smelting, from each thousand weight of which the Lord King ought to have one mark, let the second smelting be weighed by the weight of the city of Exeter, and that weight shall be marked by the stamp of the Lord King. Likewise the established weight of the city of Exeter shall always be kept in the custody of two lawful men in the market towns, and in the custody of the clerk appointed by the Lord King. . . .

And in any town where a second smelting has been decreed let there be two lawful and rich men who shall receive from the merchants the mark of the Lord King, in the presence of the wardens and the clerk of the second smelting and of the stamp for weighing and marking, and both the clerk and the wardens shall not permit the tin to be carried away until the treasurer of the Lord King shall have received the mark of the Lord King and the customary tax on the tin.

And the treasurers of the mark of the Lord King may make statements and chirographs about the money of the Lord King against the wardens and the clerk of the weight and the stamp. And in the chirographs shall be enumerated the day of receiving, and the amount of money received, and the number of thousands and hundreds of pounds of tin received, and the names of the merchants who acquired the tin. Likewise the treasurers of the Lord King by statements and chirographs of this kind shall deliver the money of the Lord King to the chief warden of the stannaries. . . .

No one may presume to have in the market towns any weights with which to weigh tin except they have been previously measured in the presence of the keepers of the weights, and judged by the weight of the Lord King, and marked by the stamp of the mark of the Lord King; The wardens and the clerk of the first smelting, as they love themselves and their own, shall diligently and mindfully make a record of the thousands and hundreds

and pounds which have been weighed and marked by the weight and stamp of the warden throughout the whole year. And let no Christian man or woman, nor any Jew, presume to buy or sell any tin of the first smelting, nor to give or carry away, outside the stannaries or outside the places appointed for weighing and marking the first smelting, until it shall have been weighed and marked in the presence of the wardens and clerks of the weights and stamp of the ferm.

Let no Christian man or woman, nor any Jew, presume to have within or outside the stannaries any of the first smelting beyond a fortnight unless it be weighed and marked by the wardens and clerk of the weight and seal of the ferm. Let no Christian man or woman, nor any Jew, carry tin in any way, by land or sea, beyond Devon or Cornwall, except he first have permission

of the chief warden of the stannaries. Let good and lawful men be appointed in the harbors of Devon and Cornwall to take the oath of all ship-hands and sailors arriving there, that they will not carry away, nor permit to be carried away in their ships, any tin except it be weighed and marked by the royal customs, and except they have the writ of the chief warden of the stannary. The stamp of the ferm shall always be guarded under the seal of the warden and of the clerk except while they are using it at the appointed places. In weighing the tin let the tongue of the scale balance justly between the weight and the tin, so that the scale is not drawn towards the tin, in accordance with the wish of the buyer, on any just scale.

## ► money and coinage

### INTRODUCTION

Throughout the world in early times trade was conducted by barter, so much of one commodity (animal skins, for instance) would be traded for so much of another (bread, for instance). In many places, especially for large transactions of the kind carried out by states or exceptionally wealthy merchants, precious metals (gold, silver, and copper) eventually came to be used by a medium of exchange. Goods were traded for a certain weight of one of the metals in the form of ingots or nuggets (or dust, in the case of gold), and the metals could later be traded for other goods. Once the economy of the eastern Mediterranean revived after the collapse of international trade in the Iron Age (ca. 700 B.C.E.), the kingdoms of Asia Minor began to standardize the trade in precious metals

(which were readily abundant in local streams) by stamping the royal seal into ingots to testify to the purity of the metal. This soon evolved into the practice of making small lumps of metal just large enough to bear the seal, the first coins. The practice quickly spread throughout the Mediterranean world and eventually by way of the established trading networks on the Indian Ocean and through inner Asia to other ancient civilizations (Iran, Ethiopia, India, and China).

A blank coin-shaped lump of metal is called a flan. In medieval mints workmen heated a flan in a fire and then placed it on an anvil with an embedded die bearing the image (type) of one side of the coin. The die with the type of the other side would be placed above it and stuck with a hammer, leaving impressions on both sides of the coin. Dies were steel or iron rods as big around as the coin, with negative images of the coin's types hand-carved on one end.

Coins have two sides, the front, or obverse, usually bearing the portrait of the ruler in whose name the coinage was issued or of some allegorical or mythological figure. (Jesus often appears on Byzantine coins, for example.) For this reason, the obverse is often called the "heads" side. It usually contains a list of the ruler's titles written around the outer edge of the coin. The back of the coin is called the reverse, or "tails," side. The designs on the reverse are more various but typically have a propagandistic message related to the ruler who issued the coinage. The coins of medieval Ethiopian monarchs, for instance, generally bore a Christian cross. Islamic coins were unusual in lacking a portrait, since Islam forbade figurative representations. They generally bore a quotation from the Koran instead.

Coins often are made of gold, silver, or bronze. During times of economic decline, coinage may nearly disappear and be limited to gold issues intended for state use and other large transactions. In times of economic prosperity silver becomes more common, and coinage returns to everyday use. This is illustrated in the fluctuations of economic activity in Europe after the collapse of the Western Roman Empire, where silver disappeared until the restoration of security under Charlemagne. Smaller denominations were issued in bronze or copper. In most times and places the day's wages of an unskilled laborer were one silver coin about the size of a modern American quarter.

Medieval coins are mostly known from examples recovered through archaeological research. The most important source of coins comes from hoards. Given the inadequate or nonexistent banking institutions of the medieval world, many people simply buried large numbers of coins (up to hundreds or thousands). With the constant social dislocations of the era, many of these hoards were never recovered by their owners. For instance, hundreds of thousands of Islamic

coins have been recovered from hoards in Scandinavia. They tell the story of Viking traders who sold their amber and furs to Arab merchants at markets in Kiev Rus and elsewhere on the border between Europe and Asia and then returned home with their profit.

Coinage arrived late to China (in the seventh century). Chinese coins were limited to bronze issues and always stood as equivalents to a fixed amount of gold or silver bullion, held either by the government or by private merchants. Because coins were understood in this way, paper currency, also backed by precious metal reserves, gradually replaced even bronze coins throughout the Middle Ages. This more abstract system of money is more like that developed in the West in the 19th century. Chinese coins were also unusual in being cast bronze (rather than die-struck flans). A square was cut out of the middle so that they could be suspended from a string or put on a counting stick, and they bore the name, rather than the image, of the ruler on the obverse with the date of issue on the reverse.

In the Americas and sub-Saharan Africa commerce was mostly conducted by barter, though in the later medieval period both areas began to use large pieces of cast bronze or copper as currency. In the Americas the bronze took the form of symbolic ax heads (too thin to have been of practical use).

## AFRICA

BY BRADLEY A. SKEEN

As in the rest of the world, trade in Africa was originally conducted by bartering goods directly (for example, so many cattle for so much wheat). However, as trade became greater and more sophisticated, people sought media of exchange and assigned arbitrary values to markers that would facilitate trade, developing a simple kind of money or currency. Coins had been invented in Asia Minor (Turkey) during classical antiquity and were introduced into Egypt and the rest of North Africa in ancient times and slowly to other parts of Africa in the Middle Ages. Because of the unique economic position of Egypt within the Roman and Byzantine empires, coinage there took on a unique form.

Egypt was by far the richest province in the Roman Empire and, after the collapse of the Western Roman Empire in 476, also in the Byzantine Empire (as the East may thereafter be called). Egypt's wealth was due to the extraordinary agricultural productivity of the Nile Valley, which was fertilized and watered every year by the inundation of the Nile flood. Land in Egypt produced roughly 20 kernels of grain for every one seed planted, compared with a worldwide average of seven kernels returned for each seed. Coins were essentially markers for agricultural wealth.

The exceptional wealth of Egypt funded the last challenge to the unity of the Roman Empire in the civil war of Marcus Antonius (82 or 81–30 B.C.E.) against Julius Caesar's adopted son, Octavian (later the emperor Augustus, r. 27 B.C.E.–14 C.E.), in 31 B.C.E.; Cleopatra (r. 69–30 B.C.E.), the queen of Egypt, paid for the war. Therefore, once he occupied Egypt and had added it to the Roman Empire, Octavian decreed that ordinary coins would never again be minted or even circulate in Egypt. In this way he hoped to prevent any future governor of Egypt from using the wealth of the country to fund a rebellion. (The post of governor was also closed to the Roman aristocracy and was entrusted to low-level bureaucrats who could never hope to aspire to the throne.) Indeed, Egypt never became a seat of rebellion, even during later periods of intense civil wars within the empire. This decree continued in force throughout the Roman and Byzantine periods, right down to the Islamic conquest. Taxes were collected directly in kind, mostly as grain.

Trade within Egypt was conducted in a special billon coinage. Billon is a cheap metal consisting mostly of copper, alloyed with a small amount of silver and any other handy metal scraps, such as lead. Often the silver was plated onto the surface of the coin to give it an appearance more like that of the standard silver coinage of the rest of the empire. In Byzantine times—in the reign of Justinian I (r. 527–65) and later—Roman authorities dispensed with billon and even its small amount of silver in favor of a pure bronze coinage. The situation became somewhat more complicated after 296, when the emperor Diocletian (r. 284–305) introduced a small issue of gold coinage into Egypt to allow the conversion of billon coinage into a standard currency that could be used outside Egypt.

The Egyptian billon and bronze coinage was similar to ordinary Roman coinage in its types, that is, the images and designs stamped onto the coins. It usually carried the types of the ruling emperor's bust (surrounded by a legend of his name and titles) on the obverse, or "heads" side, and various nationalistic designs and slogans on the reverse, or "tails" side. The legends were written on the coins in Greek, the official administrative language of the eastern half of the Roman Empire.

Because the billon metal of which the coins were made was worthless compared with pure silver, no one outside Egypt would accept the coins as payment. (Indeed, it was illegal to spend them outside Egypt.) Billon coins were accepted for payment in trade within Egypt largely on the force of the imperial laws requiring people to accept them. In this way the Romans stumbled on a modern principle of economics in which currency has no intrinsic value but is accepted on the basis of the faith and credit of the government that issues it. Elsewhere in the Roman world merchants and government

*Manilla, an open bracelet traded as currency in western Africa; 12th–18th centuries* (National Museum of African Art, Smithsonian Institution, Photograph by Franko Khoury, Gift of Tom Joyce and museum purchase with funds donated by Carl Jennings, 2002-10-35)

officials carrying out large transactions treated coins as mere bullion: The coins were weighed rather than counted. However, this practice was unnecessary in Egypt, since the billon coins were detached from the real value of precious metals and since this form of coinage was never attempted anywhere in the world outside Roman and Byzantine Egypt.

Coinage in the other provinces of the Roman and Byzantine empires in North Africa did not differ significantly from that of the European and Asiatic provinces. The short-lived Vandal Kingdom (430–533) based in Carthage (modern-day Tunisia) issued a coinage closely copying the previous Roman coinage before the kingdom was reconquered by the Byzantine emperor Justinian I.

Coins were minted in Axum from around 200 to 800. The kings of Axum seem to have issued the coinage to further the overseas trade that was the basis of their wealth and power. In the early fourth century (ca. 330) the coinage of King Ezana was the first to display the symbol of the cross after he converted to Christianity (predating the introduction of Christian motifs on Roman coinage). The obverse of his coins showed his portrait (often without legend), while the reverse showed the cross with the motto "May it please the nation," indicating, perhaps, a use of the coinage as a vehicle of propaganda in converting the Axumite population at large. King Mehadevis in the early fifth century added to his coinage the motto of the Roman emperor Constantine (r. 306–37), "In this sign [the cross], conquer!" suggesting a more militant attitude to converting the country to Christianity.

Most Axumite coins were gold; the remainder were bronze, except for a small number of silver issues. They were all similar to the type established by Ezana. Most of

the bronze coins have been found in Ethiopia and most of the silver in southern Arabia, indicating the extent of Axumite trade with this area. The coins were issued to standard weights based on those of the Byzantine Empire, suggesting that Byzantium was Axum's major trading partner, though in fact few Axumite coins have been found within its borders. Axum also followed Byzantine conventions by inscribing the legends on its coins in Greek, the language used on Byzantine coins as well.

At the turn of the fifth century King Ouazebas added a halo to his image on his bronze coins. The halo was plated in gold, using a unique mercury gilding process, unparalleled in the history of world coinage. No doubt the type referred to the sacred nature of the Ethiopian kingship, a conceit modeled on the ideology of the Byzantine emperors.

After the Islamic conquest of areas surrounding Axum in the seventh century, the state began to decline, especially because of the loss of overseas trade, and this decline was reflected in various ways in its coinage. The language used in the legends on the coins was changed from Greek to the native Ethiopic language of Ge'ez. This act was undoubtedly a response to the loss of the Byzantine Empire as an important trading partner and the end of attempts to circulate the coinage outside Ethiopia. The general level of craftsmanship in the manufacture of the coins also markedly declined: The artistry in the portraits and legends became noticeably cruder. The gold coinage became increasingly debased (devalued) through being alloyed with silver. The legends on the coins changed from the triumphal propaganda of Christianity among the early kings to pleas for peace, suggesting civic unrest at the end of the kingdom. Before the end of the seventh century Gersam, probably the last king of Axum to issue coinage, reverted to the older tradition and placed on his coins the legend "He shall conquer through Christ!"—perhaps trying to recall the state's lost glory. By the 10th century it is clear that all use of coinage had ceased in Ethiopia; trade was instead conducted through barter or by using such commodities as salt as a currency.

Most areas of Africa did not use coins but employed other markers of value in their trade. The most common were cowrie shells (from a type of marine mollusk) and glass beads. Today these often seem strange media of exchange because modern peoples do not assign any value to these objects. However, the medieval African cultures that used them did assign them a conventional value that allowed them to be used as currencies. Even gold, as far as its intrinsic worth in industry and other practical uses is concerned, would hardly be more valuable than copper or silver except for its conventional valuation. Of course, the worth of modern paper currency is based entirely on people's faith in it. However, Islamic and European traders

were, from their viewpoints, able to profit handsomely from the use of these items in trade, since they could easily obtain or manufacture them at the cost of only a fraction of their valuation in African markets.

Katanga (now Shaba) in central Africa is one of the richest copper-producing areas in the world. By the 13th century (if not earlier) traders in the area had begun to use copper as a currency. Initially, small copper nuggets were employed, then ingots, and eventually cast pieces of copper (weighing up to 11 pounds) in the form of either a cross or the letter *H*. These traded as currency throughout central Africa up until the 20th century.

In the later Middle Ages, Mogadishu, Mafia, Zanzibar, and Kilwa on the East African coast became centers for Arabic trade with the interior of Africa (although they did not entirely lose their pre-Islamic identities and conversion was mostly limited to the elite classes). As their rulers became more economically sophisticated and while the economy of the area grew, these cities began to mint their own coins, copied from Arab models. More than half of their coinages were bronze; the remainder were silver. All gold coinage in this area was imported from other parts of the Islamic world

Many archaeological sites in Africa show that coins from the Islamic world (and even those from places farther afield, such as China) were traded alongside other local currencies. Even the excavation of the isolated city of Great Zimbabwe in southern central Africa (which grew wealthy exporting gold) has produced glass beads, cowrie shells, and a single coin, minted at Kilwa.

## THE AMERICAS

BY PENNY MORRILL

Scholars are not in agreement concerning the existence of markets or currency in Mesoamerica and the Andean highlands. Some argue that among the Aztec, Maya, and Inca, markets were gatherings primarily for redistribution and reciprocity rather than for transactions that involved barter or currency. Others view these markets as opportunities for a variety of types of exchange. This scenario seems more plausible. In the latter case it is believed that market-trade gatherings took place in Mesoamerica and in the Andean highlands. After the Spaniards arrived in the early 16th century, they wrote of markets but without detailed descriptions of the places where these markets were, how the markets were organized, and how often market days took place or even whether participants were using a barter system or currency or both.

According to reports, Spaniards were awestruck by the marketplace in Tlatelolco, the market area of the Aztec capital Tenochtitlán. It was vast, well regulated, and filled

with a grand variety of products. In markets throughout the Americas fruits, animals, and textiles were probably traded as barter among farmers, merchants, and housewives. However, all evidence suggests that the exchange of goods was controlled and overseen by the elite, resulting in the development of currency.

The famed 16th-century Franciscan ethnographer Fray Bernardino de Sahagún (1499–1590) interviewed members of the Aztec elite soon after the conquest. His descriptions are among the few that survive, and they provide a view of how trade took place between the Aztec emperor and the leaders of other nations. The Aztec merchants made the transactions but as emissaries of the emperor. Sahagún's informants describe how the rulers controlled trade in luxury goods, a practice that spanned centuries among the elite of Teotihuacán and Oaxaca and in the Mayan region. The extravagant burials at Sipán, Chan Chan, and Sican in Peru indicate the vast wealth of the elite among the Moche, the Chimú, and the people of Sican. The other important piece of information provided by the Aztec's descriptions is the high value given certain items, in particular, jade, brilliantly colored feathers, and ocelot pelts. Jade was considered sacred, with associations to water and vegetation. These jade beads had measurable value and were used as currency.

One scholar uses the term *trade in metaphors* to describe 18th-century commerce between North American Indians and Europeans, meaning that the value placed on goods often related to spiritual qualities. While this term was descriptive of a barter system (wampum), it could also characterize one based on currency. During the rise of Classic Period (ca. 150–ca. 650) cities in Mexico, especially Teotihuacán, the Chalchihuites culture of Zacatecas in northern Mexico mined and traded turquoise. The people of Chaco Canyon in New Mexico traded turquoise with the central Mexican groups during the Early Postclassic Period (ca. 900–ca. 1200). Turquoise was a valued commodity for its references to water and vegetation and could have been used, like jade, as currency. However, there is no archaeological or later ethnographic evidence of the use of currency among North American Indians.

The Aztec traded fine textiles for highly desirable products from the tropics. It seems that great quantities of mantles (*tilmatli*) and cotton cloth (*cuachtli*) were exacted in tribute by the Aztec from those whom they had conquered. The acquisition of this kind of wealth provided the ruler with the quality of goods he could trade for feathers and jade. Therefore, cloth was a medium of exchange that had been given a specific value or price. A fine mantle decorated with feathers could be worth 100 canoes, and 40 of these mantles could be traded for a slave who could sing and dance.

In his 1555 *Memoriales* (Memorials) the Franciscan Fray Toribio de Benavente Motolinía describes markets in Tenochtitlán, Texcoco, Tlaxcala, and Tepeaca. He points out that in the different provinces people used various forms of currency. In some areas people used cloth as a measure of value; in others copper ax-money was used. Fray Motolinía describes these specialty axes as made quite thin and in the form of a tau. Where gold was plentiful, Fray Motolinía says that the people used gold dust as their medium of exchange. The most common currency was cacao; using cacao as money was a practice that continued long after the Spanish conquest.

Chocolate was a beverage enjoyed only by the elite. This restriction made the beans highly prized, and they acquired an extrinsic and intangible value. Cacao functioned well in small transactions because of its lesser value compared with copper axes or gold dust. Cacao beans were individually counted, even in large numbers. That cacao was used extensively as currency is corroborated by the fact that there were words in Nahuatl for the larger quantities: a *xiquipilli* was a sack of 8,000 beans, and 3 *xiquipilli* were known as a *carga*. To appreciate the wealth of the Aztec ruler, colonial observers record that at the time of the conquest Montezuma II (r. 1502–20) had 40,000 *cargas* stored in his warehouse. The Aztec ruler was able to achieve this kind of wealth by annually requiring 980 *cargas*, or 2 tons, of cacao beans in tribute from the peoples the Aztec had conquered.

The development of ax-money is perhaps the most remarkable form of exchange in the Americas because of its widespread distribution. Before 300 ax-monies were produced of arsenical bronze in southern Ecuador and northern Peru. After 950 copper-arsenic alloys were being used in these same regions. It is thought that Batán Grande on the north coast of Peru was a primary production center for arsenical bronze, which was then exported to Ecuador in the form of ingots.

The discovery of ax-money in western Mexico reveals the long-distance trade that took place along the Pacific coast between these two regions of the Americas. After 1200 ax-monies of arsenical bronze were produced in western Mexico and Oaxaca, although the copper-alloy axes were the most common in Mesoamerica and the Andes. Interestingly, the form, a rounded T-shape, occurred in Ecuador and Mexico. In both regions metalsmiths created the alloyed metals and poured the molten metal into a mold. To shape and harden the metal, the ax was alternately cold-hammered, annealed (heated), and cold-hammered again until it reached the desired thinness and strength. The Aztec nobles who informed Bernardino de Sahagún illustrated the text with depictions of the production of axes, showing the furnace and molten metal poured into the mold. Sahagún seems to have interviewed a metalsmith, for he records the words of his infor-

mant as follows: “I cast copper. I liquefy copper. I spread it. I alloy it. I solder it. I add tin to it. I harden it.”

The axes were traded as currency or as an indicator of value in South America. In Mexico the ax-monies not only were collected in tribute but also were repositories of the metal itself. It seems that the axes carried powerful symbolism. In one Mayan creation myth the copper ax was thought to hold up the sky. Axes appeared before the Spanish conquest in codices from the eastern Mixteca-Puebla region, where they were held in the hand of the rain god, Tlaloc, and of the god of the dead, Mictlantecuhtli. In one history produced soon after the Spanish conquest the *Relación de Michoacán* (1539–41), the author records that axes were carried in procession as symbols of royal power.

One of the people Sahagún interviewed indicates that gold was the most desirable, or “cherished,” among metals. He speaks of gold to Sahagún: “It excites one; one is provided solace; it provides restitution. . . . It is one’s lot, the property of the lords, the property of the ruler.” Such slender clues are all that remain for historians as they attempt to find evidence of the use of currency among the peoples of the Americas. Taking into account the archaeological record and the early colonial writings of Sahagún and others, it would seem that emblems of value, like jade, feathers, cloth, copper axes, and gold, were hoarded and traded among rulers and the elite. These transactions could be characterized as high-level bartering. Cacao may have been the only true currency, used by the powerful and subservient alike. The best evidence for this conclusion comes from the second letter Hernán Cortés (1485–1547) wrote the Spanish king: “Cacao is a fruit like the almond, which they grind and hold to be of such value that they use it as money throughout the land and with it buy all they need in the markets and other places.” Cortés later paid some of his soldiers with cacao beans.

## ASIA AND THE PACIFIC

BY KENNETH HALL

Cowrie shells imported from the Pacific Ocean region were the earliest form of Chinese money. These shells were strung in units of 10 or 20 and called peng, which were used continuously in various levels of exchange throughout Asia and the Pacific in the medieval era. In the seventh century copper coinage became the marketplace exchange standard and was supplemented by locally minted gold, silver, iron, lead, and pottery coins of varying value. Under China’s Tang rulers (618–907) the cast copper qian became the monetary standard. The qian was a round copper coin with a square hole in the center, weighing one-tenth of a liang or tael (about 1.4 ounces). They were also strung together, which served as a

convenient way to carry and quickly count the coins. Song China’s (960–1279) official rate of exchange was 1 liang of silver to 1,000 copper coins and 1 liang of gold to 10,000 copper coins, although this rate of exchange was subject to a metal’s market value.

Japan’s minted currency between 708 and 958 was modeled after China’s qian, consisting of bronze coins valued at one mon each and equivalent to the qian relative to market value. From 958, when domestic mining ceased owing to internal political conflict, until 1587, when powerful samurai lords began to issue their own gold, silver, and lead coins, the Japanese economy depended on imported Chinese cash mixed with locally minted copper coinage that was the qian equivalent. Korea used minted cast-iron coins patterned after Chinese copper cash from 996, but because these coins were less accepted than Chinese qian coins, the Korean iron coinage was replaced by locally minted copper coins until the early 17th century.

Paper currency developed in 11th-century Song China as a solution to the local shortage of copper for the minting of coinage and as a marketplace convenience in an era of widespread economic prosperity. Paper money issued by the Song government had its roots in “flying cash,” which developed during the Tang Dynasty out of the need to avoid the hazards of robbery during transport and the inconvenience of carrying strings of metal coins in that era’s widespread tea trade and tax collections that required cash payments. Because of their weight, it was difficult for an individual to carry more than three or four strings on their person. The flying-cash system allowed merchants to make monetary payments at the Tang capital and receive certificates of deposit from the government in return, which they could present at any provincial treasury to draw the equivalent sum in coinage. Song Dynasty rulers implemented a “money of convenience” system, which also allowed payments at the imperial capital that could be drawn upon in the provinces.

In addition to these currency reforms enacted by the Song government, in the same period private merchant houses issued paper credits: “deposit shops” stored cash, gold, and silver for a fee and honored checks drawn against these funds by the depositor. Goldsmiths and silversmiths also issued promissory notes that were accepted in marketplace exchanges. Eventually, wealthy urban merchants commonly agreed to print monetary notes denoting equivalent values to strings of cash. This new money used a common kind of paper, designs featuring buildings, trees, men, and other objects, and the notes contained the seal of the shop of issue to create a sense of unity and trust among their users. Interlocking red and black marks denoted authenticity, as a check against counterfeiting. Merchants readily accepted these notes and converted

## CHINESE COINAGE

The Chinese emperor Gaozu (r. 618–26) was the first ruler of the Tang Dynasty and the man who was responsible for introducing the Chinese system of coinage, which was followed to the end of the 19th century. Bronze coins were cast with holes in the middle, which allowed them to be strung together, with 100 of them forming a ch'ien. On occasion, strings would consist of 95 to 98 pieces. Between 700 and 2,000 ch'ien equaled a tael of silver, depending on market conditions and the quality of the silver. The coins of Gaozu and his successors featured four characters, which included the name of the emperor and the year of his reign; later Tang coins sometimes included the location of the Imperial Mint, which was at Layang in Honan Province. Initially it was difficult to ensure complete uniformity of the money in terms of its casting, but this was finally achieved during the early years of the Song Dynasty. The emperor Xiaozong (r. 1162–89) introduced the system in 1180, by which his name was on the inscribed on one side of the coin and the regnal year on the reverse.

When the Mongols captured Peking (modern-day Beijing) in 1213, they and their successors of the Yuan Dynasty, notably Kublai Khan, issued very little new bronze or copper coinage, with most people preferring to conduct transactions with paper money, described by the Venetian traveler Marco Polo. The Ming Dynasty that began in the 14th century returned to the Song custom of issuing coins, with additional characters on the reverse to indicate the place of minting and the coin's value.

them into metallic cash in return for a 3 percent fee for each 1,000 coins exchanged.

In times of perceived financial crisis there were runs on these shops, which were vulnerable to shortfalls. In such times the shops would barricade their doors, causing periodic distrust in this particular financial arrangement. The Song government intervened in 1022, replacing the preexisting systems by standardizing and regulating their realm's monetary system by the issue of government paper currency backed by the public's deposits and cash reserves in a system similar to the U.S. Federal Reserve monetary system.

Because the money quickly wore thin and to prevent counterfeiting, the first Song paper money stayed in circulation three years and then was recalled to be exchanged for

new notes or coins. Song paper currency was initially issued up to a specified value limit on the total money in circulation. At first, when there was mixed use of paper and copper cash currency in business and everyday monetary exchanges, the system worked. In the 12th century, however, when the Song faced exceptional military expenses defending China's northwestern frontiers against barbarian invasions, the Song government issued 10 million unbacked notes, which were worth about half the current strings of cash then in circulation. Owing to subsequent inflation, the Song treasury reduced the value of the paper currency so that 1,000 units of currency had the buying power of between only 940 to 960 units.

In the post-Song era the new Yuan rulers did not issue a common paper currency. Instead, from the late 13th century they instituted "commodity bills" for tea, flour, bamboo, and wine sales and purchases; teahouses, wineshops, bathhouses, and brothels in the larger cities issued handwritten paper, wooden, or bamboo tallies against prepayments of cash or as tabulations of debt. By the late 15th century the reissue of paper currency became a hopeless quagmire under the mismanagement of the Ming bureaucracy. In the end what had been the Song Dynasty's well-intended issue of paper currency in an attempt to maintain Chinese productivity in the face of a copper shortage became a bureaucratic nightmare.

By the 12th century regional Indian currency was a mixture of commodities, including gold and silver, although rice was the frequent standard of reference in marketplace transactions. For example, in 11th-century southern India, one kalanju (about 0.11–0.13 ounces) of gold was consistently quoted as equivalent to 16 kalam of rice; by the next century, as the result of inflation caused by increased availability of rice, 13 kalam of rice equaled only one kasu (roughly half the value of a kalanju of gold). The silver kalanju coin was the equivalent of the gold kalanju in 11th-century transactions, but in the following century it was worth only one-half to one-quarter the value of a gold kalanju coin because of the rulers' devaluation of the precious metal content of silver coins and an increased local preference for gold over silver. By the 13th century gold kasu coins were replaced by copper kasu coinage, valued at roughly 411 copper kasu to one gold kalanju. In addition, a new copper coin was issued, called the fanam, which would be the subsequent market standard in southern India. In contrast, from the 16th century forward the rupee was the market standard in northern India.

Modeled on the round coinage of the Gupta Empire (ca. 320–550) in northern India, which depicted images of Hindu deities and accompanying inscriptions, from the sixth century southern Indian coins included symbols and images but of an imperial rather than religious nature (fish, tiger, bow), the name of the reigning monarch, and the crests of

Gold coin; Tughluq Dynasty, India, 1325-26 (Arthur M. Sackler Gallery, Smithsonian Institution, The Catherine and Ralph Benkaim Collection, S1999.18)

conquered populations acknowledging the monarch's accomplishments, and they were widely circulated throughout his realm, not just in a specific area that had been conquered. These were conspicuous statements of political legitimacy, personalizing the role of the ruler as the source of societal prosperity. Archaeological and inscriptional evidence indicates that monetized exchange, using copper coinage for minor transactions supplemented by silver and gold coinage for more expensive purchases, had become the marketplace norm by roughly 1300 throughout India.

Some historians address the economic consequences of this shift to copper coinage, citing the importance of this lower-denomination monetization as evidence of a growing marketplace economy, the need for smaller denominations for smaller purchases by a growing number of less wealthy people who were taking part in a currency-based and not barter-based economy, and overall societal prosperity. Others assert that the use of copper coinage demonstrates a political evolution: More mature political systems needed lower denomination coinage for the regularization of their collections of taxes. Smaller coinage units made possible the collection of the increasingly minute tax assessments in annual tax payments.

Differentiated coinage also supported the state's demand that taxes be paid in cash rather than in kind, and it allowed the state to transport, bank, and redistribute collected funds rather than having to store grains and other local production, which were subject to the vagaries of rot, mold, fire, flood, and other natural disasters. These monetary revenue

assessments are thought to have been beneficial to society by forcing rural laborers to innovate and produce agricultural surpluses, cash crops (for example, tea and pepper), and handicrafts (for example, cotton) to pay the increased state assessments rather than go into debt. Consequently, there was widespread opportunity to achieve a higher standard of living, which led to increased participation by commoners as recorded donors to Hindu and Buddhist temples that had previously been sustained by wealthy landholders and state elite.

Owing to local participation in the Indian Ocean trade network, use of local- and foreign-minted metallic coinage was widespread in the coastal regions of Southeast Asia from Roman times. In the post-500 medieval era the use of coinage was associated with the development of new states based in the prosperous agricultural plains of Myanmar (Burma), Cambodia, Thailand, and Java. From the sixth to the ninth centuries locally minted high-denomination silver coinage prevailed in donations to Hindu temples and Buddhist shrines. However, from the ninth to the 15th centuries, while silver remained the monetary standard, Chinese copper coinage was widely used in marketplace exchanges in an age when China regularly ran trade deficits and paid for its imports with an outflow of copper cash that was distributed along the international trade routes as far west as Africa. In Vietnam direct Chinese cultural influence resulted in the use of the Chinese monetary system; in other locales, such as Pagan, Myanmar; centers of Thai society; and Angkor, Cambodia, there were a variety of exchange options.

Ma Huan, a Chinese scribe who traveled throughout Southeast Asia in the early 15th century, reports that copper cash was widely used among the various countries he visited, especially in Java and the Strait of Malacca region. However, he reports that copper cash was not widely used in the mainland countries. Inscriptional records support his report. In Pagan from 1100 to 1300 a klyap was the silver standard (1 klyap equaled roughly one-half an ounce of silver; 12 klyap of silver purchased 1.5 units of gold; 3 klyap purchased roughly 53 ounces of copper), although in some transactions rice and cloth were the preferred units of value. By the end of the 12th century silver ingots were weighed and given at each transaction, and silver ingots were used as the currency standard by which to measure value and as the base medium of exchange, although in smaller transactions the value was based on rice and copper khwak. The predominant use of silver depended on local preference and access to the "Great Silver Mines" (Bawdwingyi) located in the northeastern Shan hills. Local land taxes were collected in rice, copper, or cloth; when lands were not in production agriculturalists had to pay their taxes in cloth. In contrast, skilled artisans received payments in

silver when they were involved in substantial transactions, including the building of temples.

Neighboring Angkor also used silver ingots as a medium of exchange and as a measure of value and used cloth and rice as transaction standards as well. Locally silver was valued in tamlin units, and cloth was valued in longer (yau) or shorter (ulah) lengths. Cloth and silver were interchangeable as measures of value and units of account in all exchanges, including land and slave transfers. In small exchanges rice, grain, and Chinese copper coins were the norm. A Chinese visitor around 1300 reported that the value of hemp cloth was the standard used in local marketplace transactions for large transactions and silver and gold in major exchanges, including the purchase of expensive imported cotton and silk textiles. At that time a slave was worth up to 100 pieces of cloth, in contrast to previous times when 30 to 40 pieces was the normal rate of exchange.

## EUROPE

BY ALAN M. STAHL

Although much of the medieval economy was based on barter or payments in agricultural produce, coinage was present in all periods and regions of Europe during the Middle Ages. In the period of transition from the late Roman Empire, coinage in Byzantium continued the Roman traditions, while that of Europe was primarily of gold and was restricted to large transactions. With the dawn of the Carolingian age, around 800, Europe's coinage shifted to the silver penny, and coins became more common. During the late medieval period and early Renaissance, from about 1200 to 1500, European coinage circulated in a variety of metals and denominations and was universal throughout the economy, while Byzantine coinage suffered from the political and economic contraction of the empire. In Renaissance Europe other forms of money, such as credit and letters of exchange, supplemented the supply of coinage.

Like most aspects of life, coinage in the early medieval period represented a partial continuation of that of the late Roman Empire. Byzantium, its successor in the east, maintained the Roman system of coinage in three metals: gold, silver, and bronze. Of these three, only the gold coinage was continued in a significant fashion by most of the European states that succeeded the Roman Empire. Silver and bronze coinages were characteristic of the Ostrogothic and Vandal kingdoms but not of the others.

The principal late Roman denomination of gold coinage was the solidus, which was of pure (24 carat) gold and weighed just under one-sixth of an ounce; the solidus was accompanied by the tremissis, a coin one-third its weight. It

was the tremissis that became the most common gold coin of early medieval Europe. The late Roman silver denomination that carried over into the Middle Ages was the siliqua, which weighed about one-twentieth of an ounce. The late Roman bronze coinage was of a very diverse nature, as was that of the few early medieval kingdoms that issued bronze coinage.

Byzantine coinage is considered as having started with the reforms of the emperor Anastasius (r. 491–518). The most prominent feature of these reforms was the creation of the bronze follis and its divisions and the establishment of a fixed ratio between it and the gold solidus. In succeeding reigns the gold solidus remained unchanged in standard but was joined by coins of similar appearance with lower weights, which may have been intended mainly for trade. Copper coins steadily declined in weight, and silver issues became erratic in standard and quantity. In the wake of the loss of much of its territory as the result of the Muslim conquests of the sixth and seventh centuries, Byzantine minting was eventually restricted to Constantinople and a few minor Italian mints.

The most direct European heirs of the Roman coinage tradition were the Ostrogothic kings of Italy of the sixth century, who issued coins of a wide variety of denominations with an appearance that maintained the traditions of the Roman mints. The Ostrogothic gold solidi and tremisses generally bore the name of the contemporary Byzantine emperor with at most a monogram to indicate the Ostrogothic king responsible for their minting. The kings did, however, put their own names on many of their silver and bronze issues. There was a similar coinage in the Vandal kingdom of North Africa in the same period. Lombard rulers replaced the Ostrogoths in Italy after a brief period of Byzantine reconquest in the sixth century and issued mainly gold coins imitating in an increasingly stylized manner those of the Byzantine emperors.

The Visigothic kings who ruled the Iberian Peninsula in the sixth and seventh centuries issued a coinage mainly of gold tremisses. Like the Ostrogoths, they put the name of the Byzantine emperors on their sixth-century coinage, but at the end of the century they began to put the names of their own kings on their coins. This coinage ended with the Muslim conquests of the early eighth century.

The Merovingian Franks, who ruled what was to become France as well as parts of the Low Countries and Germany, also mainly issued gold tremisses bearing the name of a Byzantine emperor in the sixth century. This changed in the seventh century when most of their coins bore the name of a mint city on one face and that of a minter on the other. In the course of the seventh century the Merovingian tremisses became debased and gradually became silver rather than gold. The coinage of Frisia, on the European side of the English Channel, and Anglo-Saxon England was based on that of the

Merovingian kingdom and likewise changed from gold to silver in the course of the seventh century.

The most significant changes to the Byzantine coinage in the eighth through 12th centuries were in the gold issues, which changed in content and appearance. Originally of 24-carat metal, Byzantine gold coins underwent a series of debasements until by the 11th century they contained no more than 8 carats, or one-third gold and two-thirds silver. In the same period they became broader and went from being flat to concave. Silver coinage continued to be erratic in standard and was in most periods rare. Copper coinage was plentiful, especially the *folles* denomination. Beginning in the late ninth century *folles* ceased to bear the name of the emperor, and the large series of anonymous *folles* of the 10th and 11th centuries had mainly Christian religious images and legends.

In Europe the coinage of the central Middle Ages was almost entirely in silver and of a single denomination, the penny. This coinage grew out of the debased *tremisses* of the seventh century in France and England. In the late eighth century Charlemagne on the continent and Offa in England reformed the coinage to create pennies of consistent standard and appearance. The penny denomination spread to Italy and beyond the limits of the ancient Roman Empire as coinage expanded across the continent. By the 12th century silver pennies were issued by hundreds of minters throughout Europe, and each minter used its own images and standards of weight and fineness. Although pennies were the only coins regularly minted, they were recorded by the terms *shilling* for 12 pennies and *pound* for 240 pennies.

In England the issue of pennies remained in royal control and continued the ancient Roman practice of featuring the image of the ruler on the obverse (the front of the coin).

Silver penny of King Alfred; Britain, ca. 886–99 (© Museum of London)

In France royal issues were only a small part of the coinage after the breakup of the Carolingian Empire in the ninth century; coins of seigneurial rulers and of bishops and abbots predominated. In Germany the coinages of lords below the imperial and royal levels were also of great importance; a special class of German pennies was the 12th-century *bracteates*, which were very broad and thin silver pennies whose artistic images were stamped on one side only. In Italy the coinages of communes (self-governing towns) were the main issues of the central Middle Ages; the most apparent development among their pennies was the frequent debasements that brought some of them to be mostly copper by the 12th century. Pennies of the new states of Scandinavia and eastern Europe were usually royal in origin, while those of the crusader states of the Levant and Greece generally followed the seigneurial model familiar to the French settlers who made up much of their ruling class.

The debasement of the Byzantine precious metal coinage was brought to an end by the reforms of Alexius I Comnenus (r. 1081–1118) at the end of the 11th century. Instead of a system of coins of pure gold, silver, and bronze, the late Byzantine coinage was based on a series of denominations of alloys of the three metals, with the highest-value coin being the *hyperpyron* of about 85 percent gold and 15 percent silver. The coins of all denominations remained concave. No coinage was minted in the names of the Latin rulers who conquered Constantinople in 1204, though some imitations of

earlier Byzantine coins are attributed to them. The rival empires in exile, especially that of Nicaea, continued the earlier Byzantine coinage systems, which they maintained after the recapture of Constantinople in 1261 and for the most part until the end of the empire in 1453.

The expansion of the denominations of European coinage beyond the silver penny began in Italy, which had the closest ties to Byzantine and Islamic traditions of multimetallc coinage and where the penny had reached the lowest level of silver content. Norman kings of Sicily in the 12th century produced large silver and gold coinages that served as the inspiration for new issues of northern Italian minters. At the end of the 12th century Venice produced its *groat*, a large fine silver coin worth 24 of its base pennies; the example was soon followed in Tuscany and in other Italian mints. In 1252 Florence and Genoa each introduced a gold coinage (the *florin* and *genovino*, respectively), which set the standard for the Venetian gold *ducat* introduced three decades later. In the Italian merchant cities the gold coinage was maintained unchanged over time, and market forces were allowed to set its value in terms of the local silver issues.

France and England also introduced large fine silver coins and gold coins in the 13th century, but the royal minters sought to keep all of the denominations in a fixed ratio of values, necessitating frequent changes in the weight of the issues of the English gold noble and the French *ecu*. In France kings of the 14th and 15th centuries sought added minting profits by debasing the silver issues, producing an ever-changing monetary standard. Large silver and gold coinages were widely minted in central Europe in the Late Middle Ages, especially after the discovery of rich silver deposits in Bohemia and gold in Hungary.

A negative balance of trade in the Late Middle Ages appears to have drained much of the gold and silver from Europe through Muslim lands to eastern and southern Asia, creating a European bullion shortage that was not fully alleviated until the arrival of supplies of gold and silver from the New World in the 16th century. In the meantime the development of nonmetallic money in the form of bank credit and letters of exchange compensated to some extent for the shortage of coinage.

## THE ISLAMIC WORLD

BY MUHAMMED HASSAN ALI

In the early days of Islam silver Sassanian coins and gold and copper Byzantine coins were used as local currency. In 697 the caliph Abd al-Malik (r. 685–705) minted the first Muslim coins devoid of figurative representation. He then issued a decree making these coins the only allowable currency in the land. All other coins were to be handed over to the treasury

to be melted down and restruck. Those who did not comply faced the death penalty. Abd al-Malik's coins used quotations from the Koran as the main design element; hence each piece carried a message of the faith. Abd al-Malik's coinage resulted in a new, distinctively Muslim numismatic type that set the Muslim Empire apart from both its non-Muslim neighbors and its pre-Muslim past. As the most frequently seen product of the state and the official affirmation of the faith, its politics, and its economy, coinage played a vital role in asserting Islam's uniqueness and the legitimacy of its rule.

Although changes were to take place in succeeding centuries, the main elements that characterize Muslim coinage were now in place. Generally, the obverse (front) of the coin had a text stating the unity and uniqueness of God. The reverse bore a statement of Muhammad's role as the messenger of God. The mint and date were inscribed on most coins. The standard denominations for traditional Muslim coinage were the *dinar* in gold (based on the Byzantine gold *solidus*—the name derives from the old Roman silver *denarius*), the *dirham* in silver (based on the Sassanian silver *drachm*), and the bronze *fals* (based on the Byzantine bronze *folles*).

The mint was responsible for ensuring the purity and weight of the coins. At the mint obsolete coins (either foreign coins or coins from previous governments) and bullion were examined to determine purity. They were then heated and refined to conform to the established alloy standards. After smelting and casting, the ingots were rolled out and cut into disks. Each disk was then placed on the obverse die, and the reverse die was set on top. Finally, the top side of the die was struck with a mallet, impressing the design clearly on both sides of the coin. A bronze die set could be used several thousand times before it had to be discarded.

The metals used in Muslim coins were gold, silver, and copper. The alloys of gold and silver were generally of high purity. The principal source of gold for the Muslim world was Africa, coming to the heartlands through the trans-Saharan trade route. Apart from a small amount that was cast into ingots in Timbuktu, gold was carried as gold dust and made into *dinars* in the North African mints. The regions that were to benefit most from the expansion of the gold trade were the cities of North Africa and Muslim Spain.

The principal silver mines in the Middle East were in Transoxiana and the Hindu Kush. In about 1000 the Muslim world experienced a silver shortage, and silver coins virtually disappeared from circulation. The Ayyubids (1169–1260) started issuing silver coins, and by the mid-13th century silver was again plentiful. This time silver came from Europe (with the crusaders) and from the silver mines in Anatolia.

Generally, medieval Muslim coins indicated the place and date of their mint, the name of the ruler, his father's

Silver dirham coin; Anatolia, 1242–43 (Los Angeles County Museum of Art, The Madina Collection of Islamic Art, gift of Camilla Chandler Frost, Photograph © 2006 Museum Associates/LACMA (M.2002.1.143))

name, and the name of his heir apparent or envoy. When a new caliph came to power, he had a new coin struck in his name to make the change of rule official. When a revolt took place, the leader of the uprising would establish himself by immediately substituting his own name on newly minted coins. Sovereignty was expressed by the right of *sikka* (the ruler's name on coinage).

In an age before newspapers, radio and television, the mosque and coinage were the primary means of communi-

cation between a ruler and his people, and statements made through both media had the power of law behind them. Allah's protection was invoked for the well-being of the sovereign, whose name was proclaimed by the preacher) during his sermon. In daily life coins bearing the sovereign's name reminded his subjects of his power and responsibility for their economic needs. A change of ruler was made official when the new ruler was first mentioned publicly in the sermon and when coins were issued in his name. Thus, coinage performed the dual function of proclaiming religious affiliation and publishing the current state of political life.

From the earliest times it was clear that a certain unease existed over the power of money. There are repeated warnings in the Koran about money's transient nature: "Woe to every kind of scandal monger and backbiter who piles up wealth and lays it by thinking that his wealth can make him last forever." Added to this concern was an anxiety about the insidious tendency of money to distract the believer from the "true path." The caliph had to reconcile the competing religious demands with more temporal concerns—a tension that was reflected in Islamic attitudes toward money. The system of ethics established under Islam had to be reconciled with the needs of an earthly community and the monetary requirements of the state.

As a consequence of this unease about the power of money, religious scholars attempted to regulate money's influence and to prescribe certain conditions according to which believers could possess money and remain ethical. One of the principal conditions was to give *zakat* (alms tax). Interest was prohibited according to Islamic law, as was the use of promissory notes as a medium of exchange (hence the aversion to paper money).

While the "canonical" exchange rate was 10 silver dirhams to one gold dinar, the going rate was determined in the

## VARIATIONS FROM "STANDARD" COINAGE

While the use of figural imagery was discouraged, there are a number of interesting exceptions in coins that illustrate variations from strict adherence to the letter of religious law. Many of the images were common to contemporary Muslim art and were designed for secular contexts, such as metalwork and ceramics. For instance, during the 12th and 13th centuries in the region covered by northern Syria, northern Iraq, and eastern Anatolia there appeared a fascinating and unique series of bronze coins struck by a number of dynasties of Turkoman origin. These coins contained designs coming from a complex and disparate range of sources. The earliest coins bore Byzantine Christian imagery, such as an enthroned Christ and Saint George and the dragon. From the mid-12th century coins with ancient Hellenistic and Sassanian portrait heads appeared concurrently with others showing various astrological symbols. It may be that the appearance of these coins is evidence of a politically motivated antiquarian interest in the past civilizations of the region. The Seljuks of Anatolia under Kaikhosru II (1237–46) adopted on their silver coins the image of a lion and sun (representing Leo) and used ancient Persian names, features that have been ascribed to a revival of Persian interest at this time.

marketplace by supply and demand. This rate fluctuated from as low as 7 to as high as 14 dirhams to the dinar. Despite religious regulations, Muslims developed a number of financial instruments to facilitate international trade. Concern about the ethics of financial transactions led to the development of the post of the *muhtasib*. The *muhtasib* was a functionary of the state and was appointed by virtue of his high moral integrity and knowledge of Islamic law (sharia). His role was to make sure that in all areas of commerce the sharia was upheld. Thus, he would check weights and measures, and even test for counterfeit coins. He made sure that merchants did not charge interest and dealt severely with hoarding.

Coins were not the only means of payment. Something similar to modern checks was also used. The word *check* derives from the Arabic word *saqq*, which refers to a written vow to honor the payment for merchandise when the trade destination is reached. Medieval Muslims used a “banking system” that allowed a merchant in Canton China to draw from his account in Baghdad. The use of *saqq* was born out of the need to avoid having to transport large sums of coins, owing to the dangers and difficulties of long-distance travel. Traders used *saqq* as bills of exchange, promissory notes, and letters of credit to facilitate commercial activity, making transcontinental trade possible.

On special occasions, such as the end of the Ramadan (the month of fasting), rulers might distribute coins among the people as largesse. In Fatimid Egypt the caliph specially minted gold *kharubas* (tiny gold coins) for distribution to state servants on such occasions. In Iran coinlike tokens were frequently distributed at weddings. Coins were often pierced and sewn onto women’s clothing. The range and amount would be an obvious status symbol for the woman’s family.

In the early 13th century the nature of the coinage changed substantially. The most conspicuous change was the use of pictorial types and noncircular frames and borders (such as the six-pointed star of Aleppo and the square of Damascus). By the 13th century the Muslim lands had been carved into many dynasties, each producing its own coinage. Initially, they acknowledged the nominal leadership of the caliph but later became completely independent. The Fatimids were the first to depart from classical coinage. Caliph al-Muizz (r. 953–75) introduced coinage that carried a clear Shia message. From then on Fatimid coins carried distinctly Shia proclamations. Fatimid coins had three concentric circles and the words “Ali is the Friend of Allah,” a typical Shia proclamation. During the apogee of the Fatimid Caliphate these coins became the most widely used trade coins of the Mediterranean world.

Due to a silver shortage in the East, the Seljuks issued large copper coins. They also borrowed designs from ancient

Greek and Roman, Sassanian, and Byzantine sources. The Seljuks of Asia Minor (12th–13th centuries) had silver coins showing a horseman with a mace over his shoulders or a lion and sun. Farther east the Ghaznavids (10th–12th centuries) struck coins with Sanskrit inscriptions.

The Mongol destruction of Baghdad in 1258 meant the effective end of the Abbasid Caliphate, but in 1261 Baybars (r. 1260–77) installed one of the few surviving Abbasids as caliph in Cairo. The move symbolically established the Mamluks as the leaders of Sunni Islam, though the caliph exercised no real power. On the obverse of their coins was the full name and titles of Baybars over an image of a lion; a figural image included on the coin, and the name of the caliph was not mentioned. The Almohads, who succeeded the Almoravids in the 12th century, introduced new coinage; notably, their dirham was square.

The Nasrids were the last to mint Muslim coins in al-Andalus. These coins were carefully struck and bore long legends containing passages from the Koran and genealogies of the rulers. The Nasrid coins did not show a date, but they are identifiable by the motto “None victorious save God.” Nasrid coins had a square within a circle (a common feature in coins from North Africa and Spain from the 12th through 15th centuries).

In the 13th century the Mongols swept through Asia. The khans of the Golden Horde issued an extensive series of small silver coins. The Ilkhanids of Persia struck large coins. In the 14th century Timur (1336–1405) revived the power of the Mongols and struck silver and copper coins. Timurid coins on the obverse featured the profession of faith with the names of the first four caliphs in the margin.

The Safavids were Shiites, and this adherence facilitated their distinction from the Sunni Ottomans to the west and the Sunni Uzbeks and Mughals to the east. On the obverse Safavid coins featured the profession of the faith followed by the Shia allegiance, “Ali is the Friend of God.” Around the margin were the names of the 12 imams. On the reverse was a characteristic Safavid honorific, proclaiming the king as “the servant of the King of Holiness.”

Original Ottoman coinage consisted of small silver coins. A notable Ottoman innovation was the *tughra*, an elaborate monogram formed of the sultan’s name and titles, which occupied one side of the coin. The Ottoman imperial *tughra* was also on all official documents.

## Europe

~ “The Value of Foreign Coin in England” (1266) ~

Kinds of silver, namely: of Montpellier which is so good that an examined pound failed of full measure by one penny or two at most. The same for the silver of Eregha. The silver of Fugacio from which place the pound failed by four pence at most. The silver of Vrucela and of Flanders whence the pound failed by four pence. Silver of Verona; the pound usually lacked twelve pence. The silver of Valencia failed by eight pence; silver of Pampeluna, the pound lacked two pence. And all these things have been decided on the scales.

Concerning the denarii of Venice: a pound was under weight only by one penny. The same for the money of Genoa. Likewise those of Montpellier of Spain. The legal money of Cologne: a pound lacked six pence. The false money of Cologne: whence a pound failed by three shillings. The Brussels pound is commonly short three shillings. The Marseilles pound lacks six pence. But in

these things the money-changer is watchful so that he may buy a pound of whatever silver he pleases according to what returns a better profit to himself rather than to what will redound to the profit of the king, wherefore the latter receives a fixed payment of ten pounds. Wherefore, whether the money-changer is industrious or not the profit and not the loss will be the king's. But the king will not suffer from lack of diligence. Moreover, from silver vessels the money-changer receives thirteen pence for each pound; and similarly from gold vessels. And if these vessels are intact and exposed for sale, what can be sold for profit over and above the weight ought to be sold. And likewise concerning the profit on gold vessels when a gold cup is sometimes worth more than its weight by twenty shillings, or one mark, or ten shillings.

## Europe

~ Charles the Bald: Excerpt from  
the Edict of Pistes (864) ~

C.8. It is ordered that denarii of all kinds, of proper weight and full content, just as is contained in the capitularies of our predecessors and royal progenitors, in the fourth book, the thirty-second capitulary, should not be rejected until Martinmas . . . nor should good denarii be rejected, but they should not be accepted unless properly and well weighed. . . .

C.10. And from the time of the feast of St. Martin throughout our whole realm, no denarii, except those of our new mintage should be accepted. And from that day any one who produces another denarius for a business transaction should be deprived of it by the count or other official, just as is contained in the second book of capitularies, in the eighteenth chapter.

C.11. And on the denarius of our new money there should be on the one side our name in a circle and the monogram of our name in the center, and on the other side the name of the state and a cross in the center.

C.12. Following the custom of our predecessors, just as it is found in their capitularies, we decree that in no other place in all our kingdom shall money be made except in our palace, and in St. Josse and Rouen, which right in the past belonged to St. Josse, and in Rheims, Sens, Paris, Orleans, Chalon-sur-Saone, Melle, and Narbonne.

C.13. And those who have control of the money, with no desire for favor or gain, should select faithful coiners, as if they were seeking our favor and the grace of God. And the coiners should themselves take oaths that they will perform their office faithfully, as well as they know how. And they should not coin a denarius of mixed metal nor one of light weight, nor should they consent to such a thing. And, without any deception or evil disposition towards those whose silver they accept for purifying, they should cleanse the silver, and without practicing any deception in weighing it, they should change the purified silver into denarii. If

it be reported that any one has acted contrary to his oath, he will be tried by the judgment of God; and if it be proved that he acted contrary to his oath he will lose his hand just as was decreed for false coiners in book four of the capitularies, chapter thirty-three, and as a sacrilegious person and despoiler of the poor he will be subjected to public penance by order of the bishop;—for he committed no greater fraud if he coined a denarius of mixed metal or of light weight

than he would have done by taking the silver of the State, or of the Church, or of the poor, in purging and coining silver with evil intent. In those regions where trials are conducted according to Roman law, he will be tried in accordance with that law.

## ► music and musical instruments

### INTRODUCTION

When studying medieval music and musical instruments, it may be best to begin by understanding that the terms *music* and *musical instruments* had different meanings in different cultures; indeed, in some cultures there were no words for them. Many North American cultures, including the Inuit, had no word for music or the general concept of music. On the other hand, many western and central African cultures, such

as the Yoruba, Igbo, and Hausa, had no word for music but understood the concept of music. Some medieval languages, such as those of the Czechs and some South Americans, had no general term for music but had terms for either vocal or instrumental music. For instance, the Czechs could speak of *hudba*, meaning "instrumental music," but could only infer the idea of vocal music in its relation to *hudba*.

Music theorists have struggled for a definition of music that would apply to all cultures, even those that had no words for music or musical instruments. Two definitions stand out and are similar to each other: "sound organized in time" or "sound and silence organized through time." Both definitions function fairly well as generalizations but can give one trouble if they are applied to specific cultural practices. A key element of the second definition is the addition of "silence," which works well for musical compositions that include pauses that match the beat of the piece. A general observation that seems applicable to all cultures is that whatever the musical form, musicians distinguish between sounds that are acceptable for music and sounds that should be excluded from music. To observe how what to use and what not to use in music vary among cultures, one need only listen to Chinese classical opera and then to a medieval European madrigal. What musicians would accept as musical notes varies enough between the two that they sound almost nothing alike, but both are music. Indeed, what one culture regards as sophisticated music expressing ideas and emotions may sound as though it is only noise to members of another culture.

Music has qualities that are important to people, qualities that resist efforts to stamp them out. Among some Muslim schools of thought, music should be forbidden because of negative passages about it in the Koran and in the Hadiths, accounts of Mohammed's life and sayings. Still, music persisted in being part of popular culture in the Islamic world throughout the medieval era, and in places such as Afghanistan, Turkey, and North Africa, it was regarded as an im-

portant expression of national identity. On the other hand, in China music was often regarded as perhaps the highest of arts. Confusing the issue in China, the Islamic world, and other cultures was the ancient practice of combining stories with music for oral presentation. Stories often were written in verse, and storytellers would use music as a way to help them remember the verses with the appropriate beat. Was that literature or music? That is a question about which people could argue without reaching a conclusion, but for many medieval listeners what they heard was a combination of sounds and ideas designed to stir their emotions. Medieval musical theorists frequently ascribe certain emotions to specific kinds of sounds.

Even the notion that music has patterns that define it has its challenges. In medieval India and China musical forms were usually supposed to duplicate traditional patterns established in ancient times. A composer could rearrange the patterns for a particular tune but was not supposed to innovate. The sounds were meant to be familiar to audiences and to evoke connections to a golden past, yet in medieval Europe singers and musicians typically improvised. A musical composition was learned by listening to it, but it was possible for a musician never to play a piece exactly the same way twice, because he or she might vary the sounds to suit the interests of an individual audience. Even religious chants may have been varied by singers.

In literate societies musical theorists debated what the sounds and forms of music were supposed to mean, but it would be an error to believe that only cultures such as those of the Islamic world and India, where music was sometimes analyzed as mathematical constructs, had enough subtlety for complex combinations of sound. For instance, African drumming had a rich arrangement of sounds that held great meaning for listeners. Different pacing of drumming, different tones, and different pitches could evoke such emotions as fear, anger, or compassion and could even convey words and sentences. Among medieval Americans chants in which certain sounds are repeated, seemingly without linguistic meaning, nonetheless conveyed ideas about humanity's relationship to nature or with the supernatural world and transported audiences into states of consciousness in which they saw extra dimensions to the world or felt profound emotions connecting them to their families, tribes, and cultures.

## AFRICA

BY AMY HACKNEY BLACKWELL

Music was essential to many events in African life. The people of precolonial Africa produced and listened to a wide variety of music. People traveling from North Africa, from the Mid-

dle East, and throughout sub-Saharan Africa picked up musical instruments and techniques on their travels and brought them back to their homes. Arabic musical styles were incorporated into the music of much of eastern and western Africa above the Congo. The people of East Africa picked up styles and instruments from trade with Arabia and India.

Throughout medieval Africa people sang. People sang work songs every day to wile away their time spent doing ordinary tasks. Festivals were occasions for a great deal of music and singing, often performed to accompany dancing. People sang and performed particular songs to mark marriages, births, and deaths. The courts of kings and chiefs might have their own courtly music that would be performed only there. African peoples had special music to accompany dances of love, dances to welcome visitors, war dances, rites of passage, and dances used to communicate with spirits. The music would set the pace of the dance, whether slow and stately or fast and frightening. Skillful musicians could tell dancers how to perform.

Different African groups had their own singing styles. For example, the small people who lived in the rain forests of the Congo sang morning songs known as *yelli*. Many of their songs used several voices that quickly traded off notes of the melody. People in southern Africa often sang a cappella, without instrumental accompaniment. The call-and-response method, in which a lead singer would call out single lines to a song and the rest of the group would either repeat those lines or sing their responses, was a common singing technique in much of Africa.

Improvisation was essential to African music. While people knew basic rhythmic motifs and tunes, they rarely wrote down their pieces in any sort of musical notation and thus performed entirely from memory. They would often play and sing music for hours, spinning variations of tune, rhythm, and lyrics as the mood struck them.

Griots—professional singers, poets, and bards—performed throughout the savanna belt of western Africa. Griots were also known as *jail*, *jeli*, or *guel*. Griots functioned as local historians, memorizing the lineage of the families in their area and reciting these lists when called upon. They also could tell folktales, sing folk songs, recount battles, and spin exciting stories from other historical events. Each village in the region had its own griot, who studied for years to master the historical knowledge and musical techniques. Griots traditionally played a drum called the talking drum. The griot would hold the drum under his arm and squeeze it to raise or lower the pitch while hitting the drum with a stick held in his free hand. The heads of talking drums could be made of various skins, including lizard skin and fish skin.

African people used a number of different instruments. Drums and other percussion instruments were extremely common throughout Africa. People made rattles out of locally available materials, such as gourds and seeds. The *hosho*, for example, was a Zimbabwean rattle made of a gourd with its dried seeds inside it. African musicians used metal bells, tubes that resonated when stamped on, and xylophones. Other common percussion instruments included gongs, clap sticks, and clay pots. The simplest form of percussion instrument was the human body; people clapped their hands, thighs, and chests and stamped their feet to create rhythms. People also wore percussion instruments on their ankles or wrists. For example, they might wear clappers made of shells that would bang together when they stamped their feet during a dance. In Zimbabwe people wore rattles called *magavhu* on their legs.

Africans constructed many different types of drums. Most drums had heads made of stretched membranes from animal skins. The drum frame might be made of wood or another hard material. Drummers often made drums out of hollow tree trunks carved into shape. Drums might be cylindrical, barrel shaped, semicylindrical, or hourglass shaped. Musicians could adjust the tension of their drumheads, changing the pitch and timbre of the instrument. Some drums had one head with an opening on the other end to let out the vibrations. Others had two heads. The *kebero* was a double-headed drum used in Ethiopia and Eritrea. The *ngoma* drum was common in East Africa, where it was made of wood with cow-skin heads on each end. The western African *djembe* drum was a large drum shaped like a goblet; the player sat next to it and beat it with his hands.

Drummers played their instruments by striking them with their hands and with sticks. Different hand strikes and combinations of fingers and sticks could create different sounds. Well-designed drums could produce a number of different pitches, depending on how they were struck. Drummers learned to relax their entire bodies, including their shoulders, and to use their elbows to support their hands. Good drummers moved their hands from the wrists.

Drums were the most important instruments in sub-Saharan Africa. Drum music could be extremely evocative. Many African groups used drums to communicate with the dead or to rouse people to wild dancing at festivals. The drumbeat was the heart of almost all African dances, providing the rhythm of the movements and linking participants with a common beat. Drums could be used to communicate messages from village to village and to inspire warriors to feats of valor. African drummers created extremely complex rhythms. In western Africa ensembles of musicians played a complicated form of rhythmic music that can still be heard

Drum; brass, originally inlaid with silver; Syria or Egypt, 15th century (Los Angeles County Museum of Art, The Madina Collection of Islamic Art, gift of Camilla Chandler Frost, Photograph © 2006 Museum Associates/LACMA [M.2002.1.574])

today in the style known as Ewe drumming. In this style, a master drummer coordinated the playing of several other musicians on drums, rattles, and bells, guiding the players in a kind of rhythmic dialogue. The Beti people of Cameroon played a type of music called *bikutsi*, which involved a great deal of stomping on the ground in 6/8 time accompanied by a harp. A *bikutsi* performance might last all night, starting with poetic recitations of myths accompanied by dancing, after which the women would dance and sing alone and air their daily problems. The *ikinimba* style of music in Rwanda used instruments to accompany songs that recounted tales from Rwandan myth and history. In Uganda groups of drummers would each play *gnoma* drums of different sizes to create a variety of pitches.

The wooden xylophone known as the marimba or *balafon* appeared in western Africa around the 12th century. *Balafons* had keys made of wood dried over a fire affixed with leather straps to a wooden frame. The maker would tune the keys by shaving off bits of wood. A *balafon* could have anywhere from six to 21 keys, tuned to whichever scale was common in the maker's region; African music uses several different scales with different numbers of notes. Under the keys hung gourds that would resonate and amplify the sound of the keys; each gourd had a hole at its bottom end covered with the silk from spiders' egg sacs to create a vibrating membrane. The player would strike the keys with mallets or sticks. The *balafon* could be played as a solo instrument or as part of an ensemble with

several musicians. Musicians from Mozambique played another kind of xylophone called a *mbila*.

The *mbira* was a type of thumb piano invented in Africa. It consisted of a wooden board with several metal or wooden keys affixed to it. It could be attached to a resonator, such as a gourd or a skin-covered frame, to make it louder. Players plucked the keys with their thumbs. Historians believe that this type of instrument was invented in Africa twice in separate locations. The earliest forms of *mbira* were made with wooden or bamboo keys and were constructed in western Africa around 1000 B.C.E. Another version of the instrument with metal keys appeared independently in the Zambezi River region around 1000 C.E. Variations on the *mbira* design spread throughout sub-Saharan Africa. Different peoples used different numbers of keys, different tunings, and different methods of playing. *Mbira* playing was obligatory at many religious ceremonies and festivals. In Zimbabwe, for instance, the *mbira* was believed to have a special capacity to communicate with ancestor spirits.

African musicians also played wind instruments and stringed instruments. People made flutes from animal horns, gourds, reeds, and bamboo. Some flutes had multiple pipes, similar to European panpipes, a style adopted from Islamic cultures. The Ethiopian flute known as the *washint* had four holes for the fingers; it was popular in the highlands. Trumpets could be made of gourds, wood, or metal. Musicians also used stringed instruments, such as lutes, harps, lyres, and zithers, playing them by plucking the strings or drawing bows over them. The Luo people of western Kenya, for example, played an eight-stringed lyre called the *nyatiti*. In Ethiopia noblemen and monks played the *begenä*, a large lyre that was used to accompany prayers. Another Ethiopian lyre, the *krar*, was tuned to a five-note scale and was played by plucking, strumming, or bowing. In Rwanda people played a stringed instrument called the *umuduri*.

## THE AMERICAS

BY LAWRENCE WALDRON

At the advent of the Common Era the musical forms of the Americas had settled into distinct traditions. Music accompanied celebrations of every stage in life and every major phase of the year, and archaic and prequest Indians punctuated their lives with rhythm and melody. As in ancient times, the human voice was the chief of their instruments, and with the accumulation of stories, songs, and myths many Native American groups codified their singing styles to match lyrical themes.

The vocal quality of most American singing before the Spanish conquest can be described as almost universally

monophonic in that second and third vocalists seldom accompanied the singer or chanter in harmony. Rather, secondary singers often joined the melody of the first singer with slight variations or with an occasional switching of octaves. These monophonic melodies could be quite complex, especially among the Indians of the eastern United States, where complex rhythms and even some call-and-response styles may have predated contacts with colonial-era African slaves. Native voices could speak, chant, or sing over music in vocal qualities that could be relaxed and natural, sustained from the diaphragm, nasal, in shrill falsetto, or in imitation of animals and other sounds in nature.

In the prequest period the most common instruments throughout the Americas were wind and percussion instruments. They achieved standard designs and, as with the human voice, came to be used in ways dictated by tradition. Many indigenous traditions are still extant today, giving a good idea of how Native American music in the early second millennium might have sounded. Most of these extant forms, however, have been inflected in some way by European or African musical styles since the colonial period.

The first 1,500 years of the Common Era represents a time of increasingly distinct and deliberately crafted musical forms, and this period of coalescing traditions also saw some greatly diversified music. Such changes stemmed from the migration of groups into new cultural regions or the occasional invention of new instruments.

Instruments such as the flute were a common part of the ritual traditions throughout the Americas. Other instruments were used only regionally. One of these was the *bullroarer*, a blade of wood whirled on a string to create a variety of whirring noises, which was used mostly in the South American Amazon. This represented an American invention shared only by unrelated cultural groups in Australia and a few on other continents. Bone scrapers, notched bones rasped with a stick, were a standard instrument at Mesoamerican funerals and also were played at dances from the Amazon to the Cheyenne territory of the North American Plains. Aztec rattles made out of desiccated gourds or ceramic had relatives all over the American continent and were used in both religious rituals and seasonal festivals. Transverse wooden trumpets, instruments blown from the side instead of the end, could be heard in Brazilian rituals, but trumpets to the west in the Andes were made of clay and blown from the small end like the modern trumpet.

With hundreds of ethnic groups, North America exhibited perhaps the greatest diversity in the application of musical instruments. However, South America bears the distinction for the greatest variety of instruments themselves. In almost all North American rituals and celebrations the

voice was believed to carry the spirit of the orator or singer in addition to articulating clearly the content of prayers. In gatherings around sacred fires only the sound of tobacco offerings crackling in the flames could be heard accompanying the singing or chanting voice.

An early version of the Iroquois Dawn Song, a ritual that marked the commencement of the ritual calendar, is an example of a ceremony that involved only the human voice. However, most American Indian musical expression also involved a steady beat of drumming and other percussive instruments.

Drums and rattles accompanied the voice in celebration in the harvest dances of the Pueblo Indians, the chanting of creation myths in the Canadian woodlands, and the initiation ceremonies of the Pacific Northwest peoples. The drums of the North American Plains, Great Basin, and Eastern Woodlands were most commonly round elk-skin or buckskin drums. Some could be as much as three feet across and were stood on legs and beaten in a circle at large gatherings. Others were held by hand for use either in accompaniment to other instruments or in more solitary shamanic rituals, as in Pueblo and Eastern Woodland contexts. Both varieties were beaten with sticks, creating at once a sharp percussion and a low, resounding tone. Several Iroquois groups played a small

drum partially filled with water whose tone changed as the drummer turned the water inside.

A variety of rattles accompanied Indian drumming throughout the Americas. Rattles often were made of wood in North America and were constructed with a basketry bulb in the Andes. Animal rattles were also made and could be varied in their construction, from the rawhide types of the American Northwest to eastern examples made of entire shells of turtles, gutted and then filled with seeds or pebbles. Shamans of the Northwest Coast employed wooden rattles that were elaborately carved into the shape of certain animal spirit guides or clan emblems. These rattles, carved expertly with stone tools, were fully fledged sculptures in their own right and were often painted and inlaid with abalone or other pearlescent shells.

The Aztec employed a great many percussive instruments. Members of the Eagle and Jaguar warrior classes marked human bones with notches, which they played with a scraper at memorial ceremonies for soldiers lost in battle. The rasped bone was often accompanied by the rhythm of a turtle shell repeatedly struck by the multiple tips of a deer antler. Aztec drums were made either by stretching animal skin over a wooden barrel or by cutting an H-shaped slit into a hollowed log. The latter, called *teponaztli*, were stood up on tripods to avoid deadening the drum's tone. As the loosened tongues between the slits were hit by sticks, they vibrated, producing a deep pulse that resonated briefly. Like Northwest Coast rattles, *teponaztli* were sometimes decoratively carved with zoomorphic symbols, in the Aztec case representing the warrior class.

In dance grounds and sacred caves the Taíno of the Caribbean performed rituals dedicated to their various *zemi*, nature spirits usually represented by wooden and stone sculptures or petroglyphs. During these celebrations Taíno musicians played slit drums, similar to those of the Aztecs, in a steady rhythm while the shamans played wooden rattles or maracas. As with slit drums and other percussion instruments, maracas had developed on the South American mainland some time in the first millennium. They were not always used as percussion instruments, however.

The maraca consisted of a small gourd containing seeds, with a handle attached on one end in the manner of a rattle. Shamans and chanters from the Caribbean Indians to those of the Amazon and Panama would twirl or rotate the instrument to create a whirring sound rather than shaking it like a rattle. After it was encountered in the Caribbean islands by Europeans, the maraca eventually became a popular instrument in Latin American music. However, those later musicians did not play it like an Amerindian idiophone, choosing to shake it back and forth like a percussive rattle instead.

Rattle; slip-painted ceramic, Maya culture, Mexico, 700–1000 (Los Angeles County Museum of Art, Gift of Constance McCormick Fearing, Photograph © 2006 Museum Associates/LACMA [AC1996.146.45])

Carib Indians, some of whom seem not to have used drums, developed virtuosic techniques of playing the maracas whereby the seeds inside the gourd were made to produce unique and individual noises. The instrument could thereby imitate the sound of rain, hurricanes, and other natural phenomena. Carib singing accompanied by the maracas could involve many unusual sounds, including the creation of sympathetic vibrations between vocal chords to produce a style of polyphony similar to that of Mongolian throat singing.

The Aztec employed several idiophones in their religious rituals. Many of these unique devices produced, like the Amazonian maraca, sounds analogous to those found in nature. Mexican “rain sticks” were called *ayon chicuaztli* by the Aztec and were used to imitate the sound of trickling water, falling rain, rivers, and splashing. They were used in the worship of mountain and water deities.

Indian dancers wore a variety of implements to accompany ceremonial music with their own peculiar sounds. Attached to clothing or to the body of a dancer, shells, seeds, and bells could create bursts and waves of sound as the performer moved. Throughout North America Indians danced with these idiophones either in hand or affixed to their wrists, ankles, torso, or head. Northwest Coast peoples wore clamshell clappers, whereas the Anasazi wore ceramic bells. These little bells may have been baked-clay imitations of earlier metal ones acquired from the Maya through trade. In both the Anasazi and Maya cases the bells were made in different sizes and thicknesses to create different musical tones.

By the Common Era most of the wind instruments of the Americas seemed to have been highly developed. Ancient instruments inherited by preconquest Indians included various flutes and whistles made of either wood or bone; trumpets made of conch shells, clay, wood, and cane; and wooden panpipes. Many of these instruments seem to have issued from some original stock of Pacific instrument types that evolved into unique forms adapted to individual ethnic groups and performances. Some ancient instruments fell out of use for a time, only to be reintroduced later.

The ocarina is a ceramic flute that produces a range of haunting, airy tones. While ceramic instruments of this type may have been developed by many different archaic Indians before the Common Era, the later examples all seem to have spread from the South American Andes. By the second millennium of the Common Era variations on the Andean ocarina could be found in territories as far north as Nicaragua and central Mexico.

Several kinds of clay trumpets also seem to have originated in the Andes. These were played by Moche and Inca musicians but may have evolved from smaller Nazca prototypes invented earlier. The Maya and Aztec are known to have

played trumpets of this type as well as wooden ones. One variety of Andean trumpet was tubular, with its bell carved in the shape of an animal or human head. This imagery may have referred either to religious ceremonies involving zoomorphic deities or to warrior-cult imagery of trophy heads taken in battle. Another trumpet featured a spiral tube that added to the resonance of the instrument and strengthened the ceramic shaft. Peruvians also were known to have played long trumpets of silver and copper more in the manner of those found in Europe.

The *quena*, a type of wooden clarinet, was played at Inca weddings, harvests, and various dry-season festivals to the accompaniment of drums and flutes. Panpipes were played at any performances involving festive drumming and were ubiquitous throughout the Inca realm. This instrument had remained virtually unchanged from before the Common Era. Panpipes came in different lengths and sizes to attain different tonal ranges. Musicians often held a set of panpipes in each hand, skillfully switching between them to play different parts of a melody. Many of the Andean wind instruments were adapted to Christian worship and festivals in the colonial period.

The Moche whistling vessels were decidedly an Andean novelty that did not appear elsewhere in the pre-Columbian world. These unique creations produced musical whistles when the water inside them was agitated. Different levels of water produced different musical notes when the pot was shaken.

## ASIA AND THE PACIFIC

BY ILCIA SPREY

In medieval Asia and Southeast Asia music was an integral part of culture in all areas of life. In religion music was used to communicate with and honor the gods. For rulers, the presence of music at their courts brought power and heightened status. For the growing urban-based middle class, patronage of musical theater was a sign of their growing sophistication. In rural villages singing made work go faster and was an essential element of festivals and communal rituals. Music was also a powerful medium of cross-cultural influences that moved throughout the region with traders and holy men.

While musical compositions were taught by a master to his pupil by repetition, lyrics were collected without accompanying notation. Indian musical compositions were based on ragas, or melodies, which were themselves based on centuries-old works of earlier composers, all of which combined with improvisation in an effort to achieve the perceived ideal of musical, cultural, and spiritual harmony. A raga consisted of five or more notes upon which the musician built a melody. In *Bharata Natya Shastra*, a third-century Indian

Bronze zither; China, Ming Dynasty, 1368–1644 (Freer Gallery of Art, Smithsonian Institution, Gift of Charles Lang Freer, F1915-101)

work on musicology, more than 30 instrumental ragas are identified, but ragas also could have vocal accompaniment. In southern India ragas were composed for specific rituals, and in northern India ragas were created to be played at specific times of day (such as dawn, morning, afternoon, or night) to evoke certain desirable feelings or responses (such as awe, fear, joy, or laughter). During the Gupta Empire (ca. 320–ca. 550) Faxian (fl. 399–414), a Chinese monk traveling throughout India, remarked that music played an important role in the daily life of even the lowest social classes while at work and for entertainment.

In China cultivation of musical skills and preservation of lyrics were encouraged by Confucianism, which taught that with their works, composers could produce in their audience the desired balance between the human world and heaven. Confucius (551–479 B.C.E.) is credited with the first collection of written Chinese music, known as *Youlan* (Solitary Orchid). These classical works use the five-tone Chinese scale common thereafter in East Asia, in contrast to the seven-note scale developed in India and adapted in Southeast Asia. The earliest recorded Chinese lyrics are in a collection known as *Shi jing* (Book of Songs), consisting of some 305 poems that were set to music for a variety of purposes, including as ritual hymns, traditional festival songs, and folk songs, some of which are thought to date to the 11th century B.C.E. In the early Imperial Period (553–794) Japanese musicians wrote and signed their compositions, which included original works that were consistent with earlier Japanese musical traditions and adaptations of Chinese music.

The earliest depictions of musicians appear in Gupta-era temple carvings and sculptures. During the Gupta era and thereafter Indian Vedic hymns and mantras—repetitious chanting—were the centerpiece of temple worship. *Dhrupad*, based on Vedic tradition, served as a form of worship by making offerings of pleasing sounds to the Hindu gods. If *dhrupad* were meant to please the gods, then the melodies of the ragas played in a temple setting were meant to create a trancelike

state in worshippers and help them first move toward union with the Hindu deities and later, in the Buddhist faith, reach enlightenment.

Gupta-era India is noted as a cultural golden age in which the emperors made their court the center of artistic life with poetry, drama, and musical performances. The emperor Samudra Gupta (r. ca. 330–ca. 80), noted as both a brilliant general and a politician, took pride in his ability to play the lyre, as seen in the gold coins he ordered struck showing him playing that instrument. Respect for and development of Indian cultural forms continued into the following centuries under other rulers, with the most notable development in religious music being the widespread adoption of the bhakti form of Hinduism in 13th- through 18th-century India. Its intent was to express through poetry, composition, music, dance, and song the believer's passionate devotion to God.

At the end of the first century Hinduism and Buddhism, along with their respective musical traditions, spread into Southeast Asia, and Buddhism spread into China. In Indonesia carvings at the ninth-century central Javanese Buddhist temple of Borobudur and at the Hindu temple complex of Prambanan show musicians accompanying dancers. While China and its neighbors embraced Buddhism, ancestor worship remained prevalent, and in sixth-century China *ya-yüeh*, a form of music meant to please ancestral spirits, was commonplace, as were its Korean and Vietnamese counterparts, *ah-ah* and *hát chá vãn*.

Buddhist monks throughout Asia used the rhythm of the music to learn and recite sacred texts, and during religious festivals singing was accompanied by drums. In Nara (710–94) and Heian (794–1185) Japan the social and political elite patronized Buddhist monasteries. Their complex rituals and chanting, called *shomyo*, consisted of music and recitations of sutras, the teachings of the Buddha, in one of three languages (two of which only the court elite would have known): Sanskrit from ancient India, Chinese, and Japanese. In the Kamakura Period (1185–1333) the idea of salvation was made more ac-

cessible to the masses, and Buddhist chanting was performed exclusively in Japanese. The formalization of traditional Japanese Shintoism in the Nara and Heian eras led to the development of a unique form of sacred ritual music, *kagura*, which combined music and dance as a way of making religion more accessible to the general public. In Japan religious music also played a social role. In the 13th century Zen Buddhist priests of the Fuke sect played music to earn alms for the poor and to gain personal enlightenment. In the Kyūshū region of Japan itinerant blind musicians known as *moso* sometimes dressed as priests and performed music accompanying religious and semireligious texts to purify households.

By the end of the Han Dynasty (202 B.C.E. –220 C.E.) musical performances had become an integral part of Chinese court life, as demonstrated in the establishment of the Imperial Music Bureau (Yueh Fu), which was maintained by subsequent dynasties. It oversaw the collection and supervision of court songs, chants, and military music. Its agents went into the countryside to gather popular ballads and folk music. After examination these songs were either allowed to be performed or rejected if their topic was disruptive to social and political harmony. Over the centuries the music of other peoples entered China along the overland and maritime trade routes, and during the reign of the Tang emperor Xuanzong (r. 712–56) the Pear Garden Academy was established to preserve the nature of Chinese music and to train musicians.

In Indonesia gong orchestras originally played formal music for special community ceremonies and celebrations and at important events at the palace, or *kraton*, of the local rulers. It became a sign of wealth, power, and cultural patronage for the royal court to have a gamelan (percussion orchestra) in residence. Gamelans were composed primarily of a variety of wood, iron, and bronze drums and gongs but also could include flutes. Gamelans always accompanied dramatic and dance presentations, many of which were inspired by or adapted Indian literary and ritual traditions. By the 14th century in Burma, Thailand, Cambodia, and Vietnam gongs of various sizes arranged in circles were played by men at court and as part of royal processions, to announce the approach of the king.

The Japanese royal court developed a unique form of music, called gagaku, meaning “elegant music,” which consisted of formal compositions played by wind, string, and percussion instruments. Gagaku began in India and was later adopted in China as *ya-yüeh*. Japanese monks studying in China learned its techniques and brought it back with them to Japan in 612. Korean and Vietnamese musicians also had some influence on its ultimate form in Japan. Gagaku changed from its initial musical form in the temples, becoming an exclusive part of the Japanese imperial court culture beginning with the Heian

Period. For over a millennium gagaku was played by generations of the same families and by musical guilds. Traditional gagaku pieces became so valued that no new compositions have been created since the 10th century.

In 14th-century Japan, Noh, a form of musical drama, first appeared, combining elements from folk and court entertainments, including gagaku. It had its roots in Chinese musical drama, which was brought from China to Japan by the actor Kanami (1334–85), who enjoyed the patronage of the Ashikaga shogun Yoshimitsu (1358–1408). In Noh the male musicians, or *hayashi*, play the four traditional instruments: the flute (*fue*), the drum (*okawa*), the shoulder drum (*kotsuzumi*), and the stick drum (*taiko*); the *jiutai*, or chorus of six to eight men, sings. Musicians and actors work together to achieve a state of *sen no rikyu*, or transcendence, a concept much valued in Japanese society.

The musical spirit lived in rural villages, where formal and informal music was played year-round. Instruments played by local musicians and the poor were made from readily available and inexpensive natural products, such as bamboo for pipes and flutes. Itinerant and local musicians were vital to festivals and weddings, marked by music, singing, and dancing, which were an important part of popular life and enhanced the local sense of community. In the *minyō*, or Japanese folk music tradition, women played wind instruments that accompanied singing by both males and females at communal gatherings; people sang without instrumental accompaniment while at work. In rural China, and in particular in the southeastern province of Yunnan and in the adjacent hill regions of Southeast Asia, workers also surrounded themselves with music, using it while working to establish a rhythm in the transplanting of rice or while engaged in elaborate courting rituals.

Tibetan folk music included a number of a cappella *lu* songs, noted for their high-pitched notes. The topic of many of these songs dates back more than 1,000 years to the deeds of Gesar, the legendary king of the Ling state. In Korea *pansori* was folk music created by a singer and drummer. While topics were limited to concerns of local interest, each singer personalized the lyrics, often including humor in order to inspire audience participation.

Medieval musical instruments fall into one of four categories: woodwind, percussion, stringed instruments plucked by the musician, and stringed instruments played with a bow. Bowed instruments, such as the Chinese *huqin*, *erhu*, and *jin-gu*, are similar to modern-day fiddles, with either two or four strings that produce various pitches according to their size. The Burmese harp, or *saungi*, which dates back to at least 800, is an example of a stringed plucked instrument. The body, or resonator, of the harp, which is 32 inches long and 6 inches

deep and wide, sits on the lap of the musician. Its neck, which is attached on the player's left-hand side, arches inward and upward approximately 2 feet. It has 13 to 16 strings, which are connected at an angle between the body and the neck of the instrument. The musician's left hand dampens the strings, and the fingers of the right hand pluck them.

A similar instrument is the Japanese *biwa*, a short-necked instrument influenced by the Indian sitar and by the Arabic *ud*, which had crossed into Asia along the Silk Road during the Han era. These instruments came into Japan during the Nara period. The *biwa* has a pear-shaped body, four frets on the neck, and four strings, which are plucked with a plectrum. The sitar is more than 700 years old and is the primary instrument used in ragas, occasionally accompanied by flutes and other reed instruments.

Japanese music was influenced by the introduction of foreign instruments. The *shakuhachi*, a long, thin, wooden flute with six holes, is played by blowing into an opening on its end. It was first used in Buddhist gagaku music. The koto is a little over 6 feet in length and looks like a zither. Aristocratic Japanese found the koto vulgar when it was first introduced in the sixth century, but by the 16th century it was slowly being adopted by the growing middle class. The *Tale of Genji* (ca. 1010) mentions it, and by late medieval times it was associated with geisha culture. The three-stringed *shamisen*, with a long, wooden neck, no frets, and a resonance box, reached Japan by 1500 from the Ryukyu Islands (Okinawa). It is played by plucking and depressing the strings. As with the koto, the upper classes rejected it, but the merchant class adopted it, and it eventually won a place in shogunate court music. The popularity of the *shamisen* led to the decline of the *biwa*.

In early medieval Japan, Indonesia, and India these formal music traditions were studied by the upper classes and embraced by the reigning courts. However, by the early 15th century the middle class had taken up music as a status symbol, coinciding with the decline of the old imperial courts and the rise of the new military regimes; wandering minstrels maintained the earlier folk musical traditions and began to create new popular music that was a blend of the court and folk musical traditions.

Music was central to the culture and life of the Aboriginal peoples of Australia, as its focus was on the physical and supernatural worlds and their connection to both. Singing and music were (and still are) part of their larger oral tradition of transmitting knowledge, and the melodies were unique to each group or band. In their youth they sang of nature in karma songs, in adolescence they learned songs to entertain, and in later life they demonstrated their maturity and wisdom by singing their group's most sacred melodies. The instruments that accompanied much of their singing

generally either used wind to make sound or were percussive, often consisting of two pieces struck together to create sound. They had no stringed instruments.

Perhaps the best-known aboriginal musical instrument is the didgeridoo, which is made from a hollowed-out tree branch and is approximately 5 feet long. Its exterior is polished with bee's wax and decorated with symbols relevant to the particular band or group. The player blows into one end, vibrating his lips over the narrower end and generating a deep resonating tone that flow out through the wider end. Another wind "instrument" is the gum leaf, the leaves from the eucalyptus tree. They place a single thin leaf between their hands and blow against it, producing a whistling sound. There is also the "bull-roarer," a flat piece of wood between 12 and 16 inches in length and about 2 to 3 inches wide, which is swung on a rope in circles, thus creating a whirring sound. Percussion sounds are made by hand clapping, hitting sticks against one another, striking a hollow log with a stick, or using an hourglass-shaped drum whose striking surface is made from either lizard or animal skin stretched and secured to the drum's sides.

The Maori of New Zealand, like the Australian aboriginal peoples, make music a central part of all rites, ceremonies, and rituals and have many similar musical instruments, including the bull-roarer and a drum covered with stretched shark skin, which is struck with the fingers or open hand. The Maori have unique instruments made from the resources of both land and sea, including two kinds of flutes. The *koauau* is a 6-inch-long flute made either of wood or from the larger bones of a bird. Along its length is a hole into which the player blows and three to six finger holes that are left open or covered by the player's fingers to make various tones. Traditionally, the *koauau* was associated with romantic seduction. The other kind of flute, the much shorter *nguru* at only 2 to 6 inches long, has two or three finger holes, is shaped like a whale's tooth, and is blown into at one end. The air travels through the wider middle section of the instrument and then through the other, narrower end.

## EUROPE

BY ALICE CLARK

Music held an important role in medieval culture but in ways sometimes different from those of modern culture. During the Middle Ages much music was transmitted anonymously, if it was written down at all. Most instrumental music was in fact improvised, and little of it made its way to parchment. Those doing the writing tended to view instrumental music as less important than vocal music, especially sacred music, and most instrumentalists were of relatively low social status

and probably could not read or write words, much less music. This instrumental music was for the most part functional: dance music, fanfares, and such. The instruments involved often appear to have Middle Eastern roots, and many eventually developed into the instruments familiar to modern-day audiences: For instance, the *vielle* is a distant ancestor of the violin.

A second major difference from our own time is that most music ordinary people experienced was monophonic, having one melodic line with little or no accompaniment. Such was true of most instrumental music and of the other main musical repertory, chant or plainsong. There were many local forms of worship in early medieval Europe, but they were replaced in the Carolingian Period (751–987) by what is called Gregorian chant. Charlemagne (r. 800–14), as part of his efforts to unify his empire and to reform worship and education, sought chant books and singers from Rome, and this mixture of Roman music with the local Frankish rite was written down and transmitted across Europe, creating a repertory that was actively used until the 1960s (and is still used to some extent).

The need to teach and to learn this new chant apparently led to the development of Western musical notation and practical theory. The earliest form of notation gives only melodic gestures because writing was meant to supplement memory; later developments include staff lines and clefs that allow pitch to be fixed. The modal system and other theoretical tools were used to classify chants and to make it easier to teach them to boys who did not already know the repertory. Chant notation does not give precise information about rhythm, and the free style heard on modern recordings seems to have been the norm for most of the Middle Ages. While all chant is monophonic, it contains a wide variety of musical styles, ranging from the simplest formulas used to recite prayers and readings to elaborate graduals and alleluias, full of melismas (many notes set to a single syllable of text). Chant was performed mostly by choirs of canons, monks, and nuns. These groups were not trained musicians in the modern sense because the goal of singing chant was not to entertain an audience or to display vocal skill but rather to transmit the text and to worship God.

Another important area of monophonic music is that of secular song. The troubadours, poet-composers from what is now the south of France, wrote in the language of Occitan (also known as Provençal). Eleanor of Aquitaine (ca. 1122–1204), granddaughter of a troubadour, probably played a major role in taking the idea of secular song to France when she married Louis VII (r. 1137–80) and then to England when she married Henry II (r. 1154–89); one of her grandsons, Thibaut de Navarre (r. 1234–53), was himself a trou-

vere, a poet-composer in French, as was her son Richard I, “the Lionheart,” king of England (r. 1189–99). Secular song exists in medieval forms of German, Italian, and Spanish; there are even a few songs in English, though French was the court language of England for most of the Middle Ages.

Many medieval songs are concerned with a kind of sacralized love often referred to today as courtly love; its language is very similar to that of the devotion to the Virgin Mary that developed around the same time. These songs are usually strophic, with one melody used for multiple stanzas of text, and mostly syllabic, with one note for each syllable. When melodies are written down at all, they are presented without accompaniment, in a notation like that of chant, so there is normally little or no information about rhythm. This lack of information has led to some controversy, but many scholars and performers today believe that these songs were performed mostly in a free rhythm, shaped by the text. There is less agreement on the question of the use of instruments: Some argue for the use of improvised instrumental accompaniment; others say that at least some types of songs likely were unaccompanied.

*King David playing the psaltery; detail of a manuscript page, Italy, 1473 (The Pierpont Morgan Library)*

The focus on monophony, characteristic of much medieval music, is in keeping with what is found in most of the rest of the world. Medieval Europe, however, also developed polyphony, or music with more than one melodic line. This addition of a vertical aspect to music led to new developments, but monophonic music continued to be important throughout the Middle Ages.

The first documented examples of medieval polyphony come from the Carolingian Period, starting with simple movement in parallel fourths or fifths. More elaborate styles developed, culminating in the music of the Notre Dame school. Notre Dame polyphony, like the styles that preceded it, is based almost exclusively on chant, and much of it functioned within the liturgy. This music came into being at the same time the cathedral of Notre Dame in Paris was being built, in the late 12th and 13th centuries, and the music was copied into manuscripts that circulated as far away as northern Scotland, Rome, and Poland. According to an anonymous writer who apparently was an English monk who had studied in Paris, the *Magnus liber organi* (Big Book of Organum, ca. 1170) was a collection of polyphony for church services throughout the year; it was collected initially by Léonin (a canon of Notre Dame active in the second half of the 12th century) and then improved by Pérotin (d. ca. 1238), a slightly later composer, though it is less certain precisely who he was.

These and other mostly anonymous composers wrote mostly in two styles: *organum purum*, a florid style in which a top line moves in free rhythm over a sustained-note tenor (the lower voice, which bears the preexisting chant), and *discant*, in which both voices move at approximately the same rate with a steady beat. The development of the *discant* style forced Notre Dame musicians to create, for the first time in medieval European music, a way of notating rhythm. Notre Dame polyphony, like all polyphony before the 15th century, was performed by soloists; parts of the liturgy normally sung by the choir continued to be performed in monophonic chant.

*Discant* style led to the development of perhaps the quintessential genre of medieval polyphony: the motet. In a motet a fragment of chant, given a repeated rhythmic pattern, underlies one to three other voices, each with its own text. The result may sound chaotic to modern ears because the texts often cannot be understood at first hearing, but in the motet composers can show great skill, ranging from links to other motets to number symbolism to palindromic rhythms to dense intertextual connections to the Bible, the liturgy, or secular works, such as the *Roman de la rose* (Romance of the Rose, ca. 1230). Many of the subtleties of this genre cannot be heard (though some can), but this very fact emphasizes that

for medieval people, as for the Greeks before them, music not only was about sound but also was also a link to higher, inaudible harmonies. (We still use such words as *harmony*, *consonant*, and *dissonance* in general, nonmusical senses.) These motets often link sacred and secular ideas in ways that may surprise us but that are entirely characteristic of medieval thought, where the separation of those spheres that we find normal did not exist.

In the late Middle Ages, however, polyphonic genres developed that are more accessible to the general listener. Guillaume de Machaut (ca. 1300–77) was instrumental in the 14th-century flowering of polyphonic secular songs in French, based on fixed forms. These songs, unlike the motet, a genre to which Machaut and his contemporaries also made important contributions, are dominated by the top voice, which was composed first and which was usually the only one given a text. (There is some disagreement over whether the untexted lower voices were sung or played on instruments.)

France tends to get the bulk of attention from both scholars and performers of medieval music, in part because more information and musical sources survive from France than from elsewhere in Europe. Nevertheless, other important repertoires exist, including the Italian songs of Francesco Landini (ca. 1325–97) and his contemporaries as well as the English motets of the 14th century. Indeed, the end of the Middle Ages is marked by a kind of synthesis of French, English, and Italian styles, which can be heard in the works of such composers as Guillaume Dufay (ca. 1400–74).

While music was an important part of medieval culture, it did not focus on the kind of personal expression typical of the 19th century onward, nor was most medieval music created or performed by professional musicians as such. Much music served a purpose, especially within worship. With a few exceptions, notably in the troubadour repertory, most music is not assigned to a composer in the surviving sources. There was less sense of ownership of creative works than is generally true today; moreover, it was common to rework music initially created by others. Even where a composer's name is known, little or no information may exist about that person's life or career, or precisely which pieces he (or sometimes she) wrote. Professional instrumentalists and minstrels did exist, but they were often illiterate and of a lower social class, and some had nonmusical responsibilities at court. Most other composers and performers were not full-time musicians: They served the church (like Léonin), or they were government officials (like Machaut). They cared about music but viewed their musical activities as only one part of their lives and not necessarily as something that either defined them or belonged to them in a way that is often true of music and composers today.

## THE ISLAMIC WORLD

BY MUHAMMED HASSAN ALI

Music crosses continents, cultures, and people. Like language, it enables people to communicate. Today, as in the medieval era, one can hear the melodious call to prayer (*adhan*), and Muslims are taught Koranic recitation (*qirat*) with vocal undulation. In the Sufi tradition, chanting (*sama*, literally “listening”) is an important part of *zikr* (remembering). These are all a cappella forms of music, meaning that they are performed without instrumental accompaniment. Regional forms of devotional expression included *qasida* in Iran and *ginnan* in northern India.

With the advent of Islam in the seventh century a new form of music emerged. It elaborated on the pre-Islamic conventions of the Persians, Byzantines, Turks, Berbers, and Moors. The Arabic language was a catalyst, and within a century the new art form was established from central Asia to the Atlantic. While this form dominated what is called art music, folk music retained its indigenous character. The music of the pre-Islamic Arabian Peninsula was principally vocal. Allegedly, singing originated with the caravan song, from which developed a more sophisticated secular song. These traditions entertained desert travelers and pilgrims. Instruments accompanied the singer, and the most popular were the short lute (*ud*), long lute (*tunbur*), flute (*qussaba*), tambourine (*duff*), and drum (*tabl*).

Even at its most complicated, Muslim music was traditional and transmitted orally. A notational system existed but was used only for pedagogical purposes. A large body of medieval writing about music survives in which musical theory was related to various areas of intellectual activity; hence the extreme importance of understanding music as an element of the culture involved. Medieval documents show that Muslim music was mainly an individual, soloist art. Small ensembles were actually groups of soloists in which the principal member, usually the singer, predominated. Musical performance therefore displayed many singing and vocal techniques, such as special vocal color, guttural nasality, vibrato, and other stylistic ornaments. Although the music was based upon strict rules, preexisting melodies, and stylistic requirements, the performer enjoyed great creative freedom. The artist was expected to bring his contribution to a given traditional piece through improvisation, original ornamentation, and his own approach to tempo, rhythmic pattern, and the distribution of the text over the melody. Thus the artist functioned as both performer and composer.

The repertoire in common use comprised a wide variety of forms. One category included unmeasured improvised pieces, such as the *layali*. An equivalent instrumental impro-

King Khusraw Parviz Listens to Barbad the Concealed Musician, illustration from a manuscript of the *Shahnameh* (*Book of Kings*); Iraq, ca. 1300 (Los Angeles County Museum of Art, The Nasli M. Heeramaneck Collection, gift of Joan Palevsky, Photograph © 2006 Museum Associates/LACMA [M.73.5.406])

visation is the *taqsim*, and this in some cases was accompanied by a uniform pulsation (*taqsim ala al-wuhdah*). The metric songs embraced various poetic forms and metric structures, such as *qasida*, *dor*, and *muwashshah*. Artistic recitals were almost always accompanied by one or more instruments to enrich the performance. Traditional forms combined categories to create large compositions similar to a suite, using vocal and instrumental features. The whole was linked by the unity of the mode and a defined rhythmic development.

The music itself was characterized by a subtle organization of melody and rhythm in which the vocal component predominated over the instrumental. This gave the performer a relatively high degree of artistic freedom. The artist generally concentrated on the details forming a work, being less concerned with following a preconceived plan than with allowing the music's structure to emerge empirically from its details. Melodies were organized in terms of modes (*maqam*), which were characteristic melodic patterns with prescribed scales, preferential notes, typical melodic and rhythmic formulas, variety of intonations, and other conventional devices. The performer improvised within the framework of the *maqam*, which is also imbued with ethos

(*tathir*), a specific emotional or philosophical meaning attached to a musical mode. Rhythms were organized into rhythmic modes (*iqaat*), cyclical patterns of strong and weak beats. Classical music was the aristocratic music of the court and the upper class and underwent development and modification in the hands of gifted musicians throughout several centuries. Rhythmic and melodic modes grew in number and complexity, and new vocal and instrumental genres arose. In addition, a body of theoretical works emerged, influencing the music.

The Arab philosopher Al-Kindi (d. ca. 870), in his 13 treatises on music theory, discussed the ethical and cosmological aspects of music as well as its mathematical and acoustic qualities. The Brethren of Purity wrote about the spiritual aspects of music. Scientific studies of music (those that are strictly mathematical in nature and independent of the human ear) were discussed by the philosophers Al-Farabi (ca. 872–ca. 950), Ibn Sina (known in the West as Avicenna, ca. 980–1037), Ibn Zayla (ca. 983–1048), and Safi ad-Din al-Urmawi (d. 1291). These writers dealt with the theory of sound, intervals and their ratios, harmonies and dissonances, genres, systems, modes, rhythms and rhythmic modes, and the theory of composition of musical instruments.

Discourses on music were also part of a broader discussion on topics as diverse as literature, medicine, history, geography, and religion. Al-Isfahani (897–967), in his *Kitab al-aghani* (Book of Songs), collected songs that were popular during his day and added details about their authors, their backgrounds, and technical information that he found interesting. Al-Katib's (d. 765) encyclopedic work on music (which translates as "Perfection of Musical Knowledge") covers a wide range of music theory and practice, including observations and advice, phonetics, breathing, pronunciation, arrangements of musical concerts, audience reactions, plagiarism, classification of voices, treatment of voice, and problems relating to modality.

Music had several roles within Muslim society. In addition to its role in religion, art, and folklore, it played a part in medicine. Muslim physicians believed that music had therapeutic qualities and harnessed these qualities for their patients. In the pre-Islamic Arabian Peninsula the Bedouins used music on the battlefield to rouse the spirit of their soldiers and terrify the enemy. In 1299 the Ottoman Empire instated a permanent military band for the same reasons. The military band also graced ambassadorial receptions during times of peace. In the nomadic cultures of the Arabian Peninsula and North Africa poetry and music had social and historical functions in addition to literary and religious ones.

All music was transmitted orally and gave learning it a particular character of its own. Expertise was difficult to ac-

quire as it needed both inborn talent and long training. Training was always individual, based on a master-pupil relationship that began as purely pedagogical but ended as almost parental. The finished ideal was a student with an extraordinary aptitude for music: creative as a composer, practiced as an instrumentalist and singer, gifted with a phenomenal memory, able

## RUBAB AND REBAB

The rubab was a stringed instrument invented in Afghanistan probably in the 600s and played in India, Iran, and south-central Asia. It was made from mulberry wood and had strings of kid gut. Although its shape varied from region to region, in general the sound box was shaped like a boat with a thick, horseshoe-shaped aft. The neck was about one-third the length of the box, with a pronounced downward hook at its end. Goatskin covered the main body. It had three strings for melody and 12 resonant, or sympathetic, strings. Resonant strings would seldom be touched by the musician; instead, they resonated with three melody strings, giving the instrument a rich tone. There were frets across the neck, and the strings were stretched over these frets and down the hooked end. The musician would pluck the strings.

The rebab developed during the 700s or possibly earlier in Afghanistan and became popular in the Near East, southern Europe, North Africa, and even Southeast Asia. It seems to have traveled wherever Muslims traveled. It may be confused with the rubab, but it was a different instrument. Like the rubab, the rebab was a stringed instrument, and its body was also covered by goat skin. But it was mostly played with a bow drawn across its strings and just occasionally plucked. It had a bowl-like box with the strings stretched over the bottom of the bowl. The neck was three to four times as long as the diameter of the box. It could be played with the base of the rebab set on the ground and the neck pointed upward. A spike at the bottom of the base was common and was set into the ground. Also common were stands, instead of spikes, of two legs that rested on the ground. Among regional variations were the size of the box and the number of strings (ranging from one to three). The strings were stretched over a bridge to pegs that were used for tuning them. Both the rubab and the rebab are still played in folk music and Arab classical music.

to improvise effortlessly, able to write good prose and verse, and having a wide general cultural knowledge.

During the Abbasid Dynasty (749–1258) Muslim music reached its zenith. At that time music in al-Andalus began to attain a character that was distinct from Arabian music. Politically, Abbasid hegemony began its decline in the 11th century, ending in the Mongol invasion in 1258. In al-Andalus the Spanish captured Granada in 1492, effectively ending the golden age. This split the Muslim world into smaller, independent states. Musical life, however, continued. Although it was less fertile and less original than before, it benefited in some ways from decentralization. At the various smaller courts music was encouraged by rulers anxious for prestige and was able to assimilate new local contributions, leading to greater diversity. The Sufi orders, primarily in Turkey and Iran, contributed the most to developing art music at that time. They did this by promoting music for their own religious needs and by creating conditions for a wider musical culture in general.

Many varied musical instruments were in use during the medieval period. One issue with the written sources is that they may use several different names to refer to one instrument, or conversely one name may be used to refer to several different instruments. For example, the term *mizmar* could refer to wind instruments in general, double- or single-reed instruments, or even the psalm.

Idiophones included metal castanets, cymbals attached to a dancer's thumb and middle finger; wooden spoons; copper plates; and oil containers. The Bedouins used a wooden coffee grinder (*mihbaj*), which consisted of a 1-foot-tall base and a 2-foot-long pestle. The *mihbaj* served a dual purpose of being a household item and, in the hands of an artist, a percussion instrument.

Membranophones were circular or rectangular frame drums (*duff*). Some had jingling disks, while others had strings stretched under the skin. One type of vase-shaped drum (*darbukkah* or *tablah*) was made out of earthenware. The *zarb* was placed under the left arm or between the legs and beaten in the middle and near the edge with both hands. Cylindrical drums (*tabl*) with two skins hung from the player's neck and were beaten with two flexible sticks. These were typically used at processions and open-air ceremonies. Kettledrums (*naqqarat*), hemispherical with skin stretched on top, came in pairs (a large one and small one). These were played during pilgrimages. During the late Abbasid and Fatimid (909–1171) dynasties kettledrums were beaten before the daily prayers.

Aerophones included reed instruments, flutes, and horns. Oblique reed flutes (*nay*) did not have a mouthpiece and came in different lengths. They usually had five or six holes on the

upper side and one hole on the bottom side. Notes could be modified by blowing more or less forcefully. Double-reed instruments (*zurna* or *ghayta*) were similar to the oboe. These were made out of wood and widened at the bottom into a bell shape. The reed, enclosed in a small brass mouthpiece, was held entirely inside the player's mouth as the lips pressed on a small metal ring. These instruments had seven or eight finger holes. A great variety of single-reed instruments had two pipes, some with pipes of equal length and others with one pipe longer than the other. Other aerophones were the horn (*buq*) and the long trumpet (*nafir*).

Chordophones were string instruments, most of which were plucked, not bowed. The most prominent string instrument was the short-necked lute with a pear-shaped body, called the *'ud* or the *amir al-tarab* ("the prince of enchantment"). Initially it had four strings and frets, but later versions had five double strings and were fretless. Long-necked lutes were widespread. The *sitar* had four strings and 25 movable frets. It was plucked with the nail of the index finger. The *tar* had a figure-eight body and was covered with skin. It had three double strings and was plucked with a plectrum, or a pick. Others—such as *tambur*, *komuz*, and *dombra*—had two, three, or four strings. The two main types of instruments were essentially trapezoidal boxes (*cithar*). The *qanun* had 24 triple strings, under the end of which were little movable bridges to allow the player to modify the tuning. It was held on the player's knees and was plucked with a plectrum attached to each index finger. The *santur* had 72 strings grouped in fours and supported by 18 movable bridges in two rows of nine, which divided the whole into three registers. It was struck with two sticks. The only bowed instrument was the *rabab*. A simple one was either rectangular or round, covered in skin, and strung with a single string. Another kind was oval or spherical and had two strings. A more complex type (*kamanja*) had three or four strings and a wooden body ending in a peg. All these were played by holding the bow steady and moving the instrument.

## ► natural disasters

---

### INTRODUCTION

Natural disasters can occur when human behavior conflicts with events within their natural environment. Planting crops in drought-prone areas, building on the sides of volcanoes, and settling on floodplains are examples of human beings acting in ways that might bring them into risk of natural catastrophe. Disasters can be made worse by the behavior of people. In the case of droughts, a famine can begin because a war destroys whatever crops manage to resist the drought, because farmers are so heavily taxed that they cannot profit from their farms and therefore do not plant crops, or because a government mismanages resources that could help people, such as through failure to save reserves of good harvests against future bad times, failure to distribute food to those who need it most, or failure to protect the trader and trade routes that could bring food into a drought-stricken area.

Still, people throughout the medieval world also could take action to change their environment so as to control natural events or at least manage natural disasters to minimize destruction and suffering. Among the most basic of these measures was the building of levees such as those built and maintained in China and the Near East. Both regions had rivers that could jump their banks, flooding the countryside and sometimes changing their courses. Levees were designed to hold rivers in place, and in China a government was thought to be negligent if it did not properly maintain its levees. A

way to lessen the intensity of floods was to construct irrigation canals. In China, India, and the Near East people built new channels to send river water to previously unwatered areas, bringing new land under cultivation and simultaneously draining water from the main flow, lessening its intensity.

The ingenuity that medieval people used to manage water is impressive. In the Netherlands people erected huge levees to manage the flows of the ocean. Dams were put up in arid regions such as North Africa and the Near East, and in al-Andalus dams were used to help foster its agricultural revolution of the 800s. The solution of terraced farming on mountainsides to control flooding and retain water during dry periods seems to have been reached in several cultures, such as in Japan, China, Sri Lanka, and Yemen.

Water was a visible quantity, its availability or unavailability known to longtime residents of the land. Other aspects of the natural world were not so easily seen but could reveal themselves with terrifying suddenness, such as volcanic eruptions and earthquakes. The effects of these events in medieval times are hard to gauge, usually because of an absence of documentary evidence from people who lived at the times of the events. Even so, archaeologists and historians as well as scientists from fields such as geology and climatology have tried to identify such events and understand what they meant for people.

For instance, in the early 500s the volcano Krakatau erupted with such violence that it darkened the skies of the world for about three years. The tsunami from the explosion

may have destroyed a Sumatran civilization: The darkened skies brought about crop failures around the world, causing untold deaths. Earthquakes seemed to leap out of the ground at people, wrenching open the earth and causing buildings to fall, yet people could plan to a degree for such events. For example, people in the areas of modern-day Afghanistan and Pakistan developed a building technology that incorporated wood into walls of stone, giving the walls the ability to flex and remain standing during the frequent shocks in the area. In Japan construction techniques with wood allowed entire structures to bend during shocks. Indeed, in both the Near East and Japan deaths caused by collapsing structures most often occurred when the building contractors cut corners and broke building codes, constructing substandard structures.

Violent weather was something else people anticipated when building. The mobile huts of the nomadic peoples of central and northern Asia were admirably suited to parting violent windstorms around themselves, like boats gliding through water. The Inuit of North America similarly made use of building shape to deflect the effects of snowstorms. In Southeast Asia many cultures built longhouses high on stilts to avoid floodwaters yet with sleek roofs of reeds that sent water from storms out and away from the houses.

With storms and all other forms of natural disaster, sometimes there was nothing to be done but stay away. For instance, during medieval times, Indians tended to avoid settling in the coastal plains that flooded frequently because of monsoons. Even the most careful water management could not save the great cities of the Silk Road from a change in climate that dried the land, forcing residents to leave. Further, whether the threat was from forest fires or volcanic explosions, people sometimes had to move into harm's way to find food for foraging or to find fertile land on which to grow food. Sometimes there was no escape, whether because of war or geography, and living with drought or avalanche was just something to be endured.

## AFRICA

BY LEAH A. J. COHEN

The record of natural disasters in medieval Africa is fragmented, and many of the links between climate change, drought, flood, and famine have yet to be uncovered and documented. The sources of information regarding these and other natural disasters are pieced together from a variety of sources, including mythology and tradition, archaeological records, the travel documents of Arabian and European explorers, ice and sediment cores, data about sea temperature, and extensive records of Nile River flows. This information illustrates that disease epidemics and cycles of drought and

flooding were the most commonly documented natural disasters for humans in Africa during this period.

The occurrence of droughts in East Africa near the start of the medieval period has been linked to a massive volcanic event in Java in 535. The gases that billowed into the atmosphere and spread around the globe reduced sunlight all over the world, which resulted in a sudden drop in temperatures and a reduction in rainfall in many regions. The northeastern monsoon that flowed between India and the African coast and traditionally brought seasonal rains to East Africa was much drier than normal. It is estimated that these dry conditions lasted two to three years.

Some historians and scientists have made a link between the extreme dryness that followed the Java eruption and the East African origins of the bubonic plague outbreak that traveled with traders up the Nile and possibly the Red Sea, reaching Egypt by 542. This outbreak then traveled across the Mediterranean and spread throughout Europe. It is thought that a dramatic transition from dry to wet conditions, which happened during the recovery from the dry period, created conditions that allowed the resident East African rodent population, on which plague-carrying fleas lived, to explode faster than their natural predators' populations. This meant that the rodents' habitat expanded quickly and put them in contact with other animals and humans that did not have a natural resistance to the plague. The plague outbreak has been blamed for the comparatively sudden switch from agricultural to pastoral livelihoods in eastern Africa. Historians theorize that the rapidly expanding population of infected rodents congregated in areas where crops were stored, which resulted in the transfer of disease to farmers more quickly than to herders, who had less contact with the rodents. It is also thought that many of the port cities on the eastern coast of Africa were abandoned as a result of this outbreak of plague.

Aside from the two- to three-year dry spell in the sixth century, many other periods of drought occurred from region to region throughout the African continent. Stories of drought are scattered throughout the mythologies of many African cultures from medieval times. For example, the fall of the empire of Ghana in the 12th and 13th centuries has been attributed to several factors, one of which was a severe drought that devastated the land and natural-resource base of the empire. Furthermore, tradition tells of a severe drought in the empire of Mali prior to its peak in the 13th century that ended because the first king of Mali converted to Islam. The exact dates of his rule and the drought are unknown. A number of travel, church, and government records suggest a drought in Ethiopia sometime between 1252 and 1274 that caused widespread famine. An Arabian travel document re-

## CYCLONES OF AFRICA

In the summer in southern Africa there is a threat of violent tropical storms. These are cyclones, also often called hurricanes or typhoons. They develop winds of more than 80 miles per hour and can generate tall ocean swells that become storm surges when they break across a coastline. These surges can be very destructive, overwhelming houses, people, and animals. In addition, the cyclones can sometimes drop enormous amounts of water inland, causing rivers to swell into lakes. Sometimes the cyclones sweep from east to west across the continent to Angola. A challenge to the medieval peoples of southern Africa was to anticipate the worst storms and to prepare for them.

An insidious aspect of the storms was that the worst ones did not occur every year. Often, storms formed in the east, hit Madagascar, and then weakened and often turned toward the sea. Perhaps unaware of the danger, farmers would move into lowlands and could prosper during years when the worst storms did not come. In the lower reaches of the Zambezi River, this seems to have been common, but it took only one severe cyclone to swell Lake Malawi, sending torrents down the Zambezi to cause the lower reaches of the Zambezi to swell outward, its channels unable to carry the load of water, flooding the land.

There were people who began their settlements with a few mud houses covered with thatch, and the settlements developed into cities and towns on the east coast. Although many of their buildings were made of stone, most people still lived in traditional houses even at the height of the cities' prosperity in the 1300s and 1400s. Most of these cities were in low-lying areas, thus making them very vulnerable to storm surges. How did the peoples of the cities avoid being swept away? An answer may come from the work of archaeologists who have uncovered walls made of massive stones. These were likely to have been storm walls, intended to fend off surging water.

corded in the mid-19th century tells the story of the king of France who waged a war of revenge on Tunis in northern Africa during a period of severe drought in Africa sometime between 1250 and 1270.

The frequency with which drought mythologies occupy the African folklore and tradition is not the only evidence supporting the natural occurrence of drought on the continent. Nile flow records and the analysis of sediments in African lakes also indicate dry and wet periods. However, the picture is no less fragmented from these data sources, which often suggest a great variability in drought and flood conditions. The major climatic event of this period was the Medieval Warm Period (approximately 800 through 1300). Climatic conditions in general were dry during this period in Africa, but many factors created variations in local conditions of drought and flood throughout Africa. Records from the Nile and elsewhere for the period from 970 through 1500 indicate fluctuations in the seasonal flood levels. Some scientists have concluded that the Nile flow data indicate lower general flood levels during the Little Ice Age, approximately 1300 through 1850, compared with the Medieval Warm Period.

Some of the most extreme conditions occurred during the Medieval Warm Period, which caused severe famines. There is evidence of a series of great floods in the Nile River valley in the early ninth century. Nile flow records also indicate low average flood levels between the seventh and 15th centuries, with particularly low flood levels in 967, which would certainly have lowered agricultural productivity, creating famine. The variation in local drought conditions is so great that droughts that were detected around Lake Naivasha in Kenya in the late 14th and early 15th centuries (which occurred within the 1270–1850 period of generally increased moisture) were not detected around Lake Hayk in northern Ethiopia, although both regions are in East Africa. Other climatic data suggest a pattern of increased moisture for eastern Africa near the equator and a pattern of drought in central equatorial Africa during the Little Ice Age. Although reasons for the demise of the civilization of Great Zimbabwe (11th through 15th centuries) in southern Africa is unknown, many researchers theorize that it was at least partially due to severe drought.

These climatic changes did not necessarily result in disaster for the human populations living in these areas. Throughout Africa's history humans have adapted to the ever-changing environmental conditions by altering livelihood strategies and migrating. One notable example of adaptation to environmental conditions comes from the Nile Valley. The seasonal flooding of the Nile River, which brought water and fertile soil deposits to the valley, was the lifeline of the population rather than the curse. Disaster followed if the Nile flood levels were lower than anticipated. Low flood levels meant less water for irrigated agriculture and a higher sediment load in the floodwaters, which hindered the flow of water through the irrigation canal systems. Therefore, if the

Nile did not flood, it caused agricultural production to decline and those who depended on it to experience famine.

Throughout the medieval period the natural fluctuation in wet and dry conditions in western Africa dictated human movement. While it meant disaster for some groups, it meant success for others. For example, during a period of increased dryness between 1000 and 1500 the Mali Empire was able to explore farther south, since this change in climate moved the northern boundary of the deadly tsetse fly southward. However, this dry period also forced human groups living in the northern areas bordering the Sahara desert to move south as the desert expanded, creating situations of increased conflict over territories.

At the end of the medieval period areas of northern Africa experienced another massive plague epidemic. This time it was the pneumonic plague, which traveled easily and was especially infectious and deadly. This epidemic was responsible for killing a substantial percentage of the Egyptian population and remained present in the population, periodically causing outbreaks for centuries.

Although earthquake disasters were not a common cause of devastation in Africa in medieval times, earthquakes in 1302 and in 1323 severely damaged the Pharos of Alexandria, an ancient tower on the island of Pharos in Alexandria, Egypt. The tower, which was built sometime in the third century B.C.E., was first a landmark of the Egyptian coast and later a lighthouse.

## THE AMERICAS

BY KEITH JORDAN

Contemporary knowledge of natural disasters in pre-Columbian North America is limited to scientific data drawn from geology and biology. The impact of disasters on indigenous peoples can be inferred by attempting to relate these environmental changes to changes in behavior reflected in archaeological finds. Whether and how much an adverse environmental effect influenced cultural developments such as social collapse or the abandonment of settlements is often difficult to determine.

Humans respond to disasters in many and complex ways, and the dating methods for archaeological materials are often insufficiently precise to allow for clear correlations between natural and cultural change. For example, in the Southwest a drought that occurred around 1090, identified from the study of tree rings, corresponds to the beginnings of the decline of the Anasazi (Ancestral Pueblo) sites of Chaco Canyon, New Mexico. Some construction at Chaco Canyon nonetheless continued into the following century, indicating that the drought was not sufficient to cause the site's loss of

prestige and subsequent abandonment. If the ruling elite at Chaco based its power in part on controlling rituals designed to maintain agricultural abundance, as some archaeologists think, then the drought might have undermined their power by calling into question the effectiveness of their rituals.

Similarly, a massive drought struck the Southwest between 1276 and 1299, according to the tree-ring evidence. This corresponds roughly to the period when the Anasazi abandoned the northern Southwest, migrating south to become the modern-day Pueblo peoples. In fact, the drought itself seems to have spread from north to south. The correlation, however, is not precise. Some areas that were little affected by the drought, like river valleys, were still abandoned by the Anasazi, and the archaeological evidence shows that people started leaving the northern Southwest before the drought. It seems that other, more social factors also influenced the Anasazi migrations.

In the Eastern Woodlands two quarter-century periods of drought around 1200 may have contributed to the decline of the Mississippian city of Cahokia in Illinois. Geological evidence for a late-13th-century earthquake in the Midwest that may have damaged the main platform mound at the site suggests that more than one kind of disaster afflicted the city at this time. The final collapse of Mississippian culture in the Southeast, however, seems to have been the result of a disaster combining natural and human aspects. The expeditions of the Spanish explorer Hernando de Soto (ca. 1500–42) and others into the southern United States during the 16th century introduced smallpox and other European diseases to native peoples with no resistance to these organisms. The resultant plagues decimated the Native North American population and destroyed cultures as complex systems of religious and political beliefs perished along with the chiefs and elders.

Around 590 the volcano known today as Loma Caldera in El Salvador erupted, burying a nearby Mayan village, Cerén, under 16 feet of ash. What was a disaster for the inhabitants of Cerén turned out to be good fortune for archaeologists. The ash preserved the remains of the town, providing a window into the everyday life of Mayan commoners just as the similar burial of Pompeii in 79 C.E. did for the ancient Romans. Unlike the Pompeians, however, the Maya of Cerén seem to have recognized the threat of eruption and evacuated the village before the ash started to fall, leaving no bodies behind.

Core samples taken from lakes in Yucatán provide evidence of a massive drought in the 10th century. Some scholars blame this and other disasters for the collapse of Classic Mayan civilization, but there are problems with any simplistic version of this idea. Classic Mayan cities began to be abandoned a century before the drought. The fall of Mayan kingdoms also occurred in areas south of Yucatán unaffected

*Jade figurine of Tlaloc, the rain god, who could also provoke storms and floods; Mixtec culture, Mexico, ca. 1200–1521 (© The Trustees of the British Museum)*

by the drought, and some Yucatán cities survived most of the other Mayan city-states by 100 years or more, gaining in political power and influence.

One major Mesoamerican series of disasters is known through the oral histories of its overpowering impact, as preserved by the Spanish invaders of the 16th century and their Native American informants. In 1449 a flood struck the Aztec capital of Tenochtitlán, located at the site of modern Mexico City. The city was situated on an island surrounded by freshwater and saltwater lakes. The flood caused brackish water to contaminate the city's freshwater drinking sources and irrigation works, but that was just the beginning of a long period of troubles for the Aztec. The following four years were unusually cold and even included uncharacteristic snowfalls, causing severe crop failures. This in turn led to extreme fam-

ine conditions by 1452. Allegedly, even members of the Aztec nobility were forced to sell their children as slaves to the inhabitants of agriculturally prosperous areas like Mexico's Gulf Coast, and some resorted to cannibalism to survive.

The worst part of the famine corresponded to 1454, the year One Rabbit in the Aztec calendar. After this experience, the name of the year became a sort of shorthand in Aztec speech for starvation. The Aztecs recovered within the 1450s and went on to conquer many of their neighbors. Significantly, one of the first areas they turned to in their expansion was the Gulf Coast. They sought to dominate the region for its grain reserves to prevent such catastrophic food shortages from ever befalling Tenochtitlán again.

A repeated source of natural calamities for centuries on the Peruvian coast is the meteorological phenomenon christened El Niño. This is a warm-water current from the western Pacific that reaches the Peruvian coast every year in December, hence its name in Spanish after the infant Jesus. Usually it lasts for only a few weeks, but every three to seven years it becomes a major event, lasting up to months and creating floods, droughts, and the mass death of the cool-water sea life relied upon as a food source by many coastal peoples.

Some of these El Niño events are truly catastrophic in magnitude. According to geological and archaeological evidence, the Moche civilization of the northern Peruvian coast was beset by multiple disasters in the late sixth century. A drought during the period between 562 and 594 was accompanied by a powerful El Niño event—possibly lasting as long as 18 months—that caused widespread flooding. A Moche capital at the present-day site of Cerro Blanco was inundated. Its buildings, constructed of unbaked mud bricks, were severely damaged. Irrigation systems were swamped and destroyed, and famine and disease epidemics almost certainly followed. Furthermore, there is some evidence that an earthquake struck the Moche area during this calamitous time.

The Moche sought to control these disastrous phenomena in the only way they saw as effective: through religious ritual and human sacrifice. Excavations near the structure known as Huaca de la Luna at Cerro Blanco show that during El Niño events the Moche killed and dismembered human sacrificial victims and threw their bodies from a natural elevation into the flood-borne mud. Cerro Blanco survived the sixth-century disasters and was rebuilt, but it lost much of its influence as another Moche city, Pampa Grande, rose to dominate the region. At the same time, another kingdom in the Peruvian highlands, Huari, seems to have profited from the disasters. Not only did the natural events weaken the Huari state's potential rivals on the coast, but Huari's sophisticated irrigation systems allowed it to survive the drought and probably attracted less-fortunate neighbors.

The final natural disaster to strike medieval Peru was of the same nature as that which destroyed the Mississippian chiefdoms. Smallpox introduced from Spanish colonies in Central America reached Peru in the 1520s. As in North America, the disease ravaged a population that had no prior exposure. Compounded by a civil war between rival claimants to the throne, this plague served as an unintended spearhead of the Spanish Conquest, destabilizing and weakening the Inca Empire just prior to the Spanish invasion of 1532.

## ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

The Asia and the Pacific region is prone to a variety of types of natural disasters. During the Middle Ages seismic activity caused numerous natural disasters in the region. Volcanoes, earthquakes, and tsunamis were all tremendously destructive. The climate patterns of the Indian Ocean and the Asian continent created unpredictable and sometimes violent weather that could swing rapidly between devastating storms and deadly droughts. All natural disasters could create effects that lasted long after the disasters themselves were over. Famine and disease were the natural consequences of these events and often killed far more people than the original victims of the disasters themselves.

The Pacific Rim is very geologically active. The entire Pacific Ocean is surrounded by tectonic plate edges, undersea volcanoes, and deep oceanic trenches. Three-fourths of the world's active volcanoes are located here, and 90 percent of the world's earthquakes occur in this area, which modern scientists sometimes call the Ring of Fire. Another 5 percent of the world's earthquakes occur along a belt running between Sumatra and Java up through the Himalayas.

This large amount of seismic activity meant that earthquakes and volcanic eruptions occurred with some frequency during the medieval period. The islands of Japan and Indonesia were home to some of the world's most active volcanoes, which erupted periodically and caused widespread destruction. Earthquakes and volcanic eruptions that happened out in the ocean could cause tsunamis, massive ocean waves that could reach far inland, destroying everything they washed over and sweeping thousands of humans out to sea. Japan in particular suffered numerous tsunamis in medieval times. On average, a tsunami large enough to be recorded struck Japan every seven years or so.

Many earthquakes and tsunamis struck the Nankai district, southwestern Honshū and Shikoku, threatening the important medieval cities Kyoto and Nara. The first earthquake recorded by Japanese chroniclers resulted from the Hakuko earthquake in the Kii Channel in 684, causing a tsunami to

strike the Kii peninsula. This earthquake marked the start of slightly more frequent earthquakes in the Nankai trough, southeast of the island Honshū near Wakayama Prefecture. Japanese geologists have taken soil samples that show that up until 684 earthquakes generated tsunamis approximately every 200 years, but between 684 and 1946 the frequency increased to every 160 years or so. Many Japanese earthquakes in this region occurred in pairs, with one earthquake happening in the area of the modern city of Ōsaka and another happening in the Wakayama area. Geologists believe that both the Hakuko earthquake of 684 and the Ninna earthquake of 887 followed this pattern. In 1096 the Eicho earthquake seems to have hit the Ōsaka region. The 1099 Kowa earthquake may have been one giant earthquake that covered the whole region.

A major earthquake struck the city of Kamakura on August 23, 1257. In his writings the Buddhist scholar Nichiren Shonin (1222–82) describes the destruction caused by this earthquake. This earthquake apparently was preceded by several months of smaller tremors and was followed by aftershocks that extended into November. Many of Kamakura's buildings and temples were destroyed. In 1258 several violent windstorms and rainstorms battered Kamakura and Kyoto, creating floods that killed thousands. In 1273 a massive earthquake caused a tsunami that killed an estimated 30,000 people. Another massive earthquake struck Kamakura in 1293. Historians estimate that at least 23,000 people died, though the number could have been much higher.

Earthquakes occurred in other locations in Asia and the Pacific. A 13th-century historian from Syria recounts the tale of an earthquake that occurred in 893 in a region he calls "Outer India," killing 180,000 people and destroying an unnamed capital city. Subsequent historians suggest that this earthquake actually occurred in Armenia instead. In 1036 a large earthquake destroyed Shanxi, China, killing about 23,000 people. Approximately 100,000 people died in 1290 when a massive earthquake struck Bo Hai in Hebei, China. The deadliest recorded earthquake in history struck Shaanxi, China, in January 1556, destroying houses built on cliff faces and killing an estimated 830,000.

Mount Fuji, a volcano in central Honshū, Japan, erupted at least 13 times between 781 and 1083. A large eruption in 864 sent lava down the northeastern slope of the mountain. This lava divided a large lake into two lakes, now known as Saiko and Shoujiko. Between 1083 and 1511 Fuji was quiet, with no eruptions recorded. Mount Haruna in Gumma Prefecture in eastern Honshū erupted around 550. Volcanoes in the Daisetsuzan volcanic group of Hokkaido erupted around 1400. Narugo, a volcano in Miyagi Prefecture, erupted in 837. It trembled first for a few days and then erupted, creating a

new hot spring. Nii-shima and Kozushima, both Izu islands, erupted in the ninth century. On-take in Kyūshū erupted in 708 and again for the period 1471–76.

The volcano Krakatau, in the Sunda Strait between Java and Sumatra, erupted violently in 535. The explosion created large waves on the shores of the neighboring islands, sweeping people and their property out to sea. This eruption may have played a role in the formation of the islands Krakatau, Verlaten, and Lang. Some scientists have suggested that this eruption may have caused the world's climate to change. Geologists believe that Gunung Tambora in Indonesia erupted in about 740.

Mauna Loa, a volcano in Hawaii, erupted regularly during the medieval period, though there are no written records of these eruptions. Another Hawaiian volcano, Kilauea, probably erupted regularly and emitted lava during the late medieval period. Scientists believe that Mount Pinatubo in the Philippines had a large eruption during the 15th century. Rangitoto, a volcano in the Auckland volcanic field of New Zealand's North Island, erupted around 1350, destroying some Maori villages.

Areas that were not prone to earthquakes and volcanoes suffered their share of natural disasters as well. Tropical cyclones, often called typhoons in the Pacific and hurricanes in the Atlantic, affected the southeastern coast of Asia, the Bay of Bengal, the northern coast of Australia, and the islands of Indonesia and New Guinea. These storms could bring with them winds of up to 190 miles per hour, often destroying houses, trees, and crops. Typhoons caused large floods, especially in the Bay of Bengal and at the mouths of rivers in Southeast Asia and China.

India's climate and geography presented the risk of numerous types of natural disasters, all of which caused death and could also precipitate famines and disease. Unpredictable rainfall caused many problems in medieval times. Heavy monsoons overfilled rivers, causing massive floods that regularly drowned and displaced thousands of people and washed away crops. Tropical cyclones could produce storm surges and heavy winds that destroyed towns and crops. Cyclones also brought with them hailstorms that could destroy crops. Landslides were common in the foothills of the Himalayas, and avalanches were common in the higher elevations.

India was plagued by periodic droughts that led to large famines. India's farmers depended on regular yearly rains to water their crops. If the rains failed, then the farmers could not grow enough food to feed themselves. The effects of a famine could last for years after the rains returned because people would have consumed their seeds and working animals as food, preventing the people from replanting. In 650 drought caused famine throughout India. Famines in 1022 and 1033

killed thousands of people. Some regions were left completely depopulated after their residents died or left. Historians describe families abandoning their children and people turning to cannibalism to stave off starvation. Between 1148 and 1159 India suffered one long, continuous drought and famine.

The famine of 1344–45 was known as the Great Famine. Even the emperor could not acquire enough food to keep his household fed. The effects of this famine lasted for years. Many thousands of people died. The 12-year Durga Devi famine occurred between 1396 and 1407. Some towns were abandoned by their residents. It was said that some regions did not fully recover for 25 years after the droughts ended, a recovery that was not aided by another brief drought and famine period in 1412–13.

Sandstone stela depicting Matsya, the first incarnation of Vishnu; central India, ninth century. At the time of a great flood Vishnu took the form of a fish (Matsya) to save the primeval human and the sacred Vedas. (© The Trustees of the British Museum)

China was also prone to a wide variety of natural disasters. Rainstorms, dust storms, droughts, landslides, and floods all occurred regularly. The Yellow River regularly overflowed its banks, swamping farms and houses and leading to a regular program of levee building. Historians estimate that the Yellow River has flooded more than 1,000 times since about 1000 B.C.E. Each flood could kill thousands of people through drowning and subsequent famine. The river also changed its course unpredictably. Starting in 1194 it changed its course between its original route and the southern Huai River several times over the late medieval period.

Famines happened regularly throughout the rest of Asia. Some historians estimate that small, localized famines occurred nearly every year in medieval China, as droughts, storms, floods, landslides, excessively cold growing seasons, and other disasters destroyed crops in local areas. Often wars contributed to the bad effects of natural disasters by making it harder for people to grow crops. A large famine between 875 and 884 in China led to a peasant rebellion. China suffered another lengthy famine between 1333 and 1337. Korea was struck with famine in 1445. Japan suffered significant famines in 1231–32 and 1460–61. The Kanshō famine of 1460–61 killed an estimated 2,000 people per month in Kyoto. Many of the people dying in the city were not residents but were rural farmers who had been unable to produce crops and had fled to the city in search of food.

## EUROPE

BY AMY HACKNEY BLACKWELL

Medieval Europeans were vulnerable to many kinds of natural disasters. Bad weather, volcanic eruptions, earthquakes, floods, and drought all killed large numbers of people and destroyed vast amounts of property. Disasters also precipitated famines, the effects of which could last for years.

Floods were a major problem in northwest Europe, where the combination of low terrain and bad storms in the North Sea could create rushing torrents quickly. In 1211 the Tay and Annan rivers in Perth, Scotland, overflowed. The king of Scotland escaped by boat, but most of his court drowned. Hundreds of people died in this flood. In 1219 Saint Lawrence Lake, in present-day Norway, flooded, killing 36,000 people. In January 1362 a major windstorm in the North Atlantic ravaged the land in England, Germany, Denmark, and the Netherlands. It destroyed crops and wiped out entire towns throughout the region. The storm surge swept across the Netherlands, where it killed about 25,000 people and left some land permanently submerged, increasing the size of the Zuider Zee.

The lowlands of the Netherlands were particularly prone to disastrous flooding by the North Sea, especially during fall

and winter storms. The people living in the area built dikes to keep out the water, but during the medieval period the dikes were incomplete and often ineffective. Storm surges from the North Atlantic would force themselves up the many rivers in the region, pushing water over and through the earthen dikes. A number of floods were recorded by monks and priests who kept records at the time. (Many of the floods were named for the saint's day on which they occurred.) On December 26, 838, a large flood struck the northwest part of the Netherlands. In September 1014 a storm surge breached the dikes on the coast and killed thousands of people. Ten years later a November flood hit the Flemish coast and the area around the Yser River. In 1163 several floods hit the Netherlands, closing the mouth of the Oude Rijn with silt. On All Saints' Day (November 1), 1170, a major flood covered the northern Netherlands with seawater; this flood was known as the All Saints' Flood. Saint Nicholas's Flood of 1196 inundated the same region, washing large areas of peat out to sea. Major floods hit the Netherlands in 1212, 1213, and 1219.

In 1228 an enormous flood reportedly killed 100,000 people. Floods in 1248 and 1249 breached the seawalls and dunes in northern Holland. On December 14, 1287, Saint Lucia's Flood breached the seawalls on the Zuider Zee and killed about 50,000 people, mostly in Friesland. On October 8, 1375, Zeeland and Flanders were flooded; this flood formed the Zuudzee.

The two Saint Elizabeth's floods were major disasters in the 1400s. The first Saint Elizabeth's Flood occurred on November 19, 1404, wiping out villages on the banks of the new Zuudzee and engulfing other towns in areas. The coastal islands of Flanders were submerged. After this flood the duke of Burgundy, John the Fearless, created a straight line of dikes to protect the entire coastline of his territory. On November 19, 1421, another massive storm in the North Sea caused flooding that breached the dikes in Holland and Zeeland. The result was that 72 counties ended up submerged, 20 of them permanently, and perhaps 100,000 people died. The cities of Dordrecht and Geertruidenberg were permanently separated by the new bodies of water. The South Holland Kinderdijk, or "child's dike," took its name from a story that came out of the 1421 flood. Supposedly, a man walking the dikes after the flood found a cradle floating in the water with a cat on top of it, trying to keep it level and dry. Inside the cradle lay a baby that the cat had saved.

The many floods and storms that hit the Low Countries ended up reshaping the land. The 1170 All Saints' Flood contributed to the early formation of the Zuider Zee, opening a channel between the freshwater Flevo Lacus that made it accessible to seawater. The floods of 1212 to 1219 enlarged the Zuider Zee and caused another inland sea to form, the Wad-

denzee. The flood of 1277 created a bay known as the Dollart, currently between the Netherlands and Germany at the mouth of the Ems River; about 33 villages ended up under water.

Some of the worst disasters to befall medieval Europeans were caused by changing climate in the 1300s. Scientists believe that pack ice in the Atlantic began to increase around 1250, which led to a gradually cooler climate. By 1300 summers in northern Europe were no longer consistently warm, and the cool growing seasons led to many isolated instances of famine. The increase in bad weather that began around this time brought with it repeated severe storms in the North Atlantic and North Sea. The most severe cold of the Little Ice Age did not appear until the 1600s, after the end of the medieval period, but by the 1400s the climate in Greenland had become cold enough to make it impossible to survive by raising livestock and hunting, causing the European colonies there to die out.

Between 1315 and 1322 all of Europe suffered a major famine that killed millions of people. This famine became known as the Great Famine. During the spring of 1315, unseasonably cool weather and incessant rain ruined crops across the continent. Some farmers could not grow plants at all. Those who did could not dry their grain or cure their hay. Salt producers could not evaporate seawater to make dry salt. Food prices rose, and the poor began to starve. Travel became difficult if not impossible as roads turned to deep mud. The cool weather and rain continued during the spring of 1316, which led people to slaughter most of their livestock, including working animals needed to pull plows. Farmers ate their seed wheat instead of saving it to plant. The rains held steady through the spring of 1317. By this time many people had fallen ill with the diseases that accompany continuing damp, cold conditions, and the supplies needed to start the agricultural economy back were almost completely gone. It took Europe's people until about 1325 to restore the economy to normal.

Famine was a regular consequence of natural disasters, because any kind of disaster disrupted peoples' ability to produce and store food. Natural events combined with human unrest could compound famines. Droughts were a major cause of famine; low or nonexistent rainfall made it impossible for farmers to grow crops. The weather and the natural world were usually unreliable, so famines were unfortunately regular. Local famines occurred almost yearly in all of Europe. In 592 and 605 England experienced droughts that led to crop failures and famines. Spain suffered a famine in the 750s and Ireland experienced a famine in 772. A famine struck the Frankish Empire in 809. England experienced famines in 1005 and 1066. Another drought struck England in the years from 1135 to 1137, causing thousands of people

to starve. Famines occurred in England in 1235, 1294, and 1390; in Portugal in 1255 and 1333; in Spain in 1333; and in Germany in 1258.

Although Europe's land was not as geologically active as that of the Asian and Pacific regions, Europe had its share of earthquakes and volcanic eruptions. Most of these occurred in the area of the Mediterranean, though Iceland was also prone to volcanic activity. For example, one of the largest medieval volcanic eruptions was that of Iceland's Eldgja volcano in 934.

Several active volcanoes in southern Italy erupted during the medieval period. Although the most famous eruption of Mount Vesuvius was the one of 79 C.E., which engulfed Pompeii, the volcano was quite active throughout the medieval period. The eruption of 472 shot ashes so high that they landed in Constantinople. An eruption in 512 disrupted local commerce to the point that King Theodoric temporarily exempted residents from taxes. Vesuvius erupted again in 787, 968, 991, 999, 1007, 1036, 1198, and 1302. After this period of activity, the volcano went quiet for 300 years. People moved back onto the slopes, where they built houses and grew crops, even planting some inside the crater. This period of complacency lasted through the end of the medieval period and was not disturbed until the major eruption of 1631.

Mount Etna in western Sicily erupted several times in the ancient period, starting around 1226 B.C.E. Its best-known eruption was that of 386 B.C.E., which thwarted the Carthaginians who were attacking Syracuse. It was quiescent, however, for most of the early medieval period. Its first eruption since ancient times occurred in 1169. This eruption destroyed 50 towns and killed 15,000 people. Other volcanoes were active in the Mediterranean region. Stromboli, in the Lipari Islands north of Sicily, has exploded and shed lava almost continuously since 1 C.E., placing villages on the island at regular risk of damage. Stromboli's neighbor Vulcano was also consistently active and thus had few inhabitants.

The largest earthquake to hit medieval Europe was the Basel earthquake of October 18, 1356. Modern scientists have estimated that it was 6.2 on the Richter scale. This earthquake's epicenter was in the upper Rhine valley of Germany, but the greatest effects were felt in Basel, Switzerland, which was destroyed by fires caused by a strong aftershock. About 300 people in Basel died. The earthquake's destruction extended into Germany and France. A number of the castles in the area suffered damage.

Several other notable earthquakes occurred during the medieval period. In December 557 a large earthquake shook Constantinople. Much of the city was destroyed. The church of Hagia Sophia, then under construction, suffered a crack in its dome, which resulted in its collapse on May 7 the follow-

ing year. Another earthquake damaged Constantinople in 936. In Greece the earthquake that struck Corinth in 856 reportedly killed 45,000 people. Some 15,000 people died in an earthquake that struck Sicily in 1170. An earthquake shook England in 1318. At the end of the medieval period 35,000 people died in Naples in the earthquake of 1456.

## THE ISLAMIC WORLD

BY KIRK H. BEETZ

Wind, sand, sun, earth, and water were elements of disaster for the medieval Islamic world. Much of the story of natural disasters in the Islamic world consists of the responses of people to events that were sometimes out of their control and sometimes partly of their own making. The most devastating long-term disasters were probably to be found in Arabia, the Sahara, and central Asia, where climatic change that had begun thousands of years earlier slowly dried up water resources and often mummified once-thriving cities. Short-term disasters were chronic, including earthquakes, floods, droughts, and crop failures.

Islam arose in a land of varied geography. The Hejaz along the Red Sea coast was rough, hilly terrain marked mostly by small towns and villages that were part of the trade routes between the Mediterranean world, East Africa, and southern Asia. The southwest of Arabia was Yemen, the southeast was Oman. Oman had a range of mountains along its eastern end against which winds pressed clouds that dropped rain. At the outset of the medieval era Oman had forests as well as lands that were already desert. From the 500s to the 1000s those forests were continuously logged to provide fuel not only for homes but also for smelting the copper ore that brought medieval Oman much of its wealth. As the forests fell, the land that they had anchored dried and became part of the desert. Archaeologists are still trying to sort out how the peoples of Oman responded, but at present evidence indicates that they abandoned much of their land, only to begin repopulating it in the 1100s.

On the other hand, Yemen had mountains on its western and southern coasts that extended deep into its interior. There, drought and floods were the most common natural disasters. Winds from the Arabian Sea carried clouds into the mountains, where they would sometimes release torrential downpours that cascaded down the mountainsides, flooding the settlements at the foot of the mountains. The people of Yemen developed adaptations that were unusual for the Arabian Peninsula. They built tall apartment houses in the foothills and the flatlands close to the mountains, seemingly where they would be most vulnerable to flooding but also where they were likeliest to retrieve whatever water fell during the land's fre-

quent droughts. They built dams that their governments made sure were maintained, preventing much water from gushing through gullies and valleys into the sea. Further, they built terraces on the mountainsides that curved with their contours and looked like giant steps above their settlements. These terraces prevented flooding by catching water, with the upper terraces allowing water to flow into lower ones, each absorbing enough water in its soil to prevent the people at the bottom of the terraced steps from being inundated.

During droughts, oases in Arabia could dry up, forcing people to move to the coastal towns or perish. A severe drought in 639 placed even the coastal towns in jeopardy because their crops failed. This occurred during the caliphate of Umar I (r. 634–44), who demonstrated one of the early benefits of the conquest of the Byzantine territories. He organized relief caravans to bring food from the newly conquered lands of Syria and Iraq to aid the towns of Arabia. For the long term he and his successors cleared Amnis Trajanus, an ancient canal that connected the Nile to the Red Sea, dubbing the reopened channel the Canal of the Commander of the Faithful. Via this canal, harvests of grain from Egypt were taken to Arabia. A further measure was the construction of pools to retain water for pilgrims along their routes to Mecca and Medina.

To further safeguard against droughts and famines, the governments of the Near East built irrigation canals to send water to what had been wastelands in order to spread agriculture. This was an enterprise that required constant effort, because the major sources of water, the Tigris and Euphrates rivers, periodically changed their courses. The land around them was usually flat, and they had to be kept in their courses by levees built along their banks; even so, the rivers would sometimes break the levees, shifting to new courses. People tended to build their cities near rivers, and such a shift in a river's course could end a city's history. The ruins of Babylon are testimony to what happened when its river moved away. In Syria there is the bridge of Ayn Diwar, built in the 1100s or 1200s to span the Tigris but now a bridge to nowhere over dry land.

The medieval Islamic world was notable for the abundance of food usually available to its cities, but famines sometimes struck. These were often caused by a combination of natural and human circumstances including drought, mismanagement, and war. Perhaps the worst of these occurred in India in the 1330s or 1340s and in Egypt from 1403 to 1404. The dating of the Indian famine is uncertain because the records of the time are somewhat imprecise, although it is known to have occurred during the reign of Sultan Muhammad ibn Tughluq (r. 1325–51). He was creative, talented, and very intelligent, but he was also cruel and sometimes seemed to be oblivious to why

his subjects often loathed him. During his reign he raised taxes on farmers to such a level that many of them, big landowners as well as small farmers, refused to cultivate their lands. This occurred at the same time as a drought, which led to catastrophic crop failures throughout northern India. The result was starvation so severe that entire provinces were depopulated. The sultan distributed the government's stored grain, and then imported grain from abroad, but an uncounted number of people died, perhaps in the millions. He also paid agents to bring unused land into cultivation, but these agents pocketed the money and failed in their obligations.

Off and on for several decades before 1403 Egypt's harvests had been erratic because of recurring droughts. When Timur (ca. 1336–1405) led his armies into the Near East, the Mamluk government of Egypt nearly bankrupted itself in financing the defense of Egypt and consequently raised taxes on Christians and Jews, people vital to farming in Egypt. In 1403 the Nile's annual flood was very small; most land that normally received nutrient-rich silt as well as water remained dry. Farmers became financially unable to farm and this, when combined with the drought, resulted in a death toll that remains uncertain, but hundreds of thousands probably died and recovery doubtless took decades.

As aberrations in the climate, droughts were usually not part of another phenomenon that shaped the Islamic world throughout the medieval era. This was a gradual drying of the climate in North Africa, the Near East, and central Asia. Studies of the Sahara show that as recently as 3000 B.C.E. it was a verdant land of prairies and forests. By 2000 B.C.E. people were moving to escape the drying of the land. At the outset of medieval times, the southern end of the Sahara was farther north than it is now, but it slowly spread south into overgrazed lands, drying out oases and widening the distances caravans had to travel from North Africa to sub-Saharan Africa. Archaeologists occasionally find the dried remains of a caravan from the medieval era that may have been overcome by a sandstorm and left buried for hundreds of years until winds blew the sand away. All it took for catastrophe was for an anticipated watering at an oasis to be lost because the oasis had dried. To wander away from a caravan for even a few minutes could mean death in a desert that became more unforgiving daily.

In central Asia archaeologists have barely begun to explore the once-fabulous cities of the many trade routes collectively called the Silk Road. During the early medieval era China had extended its range north of the Himalayas to include the Silk Road all the way to the Near East. When Islamic armies pushed the Chinese out of much of central Asia, the lands of the Silk Road were already drying. Water ceased flowing from the mountains because glaciers had withdrawn,

or wells had run dry. Cities that were considered in their own day to be among the most civilized and technologically advanced in the world became deserted. War further depleted the lands of their people, especially the conquests of the Mongols and Timur.

Another phenomenon that profoundly affected lives in central Asia and the Near East was the earthquake. Details for most earthquakes are scant, partly because people often deserted the devastated land without leaving records and partly because few chroniclers in the medieval era wrote in detail about what happened. An exception to this desertion was Tabriz, a town in northern Iraq that people persistently rebuilt. The city was ruined by earthquakes in 791, 858, and 1041, and because it was rebuilt each time archaeologists can identify the breakage and ruin of each event by examining its walls as well as buildings that were constructed on top of old ones. The rebuilding of Tabriz in 791 was so remarkable that Zubaidah, wife of Caliph Harun ar-Rashid (r. 786–809), who organized the rebuilding, was thereafter declared the founder of Tabriz. Later chroniclers lamented the loss in the earthquakes of 858 and 1041 of the many monuments built in Tabriz after 791.

One of the most catastrophic earthquakes in history occurred in the region of the city of Aleppo in present-day Syria on October 11, 1138. This date and much information about the events after the earthquake come from the author Ibn al-Qalanisi (ca. 1070–1160). He recorded four aftershocks. Modern geologists estimate that the earthquake was over 8.0 on the Richter scale and may have originated from earth movements in the Himalayas. Another large earthquake near the town of Gāncā in present-day Azerbaijan on September 30, 1139, may have been related to the same earth movements that devastated Aleppo. About 230,000 people died during the Aleppo earthquake. A foreshock on October 10, 1138, had been enough to warn the 67,000 or so residents of Aleppo, nearly all of whom fled the city. Buildings collapsed in Aleppo, but most of the casualties seem to have been in nearby towns and villages. The knowledge existed of how to build earthquake-resistant structures: People in what is now Pakistan had been constructing walls from a mix of stone and wood that could flex with earthquakes, and much of the destruction caused by the Aleppo quake and similar ones in the region in 1114, 1157, and 1170 may have been due in part to poor building practices. Yet even sturdy structures such as castles could not withstand the landslides that carried them off the hills on which they had been built. After each of these earthquakes, people tended to stay near their homes or search for mosques or fortresses that might be intact enough to offer shelter. They tended to forage for food as families and cooked food outdoors near where they were staying.

Perhaps a more traumatic earthquake, although not as well recorded, occurred on March 18, 1068, near Jerusalem, where the later Aleppo earthquake was not felt. The center of the earthquake was in the Hejaz, which would suggest it may have damaged sacred sites such as Medina, but what happened at Jerusalem seems to have been of greatest concern. About 100 people died in Jerusalem; moreover, the Dome of the Rock seems to have been shifted out of position. People moved it back to its customary place.

*Europe*

~ *Johannes de Trokelowe:*  
 “*The Famine of 1315*” (ca. 1315–17) ~

In the year of our Lord 1315, apart from the other hardships with which England was afflicted, hunger grew in the land. . . . Meat and eggs began to run out, capons and fowl could hardly be found, animals died of pest, swine could not be fed because of the excessive price of fodder. A quarter of wheat or beans or peas sold for twenty shillings, barley for a mark, oats for ten shillings. A quarter of salt was commonly sold for thirty-five shillings, which in former times was quite unheard of. The land was so oppressed with want that the king came to St. Albans on the feast of St. Laurence [August 10] it was hardly possible to find bread on sale to supply his immediate household. . . .

The dearth began in the month of May and lasted until the feast of the nativity of the Virgin [September 8]. The summer rains were so heavy that grain could not ripen. It could hardly be gathered and used to bake bread down to the said feast day unless it was first put in vessels to dry. Around the end of autumn the dearth was mitigated in part, but toward Christmas it became as bad as before. Bread did not have its usual nourishing power and strength because the grain was not nourished by the warmth of summer sunshine. Hence those who ate it, even in large quantities, were hungry again after a little while. There can be no doubt that the

poor wasted away when even the rich were constantly hungry. . . .

Considering and understanding these past miseries and those that were still to come, we can see how the prophecy of Jeremiah is fulfilled in the English people: “If I go forth into the fields, behold those slain with the sword, and if I enter into the city behold them that are consumed with famine.” Going “forth into the fields” when we call to mind the ruin of our people in Scotland and Gascony, Wales and Ireland . . . Entering the city we consider “them that are consumed with famine” when we see the poor and needy, crushed with hunger, lying stiff and dead in the wards and streets. . . .

Four pennies worth of coarse bread was not enough to feed a common man for one day. The usual kinds of meat, suitable for eating, were too scarce; horse meat was precious; plump dogs were stolen. And, according to many reports, men and women in many places secretly ate their own children.

## ► nomadic and pastoral societies

### INTRODUCTION

Throughout human history, one of the most fundamental changes in people's way of life was brought about by the agricultural revolution that occurred during the Neolithic Period 10,000 to 12,000 years ago. Up to that time people had lived as hunter-gatherers, depending on wild game and wild plants and often wandering great distances to obtain them. The abundance of wild food sources in the Middle East and in the valley of the Yellow River in central China made it possible for people to settle in permanent dwellings. The domestication of food plants followed quickly. Animals were also domesticated hand in hand with plants, since their dung was useful for fertilizing (as well as for fuel for cooking fires) and their labor for agricultural work, besides being a source of meat, leather, bones for tools, and other items. Cattle and goats were domesticated in the Near East and horses and swine in China. The use of the domesticated species spread rapidly to surrounding peoples, and eventually most of the domestic species were distributed throughout Eurasia and Africa. Only the dog seems to have been domesticated much earlier, although the details of that are not clear.

Many peoples on the fringes of the fertile areas, who did not have land suitable for farming, used the animals in a different way. Two kinds of animal-herding cultures developed distinct kinds of pastoralism, or ways of life based primarily on herding domestic livestock common during the Middle Ages: transhumance and nomadism.

Transhumance is a type of pastoralism that is implemented together with settled agriculture. In this form of pastoralism, some members of a family (usually boys or women) led domestic animals onto hillsides or alpine valleys that could not be used for farming cereal crops and let them graze through the summer. In the winter the herds would be moved into lowland regions near the family farm and fed on hay that was grown during the summer. This allowed otherwise marginal land to become highly productive. Specialized

breeds of dogs, extensively trained for the role, often would assist in the herding. This exploited the animals' natural instincts as predator and prey to keep the herd moving away from the dogs and in the direction the herders wished. Because male animals were more aggressive and would want to control the movement of the herd themselves, they were mostly slaughtered as calves. This left the mountain herds composed entirely of females with their calves, so that they could produce milk. Only a few selected males were kept in the valleys for breeding.

Nomadic pastoralism is a more intensive exploitation of the domesticated herds on arid land or grasslands unsuitable for the cultivation of cereal crops. In this case the herders have no permanent dwellings or farmsteads but follow the herds continuously, living in tents or wagons. Every part of the animals was used since no other agricultural source of food was available. Vegetables and cereals, when they could be had at all, were gathered from wild plants or obtained in trade. Usually the herders rode domesticated horses themselves and used horses or oxen as draft animals, even if they herded other species such as sheep or musk oxen.

American cultures were at a disadvantage because they did not bring any domestic animals (except dogs) with them during their migration from Asia in prehistoric times. North American tribes had to fall back on the less-sophisticated practice of following herds of wild animals. Ice Age hunters in Eurasia lived in this way, following herds of mammoth and other animals. Many American tribal peoples took up the same way of life, following and hunting bison (buffalo). These peoples made extensive use of every part of the hunted animals in the same way as nomad pastoralists, but they did not have any control over the movements or breeding of the herd. Hunting was carried out with simple weapons like the bow or spear; when occasion permitted, larger numbers of animals would be taken by expedients such as stampeding the herd over a cliff. The Sami or Lapps in northern Europe lived in this way, too, following reindeer herds. The peoples of the Andean cultures of South America, at least, changed this situation by domesticating a native species—the llama, a relative of Old World camels. They came to be herded between mountain valleys and lowlands in transhumant pastoralism.

## AFRICA

BY KATHARINE DELUNA

During the last three to four millennia of African history most Africans practiced a form of mixed farming in which they combined the cultivation of crops with the tending of a few animals at their homestead and supplemented such activities with hunting, fishing, and foraging in the surrounding

bush. Thus, the development of economies focused solely on animal tending, and particularly forms in which communities are nomadic for part or all of the year, represents a specialization to fit both an economic and environmental niche on the fringes of the mixed farming economy.

Pastoralism is a specialization in tending domesticated livestock such as cattle, goats, sheep, and camels for food and trade products. In Africa pastoralism has long been associated with several characteristics: the habitation of dry grassland environments, mobility within those environments, and interaction with neighbors specializing in agriculture and in hunting, fishing, and foraging. In addition to these characteristics, scholars sometimes associate nomadic pastoralists with expertise in warfare because the skills and organization necessary to defend large, dispersed herds from predators transfer well to those required for success in warfare.

Pastoralists inhabited grasslands to ensure that their livestock had access to adequate pasturage. In Africa annual weather patterns concentrating precipitation into one rainy season play an important role in determining the lifestyle of pastoralists. In many areas like the Sahel, the dry steppe region stretching south of the Sahara from the Atlantic to the Ethiopian highlands, herders spent the dry season in a base camp located near a permanent water hole and then moved away from this camp as grasses grew and rainy-season water holes filled. This seasonal pattern of movement is known as transhumance. Often some community members would stay behind in the permanent camp to cultivate a few fields. Other societies, such as the Berber-speaking camel herders of the Sahara, moved constantly from one known water hole to the next in a fully nomadic pattern resembling the mobility of hunter-forager groups. Generally, pastoralists in Africa emphasized herd size rather than the production of meat; archaeological remains consistently demonstrate that specialist herders slaughtered only those animals that were not in their reproductive prime.

As pastoralists engaged in these differing forms of mobility, they kept contact with agricultural communities on the fringes of their grassland homes. Pastoralists produced a surplus of food products, such as milk, blood, and meat, and items of utility such as skins and bone tools. These surpluses were traded with neighboring farming communities for grains, tools, cloth, and other products of sedentary life. While cooperation characterized most interactions between pastoralists and their farming neighbors, there could also be competition between them for the control of land and sometimes trade. Furthermore, both the symbiosis and the tensions between communities with different economic specializations could lead to the development of ideas about eth-

## THE KHOI

During the medieval era, the Khoi lived in the grasslands of southern Africa. They were nomadic pastoralists. Their movements may have taken advantage of the changes in weather during the year, especially the rainy season. Their name is sometimes rendered as Khoikhoi, meaning “people-people.” Historians disagree about where the Khoi originated. Their language is similar to that of the San of southern Africa, suggesting an affinity with the San, who were hunter-gatherers rather than herders in the medieval era. Even so, some linguists believe the Khoi were related to herders of sheep in northeastern Africa. Some historians suggest that the Khoi originated in what is now Botswana.

Archaeological evidence indicates that they were shepherding sheep in the 400s, but they may have been doing so since the first century. From the 400s to about the 600s the Khoi ranged over almost the whole of Africa east of Namibia. Near the end of that period Bantu-speaking peoples arrived in southern Africa and pushed the Khoi out of the eastern lands, leaving them the central plains of southern Africa. These later migrants may have come south by way of the central woodlands of Africa as well as along the eastern coast of Africa. It is likely that the migrants who took the coastal route are the ones who displaced the Khoi from the more fertile lowlands.

The early Khoi herded sheep and goats. Exactly when they added cattle is not as yet known. Their cattle were descended from cattle that had originated in northern Africa. It is possible that cattle were at first introduced to the Khoi by way of central Africa, but evidence at present indicates that the cattle were introduced by herders from northeastern Africa. The Khoi’s wealth and social status depended on how many cattle they owned. If a Khoi lost his cattle, he would turn to hunting and gathering. He could sell items such as feathers to the settled peoples of eastern Africa, thereby earning enough to purchase cattle and reinstate his status in his community.

nic identity based on subsistence practices, as was the case in 19th-century Rwanda with Tutsi pastoralists and their Hutu agriculturalist neighbors. Of course, the development of ideas tying ethnic identity to economic specialization allowed for

*Ivory pyxis carved with pastoral scenes; early Byzantine, possibly Egypt, sixth century* (© The Trustees of the British Museum)

fluid, rather than rigid, interpretations of those identities and their markers.

Specialist herding communities played an important role in northern and western Africa from the middle of the first to the middle of the second millennium c.e. These nomadic and seminomadic peoples lived within and on the fringes of the Sahara desert and played a vital role in communication across the Sahara along trade routes and between oases. With the introduction of domesticated camels in the first centuries c.e. pastoralists acquired the capacity to maintain a fully nomadic lifestyle within the Sahara desert, the Red Sea hills, and other marginal environments that had long been too dry for cattle. With camels, herders gained the mobility necessary to foster long-distance trade connections across these lands; the trans-Saharan trade network remains the most famous example.

In many areas, such as the inland Niger delta, specialists in herding, farming, fishing, hunting, and foraging came to rely on each other's skills in a cooperative fashion. In other areas of western and northern Africa, however, agriculturalists and pastoralists were often in competition for those lands that, while marginal to either activity, could be harnessed to expand the different economies and their practitioners' territorial influence. In fact, in the 14th century the Tunisian historian Ibn Khaldun (1332–1406) argued that as a result of technologies like cavalry, camels, and chariots that arrived in the fourth century, North African history could be understood as the alternation of power between sedentary farmers

and nomadic pastoralists, with the pastoralists often raiding and conquering the farmers. This pattern continued long past the 14th century and is a common theme tying western and northern African history to historical patterns in Eurasia and beyond.

Another western African pastoralist community is the Fula. The community's history is important because it influenced local culture and politics across a wide expanse of western Africa during and after the medieval period. The Fula homeland was in the Senegal River valley, and its development as a community around 1000 was influenced by, and perhaps included intermarriage with, nomadic Znaga Berber pastoralists of the western Sahara. A few centuries later, in the context of several decades of poor rains and overgrazing, some of the Fula began to spread eastward in search of new pastures for their system of transhumant herding. Over the next few centuries the Fula came to stretch across the western African savanna from Senegal to northern Nigeria, always interacting with and sometimes integrating into the farming communities they found on the fringes of their pastureland. The Fula who settled in the towns came to be important in the spread of Islam across western Africa and often held positions as clerics. One such Fula Islamic scholar, Uthman dan Fodio, led a successful jihad (holy war) against the kings of the Hausa states in northern Nigeria in the 19th century and founded the Sokoto Caliphate, an Islamic empire in northern Nigeria.

The development and spread of pastoralism in southern Africa predated the spread of agriculture and was often practiced in combination with foraging, a practice known as *pasto-foraging*. Scholars once assumed that hunting and gathering dominated the immediate precolonial economy of southern Africa, but it is probable that *pasto-foraging*, rather than hunting and gathering, was the most common form of subsistence economy in southern Africa for much of the first millennium.

Other communities in eastern and southeastern Africa practiced mixed farming. When specialized cattle keeping finally developed in these regions, it took a very different form from that in northern and western Africa. Although some specialist seminomadic herding tribes such as the Masai did emerge, most societies that emphasized intensive cattle keeping were sedentary communities, such as the Toutswe of eastern Botswana, the Nkore of western Uganda, and the herding elite of Rwanda. Most of these sedentary communities developed into large polities and kingdoms beginning around 1000 because people recognized the economic value of livestock as a form of wealth that reproduces itself and may be easily transferred via trade or forms of gifting that create networks of social obligation. The specialized seminomadic

herders who practiced their craft in the grasslands of eastern and southern Africa worked closely with neighbors who specialized in farming, hunting, fishing, or foraging. These specializations often exploited ecological niches, such as the different elevations of the hills and mountains of the Great Rift Valley, so it was important for communities to work together to ensure food security in the face of the specific threats of each environment.

## THE AMERICAS

BY DAVID H. VALLILEE

The term *nomadism* derives from the Greek word *nomas*, meaning “feed” or “pasture.” Generally, it has been defined as a circumstance in which people have no permanent home and wander in search of food and pasture. It also applies to peoples whose subsistence is largely based on hunting migrating mammals, with the result that the location of their temporary shelter is contingent upon herd movements and a need to avoid excessive hunting in one place. In many regions movement is based on seasonal changes in which some areas are abundant in animals and plants in the warmer months and others more abundant in colder months.

Nomadic pastoralism is based upon herding domesticated animals and often requires moving animals to the best pastures. Pastures in arid regions may not be useful outside of the rainy season, while pastures in mountainous and colder regions may not be accessible in winter. These conditions necessitate moving livestock between different regions seasonally. Nomadic pastoralists can move to a wide variety of places according to the availability of pastureland, whereas transhumant pastoralists move between fixed locations each season. While much of the population of the Americas during the medieval period lived in permanent settlements, people in some regions still practiced nomadic ways of life.

Between 500 and 1500 the North American Arctic region from Alaska to Greenland was dominated by two cultures, the Dorset and the Thule. The Dorset culture dominated the northern area of the present-day Northwest Territories of Canada and western Greenland from about 500 to 1000. The Dorset were a seminomadic people whose primary economic activity was hunting. They occupied autumn camps for hunting seal and walrus; late-winter and spring camps for hunting caribou, musk oxen, and polar bears on the polar edge; and summer camps for hunting, fishing, and gathering plant foods. Late in their culture they built longhouses for ceremonies during snow-free parts of the year.

More than 90 percent of the Dorset diet consisted of game and sea animals augmented by plant and sea foods, such as clams, mussels, berries, leaves, lichens, and seaweed. They

carved harpoons for hunting sea mammals and spearheads for hunting fish. The Dorset had considerable knowledge of animal behavior and precisely timed their hunting activity during the year. They intercepted migrating harp seal in narrow channels, concentrated on hunting nesting birds rather than on the more elusive migratory fowl, and specialized in the selective hunting of animals of particular ages when these groups were most abundant. Dorset carving achieved a high level of naturalism in miniature, such as tiny ivory carvings of humans holding infants, animals and human-bear composite figures, carved figures of wood and stone of humans wearing parkas, and ivory harpoon heads with animal effigies.

Around 1000 the Thule culture emerged in northern Alaska. After spreading across Alaska they began a period of great expansion from about 1000 to 1300, extending eastward across the entire North American Arctic zone and into western Greenland, overtaking most of the Dorset territory. The Thule migrated between two types of settlements, winter base camps and hunting and fishing camps. Their subsistence was based on hunting large game animals (caribou and musk oxen) and sea mammals (seal, walrus, and whale), net fishing at sea, and freshwater fishing from rivers and streams. Agricultural products were not present in their diet. The Thule economic pattern, facilitated by long-distance kayak and dogsled travel, appears to have been focused upon particular hunting endeavors and opportunities to exploit a greater variety of food resources. They also achieved cooperative hunting activities, such as whaling crews.

The Native Americans of the Great Plains encountered by Euro-Americans during the period of exploration, expansion, and trade (about 1550–1900) became emblematic of nomadic, indigenous North America, well known for their portable teepee shelters, their military achievements, and their buffalo-hunting skills. In the centuries prior to the introduction of guns and horses to the region, the nomadic inhabitants of the Great Plains hunted bison on foot with bow and arrow. Often their aim was to procure large numbers of these bountiful animals through communal hunting activities, such as bison jumps and bison corrals.

Bison jump sites are characterized by a high bluff over which the animals were stampeded so that large numbers of them would be killed and crippled by their fall and others would be killed by hunters waiting at the base of the bluff. Bison corrals were bowl-shaped rock formations where large numbers of bison could be driven into the enclosed area, trapped, and slaughtered quickly. One of the most prolific bison jumps was the Head-Smashed-In site in southern Alberta, Canada, with evidence of continuous use between 3600 B.C.E. and 1300 C.E. The Wardell Bison Corral in western Wyoming, which included a large butchering, process-

ing, and camping area adjacent to the site, was used between about 400 and 1100 C.E.

In addition to bison, Great Plains peoples in the medieval era hunted deer, antelope, elk, and a variety of smaller game animals. Seasonally available plant foods, such as sunflowers, choke cherries, grapes, acorns, wild grass seeds, turnips, and onions, contributed to their diet. These peoples moved seasonally between diverse environments, and two types of settlements were common. Base camps (winter camps and summer camps) consisted of groupings of tepees with access to seasonal resources, and hunting camps were used during times of the communal bison hunt.

By 500 most regions outside the Great Plains in the United States and southern Canada consisted of sedentary, year-round communities—ranging from hamlets to small cities—with a subsistence base of hunting, gathering, and agriculture. In some areas of the Great Plains, particularly in the eastern and southern regions, limited sedentary agriculture developed in the period between 500 and 1000. Farmers focused predominantly the cultivation of maize, beans, and squash, often making use of the fertile soil near rivers.

Between 2500 and 1200 B.C.E. most regions of Mexico and Central America shifted from hunting and gathering to sedentary, agriculturally based subsistence; however, an area in the far northeast of Mexico, the Coahuilan region, remained nomadic. The Coahuilan culture (ca. 6000 B.C.E.–1500 C.E.) occupied the Mexican states of Nuevo León, Tamaulipas, and Coahuila, along with southern Texas across the border. Inhabitants of this arid region were largely nomadic and made only sporadic or seasonal use of shelters, such as caves, grass-covered huts, cliff shelters, and open camp sites. The profusion of rock art with shamanic themes suggests that ritual practices were an important part of the society.

The gathering of wild vegetal foods was the primary subsistence in the Coahuila region. Foods gathered included agave, yucca, prickly pear, and foods from leguminous trees and shrubs such as mesquite, huisache, and huizachillo. These plants ripen at different times of the year, a condition that demanded mobility of the inhabitants to achieve a continuous food supply. Their diet was augmented by deer, antelope, bear, bison (though only sporadically), and smaller animals such as rabbits, rodents, and reptiles. While the aboriginal people had to roam the region in search of large quantities of food, they also had to remain within traveling distance of water sources in the mountains, because they lacked a means for transporting and storing water.

In addition to settled living, during the medieval period pastoralism and transhumance (seasonal movement) were prevalent in the mountainous regions of South America. The dominant ancient city of Tiwanaku (ca. 400–ca. 1100),

high in the Andean mountains in present-day Bolivia, had an agro-pastoral subsistence base and a thriving ceremonial center with monumental architecture. Subsistence included the herding of camelids (llamas and alpacas) and the cultivation of potatoes, quinoa, caníwa, coca, and mushwa, all of which adapted to the cold climate and high elevation. Their diet was augmented by hunting smaller game (deer, vicuña, guanaco, rodents, and amphibians) with bow and arrow and fishing in nearby Lake Titicaca. The total camelid population for this region probably exceeded 500,000 at the time of European contact in the 16th century. Grazing required the seasonal movement of the enormous herds between the sierra basins (above 8,200 feet) and the cold, semiarid grasslands of the highland plateaus.

Medieval inhabitants of the Andean northern coast of present-day Peru also relied heavily upon llama and alpaca husbandry. Other mammalian food sources included dogs, deer, guinea pigs, foxes, siscachas, and seals, augmented by penguins and other birds, fish, and shellfish. At the site of Pampa Grande archaeological evidence indicates that camelids were the primary food source and were also used for religious sacrifice. The bodies of several sacrificed camelids were interred in the bottoms of postholes of the central pyramid of the site, and in other regions, such as Huanacho, sacrificed camelids were interred in tomb burials.

The practice of moving herds between valleys to take advantage of fresh pastureland (intravalley transhumance) was common in the northern Andean region. Llama caravans, known through ceramic depictions, were used for moving goods in Tiwanaku and the Andean northern coast. In the northern region llama caravans were used to transport ores from mines to cities.

## ASIA AND THE PACIFIC

BY KEN HALL

Nomads populated the marginally productive regions of Asia in the medieval age. These peoples included the tribesmen who pastured their livestock in the harsh central Asian steppes and the adjacent mountainous regions of south Asia; the trading nomads whose commerce and transport of goods connected the Silk Road caravan and the Indian Ocean maritime network marketplaces; the hunting and gathering foragers who lived in Southeast Asia's dense tropical jungles; the sea gypsies who fished, gathered sea creatures, and provided local transport in the South China Sea and its adjacent regions; and the slash-and-burn cultivators who farmed the highlands of Southeast Asia, Taiwan, and elsewhere in the Pacific basin. Nomadic societies commonly made restricted cyclical movements between a series of habitation sites.

Settlement was determined by the availability of food sources, topography, and climate. Periodic community relocations were necessary when the food sources or the potential to sustain the dominant food sources was depleted at one site—due to overgrazing, depletion of the soil quality, overhunting, and seasonality. The abandoned site would again host the community after the natural habitat had reconstituted sufficiently. The survival and livelihood of some nomads depended almost exclusively on herding livestock (goats and sheep); others supplemented their livestock income with variations of settled agriculture, trading with and supplying supplemental labor to neighboring settled agriculturalists, and hunting and gathering. Some enterprising chieftains might forge temporary patron-client links among several nomad communities, using the natural mobility of their nomadic society to defend against threatening outsiders and to raid or to establish an authority over neighboring agriculturalists.

Nomads commonly lived in encampments populated by nuclear families connected by descent to the other community residents. In addition to their shared bloodlines, tribesmen shared a common language, ethnicity, religion, and culture as well as the need to cooperate to defend their grazing and otherwise productive lands against infringing neighboring tribesmen. They might ally with neighboring tribes against threatening outsiders, such as Chinese, Turk, Mongol, or assorted court-based armies. Nomadic communities were continuously vulnerable to changing circumstances, resources,

and the death of a chief, which often led to warfare among the various claimants who wished to succeed to power.

The tribal community depended on an internal patron-clientage network and a code of honor, which dictated the defense and protection of women, riches, and homeland. The tribal community consisted of segmented linkages among semiautonomous households, lineages, clans, and tribes who shared a common ancestor and formed a social pyramid dominated by the head of the senior ancestral lineage or a dominant chief. Successful leaders were temporary: A chief who acted as patron and his dependent client network continuously had to satisfy local need for a leader who could provide unity, opportunity, and protection. The supreme chief needed resources to reward his loyal followers and provide them with security in order to maintain his client base, whose loyalty and following in turn marked him as a powerful and important figure in the region. The tribal community was institutionally unstable.

While there was a patron-chief, in order to deal with immediate concerns that affected the entire group, nomads held regular tribal councils, where all men had the equal right to speak. Tribal law was enforced by a council of elders whose judgments were based on a code of honor that specified personal rights and obligations, rights of revenge, guidelines for granting and receiving asylum, hospitality, bravery, steadfastness, righteousness, persistence, defense of property, honor, and the chastity of females. While a guilty verdict in sexual crimes (notably adultery) dictated a mandatory death penalty, the code of honor favored restoration justice, by which the guilty made restitution rather than be subjected to retribution. Tribunals acted as arbitrators rather than judges in negotiations that determined guilt and consequent penalties paid in cash, services, livestock, and transfers of land rights, women, and bondsmen. The system tried to achieve a consensus, wherein an individual retained his honor rather than be subjected to alienating disgrace.

The nomads of the central Asian steppes raised sheep and goats (with a sheep-to-goat ratio of 4 to 1—sheep being the more valuable asset), which were well suited to the region's frequently dry grasslands; the region was unable to sustain cattle grazing. By choice, most central Asian tribesmen did not practice agriculture, preferring their free lifestyle on the steppes, where there was limited political centrality. Mongol tribesmen associated settled agriculture with their despised Chinese neighbors, who forced captive tribesmen to become farmers; to settle in one place was equivalent to slavery.

While the sheep and goats demanded little from the natural habitat, they were close crop eaters and quickly exhausted local pasturage. Herders had to move before their livestock destroyed the land's capability to recover. Horses were nec-

Nomad bridle bit; Khazar; Bielowodsk, Perm region, Russia; ninth to 10th centuries © The Trustees of the British Museum

essary to herd and drive the livestock; a rider on horseback increased the speed of herd movement and guarded against natural predators. The sheep and goats provided hair, wool, skins, and dairy products that were used locally and were also traded to neighboring agriculturalists for grain, salt, metal, and luxuries, such as tea, porcelain, cloth, and other manufactures the nomads could not make for themselves. Exchanges with their settled neighbors were tenuous; the nomads preferred to minimize their dependence on trade and remained as self-sufficient as possible to maintain their local autonomy. In some cases, tribesmen might enter the military service of their neighbors; wealthy tribesmen were sometimes moneylenders to their agricultural neighbors and might also become landholders who embraced resident farmers. Landholding, money lending, and other negotiated relations with settled neighbors also provided the nomads access to the grassy grazing grounds of the agricultural areas.

Central Asian nomads were skilled horsemen and horse breeders. The steppe pony was small but hardy, able to survive with limited pasturage and, because of its heavy coat, to withstand the harsh steppe winters. Nomadic horsemen were using breast straps, stirrups, and horse collars (for cart transport) by the fifth century. A variety of horses were bred for sale to their neighbors, who were always in need of horses for their military; for biological reasons horses could not be bred in the Asian tropics. Horses were supplemented by camels, which were raised for their meat, hair, and milk, but especially as a mode of transportation in both long-distance trade and travel. Camels had long-term subsistence capacity; properly fed before embarkation, camels had marginal need for additional food and water for travel that might last for weeks. The camel's broad feet allowed it to walk in the rugged rocky and sandy central Asian terrain where horses could not. The camel's transparent eyelids protected its eyes and allowed it to see in dust storms and sandstorms. Camels were especially vital to the nomad traders who dominated the transport of goods along the Silk Road overland passageway.

Central Asian tribesmen moved seasonally, annually, and in multiple-year cyclical rotations covering hundreds of miles that were determined by overgrazing, the time needed for the land to recover, variants in rainfall, and warfare in the region. Pastoral nomads moved among a network of pasturage areas that they regarded as their own and that they would defend against anyone who infringed on their unused lands. Since grass was their most valuable resource, pastoral nomads most frequently went to war over grazing rights and defended themselves from the armies of neighboring agrarian-based empires.

In contrast to the central Asian tribesmen, Afghan and other south Asian nomads made seasonal migrations, graz-

ing their herds in highland mountainous pastures in the spring and summer and returning to the lowland valleys in the fall and winter to avoid the harsh highland winters. Some of the tribes' pastoral population migrated seasonally, while others remained in the lowlands year-round to farm, trade, and provide seasonal supplemental labor to their agrarian neighbors. The balance depended on local opportunities and personal preference.

The Mongol chieftain Genghis Khan (r. 1206–27) united the diverse central Asian tribesmen and reorganized them into 1,000-man fighting and administrative forces (*minggan*). To maintain order among his ranks, he institutionalized the local codes of honor into a common code of law that provided examples of appropriate military and social behavior. The code emphasized loyalty to the Mongol military over family clans, promised rewards for meritorious service rather than for hereditary social standing, and promoted ethnic and gender equality. The Mongols adapted to the more culturally sophisticated societies they ruled. Although they had previously worshipped a universal sky god as well as various ancestral and natural spirits, the Mongols became patrons of and later converted to Buddhism, Islam, and Christianity in the various lands they conquered. Like the patron-chiefs, Mongol rulers sought prosperity for themselves and their subjects by entering into profitable business partnerships with prominent businessmen (*ortaqi*) and encouraging their maritime trade initiatives as well as the creativity of artisans and artists. Above all the Mongols' widespread authority and their victories over and subsequent incorporation of conquered peoples from China to the Middle East ensured the security of the vital East-West Silk Road trade route, which also provided the means for cultural exchange.

Central Asian nomad warriors were expert horsemen who kept several of the small, tough steppe ponies. Warriors in battle would make quick cavalry charges, shooting arrows at their enemies and then retreating to mount a new horse. Using his string of horses, a warrior could continue charging indefinitely. Opponents feared the tribesmen so much that many paid tribute to avoid being the target of mounted attacks. Until the time of the Mongols most Eurasian populations viewed the central Asian tribesmen as symbolic of ferocious barbarian cruelty and deceit. Tributary payments by their neighbors, use and sales of war captive slaves, and collections of ransoms on war prisoners subsidized a comfortable lifestyle. Warriors lived most of their lives in tents, some quite large, that were lavishly furnished.

Until the development of breech-loading (cartridge) firearms in the 19th century, the central Asian (Mongolian) composite bow was the most effective long-range tool in war and hunting. It was vastly superior to any military technol-

ogy in the medieval West, including the famed English longbow. Warriors, both male and female, always carried at least two bows, one for long-range shooting and another for close-range combat. The Mongol bow was shot from horseback, pulling the bow away from the string rather than pulling the bowstring back. A skilled archer timed shots to release when the horse's hooves were in midair, to avoid distortion in aim when the shots hit the ground.

Compared to an English longbow, which had a draw of 70–80 pounds, the Mongol bow had a pull of 100–170 pounds, depending on the strength of the archer. The English longbow could shoot up to 250 yards, but the Mongol bow could hit a target at 350 yards and well beyond. A 13th-century record of Genghis Khan reports that a shot made by one of his master archers reached 428 yards.

In south Asia and Southeast Asia the medieval era was marked by the spread of settled agriculture from lowland and coastal river valleys into previous nomadic tribal regions populated by assorted foraging and slash-and-burn cultivators, resulting in regular conflict between agrarian and nomadic populations, with substantial consequence to both. This conflict inevitably gave prominence to warrior armies, which were clients or mercenaries in the service of a coastal warrior-chief or a lowland court-based monarch. Warrior-chiefs became powerful figures in the resulting lowland and coastal-based political systems, often as retainers who were assigned political authority, landholding rights, and income rights over the conquered highlands and upstream, the proceeds of which they shared with their military clients. Frequently as an alternative to a mutually expensive fight to the death, the highland or upstream chiefs were offered and accepted a service relationship as semiautonomous clients of their would-be opponents. While inevitably the nomads lost control of the upland river valleys to newly settled agricultural communities, the negotiated alliance protected their tribal autonomy and preserved their nomadic lifestyle in the uplands and dense tropical rain forests. The upstream nomads and downstream agriculturalists engaged in peaceful exchanges, as their exchanges regularized rather than remained consequential to raids.

Symbolic of their regularized relationship, lowland and highland leaders cooperated in the establishment of symbolic Hindu and Buddhist temples in the newly incorporated regions, which linked upstream and downstream populations in a common religious tradition that superseded previous local animistic and ancestral tribal cults. Hindu and Buddhist temples were self-interested agents in the development of settled agriculture in the previously uncultivated upstream since they held assigned income rights to productive property. Temples were also indirect agents of political

centralization in the absence of effective government administrations in the border zones because each temple was ritually and administratively linked to a central temple at or near a royal court.

## EUROPE

BY BRADLEY A. SKEEN

Pastoralism, the way of life based on tending herds of domestic animals, was one form of medieval farming, but it was not the most common. Nomads drove herds of animals through the Russian steppe, while dairy and sheep and goat herders practiced transhumance (seasonal movement of livestock) on mountainsides and other marginal land. However, most medieval farmers made a living through agriculture in the strict sense (tending fields) and raised cereal crops on small plots of land; still, no farm would have been without some domestic animals. They were used for both agricultural labor (pulling plows, turning millstones, and so on) and the production of meat and other agricultural products. Bulls (oxen) used to pull plows were usually castrated to render them more docile. The diet of agriculturalists consisted mostly of items such as gruel or bread. Meat was less frequently eaten. It was rarely eaten by wheat and barley farmers as opposed to dairy farmers and steppe nomads. It would enter the diet usually at the beginning of winter, when a few domestic animals would be slaughtered and some wild animals would be taken by hunting. Some agricultural farmland probably was dedicated to horticulture and provided items like fruit, vegetables, wine, or olives.

Another way of life, nomadic pastoralism and transhumance, nevertheless was practiced widely in the Middle Ages. It was based on animal husbandry (tending livestock, such as cattle, horses, sheep or goats) in pastures. Peoples who lived in this way also ate varying amounts of cereals and fruits and vegetables (whether from a limited practice of agriculture and horticulture or from trade), but a much larger proportion of their diets was made up of foods that are rich in fat and protein, such as milk, cheese, and meat.

While pastoralism offers many advantages as a way of life, it also has limiting factors. One is that the population of herders tends to expand rapidly beyond what is needed to control the herd or is even possible to sustain from the herd. Another is that the quality of the fields used for pasturage tends to degrade relatively quickly (but still on a scale of generations) and become unusable wasteland or desert. As a result, pastoralism is usually practiced only on land that is marginal to begin with, either because it is too dry (as in Africa and the Middle East) for agricultural or because it is at too high an elevation (for example, mountain slopes).

Most of the animals used in agriculture in medieval Europe had been domesticated in the ancient Near East, but the Sami (sometimes called Lapps) people of northern Scandinavia practiced a form of pastoralism that seems to have evolved from hunting. At one time the Sami must have followed herds of reindeer and lived by hunting them, together with gathering any other resources they could from the wilderness. Eventually, the Sami began to domesticate the herds. The Sami took some animals and isolated them, either for milking or for use as draft animals to pull sledges. Some Sami still live in this way.

Nomadism is a type of pastoralism in which the herders follow the animals across vast distances as they graze on arid or semiarid plains (steppe). The herders, who by the Middle Ages were usually mounted on horses, drove herds of fully domesticated animals such as horses or cattle in a seasonal cycle, always seeking fresh pasturage. The exploitation of the animal herds is far more intensive in this type of nomadism. Every product of every animal was used: meat and skin (for leather) and also secondary products, such as milk, fur, and blood (as a foodstuff). Even animal dung was used as fuel for fires. The animals were both ridden and used to haul wagons or carry packs.

In Europe nomadism of this kind was limited to the steppes of the Ukraine and Caucasus in southern Russia, the western edge of the vast inner Asian ecosystem and cultural system, where this type life was common. Out-migration from inner Asia by nomadic Altaic and Finno-Ugric tribes, however, caused waves first of displaced Germans and then of Huns, Magyars, and Turks to invade Europe throughout the Middle Ages, bringing about the collapse of the Western Roman Empire (476), the Viking Age (ca. 400–600), and the conquest of Russia by the Mongols (1223) and of the Byzantine Empire by the Ottoman Turks (1453).

At the beginning of the Middle Ages the Roman historian Ammianus describes the Huns, who were then living in the eastern Ukraine. Their entire way of life and livelihood was tied up with the horses they herded. Ammianus expressed amazement that they had no houses of any kind and lived entirely in wagons. They dressed in the furs and leathers of the animals from their herds and of the wild animals of the steppe, especially sheep or goatskin chaps. Perhaps he exaggerates when he says that they did not understand the purpose of houses or other buildings and so dreaded going into them. Naturally they had no specific homeland. Because they were constantly moving, they attached no significance even to their places of birth.

Ammianus describes them as expert foragers, capable of living on a diet consisting almost entirely of wild roots they could find wherever they happened to be. They could sleep on

their horses. Precisely because they were bred in the saddle and spent their lives riding, they made the finest light cavalry that Ammianus, himself an experienced military officer, had ever seen. They were fearless in battle and impossible to break. If their wedge-shaped formations were broken by heavier troops, they simply use their superior speed to ride off a short distance and then reform and attack again, either with arrows or a saber charge. They were also capable of using the lariats with which they controlled their herds to attack and pull down the mounted troops of the enemy. The stirrup had been developed in inner Asia at some time in the past and had reached Europe with the Hunnic and other tribes that invaded the Roman Empire throughout the fourth to the sixth centuries, making them far more effective cavalry. Steppe tribesmen were unable, however, to attack either fixed or field fortifications.

The existence of this kind of nomadism made the vast steppes of inner Asia (beginning in southern Russia) into an open highway for trade and the transmission of ideas vital to the development of Europe. The trade was possible because of two facets of nomadism. The nomads themselves could transport goods across the steppes without an intensive transportation network such as roads, and the absence of fixed settlements across most of inner Asia meant that political and tax barriers to trade did not generally exist. However, the Islamic control of inner Asia and the terminus of the trade routes on the Black Sea and the Mediterranean in some periods of the Middle Ages at times made this trade artificially expensive and at others stopped it altogether. Commercial items such as silk and porcelain crossed the steppes to Europe, along with inventions such as the spinning wheel and gunpowder. So did epidemic diseases, including the bubonic plague that devastated the European population in the

years 1348 to 1350. Coming out of inner Asia, the disease was carried on a single Genoese ship from a trading post on the Black Sea. Islamic control of this trade was the main stimulus to the exploration of the Atlantic and Indian oceans by the Portuguese and Spanish after 1450.

Another type of pastoralism, called transhumance, was practiced in mountainous regions. In medieval Europe it was common in the Alps, Scandinavia, Scotland, Wales, Ireland, the Balkans, and the Pyrenees. In this kind of culture most people lived in small villages or individual farmsteads, and only a small proportion tended the animals (especially young people and in many places young women). The herd was sent to alpine meadows in the summer and then brought back to live in valleys during the winter, when their diet might be supplemented by hay harvested from the valleys. Trained dogs were commonly used to help control the herds and protect them from predators. The remainder of the population cultivated crops and grew hay, transported and processed items like milk and cheese, or worked as hunters or craftsmen or in other occupations. The herd sent to the high meadows consisted entirely of female animals because they were more docile. Most male animals were killed as calves because they would not be as productive as females, who could bear new calves and produce milk. Those few males kept for breeding were left in the lower valleys.

Transhumance could also be remarkably profitable. The production of wool by sheepherding in the mountains of Spain was the principal source of revenue for the Spanish crown in the Middle Ages. The taxes it generated paid for the Reconquista, the retaking of the country from its Islamic rulers, as well as for Spain's overseas exploration (for example, Columbus' discovery of the Americas) and her rise to become a great power. Accordingly, sheepherders were given many special privileges in Spanish law. It was, for example, illegal to build fences or other obstacles over their droving paths or to try to exclude them from private land.

The culture of transhumance is especially productive of soldiers, usually called in English *highlanders* (after the Scots "highland" soldiers) or by the borrowed French term *montanyards*. Because of their high-protein diet, highlanders were usually larger and more physically fit than other soldiers. They spent much of their early life hunting, which was excellent training for war in the Middle Ages. In part because of the low infant mortality rate of transhumant cultures and in part because of the small amount of labor necessary to operate the system, there were always many highlanders able and willing to leave their family farms to fight as soldiers. Transhumance was the cultural background of many of the most famous medieval soldiers, from the army of the Byzantine Empire recruited from the mountains of Asia Minor to

the knights of the kingdom of Asturias in the Pyrenees who began the Reconquista of Spain to the Vikings who terrorized Europe in the Viking Age to the Scots highlanders and to the Welsh longbowmen who repeatedly slaughtered armies of French knights during the Hundred Years' War and the Swiss pikemen who revolutionized warfare at the end of the Middle Ages.

## THE ISLAMIC WORLD

BY RASHEED HOSEIN

While the Near East was home to some of the earliest human communities, as late as the Middle Ages there were still some regions that were largely uninhabited. This lack of habitation was due largely to the limited availability of well-watered arable land. Areas that could support cultivation were quickly utilized for this purpose, leading to population accumulations in those regions. These arable regions included coastal settlements, where food from the seas could be utilized and where agriculture was possible because of the temperate climate. Inland settlements near rivers or other bodies of water used the water to produce crops via irrigation networks. Oases were regions where groundwater reservoirs permitted agricultural activities. However, any other use of this precious land would have been very difficult to justify, given the razor-thin margin between subsistence and starvation throughout much of the region.

However, just beyond those settled lands lay marginal lands, areas that were not totally desiccated but that still lacked the ability to sustain continuous or even prolonged human settlement. The masters of these borderlands were the pastoral nomads (often called by other names, such as Bedouin or herdsmen). Owing to the dryness of the land a sedentary lifestyle was impossible. Instead, these groups pastured large animal herds, drove them in migratory patterns (often well established and demarcated) in search of seasonal fodder, and occasionally resorted to raids of settled areas (*ghazw*). This lifestyle is referred to as pastoral nomadism, a lifestyle that is migratory in nature and that involves the shepherding of animals.

In many ways it can be argued that the pastoralist lifestyle was the negation of an agricultural lifestyle, in that pastoralist activities were often diametrically opposed to the responsibilities of the cultivator. In keeping with the nature of their livelihood, nomad-pastoralists were fully specialized animal herders who were able—through specific techniques—to utilize land that was otherwise unusable, effectively allowing for limited habitation and economic production upon otherwise unsuitable land. Their mobility, the marginal fecundity of the land upon which their animals pastured, and their spe-

cialized reliance on both their animals and the environment were all mutually contingent: Movement, which was a necessary precondition of this lifestyle, precluded agriculture for the nomad-pastoralist.

While life in the wild was often brutal and harsh, it is important to note that many of the issues that people faced in medieval cities, such as crime, overcrowding, and disease, were not a part of the nomad-pastoralist life. Coupled with the somewhat salubrious and healthy nature of the dry climate, populations among the pastoralists could reach high levels, forcing migrations. This situation meant that pastoral-nomadic elements were pressed into contact (sometimes of a violent nature) with the stronger, sedentary people beyond the desert's margins.

Historical records from settled lands and empires are quick to enumerate the violent aspects of the association between pastoral-nomadic and sedentary peoples, and this image of the nomad vis-à-vis civilized society is very enduring. However, it must also be noted that while these sources relate the attacks of the pastoralists on sedentary societies, many of these same societies also conferred a higher social ranking to pastoralists than to agriculturalists. In both the classical pagan religions and the Abrahamic religious traditions, deities often show a higher appreciation for meat offerings, hinting at a different aspect of the nomadic-sedentary interchange.

Medieval historians of the Middle East were singularly interested in the dynamic of nomadic-sedentary relations. The great North African historian and sociologist Ibn Khaldun (1332–1406) presents some interesting observations on the dynamic social interactions between city dwellers (whom he terms *hadara*) and nomads (called *badawi*). Agreeing with the earlier Muslim historian al-Masudi (d. 957), Ibn Khaldun suggests that there was also a concomitant evolutionary relationship between the two groups. Al-Masudi defines the *badawi* as those people who are not yet sedentary in their lifestyle, living a rough and free existence in the borderlands. They fought and stole as necessity demanded, and as the result of the marginal life that pastoral nomadism required, the welfare of the group became paramount. The collective could supply the various needs of the individual far better than the individual could supply by himself.

Ibn Khaldun also observes that it was a natural occurrence for the *badawi* to mature and become *hadara*. The most important identity construct for each of these groups was a notion of group solidarity, which Ibn Khaldun calls *'asabiyyah*. This solidarity was born out of necessity, for living in the wilds required a high degree of cooperation. This *'asabiyyah* made the *badawi* superior to the *hadara* because living a civilized town life required one to live within the strictures of man-made law, which forcibly subverted the nature of hu-

man beings, making them weak. When conflict occurred, the group with the higher *'asabiyyah* always won. Once the conflict was finished, the transition from *badawi* to *hadara* began anew as the victorious nomadic elements settled in to city life, unintentionally weakening themselves and opening the door to their downfall when the next nomadic group arrived two or three generations later.

This cyclical pattern was repeated throughout the Middle East during the Middle Ages. Starting with the Arab conquest and empire in the seventh century, the Turkic migrations and subsequent empires of the 10th century and later periods, and most notably the great Mongol invasion of the 13th century, waves of essentially pastoralist groups came from the margins and violently interacted with the established sedentary groups they encountered, forever changing the political and cultural landscape of the region. However, it is important to note that such medieval historians as Ibn Khaldun do not glorify these people, for while civilized life

Pastoral scene from a manuscript of the *Divan (Poems)* by Sultan Ahmad Jalayir (ink, color, and gold on paper; ca. 1400) (Freer Gallery of Art, Smithsonian Institution, Purchase, F1932-30)

destroys fortitude and resistance, Khaldun equates the existence of the *badawi* with that of wild, untamable animals and dumb beasts of burden. Whether this recorded legacy of warfare and raiding is accurate or merely a case of historical source bias, the nomadic lifestyle as we understand it was not a self-sufficient enterprise. Nomadism was simply the best way to maximize the meager resources of areas that were otherwise unusable.

The domestication of livestock, specifically of sheep, goats, and the now-extinct aurochs (related to modern cattle), was the key for pastoral-nomadism. Based on the topography and the moisture of a region, there are different types of pastoral-nomadism. Transhumance, or “vertical” pastoralism, was practiced in regions where mountains are prevalent, such as the Zagros region in Iran and the eastern regions of the Anatolian peninsula. This form of pastoralism was characterized by the movement of herds (primarily sheep and goats) from low-lying winter pastures to elevated summer pastures located in the mountains. These pasturages were fixed territories under the control of a single group, and the region between the two pastures was usually a dimorphic zone (a region where both pastoral and sedentary activities and modes of production may overlap).

Riverain, or “horizontal,” pastoralism was the method of nomadism practiced by the pastoralists of central Iraq and the Fergana plains in central Asia. In this model the nomads pastured animals on the marginal lands adjacent to well-watered river districts. When the land could no longer support the flocks, the animals were gathered and herded into the river districts, where the pastoralists wintered with their herds. This form of pastoralism brought the pastoralists into close contact with the sedentary groups who practiced agriculture. The nature of interaction in this dimorphic zone ranged from hostility and conflict to close social ties and the creation of new social groupings.

The third major form of pastoralism was a derivative of the “horizontal” model and was best demonstrated by the Bedouin of Arabia and their use of the camel. Owing to the severe desiccation of the majority of the Arabian Peninsula, sheep and goats were of limited usefulness to the Bedouin. The camel, though, provided the Bedouin with a means to traverse the desert and locate places for habitation. Additionally, the durability and hardiness of the camel allowed for the creation of an overland aromatics trade network that connected south Arabia to the Syrian littoral. The camel also marked an important moment when populations began to leave the settled areas of the Tihamah cultural zone and move farther into the deserts, a process now referred to as “bedouinization.” In many ways the domestication of the camel allowed for the birth and eventual success of the Bedouin, as

the population of the Arabian Peninsula inverted the more accepted transition from nomadic to sedentary lifestyles.

All three of these models reflect an interesting feature of the nomadic-sedentary interchange. While there is ample evidence to support the notion that there was conflict between nomad-pastoralists and sedentary groups, there is also evidence to support the notion of cooperation. Cuneiform records from earlier historical periods, such as those that have survived from the city of Mari—located on the western bank of the Euphrates River—lay out the regional distributions of grazing lands and water rights over the dimorphic zone that marks the fringe of the Arabian Desert and the Syrian littoral, creating a picture of cooperation rather than just conflict. Due to the mobile and autarkic nature of pastoralist activities, the nomad-pastoralists could not produce refined goods, such as metal for tools or weapons, or enjoy the products of an agricultural lifestyle. Likewise, the city dwellers and agriculturalists would not have had as wide an access to meat and animal products without the pastoralists. What seems to be emerging is not a relationship of conflict but rather one of cooperation.

## ► numbers and counting

### INTRODUCTION

Owing to our physiological makeup—we have 10 fingers and 10 toes—human beings naturally use the base 10 (decimal) numerical system. The only other numerical system that was ever widely used before the 20th century was the base 60 (sexagesimal) system, which was developed by the ancient Sumerians and, in modified forms, is still used in calculating angles and in timekeeping. To people who have gone through modern educational systems, simple mathematical operations might seem almost intuitive, and more complicated operations can be carried out quickly with the aid of writing. But the situation in the Middle Ages was quite different. One trick that people used to perform, which seemed miraculous to crowds of onlookers, was to calculate simple sums in their heads (such as  $50 \times 10$ ). The ability of Pope Sylvester II (who imported Arabic numerals to Europe) to do the same inspired the attribution of several books of magic to him.

At the beginning of the Middle Ages many different systems of writing numbers existed, varying from culture to culture. In the Byzantine Empire and India, for instance, letters were assigned to stand for certain numbers, and large numbers often had to be written out in words (as if writing *thousand* instead of *1,000*). Western Europe used the system of Roman numerals that is still employed in some archaizing

contexts today (such as on clock faces). The forms of the Roman numerals might have arisen at least in part from finger counting. But calculating was done on number tables or abacuses. The use of the abacus was limited to specially trained professionals. These devices used a base 10 system of numerals with place columns (for 1s, 10s, 100s, and so on) exactly as in modern numerical notation. The sums in each column were marked with pebbles (*calculi* in Latin) or beads. Calculations were done by adding or removing beads from the appropriate column and adding one to the next column to the right when a column reached 10. But before the Middle Ages there was no way of directly reproducing this system in writing.

The modern system of numbers now used throughout the world was developed in medieval India. In the sixth century the Indian mathematician Aryabhata introduced a new system of numerals based on the Sanskrit alphabet. (Before that time whole words were used to allegorically represent the numbers, such as *fire* for the number 3.) He differentiated consonants and vowels so that a vowel written after a consonant functioned as a power of 10 (and 100, 1,000, and so on). In the seventh century Brahmagupta became the first mathematician to use zero as a proper number rather than an empty placeholder (like a number-table column with no pebbles). With this innovation, it became possible to write down directly the decimal columns of the abacus, producing the modern form of numerical representation. This discovery was spread throughout the Islamic world by the Persian philosopher al-Khwarizmi and then to western Europe by the reception of Arabic learning in 12th-century Spain. The new mathematical concepts also were borrowed by China, in that case through anonymous merchants.

Because western Europeans received them from Islamic culture, we wrongly call the numbers of the 10-digit number system Arabic numerals, when they are actually derived from India. Arabic speakers know them as Indian numerals. They are based on some of the ancient Indian system of Brahmi numerals (which did not originally include the concept of decimal places). Many scholars today call them Indo-Arabic numerals to better reflect the historical reality.

The isolated peoples of the Americas developed their own systems of counting. Most were base 10, derived from counting on the fingers. But the system of counting in Central America was base 20, from counting on the hands and the feet. In antiquity the Maya had developed a system of numerical notation fully equivalent to modern Arabic numerals and decimal places, even without the aid of a device like an abacus. Since they used base 20, each of the numerals from 0 to 19 was represented by an individual sign. Rather than powers of 10 (10s, 100s, 1,000s, and so on), they used powers of 20 (20s, 400s, 8,000s, and so on) to express large numbers.

The zero was a sketch of a seashell, while the other numbers were additive, with a dot representing 1 and bars representing 5, so that 18 was rendered by three horizontal bars with three dots on top. Numbers were written in columns from the bottom up, such that the places were marked by rows rather than columns. For example, 404 would be written with four dots in the 1s row, a zero above that in the 20s row, and a single dot in the 400s row. The Mayan and Indian inventions of zero were quite independent.

## AFRICA

BY OLUTAYO C. ADESINA

The medieval period in Africa was a time of unprecedented advances in the idea of mathematics and a sense of arithmetic as both a cultural and an economic phenomenon. Through the fresh introduction of ideas, Africans contributed significantly to human cultures of numbers and counting. This development was manifested in several ways, one of which was in the area of computing roots of difficult equations. During the medieval period the system of numbering and counting in Africa had undergone evolution that reflected the metamorphosis from lower to higher forms of social development through political and cultural contacts with diverse parts of the world. Numerous numbering and counting systems began to exist side by side. These had a variety of origins, forms, and consequences. Therefore, in a sense, a distinction is sometimes drawn between indigenous number and counting systems and imported systems. Ancient Africans developed and adopted systems and instruments of numbering and counting, such as counting glyphs, tally marks on bones, base-10 counting systems, the quinary and denary scale of numeration (counting by fingers and toes), and games and puzzles as part of their system of numeration. For more than 10 centuries, however, from about 300 to 1450, Africa experienced major influences from other parts of the world, with diverse impacts on developments on the continent and in other parts of the world.

Despite the contacts with other parts of the world, there were marked contrasts in the development of different societies in Africa, ranging from highly organized kingdoms and empires, such as Egypt, Ghana, Mali, Ethiopia, Kongo, Ile-Ife, and Benin, with the knowledge of basic concepts of mathematics, to lower social formations, such as the hunter-gatherer societies of the Kalahari Desert, the Mbuti of the Congo forests, and the remnants of other such Stone Age communities in which changes appeared to be slow or even nonexistent. Nevertheless, in more developed social formations that experienced contacts with the outside world, it was also still possible to distinguish between what was uniquely

indigenous to Africa and what appeared to be borrowed from elsewhere.

Africa in the medieval period experienced major influences from the Romans, the Arabs, and the Iberians. From then on, numbers and counting developed in tandem with indigenous African systems. These became the precursors of many modern practices and systems in Africa. The influence of the Roman Empire, which by 200 included North Africa, contributed to transformations in the age. Thus, in the northern part of Africa the number system borrowed from or took after the Roman system. The system created by the Romans had a total of seven symbols and could be used to express numbers from 1 to 1 million. These include I for 1, V for 5, X for 10, C for 100, D for 500, and M for 1,000. The Roman numerals are read from left to right, and the symbols standing for the largest quantities are placed at the left.

The Hindu-Arabic numeral system was part of the culture introduced into Africa from other areas. This system was represented by the use of positional notation of 10 symbols from 0 to 9, with individual symbols assuming specific values according to their position in the numerals. This system made it possible to differentiate between, for instance, the numbers 2, 202, and 2,002, all without the use of additional or cumbersome symbols. The first recorded use of the system in Europe was in 976, and this followed European explorers, navigators, and adventurers into Africa in the age of European contact and exploration. The transmission of mathematical knowledge from other cultures into Africa after the Roman conquest can be traced from Iraq into Egypt, then to Morocco, and on into the Iberian world.

There is no disputing the fact that the influence of the Romans and the Arabs in the expansion of mathematics in Africa remains very important. However, there is evidence to show that some of the central ideas of calculus reached Europe from Africa. Africans continued to make profound expansions in the world of mathematical ideas. Some of the basic ideas of calculus were already known in Egypt before Sir Isaac Newton (1642–1727) created his own version between 1665 and 1670. Egyptians had been able to combine ideas under the unifying themes of the derivative and the integral to show the connection between the two and then evolve the calculus into a problem-solving tool. In particular, the idea of the sums of integral powers and the area formula were developed in Egypt in the 11th century, when Caliph al-Hakim invited Ibn al-Haytham (965–1039), a native of Basra in Iraq, to work on a Nile-control project.

Not all mathematical ideas appeared as numerate skills. The indigenous population in Africa retained the capacity for mathematical ideas—ideas that they retained in informal ways and manners. The general consciousness of an arith-

metrical sense extended into artistic works as well as cultural and commercial practices. The needs of commerce reflected an underlying culture of mathematics that remained a potent force. The utilitarian demand of counting adopted by financial and commercial interests expanded the scope of mathematics. It is significant that when the Portuguese arrived in western Africa in 1440, they were impressed by the dexterity shown by the Mandinga merchants, who traded in gold, on the upper reaches of Gambia. The use of finely balanced scales inlaid with silver and suspended from cords of twisted silk managed to convey a sense of costs, weights, and proportions. The gold dust and nuggets were weighed with brass weights. The Africans' expertise in measuring gold and in other forms of commerce was largely due to the fact that there were professionals within the group with a sense of numbers and counting. Nevertheless, that potential was not restricted to trading alone. Mathematical ideas were manifested in extraordinary and complex designs through decorative patterns. In several African cultures weaving patterns in cloths, carpets, and other products have some kind of symmetrical arrangement. This phenomenon suggests that different cultures in Africa arrived at different ways of projecting mathematical ideas. African achievements of the medieval period in mathematical ideas and practices stand as positive contributions to man's heritage of utilitarian creations.

## THE AMERICAS

BY PENELOPE OJEDA DE HUALA

A great diversity exists in the numbering systems developed in the New World. A base-10 system of counting existed among the native groups in both North and South America, including the Algonquin, the Siouan, the Athapascan, the Iroquian, and the Salishan linguistic groups of North America and the Quechua-speaking groups of South America. A base-20 system of counting existed amongst the Inuit, the Mesoamericans, and several tribal groups of California. The base-10 system, the system used today, developed by using digits of both hands to count. The base-20 system, or vigesimal system, employs both hands and feet to count.

Several number and counting systems were recorded in the period after European contact with North America. The sophistication of these systems indicates that they were in use prior to contact. Among the Zuni of New Mexico a digitally based system, using the 10 digits of the hands, was used during the early colonial period. For example, the Zuni word for 10 is *astemthla*, which means "all of the fingers of the hand." Similarly, among the Takelma of southwestern Oregon the number 10 is called *ixdil*, meaning "both hands." Other native groups in North America also indicate that their words for

numbers originate from digit counting. For example, among the Omaha the number 7, *penompa*, means "finger two," and the number 8, *pethatbathi*, means "finger three."

For the Inuit people, two hands represent the number 10, a single foot represents the number 15, and two feet represent the number 20. The number 20 also represents a person. For example, among the Inuit of southwestern Alaska, the word for the number 20, *yuenok*, means "man completed." In this way, two people would represent the number 40, three people the number 60, and so on. Five people indicate the number 100, and the term for 100 means "bundle." This designation probably originates from the fact that animal skins were often bundled in groups of 100. Numbers in between show that the digits of the hands were used for counting. For example, among the Inuit of Hudson Bay, the word for the number 8 is *kittukleemot*, or "middle finger," and the word for the number 10 is *eerkitkoka*, or "little finger." The act of counting is demonstrated even further among the Inuit in Greenland, whose word for the number 9, *mikkelerak*, means the "fourth finger."

The presence of larger units, such as words for the number 1,000, have been recorded among various tribes, including the Delaware, the Choctaw, the Kwakiutl, the Biloxi, the Wiyot, the Fox, the Dakota, the Cherokee, the Ojibwa, the Osage, the Winnebago, the Wyandot, the Micmac, and the Apache. Many tribes seem to include numbers over 1,000 in their counting systems.

In Mesoamerica a vigesimal system was employed, based on the 20 digits found on a human being, using both hands and feet. This system was employed by the Maya (ca. 1000 B.C.E.–1521 C.E.), a civilization that dominated parts of Guatemala, southern Mexico, Belize, and Honduras. During the Classical Period the erection of stelae, or upright stone slabs, was fundamentally linked to the Mayan concept of time, as stelae were often built to celebrate the passage of a ritually significant period. For example, stelae were erected to commemorate *k'atuns*, or 20-year cycles, the fundamental unit of measuring time. These events were set into stone and indicate the importance of time keeping in Mesoamerica. For example, a 20-day period was called a *uinal*. Several words exist for the number 20, including *kal*, *may*, and *uinic*. *Uinic* also means "man" or "human being" and refers to the total number of digits on a human being.

The Maya developed a counting system based on bars and dots. A dot indicates a unit of one, and a bar a unit of five. The Maya invented the concept of zero, which was represented by a Maltese cross or a shell. The Maya developed a capacity to count exponentially, and their monuments record large numbers. They were particularly obsessed with recording time, both historic and cosmic events, and were the only

culture in the Americas to develop a real written language that could be read phonetically.

This basis of counting contributed to the development of the ritually significant calendar, since the main purpose of counting was related to calendrics. Like most Mesoamerican cultures, the Maya used a 260-day ritual calendar called a *tzolkin*. This calendar, which has its origin in the Preclassic Period, probably reflects the gestation period of an infant, from the time of the first missed menstrual cycle to birth. It is divided not by months but by 20 day names and 13 day numbers. In conjunction with the ritual calendar, a 365-day solar calendar was also used, consisting of 18 months (also with individual names) of 20 days (this period of 360 days is called a *tun*) plus five unnamed days called the *Uayeb*. These two calendars were used together, simultaneously, a cycle taking 52 years to complete. This period, related to our concept of a century, was called a calendar round. To distinguish between different 52-year periods, another counting system was created, called the Long Count. This count, which began for the Maya at the mythical date that corresponds to the year 3114 B.C.E. of our dating system, was a way for the Mayan kings to record historical time.

The Aztec (ca. 1200–1521), who spoke Nahuatl, developed a pictorial language, using a mixture of pictograms, ideograms, and phonetics. Bark paper books from after European contact include sections on the 260-day ritual calendar, called the *tonalpohualli*, and the 365-day solar calendar, called the *xihuitl*. Like the Mayan version, these calendars worked in conjunction with each other and were used for ritual divination; they were also similarly divided, including the 52-year cycle, which was called a *xuihpohualli*. The Aztec picture books also include information on Aztec counting practices. Like the Maya, the Aztec used a base-20 system. Symbols were used to represent each number; for example, the flag symbol stood for the number 20, and a tree stood for the number 400. Like many indigenous groups, the meaning of certain numbers reveals their digital counting origin. For example, the number 5, *macuilli*, probably derived from the word *maitl*, or “hand.”

In the Andes no written form of language existed prior to European contact. However, records were documented by the Inca (1438–1533), a civilization that dominated the entire South American continent, including present-day Ecuador, Bolivia, Peru, Chile, and parts of Argentina and Columbia. Records were kept using a knotted textile device called a quipu, which recorded various kinds of information, such as tax or census data. The quipu contained a main horizontal cord from which yarns of different colors were hung vertically. Different-colored string as well as the type of knots, cord length, and position on the cord indicated different informa-

tion. Specialists created and read these instruments, and the development of the quipu reflects the importance of textiles in the Andean region. Chronicles from after European contact indicate that a base-10 system of counting was used in the Andes. The Quechuan (Incan) term for 10 was *chunka*.

## ASIA AND THE PACIFIC

BY TOM STREISSGUTH

The counting and numbering system of medieval China had its earliest origins in the writing of the Shang Dynasty of the second millennium B.C.E. Historians have theorized that Shang numerals were phonetic, with the symbols for the numbers correlating to the shape of certain objects. The Chinese juxtaposed figures to create larger numbers: For example, the symbol for 4,000 combines the symbol for 4 and the symbol for 1,000. Shang numerals had given way to a more abstract system of horizontal and vertical lines by the time of the Han Dynasty, which lasted until the fourth century C.E.

The short lines of Han numerals derived from the use of counting boards for calculations and arithmetic. The counting board had a series of columns, with places for counting rods made of contrasting materials or colors. A blank space without a rod indicated zero. There were arrangements of the rods for nine different values and a place-value system that changed the value of the symbols depending on their position in the matrix. The far-right column represented single digits, for example, while the next left column represented multiples of 10, the next multiples of 100, and so on. The famous *Xiahou Yang suanjing* (Mathematical Manual) of Xiahou Yang (ca. 400–ca. 470), written in the fifth century, explains the various methods of addition, subtraction, multiplication, and division on the counting board.

Mathematics was an essential part of China's educational system, which prepared young men for service in the imperial government. A standard textbook known as the *Jiuzhang suanshu* (Nine Chapters on the Mathematical Art), dating to the Han Dynasty, includes 246 word problems covering many different topics in arithmetic, trigonometry, and geometry as applied to real-world problems in engineering, finance, farming, and marketing. The book provides solutions as well as detailed explanations for how the problems are solved. The method inspired many able medieval mathematicians, including Ding Ju (fl. 1355), He Pingzong, Wu Jing (fl. 1450), and Liu Shilong (fl. 1424), to write detailed commentaries on the *Jiuzhang suanshu*.

Historians believe that the concept of zero was introduced to China during the Tang Dynasty, which began in the early seventh century. At this time Chinese merchants, pilgrims, and explorers were traveling to the Indian Subcon-

continent, where the concept of zero and the decimal point originated. In the medieval period the Chinese also discovered the use of negative numbers, the binomial theorem (a method of calculating sums of unknown integers and their powers), matrices (tables used for solving addition and multiplication problems), the useful number matrix later known in the West as Pascal's triangle, and the rule of three (a method of finding a fourth term in a proportion when three terms are already known). The golden age of mathematics in China came during the 13th century, a time of several brilliant scholars. These scholars included Qin Jiushao (1202–61), the author of the *Shushu jiuzhang* (Mathematical Treatise, 1247), and Li Zhi (1192–1279), who wrote *Ce yuan hai jing* (Sea Mirror of Circle Measurements, 1248) and *Yi gu yan duan* (New Steps in Computation, 1259), books that set out the author's method of solving algebraic equations. Other major figures of mathematics in medieval China were Guo Shoujing (1231–1316) and Zhu Shijie (ca. 1260–ca. 1320), who wrote *Suanxue qimeng* (Introduction to Mathematical Studies, 1299). In 1275 Yang Hui (ca. 1238–ca. 98) wrote *Yang Hui suanfa* (Yang Hui's Methods of Computation), describing various methods of multiplication and division, quadratic equations, and geometrical calculations. Yang Hui is best known for the composition of a magic square and his theorems in geometry that echoed the discoveries of the Greek mathematician Euclid (fl. ca. 300 B.C.E.).

The Chinese system of counting and mathematics traveled to Korea and Japan as well as to areas colonized by the Chinese, including Southeast Asia. While the Japanese adopted the Chinese system entirely, the Koreans developed their own system of counting and used the two sets of numerals, Sino-Korean and native Korean, as well as varying pronunciations when indicating abstract numbers, the passing of time, and quantities.

Along with Chinese mathematics came the *suanpan*, or Chinese abacus, which by the time of the Ming Dynasty, beginning in the 14th century, had replaced the ancient system of counting rods. This device contains a series of rods, divided into upper and lower compartments with a set of sliding beads—two in the upper compartment and five in the lower compartment. The device can make decimal (base-10) and hexadecimal (base-16) calculations, including addition, subtraction, multiplication, division, and square and cube roots.

India was the ancestral home of the modern system of numbering, counting, and mathematics. Numbers in the classical Vedic literature of India were represented by phrases. The value for 2, for example, could be expressed by the words for arm or eye; the word for fire represented 3, and the words for sky represented zero. The words were combined to give a

*Terra-cotta tile with crouching figures; Harwan, Kashmir, ca. fourth to fifth centuries. Terra-cotta tiles were used to pave the floor of the courtyard of this Buddhist sanctuary; the tiles are all inscribed with numerals in the Kharoshthi script. (© The Trustees of the British Museum)*

number greater than 9, with the 10s given first and then the single digits.

This decimal system of numeric notation and the concept of zero were passed to Arabic mathematicians studying in south Asia in the early medieval period. The numeric symbols discovered by Arab scholars in the Sanskrit texts of India eventually made their way, via the Abbasid Caliphate, to Europe, where they replaced the Roman system with what became known as Arabic numerals. Two important ninth-century Arabic texts transmitting the Indian system to the West were the Latin *Algoritmi de numero Indorum* (On the Calculation with Hindu Numerals, ca. 825) by al-Khwarizmi (ca. 780–ca.

850) and *Ketab fi isti'mal al-'adad al-Hindi* (On the Use of the Indian Numerals, ca. 830) by al-Kindi (d. ca. 870).

Indian scholars studied mathematics through Sanskrit texts and their sutras, verses that were learned by heart and transmitted to students orally. Mathematics in medieval India was an integral part of religious ritual as well as the study of the heavens. The science of trigonometry, for example, developed through the measurement of distance and azimuth of the sun, the moon, and the planets and their relation to one another.

The Gupta numerals developed in the early medieval period, during the time of the Gupta Empire, and spread across India with the armies of the Gupta rulers. This system developed into the Nagari numerals, also known as the Devanagari numerals, the “writing of the gods,” which originated in the seventh century and which were adopted into Hindi, Sanskrit, and other languages of the Indian Subcontinent. Some historians hypothesize that the idea for place value in Indian number systems came from the decimal counting rod system of the Chinese.

India's most prestigious medieval mathematician, Aryabhata, lived from 476 to around 550, during the time of the Guptas. He spent most of his life in the northern town of Kusumapura, where he wrote the *Aryabhatiya* (Treatise of Aryabhata). This work consists of 118 verse stanzas divided into four sections. The section known as “Ganitapada” (Mathematics) includes 33 verses and 66 rules. In previous times mathematics scholars worked in the form of sulbasutras, which included rules of arithmetic applied to measuring distance. Aryabhata incorporates this material in his work, in which he takes mathematics further into the realms of algebra, trigonometry, and geometry. Aryabhata teaches methods of calculating cube roots, sums of a series, the sines of angles, the volume of solids, and the solutions to indeterminate linear equations (containing variables, or unknown quantities).

Working with a base-10 counting system, Aryabhata uses 33 consonants of the Hindu alphabet to stand for integers from 1 to 25 and multiples of 10 from 30 to 100. The syllable *kha* is used to indicate zero. Consonants followed by vowels stand for a power of 10, up to  $10^{18}$ . With this system, he develops methods for calculating cube roots, formulas for adding numbers in series, and algebraic solutions to linear equations.

Brahmagupta (598–ca. 665) wrote the first books to employ negative numbers and the zero within mathematical operations. In his *Brahmasphuta-siddhanta* (Improved Astronomical System of Brahma), Brahmagupta covers quadratic and linear equations, trigonometric methods for solving distance, the measurement of arcs and spheres, and such astronomical problems as the measurement of the earth's circumference and the precise length of the year. He devel-

ops several different methods for complex multiplication, calculating the area of cyclic quadrilaterals (those defined by points on a circle), reducing compound fractions to simple fractions, and calculating compound interest.

There was no system of written notation in Polynesia, a region that encompassed several different systems of indicating number. At some period before the medieval era the inhabitants of the Pacific Islands migrated eastward from their ancestral homes in Indonesia and Southeast Asia, regions that used a base-10 system of counting. There were words denoting numbers 1 through 9 and distinct words indicating a certain power of 10. The oldest-known numbering system in the Polynesia region was also decimal, but later societies—including Maori, Hawaiian, and Tongan—developed mixed-base systems, counting by both 10 and 4, for example, in the Hawaiian Islands. Some Polynesian islanders created different numbering systems for different objects. In the Tongan language, for example, certain objects were counted by pairs (including sugarcane stalks) or scores (groups of 20): yams, fish, coconuts, and the pandanus leaf, used in weaving and cooking. Fish were also counted in their own way in Hawaii, New Zealand, and Samoa. When European explorers and missionaries arrived, Hindu-Arabic numerals were introduced, as was the concept of zero.

## EUROPE

BY JULIE-ANN VICKERS

In the early Middle Ages numerals and methods of calculation were similar to those used in Greco-Roman antiquity. The numbers we use today, known as Hindu-Arabic numerals, were first transmitted to western Europe in the 10th century. The spread of this numerical system in medieval Europe was an important factor in the development of scientific knowledge. However, medieval scholars in the Latin West and the Byzantine East did not immediately recognize the advantages of the Hindu-Arabic number system and in some cases were hostile to its adoption. Because of this view, the spread of Hindu-Arabic numerals was a slow process, taking place over centuries. It was not until after the medieval period that Hindu-Arabic numbers finally superseded the numerical systems inherited from the ancient world.

Dactylonomy, or finger counting, was one of the numerical systems from the ancient world that continued in use throughout the medieval period. This method employed the fingers of the hand for forming signs that represented numbers, as well as for counting and making calculations. A uniform system of finger numbers was common to the Byzantine Empire and western Europe at this time. From the written evidence it is not clear, however, whether numerical calcu-

lations were actually carried out on fingers or whether the fingers acted as memory aids for performing mental calculations. Although finger counting was a common and easily utilized method of performing everyday calculations, it was also used and taught by the most educated scholars in early medieval society. The Venerable Bede (672 or 673–735), an English Benedictine monk and one of the most respected scholars of his age, included a chapter on finger counting in his work *De temporum ratione* (The Calculation of Time). In this he explains how to use finger counting to assist in the calculation of the date of Easter, a feast whose date moves from year to year in accordance with the lunar cycles. In the later Middle Ages finger counting continued to be used as an aid in performing calculations with other numerical systems.

To record numbers in a permanent, written form, medieval scribes used either Greek or Roman numerals. In the Byzantine East the Ionic number system, which first appeared in ancient Greece, remained in use for the duration of the medieval period. This was a system of alphabetic numerals in which each letter of the Greek alphabet corresponded to a numerical value. Scribes wrote these numerals with a horizontal dash on top or between dots, in order to distinguish them from letters. The Roman numerals used in the West were also the continuation of a system used in the ancient world. Unlike the Greek system, Roman numerals were originally abstract signs that represented numerals. However, over the course of the Middle Ages these forms were adapted to correspond with letters of the Latin alphabet. It is important to note that the numeral zero did not exist in either the Greek or the Roman system of the early Middle Ages. The absence of zero meant that there was no place-value notation system for recording numbers. As a result, carrying out written computations in both systems was extremely complex and difficult.

For performing calculations, medieval scholars instead used an abacus, or counting board. Only after they had finished a calculation was the final result then written down using Greek or Roman numerals. The abaci of the Middle Ages were different from their modern counterparts. They consisted of a table, a board, or another flat surface drawn up with columns. These columns represented ranks, and counters were used to represent the relevant number of units in each rank column. In this way medieval scholars practiced a form of place-value notation for calculations but did not incorporate this into their written numerical systems. Still, by today's standards, calculations using the abacus look convoluted and time-consuming. In particular, multiplication and division were long and complicated procedures. In the Middle Ages mathematics was a specialized field of knowledge, and abacists, as they were known, undertook many years of study in order to become competent in these techniques. This

two-tiered process of calculating with one system and writing down results in the traditional Roman or Greek numerals persisted until the entire method was challenged by the emergence of Hindu-Arabic numerals.

The adoption of Hindu-Arabic numerals is one of the key developments in the history of mathematics because the system was the first to incorporate three important elements: decimal notation, place value, and the use of nine digits to represent all numbers. With these three elements, it was possible to perform more complex calculations with greater efficiency. The numerals originated in sixth-century India, but Arab scholars were responsible for spreading them throughout the Muslim civilizations of the Middle East and the Iberian Peninsula in the eighth and ninth centuries. For this reason we call them Hindu-Arabic numerals. Although these numerals were used in Islamic Spain from the ninth century, it was many centuries before they were commonly used in the rest of western Europe.

A French scholar and monk of the 10th century, Gerbert of Aurillac (ca. 945–1003), who later became Pope Sylvester II, was the first to bring formal knowledge of the Hindu-Arabic numerals to the West. After entering monastic life, Gerbert went to Barcelona to study and while there came in contact with the numbers used by the Arabs. He brought this knowledge back to the West and began to teach. Gerbert, however, taught only the nine Hindu-Arabic numerals and had no knowledge of zero, by that time an important element of the place-value notational system. In addition, Gerbert was not familiar with the methods used to perform calculations with the numerals, which was one of the major advantages of the system over the classical Greek and Roman numerals. Despite Gerbert's work, knowledge of the Hindu-Arabic numerals made little impact on the intellectual culture of the West at this time. These numerals were used by only a small number of scholars, and then chiefly as a means of modifying the existing methods of calculation on the abacus.

One of the major obstacles to the adoption of the Hindu-Arabic numerals was the language barrier that existed between the Islamic world and western Europe. In 12th-century Spain this barrier began to break down. Such towns as Toledo fostered exchanges between Jewish, Christian, and Muslim intellectuals, with the result that many scholarly works of Arabic origin were translated into Latin—still the language of Western scholars—for the first time. In the middle of the 12th century Robert of Chester (fl. 1150), an English scholar working in Spain, translated a book by the Arab scholar Muhammad ibn Musu al-Khwarizmi (ca. 780–ca. 850) titled *Algoritmi de numero Indorum* (Calculation with the Hindu Numerals). Al-Khwarizmi's work, written around 825, had been influential in the spread of the Hindu numerals in the

Arab world. The translation of this work into Latin meant that the West now had access to a comprehensive treatise on the operation of the Hindu-Arabic system. In Europe the system became known as *algorismus*, a Latin corruption of the name al-Khwarizmi, from which we derive the modern word *algorithm*. The practitioners of the Hindu-Arabic system were called algorists.

Despite the availability of translations, scholars of the Latin West were slow to adopt the Hindu-Arabic system. They preferred to keep using Roman numerals and the abacus, methods that had been inherited from the Roman Empire and that were steeped in prestige and tradition. It was not until the 13th century that the Hindu-Arabic numerals began seriously to challenge the traditional methods of calculation. In 1202 Leonardo Fibonacci (ca. 1170–after 1240), the son of a Pisan merchant, wrote *Liber abaci* (Book of the Abacus). The title is misleading, for the work focuses not on the abacus but rather on the methods of performing calculations with the Hindu-Arabic numerals. It describes the key concepts of place value and zero in the system. Fibonacci came into contact with the numerals in northern Africa, where his father had business interests. He soon recognized the advantages of the Hindu-Arabic method for performing complex calculations, particularly those involving commercial transactions. His book was therefore important for highlighting the practical applications of the Hindu-Arabic numerals.

Two other figures are also credited with popularizing these numerals in the West. Alexander de Villedieu (ca. 1175–1240) was a French monk who wrote a poem called *Carmen de algorismo* (Song of the Algorismus). In this poem he relates the basic operations of the numerals. Johannes de Sacrobosco (d. 1244 or 1256), otherwise known as John of Holywood or John of Halifax, was an English scholar who taught at the University of Paris. He wrote *Algorismus*, an introductory account of computations with the Hindu-Arabic numerals, a text that was responsible for introducing them into the university curriculum.
